Great American Smokeout — November 16, 2006

Since 1977, the American Cancer Society has sponsored the Great American Smokeout on the third Thursday in November to encourage smokers to quit. Approximately 45.1 million (20.9%) U.S. adults were current smokers in 2005 (*1*). Smokers can improve their chances of quitting by using proven cessation aids such as physician assistance, medications approved by the Food and Drug Administration, and behavioral counseling, including telephone quitlines (*2*). All 50 states, the District of Columbia, and certain U.S. territories now have quitlines, which can be reached by telephone: 800-QUIT-NOW (800-784-8669).

Other interventions that increase cessation include increasing the price of tobacco products, implementing sustained media campaigns, and reducing out-of-pocket treatment costs (*3*). Growing evidence indicates that, in addition to protecting nonsmokers from exposure to secondhand smoke, smoke-free workplace policies and smoke-free home rules help smokers quit (*4*). Comprehensive approaches are most effective in prompting smokers to make quit attempts and helping them to succeed (*3*).

Information on the Great American Smokeout is available at http://www.cancer.org/docroot/ped/ped_10_4.asp or by telephone: 800-227-2345. Information on how to quit smoking is available at www.smokefree.gov.

State Medicaid Coverage for Tobacco-Dependence Treatments — United States, 2005

In 2005, approximately 41 million persons in the United States had health insurance coverage through Medicaid, a federally and state-funded health-care program, managed at the state level, for persons with limited incomes (*1*). An estimated 29% of adult Medicaid recipients were current smokers in 2004 (*2*). The 2000 Public Health Service (PHS) clinical practice guideline recommends that insurance coverage be provided for tobacco-dependence treatments, including both medication (i.e., bupropion hydrochloride or nicotine patch, gum, inhaler, or nasal spray) and counseling (i.e., individual, group, or telephone) (*3*). A national health objective for 2010 is to increase insurance coverage of evidence-based treatments for tobacco dependence among all 51 Medicaid programs (objective 27-8) (*4*). The type of coverage for tobacco-dependence treatments offered by Medicaid has been reported since 1998, and most recently for 2003, from state surveys conducted by the Center for Health and Public Policy Studies at the University of California, Berkeley (*5,6*). All states and the District of Columbia (collectively referred to as states in this report) were resurveyed in 2005 regarding types of coverage and limitations in coverage since 1994. This report summarizes the results of that survey, which indicated that as of De-

cember 31, 2005, 1) 38 state Medicaid programs covered some tobacco-dependence treatment (i.e., counseling or medication) for all Medicaid recipients; 2) four states offered coverage only for pregnant women; 3) one state (Oregon) offered coverage for all medication and counseling treatments recommended by the 2000 PHS guideline; and 4) seven states (including Oregon) covered all recommended medications and at least one form of counseling. If the 2010 national health objective is to be achieved, states should offer or increase Medicaid coverage for treatment of tobacco dependence (*4*).

In 2005, state Medicaid program directors were asked to identify the staff member who was most knowledgeable about tobacco-dependence treatment coverage and programs; a survey was faxed to the identified staff member in each state. Additional follow-up was conducted by telephone, e-mail, and fax; the response rate was 100%. The survey included 24 questions about coverage of tobacco-dependence treatments, the year coverage was first offered, treatments offered only to pregnant women, and any program requirements related to patient copayments or other limitations related to tobacco-dependence treatments. So that survey responses could be validated, all state Medicaid programs were asked to submit a written copy of coverage policies for tobacco-dependence treatments or other documentation. Of 42 states reporting Medicaid coverage in 2005, a total of 41 (98%) provided some supporting documentation: 16 (38%) provided detailed treatment documentation matching survey responses, 14 (33%) provided partial treatment information (i.e., documentation for medication but not counseling), eight (19%) provided general treatment information (i.e., documentation that addressed coverage for tobacco-dependence treatments but did not specify which type), and three (7%) provided documentation conflicting with survey responses that were later followed up for inclusion in this report.

In 2005, a total of 38 (75%) state Medicaid programs reported offering coverage for at least one form of tobacco-dependence treatment (i.e., medication or counseling) for all Medicaid beneficiaries (Table 1). Four additional states reported that they covered at least one form of tobacco-dependence treatment but only for pregnant women. Of the 38 states that offered at least one form of coverage to all Medicaid beneficiaries in 2005, all covered some type of medication treatment, including generic bupropion hydrochloride or

* On the basis of response to the question, "Does your state Medicaid program cover any of the following tobacco-dependence treatments?" Each state also was asked to provide documentation regarding the year each covered treatment was first offered.
† N = 42. In 2005, a total of nine states with Medicaid programs (Alabama, Alaska, Connecticut, Georgia, Idaho, Missouri, Nebraska, Tennessee, and Wyoming) covered none of the tobacco-dependence treatments recommended in the 2000 Public Health Service clinical practice guideline (*3*).
§ Year any coverage began might differ from that listed in previous reports because earlier coverage might have existed for Wellbutrin® (chemically comparable to Zyban but approved for treatment of depression). Although providers might have used Wellbutrin to treat smokers, only generic bupropion and Zyban are approved by the Food and Drug Administration for smoking-cessation treatment. Years of initiation coverage were changed to reflect this. However, the survey did not collect data on when coverage began for generic bupropion specifically for smoking cessation.
¶ For smoking cessation only. Three states (Georgia, Maine, and Wyoming) covered bupropion hydrochloride but not Zyban. These data are not included because coverage might not be specifically for smoking cessation.
** If medically necessary.
†† P = Medicaid coverage exclusively for pregnant women.
§§ Treatment added in 2004.
¶¶ Some managed care plans might provide proactive telephone counseling.
*** State does not have any documentation or knowledge regarding the year coverage began.
††† Counseling indicated is not specific to tobacco-cessation counseling.
§§§ Treatment added in 2005.

Zyban®* (36 states), nicotine nasal sprays (28 states), nicotine inhalers (28 states), nicotine patches (33 states), and nicotine gum (31 states). During 2003–2005, two states (Rhode Island and South Carolina) added medication coverage, and three others (Arkansas, North Carolina, and Utah) expanded existing medication coverage. Some decreases in coverage also occurred; New Jersey eliminated seven previously covered tobacco-dependence treatments, and two states (Maine and Maryland) eliminated one form of medication coverage.

In 2005, a total of 14 states offered some form of tobacco-cessation counseling services for their entire Medicaid population (Table 1), and 12 additional states offered counseling services only for pregnant women. During 2003–2005, one state (Arkansas) added coverage for counseling of all Medicaid beneficiaries, one state (New Mexico) added coverage for counseling of pregnant women, and two states (North Dakota and Wisconsin) expanded existing counseling coverage.

Among the 38 state Medicaid programs covering any medication treatment for all Medicaid beneficiaries, 25 (66%) required some form of patient cost sharing (range: $0.50 to $5.00 per prescription) (Table 2). States were least likely to require copayments for nicotine gum (55%) and most likely to require copayments for nicotine nasal spray (71%). The median copayment among Medicaid programs was similar for all tobacco-dependence treatments, ranging from $2.50 to $3.00. Similarly, the median weeks of treatment covered (12 weeks) did not vary by type of medication, and little variation was observed in the median number of treatment courses covered per year (1–1.5 courses). In addition, certain states reported that they put no limits on coverage for these medications. States were least likely to offer unlimited coverage for the nicotine-replacement patch (27%), which is available over the counter, and most likely to offer unlimited coverage for Zyban (39%), which is available only with a prescription. Data collected on limitations in coverage indicate that for nicotine-replacement–therapy products that are available over the counter that were assessed by this study (i.e., patch and gum), all but one state require a prescription.

Almost one fourth of Medicaid programs that cover tobacco-dependence treatments indicated that medication coverage depended on enrollment in a behavior-modification program or participation in smoking-cessation counseling. Of the nine states that required behavioral counseling as a condition of covering medication, four covered the required counseling. In addition, approximately one third reported that their Medicaid program paid for one smoking-cessation medication at a time. Furthermore, one third of states covering medication indicated that tobacco-dependence treatments counted toward a general prescription limit.

Reported by: *HA Halpin, PhD, SB McMenamin, PhD, CA Cella, Center for Health and Public Policy Studies, School of Public Health, Univ of California, Berkeley. CG Husten, MD, Abby Rosenthal, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.*

Editorial Note: Despite publication of tobacco-use treatment guidelines in 1996 and updates in 2000 documenting that use of nicotine-replacement therapy, the nonnicotine medication Zyban, or counseling all can double cessation rates (*3*), coverage of tobacco-dependence treatments by Medicaid remains low and is increasing slowly. In 2005, one state, Oregon, covered all medications approved by FDA and all

*The drug bupropion hydrochloride is sold in its generic form and under the brand names Wellbutrin® (with an indication for depression) and Zyban (with an indication for smoking cessation). Although generic bupropion, Wellbutrin, and Zyban contain the same active ingredient (bupropion hydrochloride), only generic bupropion and Zyban are approved by the Food and Drug Administration (FDA) specifically for smoking-cessation treatment. Therefore, although some state Medicaid programs cover Wellbutrin for smoking cessation, only coverage of generic bupropion and Zyban for smoking cessation are discussed in this report.

†Of 38 states offering some type of tobacco-cessation treatment (i.e., counseling or medication).

three forms of counseling recommended by PHS clinical practice guideline. Nine states offered no Medicaid coverage for tobacco-dependence treatments, and four states offered coverage for at least one treatment option (i.e., medication or counseling) but only to pregnant women.

The number of state Medicaid programs offering any medication coverage increased by one during 2003–2005, and the number of states that expanded coverage of medications also increased by one during the same period. Coverage for counseling increased by two states, and expansion of counseling coverage increased by two states. However, 66% of states that offered coverage required patients to share the cost of treatment. In addition, almost one fourth of state Medicaid programs that cover tobacco-dependence treatments indicated that medication coverage was dependent on enrollment in a behavior-modification program or participation in smoking-cessation counseling, another barrier to using treatment (particularly because counseling was covered by only 44% of these states). Previous studies also have indicated that most programs that offer tobacco-dependence treatment benefits do not inform their beneficiaries of those benefits (*7*), creating additional barriers to successful smoking cessation.

Because decreasing the cost of effective treatments increases smoking cessation (*8*), cost barriers for smokers should be reduced. In a study that assessed the impact and cost-effectiveness of recommended preventive services, smoking-cessation treatment was among the top-ranked clinical preventive services (with childhood immunization and discussing aspirin chemoprophylaxis for adults at risk for cardiovascular disease) (*9*); these three treatments were determined to save health-care costs. Because the adverse health effects of smoking result in 14% of Medicaid costs (*10*), implementation of tobacco-dependence treatments should be a priority.

The findings in this report are subject to at least two limitations. First, although all but one state provided some supporting documentation, only 38% provided complete documentation of the treatments covered. This lack of confirmatory documentation increases the likelihood of reporting errors. Second, these results might differ from other ratings of coverage because of differing interpretations of unwritten policies.

Because smoking prevalence among Medicaid recipients is approximately 39% greater than the prevalence in the overall U.S. adult population (*2*), Medicaid recipients are disproportionately affected by tobacco-related diseases and disabilities. Substantial measures to improve coverage will be needed to achieve the national health objective for 2010 of reducing the prevalence of smoking to 12% among persons aged ≥18 years (objective 27-1a) (*4*). To help states implement evidence-based tobacco-dependence treatment and to improve Medicaid service contracts, CDC collaborated with George Washington University (Washington, DC) to develop sample specifications for the purchase of tobacco-use prevention and cessation services (information available at http://www.gwumc.edu/sphhs/healthpolicy/chsrp/newsps/tobacco). As a result, Medicaid programs are encouraged to cover all PHS-recommended treatments, cover two courses of treatment per year, eliminate or minimize copayments, and promote tobacco-dependence coverage benefits to Medicaid recipients to reduce the adverse health effects in this population.

Outbreak of Polio in Adults — Namibia, 2006

After 10 years with no detected wild poliovirus (WPV) transmission in Namibia, an outbreak of poliomyelitis cases occurred in 2006. The outbreak was traced to importation from neighboring Angola of WPV type 1 (WPV1) that originated in India. As of October 2, 2006, a total of 19 cases of polio, with paralysis onset between early May and June 26, had been confirmed by isolation of WPV1 from stool specimens, primarily from young adult males; six of the patients died. This report describes outbreak investigation and response activities and provides an update on routine and supplemental immunization activities (SIAs)* and acute flaccid paralysis (AFP) surveillance in Namibia.

Outbreak Investigation and Response

On May 8, 2006, a man aged 39 years from the Hardap region, approximately 400 km southeast of the capital city of Windhoek, was admitted to a Windhoek hospital after onset of AFP 2 days earlier. On June 5, the Regional Reference Poliovirus Laboratory at the National Institute of Communicable Diseases in South Africa reported isolation of WPV1 in the patient's stool specimens. AFP surveillance was intensified, and as of October 2, 2006, a total of 306 AFP cases had been reported for the year (Figure 1).

Of the 306 AFP cases, 19 cases were confirmed as polio through WPV1 isolation, with the most recent onset of paralysis occurring on June 26. Of the other 287 AFP cases, 201 were classified as nonpolio AFP, and the National Polio Expert Committee classified seven cases as polio compatible. Another 66 AFP cases, with inadequate† stool specimens, all virus-negative, are pending classification, including some that subsequently might be classified as polio compatible; 13 additional cases are pending laboratory results and subsequent classification. In addition to the single case reported from the Hardap region, WPV-confirmed cases were reported from two densely populated areas: 1) informal settlements (i.e., areas with temporary substandard housing, poor sanitation, and crowding) in the Katutura vicinity of Windhoek in the Khomas region (14 WPV cases), and 2) three adjacent regions bordering Angola: Ohangwena and Omusati, with one case each, and Oshana, with two cases (Figure 2).

Compared with patients with nonpolio AFP, the WPV patients more often reported having contact with persons from Angola during the 3 months preceding paralysis onset (Fisher's exact test, p = 0.007). All WPV-confirmed cases occurred in persons aged >14 years (range: 14–51 years), with 14 (74%) of 19 confirmed cases in persons aged 15–29 years. Seventeen (89%) of the 19 patients were male. Six patients with confirmed WPV died (case-fatality ratio [CFR]: 32%); four of the six who died had respiratory symptoms requiring ventilator support, and at least one other patient developed respiratory difficulty shortly before death.

In response to the outbreak of WPV cases, the Namibia Ministry of Health and Social Services (MoHSS) activated the National Health Emergency Management Committee to coordinate activities. Three nationwide SIAs were held during June 21–23, July 18–20, and August 22–24, 2006, using both house-to-house and fixed-post vaccine delivery strategies. Because most patients were adults, the first two SIAs targeted the entire population of Namibia (i.e., adults and children of all ages); the third round targeted only children aged <5 years. Monovalent oral poliovirus vaccine type 1 (mOPV1) was administered during the first two SIAs; trivalent OPV (tOPV) was administered during the third SIA, along with measles vaccine and distribution of vitamin A supplements.

Based on the number of vaccine doses administered and current population estimates, close to 100% of the target populations were reached during all three SIAs. Postcampaign monitoring conducted in nine of the 13 regions determined vaccination coverage of >95%. The second and third SIAs were conducted after onset of the last reported confirmed case of polio, which occurred on June 26, 5 days after the first nationwide SIA (Figure 1).

Previous Outbreaks in Namibia

Namibia reported no polio cases from 1990 until May 1993, when an outbreak of 53 WPV1 cases (27 virologically confirmed and 26 clinically compatible) occurred. Seventy-nine percent of patients in the 1993 outbreak were aged <5 years. A smaller WPV1 outbreak with 27 cases occurred in the northern regions of Namibia during 1994–1995 (*1*). Both outbreaks were linked by genetic sequencing to WPV imported from Angola. The most recent reported WPV case before 2006 occurred in September 1995.

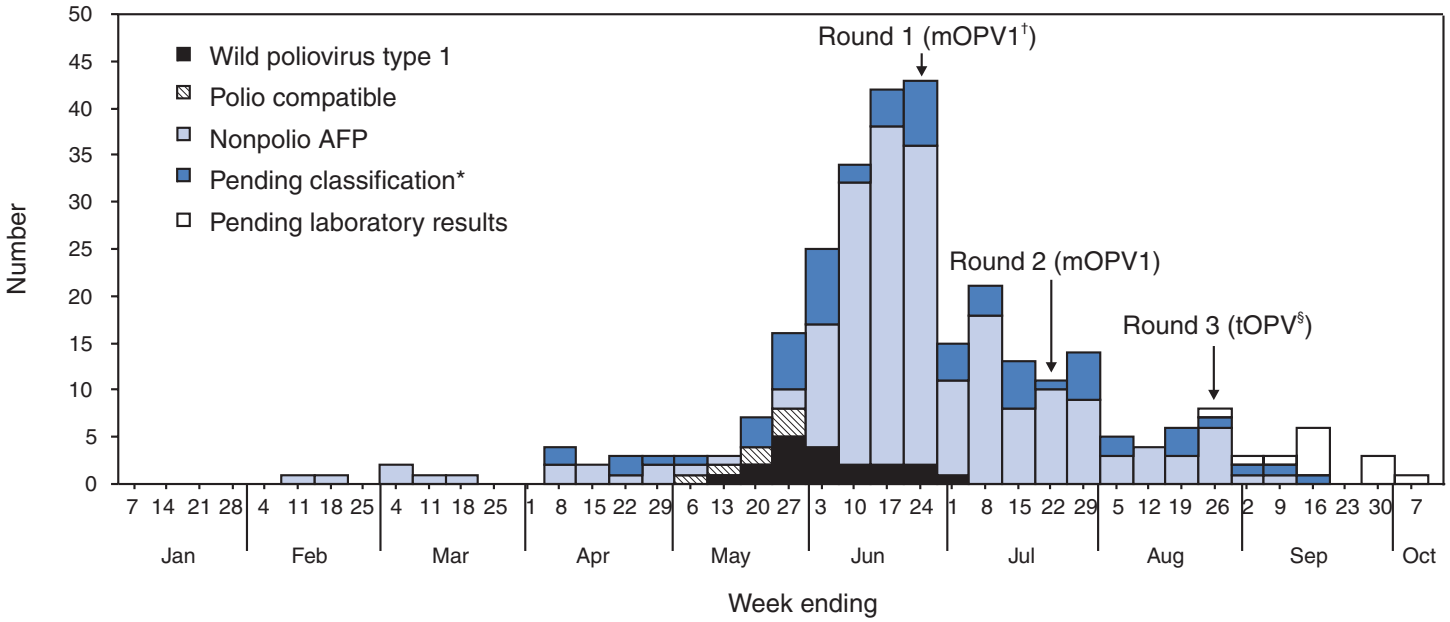
Immunization Activities

The Namibian Expanded Program on Immunization (EPI) was established in June 1990, the year Namibia gained independence from South Africa. Public health services,

* Nationwide mass campaigns during a short period in which 2 doses of oral poliovirus vaccine are administered to all persons in the target age group, regardless of vaccination history, with an interval of 4–6 weeks between doses.

† AFP cases with inadequate stool specimens are those that lack the following: two stool specimens collected at least 24 hours apart within 14 days of paralysis onset and shipped to the laboratory in good condition. Adequate stool specimens meet these criteria.

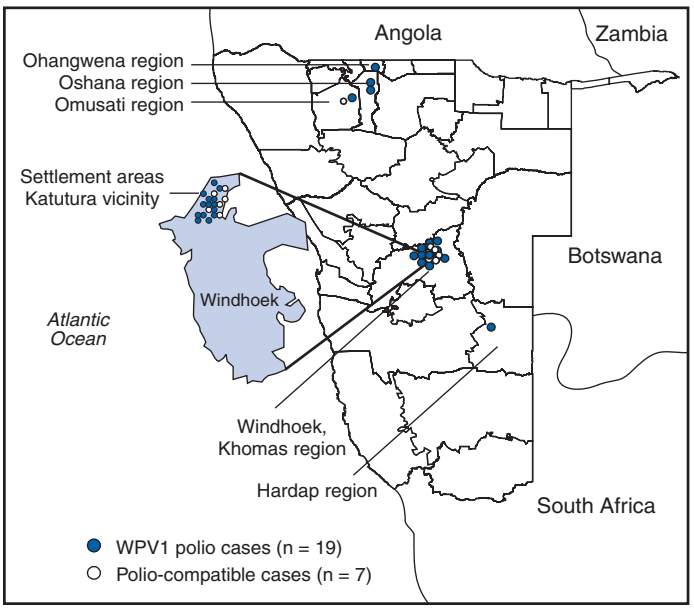
FIGURE 1. Acute flaccid paralysis (AFP) cases (N = 306), by week of onset — Namibia, January 1–October 2, 2006



* Pending classification by the National Polio Expert Committee. Cases pending classification include those with no stool specimens or inadequate stool specimens and might be classified as polio-compatible or nonpolio AFP after committee review. No poliovirus was isolated from inadequate stool specimens.
† Monovalent oral poliovirus vaccine type 1.
§ Trivalent oral poliovirus vaccine.

including immunization, had been severely disrupted by conflict during 1966–1989. Immunization services improved after 1990, with survey estimates for infant coverage with 3 doses of oral poliovirus vaccine (OPV3), increasing from 37% in 1989 to 76% in 2000 (Table). However, during 1989–2000, coverage estimates varied among regions (*2,7,8*); for example, OPV3 coverage varied by region from 48% to 78% in 1992 (*7*). Since 2000, annual national estimates of coverage with OPV3 have ranged from 64% to 83% (Table), with continued variation among regions. OPV3 coverage exceeded 80% in 20 (61%) of 33 districts in 2004 and 10 (30%) of 33 districts in 2005. In addition to routine immunization, annual SIAs have been held since 1996, targeting children aged <5 years.

FIGURE 2. Wild poliovirus type 1 (WPV1) cases and polio-compatible cases — Namibia, May 1–October 2, 2006



AFP Surveillance

Although most AFP cases are nonpolio (i.e., resulting from causes other than poliomyelitis), meeting goals for AFP surveillance helps to ensure that the surveillance system is sensitive enough to detect poliomyelitis cases should they occur. AFP surveillance is evaluated by two key indicators: sensitivity of reporting (target: nonpolio AFP rate of ≥1.0 case per 100,000 children aged <15 years[§]) and completeness of specimen collection (target: two adequate stool specimens collected from ≥80% of all AFP cases). During 2001–2005, national nonpolio AFP rates in Namibia exceeded ≥1.0 case per 100,000 persons aged <15 years (2.6 in 2004 and 2.0 in 2005). With the increase in AFP reporting during the outbreak, AFP rates in 2006 have exceeded 2.0 cases in all regions. Nationally,

§ In 2006, this indicator was changed to two cases per 100,000 children aged <15 years.

TABLE. Estimated vaccination coverage with 3 doses of live, attenuated oral poliovirus vaccine among children aged ≤12 months, by source of estimate — Namibia 1989–2006

* WHO/UNICEF estimate, based on country reports to WHO or UNICEF.
† Namibia Demographic and Health Survey (conducted in 1992 and 2000). Coverage estimates for 1989–1991 are based on data collected during the 1992 survey, shifted by year to match birth cohorts (*7,8*).

adequate stool specimens were obtained from >80% of persons with AFP during 2003–2005. However, adequate stool collection during January 1–October 2, 2006, was 67%, and exceeded 80% in only four of Namibia's 13 regions.

Genetic sequencing determined that the WPV1 in the Namibia outbreak belongs to the same cluster as the virus detected in 2005 in both Angola and the Democratic Republic of Congo, which had been imported into Angola from India. Sequencing indicated that this outbreak virus had been circulating for up to 2 years in the southwest subregion of Africa before detection in 2005. Consistent with recent undetected circulation and ongoing surveillance gaps, Angola reported 10 WPV1 cases in 2005 but none in 2006 until reporting a case with onset June 27, 2006. The genetic sequence relationships among the Namibian isolates indicate that spread of the virus occurred from a single-source importation.

Reported by: *World Health Organization (WHO) Namibia Office, Windhoek; Inter-Country Program Office, WHO, Harare; Regional Office of WHO for Africa, Harare, Zimbabwe; Polio Eradication Group, WHO, Geneva, Switzerland. National Institute of Communicable Diseases Laboratory, Johannesburg, South Africa. Global Immunization Div and Div of Viral Diseases, National Center for Immunization and Respiratory Diseases (proposed), CDC.*

Editorial Note: This 2006 outbreak underscores the ongoing threat of WPV importations into polio-free areas, the ability of WPV to spread to susceptible populations of any age, and the need for polio-free countries to maintain high levels of preparedness for the timely detection of and response to importations. In this outbreak, virus importation from Angola was indicated by sequencing data, the frequency of cross-border contacts between population groups from Namibia and Angola, and the higher frequency of contact with Angolan residents by patients with confirmed WPV infection compared with patients with nonpolio AFP.

The Namibia outbreak illustrates that populations of any age with low immunity against poliovirus are at risk. This outbreak primarily affected young adults born before 1990, an age group consisting of persons who either had not been vaccinated for polio or had been vaccinated incompletely. For the most part, this group also would not have been covered by EPI SIAs conducted four times a year during 1990–1995 and targeted to children aged <5 years. Increasing vaccination coverage among children aged <5 years in the early 1990s would have reduced transmission of WPV, decreasing opportunities for older, unvaccinated persons to acquire natural immunity, a factor possibly contributing to the high attack rate in older age groups. Previous polio outbreaks among adults included a large outbreak (138 paralytic cases, 69 confirmed WPV1 cases) in Albania in 1996, with an attack rate of 10 per 100,000 persons among adults aged 19–25 years who had been vaccinated with OPV that might have been stored without refrigeration for prolonged periods (*3*). Outbreaks affecting adults also have occurred among religious groups with low vaccination acceptance (*4*).

The CFR was 32% in this outbreak involving young adults. High CFRs in young adults during polio outbreaks have been reported previously. In an outbreak in Cape Verde in 2000, the CFR was 57% among persons aged >15 years (*5*). In the 1996 outbreak in Albania, the CFR was highest (18%) among persons aged 19–25 years (*3*). In the 2006 outbreak in Namibia, at least five of the six patients who died had respiratory symptoms, and four required ventilator support, suggesting that bulbar paralysis might have contributed to the high CFR.

During 2004 and 2005, AFP surveillance systems in Namibia and Angola, at the national level, surpassed the key indicators for sensitivity of reporting and completeness of specimen collection. However, WPV circulation in the southwest African subregion escaped detection for approximately 2 years, suggesting considerable AFP surveillance quality gaps at the subnational level. During the 2006 outbreak, only four of Namibia's 13 regions have met the 80% stool adequacy standard. Surveillance training targeting district and regional MoHSS staff members was held in July, August, and September 2006. Maintaining sensitive surveillance and stool adequacy levels in Namibia and surrounding countries is critical to rapid detection of WPV virus circulation.

WHO's Advisory Committee on Polio Eradication recommends that any polio-free country that detects imported WPV conduct at least three large-scale, house-to-house SIAs using type-specific mOPV, initiating the first within 28 days of confirmation, and continuing with at least two additional SIAs after the last virus is detected (*6*). Namibia followed these recommendations, conducting the first SIA round, which targeted the entire population, within 3 weeks of laboratory confirmation of the first WPV-confirmed case and 46 days after the first onset of paralysis. The last known WPV-confirmed case occurred less than a week after the first SIA, with no WPV-confirmed cases reported since then, although the 66 cases with inadequate stool specimen collection pending review and classification by the National Polio Expert Committee are of concern. Additional SIA rounds in Namibia will be necessary if more WPV cases are detected.

The risk for continuing WPV spread from Angola south to Namibia or north to the Democratic Republic of Congo remains high until circulation in Angola is interrupted. SIAs in Angola are planned for November 16–18, 2006. The increase in the number of WPV cases reported from endemic countries (particularly Nigeria and India) in 2006 underscores the continuing threat of importations from polio-endemic countries and the necessity for full implementation of outbreak response recommendations (*6*) by all polio-free countries until poliovirus transmission is interrupted globally.

Acknowledgment

The findings in this report were based, in part, on data provided by the Namibia Ministry of Health and Social Services.

Diagnosed Diabetes Among American Indians and Alaska Natives Aged <35 Years — United States, 1994–2004

Diabetes disproportionately affects American Indians/Alaska Natives (AI/ANs) (*1,2*), and the prevalence of diabetes is increasing among young persons in certain AI/AN populations (*3*). To examine trends in the prevalence of diagnosed diabetes among AI/ANs aged <35 years, CDC analyzed patient data collected by the Indian Health Service (IHS) during 1994–2004. This report summarizes the results of that analysis, which indicated that the age-adjusted prevalence of diagnosed diabetes increased from 8.5 to 17.1 per 1,000 population among AI/ANs aged <35 years who use IHS health-care services. Because young persons with diabetes have more years of disease and greater risk for costly and disabling complications early in life (*4*), diabetes prevention programs targeting younger age groups have become increasingly important in AI/AN communities.

IHS provides health-care services at its facilities and through tribal and urban Indian health programs; IHS also purchases services through contractual agreements with private providers (*5*). Approximately 60% of the nearly 3 million AI/ANs residing in the United States live in IHS health-care delivery areas (*5*). Diabetes cases among AI/ANs aged <35 years were identified using *International Classification of Diseases, Ninth Revision, Clinical Modification* diagnostic codes 250.0–250.9 from the IHS computerized system for ambulatory patient care for 1994–2004. The ambulatory patient-care database includes unduplicated case reports from patients who visited IHS service units one or more times during each of the years studied. Ambulatory patient-care data were analyzed from 118 of 158 service units; 40 service units (serving approximately 6% of the IHS user population) were excluded because their reported data were incomplete. Prevalence was calculated using the AI/AN population aged <35 years that received IHS health-care services at least once during the preceding 3 years. These overall population data and the number of persons aged <35 years identified in the IHS database as persons with diagnosed diabetes were used to estimate the age-specific prevalence of diagnosed diabetes among AI/ANs in four age groups: <15, 15–19, 20–24, and 25–34 years. Prevalence was age adjusted by the direct method, on the basis of the 2000 U.S. standard population, and average annual percentage changes (APCs) were modeled using regression analysis (*6*).

Results of the analysis indicated that the number of AI/ANs aged <35 years with diabetes diagnosed through IHS health-care services more than doubled from 6,001 in 1994 to 12,313 in 2004. During 1994–2004, prevalence of diagnosed diabetes among AI/ANs aged <35 years increased from an age-adjusted 8.5% per 1,000 to 17.1% per 1,000, increasing by an average of 7.7% per year (Table). Prevalence of diagnosed diabetes increased with age and, in 2004, ranged from 2.2 per 1,000 population among AI/ANs aged <15 years to 46.8 per 1,000 population among those aged 25–34 years. In 2004, the age-adjusted prevalence of diagnosed diabetes was 20.2 per 1,000 among AI/AN females and 13.7 among males (Table).

During 1994–2004, prevalence of diagnosed diabetes was greater among females than males in all age groups; prevalence also increased steadily for both sexes and in all age groups, with the exception of males aged 25–34 years (Figure). Among males in this age group, prevalence increased significantly ($p<0.05$) by an average of 5.6% per year during 1994–1997 and by 15.0% per year during 1997–2000, but did not change significantly during 2000–2004 (Table). Among all age groups, females aged 25–34 years had the greatest APC (9.1%).

TABLE. Prevalence* and annual percentage change (APC) of diagnosed diabetes among American Indians and Alaska Natives aged <35 years, by sex and age group — United States, 1994–2004

Age group (yrs)	Rate		Trend	
	1994	2004	APC	(95% CI†)
Both sexes				
<15	1.3	2.2	4.7	(2.1–7.4)
15–19	4.4	7.4	5.9	(4.5–7.3)
20–24	8.7	15.3	5.5	(4.0–7.0)
25–34	22.1	46.8	8.5	(6.9–10.1)

<15	1.2	1.9	4.5	(1.6–7.5)
15–19	3.2	5.5	6.5	(5.2–7.8)
20–24	7.6	10.7	3.7	(2.6–4.8)
25–34	20.4	38.1	7.6¶	(5.8–9.5)
<35	6.5	11.4	6.6	(5.3–7.9)
<35§	7.7	13.7	6.9**	(5.3–8.5)

* Per 1,000 population in age group.
† Confidence interval.
§ Age adjusted to the 2000 U.S. standard population.
¶ APCs varied widely for intervals during the period: 5.6% ($p<0.05$) during 1994–1997, 15.0% ($p<0.05$) during 1997–2000, and 1.2% ($p = 0.19$) during 2000–2004.
** APCs varied widely for intervals during the period: 4.9% ($p<0.05$) during 1994–1997, 13.3% ($p<0.05$) during 1997–2000, and 1.5% ($p = 0.10$) during 2000–2004.

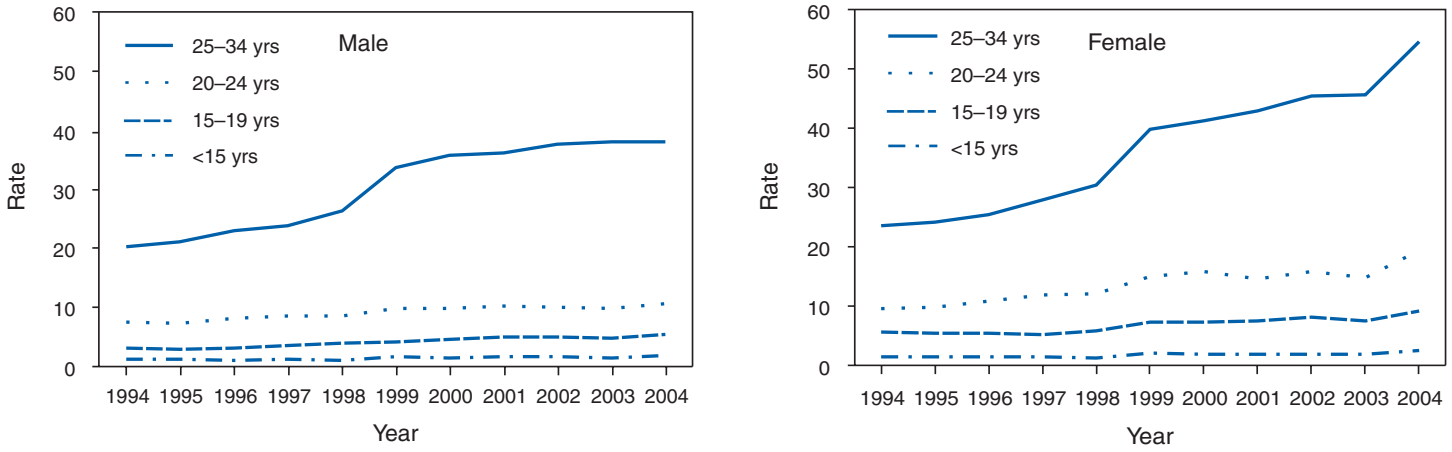
Reported by: *KJ Acton, MD, Div of Diabetes Treatment and Prevention, Indian Health Service. NR Burrows, MPH, J Wang, MPH, LS Geiss, MA, Div of Diabetes Translation, National Center for Chronic Disease Prevention and Health Promotion, CDC.*

Editorial Note: The findings in this report indicate that, during 1994–2004, the prevalence of diagnosed diabetes doubled among AI/ANs aged <35 years in the IHS health-care delivery system. This increase in diagnosed diabetes might be the result of increased incidence of diabetes (*3*), increased screening for diabetes, or a combination of both. Screening for diabetes increased in AI/AN communities after implementation in 1997 of the Special Diabetes Program for Indians (SDPI) (*7*). In partnership and consultation with tribal leadership, IHS provided SDPI grants to create and enhance approximately 400 new diabetes prevention and treatment programs in AI/AN communities in the 35 states that contain the 12 IHS administrative areas.

If the increase in diagnosed diabetes described in this report represents an increase in the actual total prevalence (i.e., diagnosed plus undiagnosed) of diabetes among AI/ANs aged <35 years, that would be of particular concern. Earlier onset of diabetes increases the lifetime duration of disease and thus the risk for costly and disabling complications (*4*). The large increase among young females also is of concern because diabetes is a major cause of congenital anomalies, malformations, and perinatal death in the offspring of young women with diabetes (*4*). Furthermore, the children of mothers with diabetes during pregnancy might be at increased risk for having diabetes themselves (*3*). The greater prevalence of diagnosed diabetes among AI/AN females might have resulted from a greater number of health-care visits (e.g., for prenatal care) compared with males (*5*). Increasing rates of diabetes detected during pregnancy screening (*8*) might explain why the greatest APC was among females aged 25–34 years. Why the prevalence of diagnosed diabetes among males aged 25–34 years remained level during 2000–2004 is unknown.

The findings in this study are subject to at least five limitations. First, the data underestimate the actual prevalence of diabetes because they do not include information on persons with undiagnosed diabetes. Second, outpatient visits for diabetes screening might have been miscoded as diabetes visits, resulting in overestimates of the prevalence of diagnosed diabetes if the screening results were negative. Third, lack of clinical data did not enable distinguishing between type 1 and type 2 diabetes. However, previous studies have determined that, among AI/ANs, diabetes is predominantly type 2 (*3,4*). Fourth, approximately 6% of persons using IHS health-care

FIGURE. Prevalence* of diagnosed diabetes among American Indians and Alaska Natives aged <35 years, by sex and age group — United States, 1994–2004



* Per 1,000 population in age group.

services were excluded from this analysis because of incomplete data. Finally, data on diabetes prevalence were not collected for the 40% of the AI/AN population who do not use IHS or tribally operated health-care facilities (*5*). However, despite these limitations, previous research has indicated that IHS data are sufficiently consistent over time to estimate trends (*2*).

Randomized controlled trials such as the Diabetes Prevention Program (DPP) have determined that lifestyle interventions to reduce weight and increase physical activity can prevent or delay diabetes among adults at risk (*9*). In 2004, as part of the SDPI, IHS awarded 36 diabetes-prevention demonstration projects to translate DPP findings at the local level. In 2006, in collaboration with IHS, the American Association of Indian Physicians, and other partners, the National Diabetes Education Program (NDEP) distributed the "Move It! And Reduce Your Risk for Diabetes" kit to schools to help increase physical activity among young AI/ANs (available at http://www.ndep.nih.gov/diabetes/aian/moveit.htm). NDEP is a program sponsored by CDC and the National Institutes of Health to promote diabetes prevention and also control strategies for improving the treatment and outcomes of persons with diabetes.

In collaboration with IHS, CDC established the Native Diabetes Wellness Program (formerly the National Diabetes Prevention Center) to identify and share culturally relevant and appropriate interventions. One activity of this program was development and dissemination of The Eagle Books series for children, which focuses on physical activity, eating healthy foods, and learning about health and diabetes prevention (available by telephone, 800-CDC-INFO, or e-mail, cdc-info@cdc.gov). Information regarding a related CDC exhibit is available at http://www.cdc.gov/gcc/exhibit/exhibitions_changing.htm.

West Nile Virus Activity — United States, January 1–November 7, 2006

This report summarizes West Nile virus (WNV) surveillance data reported to CDC through ArboNET as of 3 a.m. Mountain Standard Time, November 7, 2006. A total of 41 states and the District of Columbia had reported 3,830 cases of human WNV illness to CDC (Figure, Table).

A total of 2,093 (55%) cases for which such data were available occurred in males; median age of patients was 51 years (range: 3 months–99 years). Dates of illness onset ranged from January 6 to October 22; a total of 119 cases were fatal.

A total of 306 presumptive West Nile viremic blood donors (PVDs) have been reported to ArboNET during 2006. Of these, 42 were reported from Nebraska; 33 from Texas; 26 from Colorado; 24 from Utah; 20 from Louisiana; 15 from California; 13 each from Arizona and Oklahoma; 12 from South Dakota; 11 each from Kansas and North Dakota; 10 each from Iowa, Mississippi, and Wisconsin; seven each from Indiana and Ohio; six from Idaho; five each from Minnesota and Virginia; four each from Kentucky, Missouri, and Montana; three each from Illinois and Nevada; two from Michigan; and one each from Arkansas, Maryland, New York, Oregon, Pennsylvania, and Wyoming. Of the 306 PVDs, three persons (median age: 73 years [range: 26–74 years]) subsequently had neuroinvasive illness, two persons (median age: 45 years [range: 41–49 years]) subsequently had other illness, and 65 persons (median age: 47 years [range: 17–71 years]) subsequently had West Nile fever.

§ Cases with no evidence of neuroinvasion.
¶ Illnesses for which sufficient clinical information was not provided.
** Total number of human cases of WNV illness reported to ArboNET by state and local health departments.

In addition, 3,214 dead corvids and 745 other dead birds with WNV infection have been reported in 42 states and New York City during 2006. WNV infections have been reported in horses in 34 states, in one squirrel in Kansas, and in two unidentified animal species in North Carolina and Wyoming.

WNV seroconversions have been reported in 846 sentinel chicken flocks in 12 states (Arizona, Arkansas, California, Florida, Iowa, Montana, Nevada, North Carolina, North Dakota, Pennsylvania, Utah, and Virginia). A total of 10,759 WNV-positive mosquito pools have been reported from 38 states, the District of Columbia, and New York City.

Additional information regarding national WNV activity is available from CDC at http://www.cdc.gov/ncidod/dvbid/westnile/index.htm and at http://westnilemaps.usgs.gov.

Public Health Informatics Fellowship Application Deadline

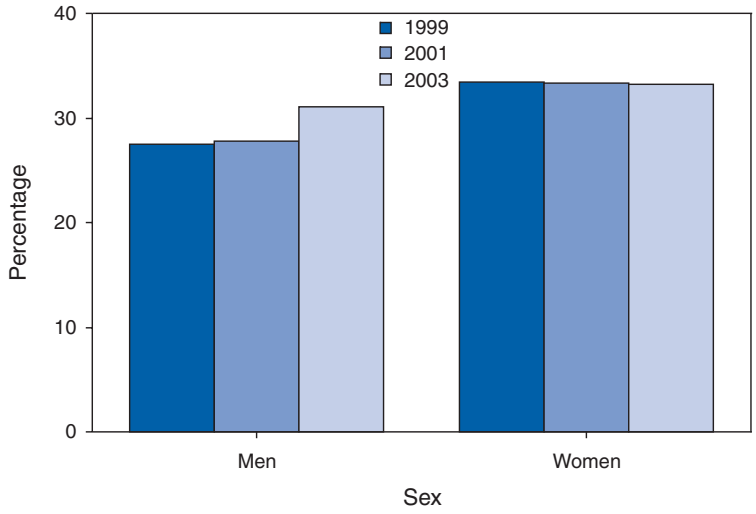
CDC offers a 2-year postgraduate fellowship in public health informatics, the systematic application of information technology to public health practice, research, and learning. Fellows receive training in both informatics and public health, are assigned to teams involved in research and development of CDC information systems, and are given the opportunity to lead one or more major projects during their fellowships.

Deadline to apply for the fellowship period beginning July 2007 is December 15, 2006. Applications are available at https://www.orau.gov/cdc/phip/login.asp. Additional information regarding the Public Health Informatics Fellowship Program is available by telephone, 404-498-6129, or e-mail, phitpepo@cdc.gov and bmcdonnell@cdc.gov.

QuickStats

FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Prevalence of Obesity* Among Adults Aged ≥20 Years, by Sex — National Health and Nutrition Examination Survey (NHANES), United States, 1999–2000 Through 2003–2004



* Defined as having a body mass index (weight [kg]/height [m^2]) ≥30.

From 1999–2000 through 2003–2004, the prevalence of obesity among men increased significantly from 27.5% to 31.1%. During the same period, no significant change occurred among women, 33.2% of whom were obese in 2003–2004. Additional information regarding NHANES is available at http://www.cdc.gov/nchs/nhanes.htm.

—: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts.

* Incidence data for reporting year 2006 are provisional, whereas data for 2001, 2002, 2003, 2004, and 2005 are finalized.

† Calculated by summing the incidence counts for the current week, the two weeks preceding the current week, and the two weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.

§ Not notifiable in all states.

¶ Includes both neuroinvasive and non-neuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed) (ArboNET Surveillance).

** Data for *H. influenzae* (all ages, all serotypes) are available in Table II.

†† Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention (proposed). Implementation of HIV reporting influences the number of cases reported. Pediatric HIV data will not be updated monthly for the remainder of this year due to upgrading of the national HIV/AIDS surveillance data management system. Data for HIV/AIDS are available in Table IV quarterly.

§§ Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases (proposed).

¶¶ No measles cases were reported for the current week.

*** Data for meningococcal disease (all serogroups and unknown serogroups) are available in Table II.

††† Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed).

U: Unavailable. —:No reported cases.

* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

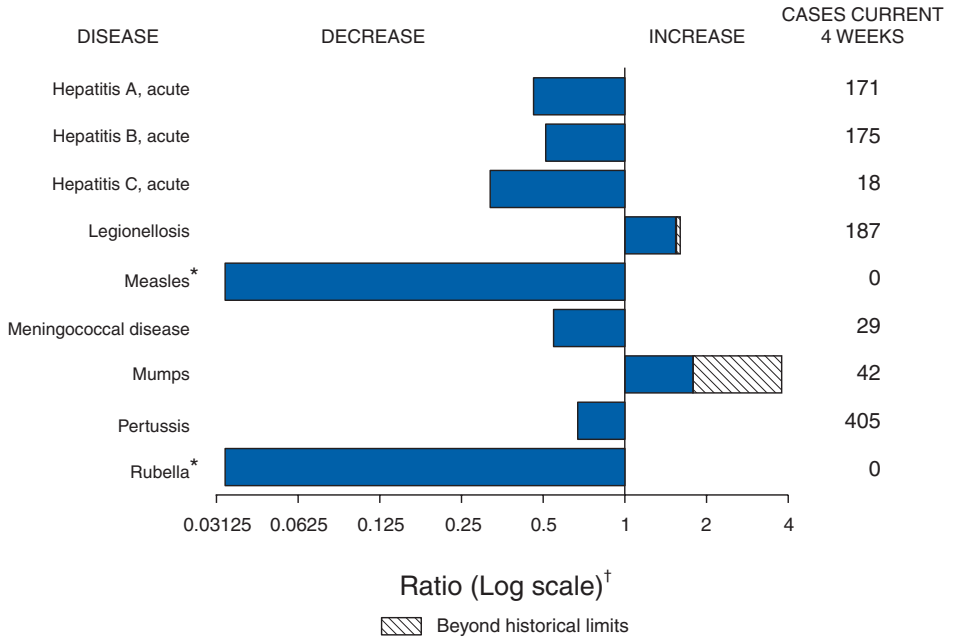
† Pneumonia and influenza.

§ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶ Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.

** Total includes unknown ages.

FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals November 4, 2006, with historical data



* No measles or rubella cases were reported for the current 4-week period yielding a ratio for week 44 of zero (0).
† Ratio of current 4-week total to mean of 15 4-week totals (from previous, comparable, and subsequent 4-week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's Internet server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to *www.mmwrq@cdc.gov*.
