Version 1.0 Contract Report 36

Alluvium, outwash, low terrace (Pleistocene - Holocene) Fine to coarse sand and gravel, with local lenses of silt and clay, gravel includes chert, quartzite, sandstone, siltstone, igneous and metamorphic rocks, limestone, and coal; lithologically similar to high outwash terrace (Qot2); surface mantled with alluvial silty sand and sandy silt; 30 to 45 feet (10 to 15 m) thick; surface forms well-developed, low-relief terrace along Ohio River valley; deposited as glacial outwash reworked by late glacial or post-glacial Ohio River; overlies older outwash deposits (Qot2); contact is sharp, drawn at scarp of next higher terrace or upland; floods occasionally.

Alluvium, outwash, high terrace (Pleistocene) Fine to coarse sand and gravel, with local lenses of silt and clay; gravel includes chert, quartzite, sandstone, siltstone, igneous and metamorphic rocks, limestone, and coal; lithologically similar to adjacent outwash terraces; surface mantled with eolian and alluvial silty sand and sandy silt; up to 170 feet (52 m) thick; surface forms welldeveloped, dissected terrace along Ohio River valley; deposited as glacial outwash; represents maximum valley filling by glacial outwash valley train deposits; overlies bedrock (Pz) or older alluvial deposits (not differentiated); contact is sharp, drawn at scarp of adjacent terrace or upland; age estimated to be 120,000 to 22,000 years old; most of terrace surface is above historic flood zone.

Loess (Pleistocene-Holocene) Silt, clayey silt, and fine sand deposited by wind; typically massive; unit thickest (up to 60 feet) near Ohio River valley and thins gradually to the south; mantles bedrock upland; mapped as bedrock where less than 3 to 5 ft (1 to 1.6 m) thick in uplands; not mapped where locally found on lacustrine terrace (Qlt) and high outwash terraces (Qot2); estimated to range in age from 22,500 to 10,000 years old; locally includes thin layers of loess inferred to be older than 30,000 years.

Sand dunes (Pleistocene – Holocene) Very fine to fine sand; locally contains lenses of clayey silt; thickness uncertain, base not observed; deposited by wind in long, linear ridges; mantled by loess up to 15 ft (5

Lake levee (Pleistocene)

water entered quieter conditions and deposited layered mixed sediments across the mouth of tributaries forming low ridges. Sand dunes (Qes) occur on many while loess (Qel) generally blankets these ridges indicating that formation is contemporaneous with lacustrine deposition and terminated prior to final loess deposition Alluvium, abandoned Green River channel (Pleistocene)

Silt, clayey silt, and fine sand deposited by water and wind. Formed where moving

Clayey silt, silty clay, and silty sand; 30 to 45 feet (10 to 15 m) thick; forms sinuous, low-lying trough inset into Green River paleovalley (Qapg); represents an abandoned channel of Green River as it migrated across the high terrace (Qot2); overlies older outwash (Qot2); contact sharp, identified by surface topography; floods occasionally. Alluvium, Green River paleovalley (Pleistocene)

Silty sand, clayey silt and silty clay with minor chert gravel; 30 to 45 feet (10 to 15 m) thick; includes Beds at Hubert Court of Ray (1965); forms broad, linear trough inset into and overlying deposits of adjacent high outwash terrace (Qot2) and lacustrine terrace (Qlt); represents abandoned Pleistocene paleovalley of the Green River, contact is sharp, drawn at scarp of adjacent high outwash or lacustrine terrace; wood from about 40 feet deep has been radiocarbon dated to $23,150 \pm 500$ ypb (Ray, 1965). Upland marginal lacustrine deposits (Pleistocene)

Clayey silt, silt, and fine sand; thickness uncertain; surface forms moderate slope and benched upland areas bordering lacustrine deposits (Qlt); represents complex transition between lacustrine deposits and loess mantling upland; deposits include loess, loessderived slopewash, colluvium, lacustrine silt and clay, and lacustrine shoreline deposits; contacts gradational and approximate, mapped on the basis of topographic Slackwater deposits, lacustrine terrace (Pleistocene)

Clayey silt and silty clay; 30 to 45 feet (10 to 15 m) thick, thicker in tributary valleys; overlying complex deposits of sand, silt, clay and minor gravel; locally mantled by loess (similar to Qel, not mapped); forms prominent low-relief terrace in tributary valleys and sheltered portions of Ohio River valley; unit deposited in lacustrine and slackwater environments associated with alluviation of the Ohio River valley by glacial outwash and resulting impoundment of tributary valleys; underlying material is of apparent mixed fluvial and fluvio-lacustrine origin; contact with fluvial units is sharp, and drawn on scarps separating adjacent terraces; contact with eolian and upland units (Qel, Qes, Qltm) is gradational and approximate, inferred by surface topography; estimated to range in age from 23,000 to 18,000 years old.

Gravel and medium to coarse sand; pebbles include brown, patina chert, quartz, and silicified fossils; locally cemented by iron oxide; thickness uncertain; unit found on uplands, covered by loess and poorly exposed; comparable to the Luce Gravel of Ray Bedrock and residuum (Paleozoic)

Consolidated shale, sandstone, limestone, coal, and overlying poorly sorted regolith, comprising the core of the uplands in the study area; includes areas of loess thinner than 3 to 5 ft (1 to 1.6 m).

Fine to coarse sand and gravel, with local lenses of silt and clay; gravel includes chert, quartzite, sandstone, siltstone, igneous and metamorphic rocks, limestone, and coal; lithologically similar to adjacent outwash terraces; surface mantled with alluvial silty sand and sandy silt; 30 to 45 feet (10 to 15 m) thick; surface forms well-developed, swell-and-swale topography on Ohio River low terrace; reworked during postglacial adjustment of the Ohio River; overlies older outwash deposits (Qot2); contact is approximate, inferred from surface topography.

Alluvium, abandoned Green River channel (Pleistocene - Holocene) Silty sand, clayey silt, and silty clay; 30 to 45 feet (10 to 15 m) thick; forms sinuous, low-lying trough (Katie Meadow Slough); represents an abandoned channel of Green River as it migrated across the low terrace (Qot1g); overlies older outwash deposits (Qot2); contact sharp, identified by surface topography; floods frequently. Alluvium, reworked outwash, Green River scrollwork terrace (Pleistocene -

DESCRIPTION OF MAP UNITS

Silty clay and sandy silt with minor sand and sparse gravel; thickness 10 to 30 feet (3

to 10 m); found along river banks and in floodplains of smaller streams; deposited by

modern/historic stream processes; deposit is inset into adjacent map units; contact with adjacent units varies from sharp to poorly defined; locally inferred on the basis of

topographic expression. Some streams in the mapped area have been rerouted for land-

use purposes; locally, some Qal dredged from these streams has been extensively

Sand and silty sand; deposited in levee ridges or overwash deposits on floodplains of

major rivers (Qafp) and on the Ohio River low outwash terraces (Qot1); grades into

Organic-rich, black and gray clayey silt, silty clay, and clay; found within low lying

areas on floodplain (Qafp) and low outwash terrace (Qot1); serve as poorly drained

pathways which channel water from the floodplain; areas that retain water year-round

Silt, sand, and gravel; thickness uncertain; forms fan-shaped alluvial-colluvial aprons

at mouths of small valleys; deposited by floods and debris flows from small tributary

valleys developed in loess-mantled uplands; extent of unit mapped by topographic

Silt, sand, clay, and rock fragments; unsorted; which has been transported downslope

Sand, silt, fine gravel, and clay; surface mantled by silty clay and sandy silt; surface

forms the lowest well-developed terrace along major rivers; 30 to 45 feet (10 to 15 m) thick; overlies older unconsolidated deposits or bedrock; contact is sharp, drawn at

Organic-rich, black and gray clayey silt, silty clay, and clay; deposited within recently

abandoned meander of Green River; can retain standing water for months; areas that

Silt, sand, and clay deposited by rivers; forms terrace above adjacent floodplain (Qafp);

contact with adjacent units varies from sharp to poorly defined; locally inferred on the

basis of topographic expression; distinguished by topographic expression from lower floodplain (Qafp), but found below Ohio River low outwash terrace (Qot1) and

Clayey silt, silty sand, and silty clay; 30 to 45 feet (10 to 15 m) thick; forms arcuate,

low-lying trough; represents an abandoned channel of Green River as it migrated across the low terrace (Qot1g); overlies older outwash deposits (Qot2); contact sharp,

Alluvium, reworked outwash, Ohio River scrollwork terrace (Pleistocene -

adjacent floodplain deposits; typically sandier than adjacent floodplain deposits.

GEOLOGIC SUMMARY

GEOLOGIC SETTING

The regional project area is located in the lower Ohio River Valley, downstream of the confluence of the Wabash River and Ohio River. The landscape of the map area is characterized by very low to high-relief bedrock uplands separated by broad valleys. Although the area is just south of the Pleistocene (Illinoian) glacial limit, both the Ohio and Wabash Rivers served as major outlets for glacial meltwater and entrained sediment during glacial stages. Rapid accumulation of glacial outwash in the valleys and along the mouths of tributaries led to impoundment and extensive deposition of slackwater and lacustrine sediment in the tributary valleys. This lacustrine deposit has a complex and gradational transition with loess mantling adjacent uplands. The loess was primarily derived from the valley-bottom outwash. The uplands are underlain by faulted Upper Mississippian limestone and Pennsylvanian coal-bearing strata steeply dipping North to

GEOTECHNICAL BEHAVIOR The Quaternary deposits identified in the map area exhibit a wide range of grain size and geotechnical behaviors. Grain size distribution is one of the primary factors affecting the behavior of soils for geotechnical, hydrogeologic, a nd agricultural applications. The grain size distribution of unconsolidated sediments is dominantly controlled by the conditions under which the material was deposited. Low energy environments allow the deposition of fine -grained materials. High energy deposits limit deposition to only coarser grained materials. Eolian processes produce very well

HAZARDS

sorted (poorly graded) materials. Fluvial processes produce moderate sorting; colluvial processes

produce poorly sorted deposits.

7.5-MIN QUADRANGLE INDEX

Flooding is a nearly annual occurrence along the Ohio River. Floods in the late winter or early spring commonly inundate low-lying areas in the floodplain. Larger floods occur roughly every 10 to 20 years (eg. 1913, 1945, 1964, 1997, 2007), and cover parts of the low terraces. The maximum flood of record in the valley was in 1937, flooding river towns throughout the valley. Only structures on the highest outwash terraces and the lacustrine terrace (Qlt) were spared flood damage. The impact of flooding is reflected in land-use patterns through the area. Older homes and businesses have survived on the lacustrine and high outwash terraces, and on the highest parts of low terraces (Qot1, Qot10, Qot1g). Trailers and less expensively built homes are constructed on the low terraces. Only barns are found on the high parts of the floodplain (Qafp). The floodplain and low parts of the low terraces are dominantly left to woodlands or used for row-crop agriculture. Most livestock husbandry in the alluvial valleys has been abandoned and is now restricted to upland areas above the 10- to 20-year flood zone. The low-relief lacustrine terrace is locally very

The silt soils that dominate the loess-mantled uplands are highly erodible. Soil piping and associated cover collapses are common hazards as ground water seeps through the silt and is commonly perched above fragipans. Great care must be taken during agricultural operations not to mobilize and lose this valuable resource.

The map area is proximal to the Wabash Valley Seismic Zone, the New Madrid Seismic Zone, and is within the Rough Creek - Shawneetown Fault Zone. Small to moderate earthquakes have been felt in the area relatively frequently. The significant thicknesses of unconsolidated sediment (locally as much as 140 feet in the regional map area) raise concerns about ground motion amplification of seismic waves and potential liquefaction. The variations in lithology and thickness between materials in different map units will likely cause different responses of these materials to
