Template Issues and Proposed Resolutions

Revision 18

John H. Spicer
Edison Design Group, Inc.
jhs@edg.com

March 7, 1996

Revision History

Version 16 (96-0158/N0976) – July 17, 1996: Distributed in the post-Stockholm mailing. Reflects decisions made in Stockholm.
Version 17 (97-0011/N1049) – January 28, 1997: Distributed in the pre-Nashua mailing. Reflects decisions made in Kona and contains new issues.
Version 18 (97-0015/N1053) – March 7, 1997: Distributed at the Nashua meeting and in the post-Nashua mailing. Contains additional new issues.

Summary of Issues

Other Issues

Member Template Issues

8.3 Can a member function template be used as a copy constructor or copy assignment operator? (closed in version 17)

8.10 What kind of entity can appear in a template friend declaration?

8.11 Clarification of conversion template instance names and using-declarations.

Other Issues

6.46 Question: What are the rules used to determine whether expressions involving nontype template parameters are equivalent?

Status: Open

A template may be declared in one (or more) translation unit(s) and defined in still another. Because such declarations may involve expressions containing nontype parameters, rules are needed to determine when one such declaration in one translation unit is considered to match another declaration in a different translation unit.

Nontype template parameters cannot be deduced from function parameters in which they are used in expressions, but they can be used in nondeduced contexts (such as return types) and when explicitly specified.

file1.c:

```
template <int I> struct A {};
template <int I, int J> A<I+J> operator +(A<I>, A<J>);
template <int I, int J, class T>
void f(A<I>, A<I*2>, A<(I + J + sizeof(T));

int main()
{
        A<1> a1;  A<2> a2;  A<3> a3;  A<7> a7;
        a3 = a1 + a2;

        f<1,2,int>(a1, a2, a7);
}
```

file2.c:

```
template <int I> struct A {};
template <int I, int J> A<J+I> operator +(A<I>, A<J>);  // error
template <int I, int J, class T>
void f(A<I>, A<I*2>, A<(sizeof(T) + (I + J));  // error
```

Answer: Expressions involving nontype template parameters are compared using an ODR-like rule (can the ODR wording be extended to cover this case?). That is, the tokens that make up the expression must be identical, and the names of entities must refer to the same entities in each translation unit. If two templates are considered to "potentially equivalent", but violate this rule, the results are undefined (or should it be ill-formed with

no diagnostic required?) Two templates of a given name in a given scope are considered "potentially equivalent" if they have identical template parameter lists and if, for every given set of template arguments, they result in the generation of functions with the same type.

In other words, function templates that are ODR-identical are guaranteed to refer to the same entity. Function templates that are not "potentially equivalent" are guaranteed to refer to different entities. And function templates that are potentially equivalent render a program undefined (ill-formed, no diagnostic required?)

```
// Guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// Guaranteed to be the different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// Undefined whether these two declarations refer to the same template
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```

Version updated: 15

6.49 Question: Where are partial specializations allowed?

Status: Open

Answer: A partial specialization must be declared in the class or namespace in which it is a member. Once declared, it may later be defined outside of the class or namespace.

Version added: 17
Version updated: 17

6.50 Question: Clarification of the interaction of friend declarations and partial specializations

Status: Open

Answer: A template friend class declaration indicates that all instances of that template are friends of the given class regardless of whether those instances are generated from the primary template, a partial specialization, or a full specialization (i.e., explicit specialization).

```
class X {
        template <class T> friend struct A;
        class Y {};
};

template <class T> struct A { X::Y ab; };  // okay
template <class T> struct A<T*> { X::Y ab; };  // okay
```

Consequently, a friend declaration is not allowed to declare a partial specialization:

```
template <class T> struct A {};
template <class T> struct A<T*> {};

class X {
        template <class T> friend struct A<T*>;  // not allowed
};
```

6.51 Clarification of nontype dependency rule in partial specializations

Status: Open

14.5.4 [temp.class.spec] paragraph 5, bullet 2 was editorially changed from

- The type of a specialized nontype argument shall not depend on another type parameter of the specialization.

to

- The type of a specialized argument shall not depend on another type parameter of the specialization.

This rule was intended to prohibit examples such as:

```
template <class T, T t> struct A;
template <class T> struct A<T, 1>;
```

There are two problems with the change that was made. The first problem is that the "specialized" vs. "nonspecialized" distinction only exists for nontype arguments, not for type arguments, so it is impossible to know what a "specialized" type argument might be. But, assuming that a "specialized" type argument is anything other than a type parameter name, the wording change prohibits a large class of partial specializations that should be permitted, such as:

```
template <class T1, class T2> struct A {};
template <class T1> struct A<T1, T1*> {};
```

Answer: The original wording should be restored.

Version updated: 17

6.52 Clarification of ordering rules for nontype arguments in partial specializations.

Status: Open

A mistake in the original description of the partial ordering rules for nontype arguments has resulted in an unnecessary complication of the partial ordering rules, a gratuitous difference in the partial ordering rules for classes and functions, and a needless restriction in the kinds of partial specialization that can be done.

The fundamental mechanism used to determine ordering of partial specializations is the template argument deduction mechanism. All of the other rules relating to partial specializations are really clarifications of the implications of the argument deduction process. For

example, the restriction that nontype arguments cannot be used in expressions in partial specializations is derived from the fact that it is not generally possible to deduce values from expressions.

Recall that the original example, which is prohibited by the WP rules, is:

```
template<int I, int J, class T> class X {};            // #1
template<int I, int J>          class X<I, J, int> {}; // #2
template<int I>                 class X<I, I, int> {}; // #3
```

But the same example rewritten as a set of overloaded function templates is permitted, and calls made using this set of templates will select the appropriate template.

```
template <int I, int J, class T> void f(X<I, J, T>);   // #1
template <int I, int J>          void f(X<I, J, int>); // #2
template <int I>                 void f(X<I, I, int>); // #3
```

Answer:

The WP should be modified as suggested by Fergus Henderson in `c++std-core-7283`:

In

```
| 14.5.4.2  Partial ordering of class template        [temp.class.order]
|           specializations
```

replace

```
| 1 For two class template partial specializations, the first is at  least
|   as specialized as the second if:
|
|   --the  type  arguments  of  the  first template's argument list are at
|     least as specialized as those of the second template's argument list
|     using the ordering rules for function templates (_temp.func.order_),
|     and
|
|   --each non-type argument of the first template's argument list  is  at
|     least as specialized as that of the second template's argument list.
|
| 2 A non-type argument is at least as  specialized  as  another  non-type
|   argument if:
|
|   --both are formal arguments, or
|
|   --the first is a value and the second is a formal argument, or
|
|   --both are the same value.
```

with

```
| 1 For two class template partial specializations, the first is at
|   least as specialized as the second if the arguments of the first
|   template's argument list are at least as specialized as those of
|   the second template's argument list using the ordering rules for
|   function templates (_temp.func.order_).
```

Version updated: 17

6.53 Clarification of rules for partial specializations of member class templates.

Status: Open

1. When a member template of a class template is partially specialized, the partial specializations apply to all instances generated from the enclosing class template.
2. When the primary template is specialized for a given instance of the enclosing class, none of the partial specializations of the original primary template are carried over.

```
template <class T> struct A {
        template <class T2> struct B {};  // #1
        template <class T2> struct B<T2*> {};  // #2
};

template <> template <class T2> struct A<short>::B {};  // #3

A<char>::B<int*> abcip;  // uses #2
A<short>::B<int*> absip;  // uses #3
```

3. When the primary template is not specialized, the individual partial specializations of the primary template may be specialized (but additional partial specializations cannot be added).

```
template <class T> struct A {
        template <class T2> struct B {};  // #1
        template <class T2> struct B<T2*> {};  // #2
};

template <> template <class T2> struct A<short>::B<T2*> {};  // #3

A<short>::B<int> absi;  // uses #1
A<short>::B<int*> absip;  // uses #3
```

6.54 Array/function decay in template parameter/argument lists.

Status: Open

Sean Corfield, in `c++std-ext-3734` raised the issue of whether the handling of nontype array parameters in the WP is correct.

The WP specifies that type decay (array to pointer and function to pointer) does not occur for template nontype parameters (this was specified by issue 2.12 in revision 6 of this paper), but seems to suggest that the decay takes place on the template argument side.

The decay should either take place on both sides or on neither side. As things now stand, you can declare a nontype parameter of array type, but you can't actually supply an array argument.

After investigating what a number of existing compilers do in this situation, my recommendation is that they decay should occur on both the parameter and argument side. EDG, g++, Microsoft, Sun, and Watcom all do the decay on both sides. Borland does the decay on the argument side, but only when the template parameter is a pointer type. cfront does the decay on the argument side, but does not allow template parameters of array type.

To summarize, all of the compilers to which I have access do the decay on the argument side in some or all cases. Most also do the decay on the parameter side.

6.55 Interaction of partial ordering and default arguments and ellipsis parameters.

Status: Open

The WP does not describe how default arguments and ellipsis parameters should be handled with respect to partial ordering of function templates.

Answer: Partial ordering comes into play when two templates are equivalent as far as overload resolution is concerned. This is the case when choosing between templates 1 and 2 for the call of `f()` and 3 and 4 for the call of `g()` in the example below.

When partial ordering of function templates containing a different number of parameters is done, only the common parameters are considered.

```
template <class T> void f(T);                 // #1
template <class T> void f(T*, int=1);         // #2
template <class T> void g(T);                 // #3
template <class T> void g(T*, ...);          // #4

int main()
{
        int* ip;
        f(ip);        // calls #2
        g(ip);  // calls #4
}
```

Version updated: 18

6.56 Question: In which contexts should partial ordering of function templates be performed?

Status: Open

The only context in which the WP currently species that the partial ordering rules should be applied is as part of overload resolution in an ordinary call. The WP does not comment one way or the other on the other contexts in which partial ordering could be applied:

1. Taking the address of a template function instance.
2. Naming a template function instance as a friend.
3. An explicit specialization.
4. An explicit instantiation.
5. Selecting a placement delete function that matches a placement new operation.

The purpose of permitting templates to be specialized is to allow a special version of a class or function to be provided without having to modify the code that uses the specialization, or even know that a special version is being used. This requires that partial ordering be done in declaration contexts as well as expression contexts.

Consider the following example:

```
template <class T> struct X {};

template <class T> void f(T,T);
template <class T> void f(X<T>, X<T>);

template <class T> struct A {
        friend void f<>(T,T);
};

A<int> a;
A<X<int> > ax;
```

In this example, class template A wants to make the f function that operates on its template parameter type a friend of the class. The friend declaration cannot be disambiguated using explicit specification of function template arguments because that would only let instances of the unspecialized template become friends. In cases like this you want the friendship to be extended to the instance that will actually be called. This can only be accomplished by using the partial ordering rules.

Answer: Partial ordering should be done in all of the contexts described above.

Version updated: 18

6.57 Enumeration types as nontype parameters.

Status: Open

When clause 14 was reorganized a year ago, a change was made that inadvertantly made enumeration types invalid as nontype arguments.

```
enum E {e1};
template <E e> struct A {};
```

Before the change the WP said (in [temp.arg]):

> *A non-type non-reference template-argument shall be a constant- expression of non-floating type, ...*

After the reorganization it said:

> *A template-argument for a non-type non-reference template-parameter shall be an integral constant-expression of integral type ...*

Answer: To restore enumaration types this should be changed to:

> *A template-argument for a non-type non-reference template-parameter shall be an integral constant-expression of integral or enumeration type ...*

Version updated: 18

6.58 Clarification of the interaction of partial specializations and using-declarations.

Status: Open

If a using-declaration refers to a class template, and a partial specialization of that class template is declared after the using-declaration has been seen, is that partial specialization used in the scope containing the using-declaration?

Answer: Yes. A using-declaration makes a named entity from one scope visible in another scope. A partial specialization declares additional attributes of a class template, it does not declare an overloaded template of that name. Consequently, any partial specializations or full specializations that are declared also apply to the template when it is referenced via a using-declaration, even if the using-declaration appeared before the specialization was declared.

```
namespace N {
        template <class T> struct A {};  // #1
}

using N::A;

namespace N {
        template <class T> struct A<T*> {};  // #2
        template <> struct A<double> {}; // #3
}

A<int*> ap;  // uses #2
A<double> ad; // uses #3
```

Version updated: 18

Member Template Issues

8.3 Question: Can a member function template be used as a copy constructor or copy assignment operator?

Status: Approved in Kona

```
struct A {
        A();
        template <class T> A(const T&);
        template <class T> operator =(const T&);
};

int main()
{
        A a1;
        A a2(a1);  // Implicitly generated copy or template?
        a1 = a2;   // Implicitly generated assignment or template?
}
```

Answer: No, a member function template cannot be used as a copy constructor or copy assignment operator. The copy constructor and copy assignment are special operations, and the existence of a template that could potentially generate such a function should not be taken to mean that the user wants the template version to be used in place of the implicitly generated function.

If the user wants the template to be used, an explicitly written function that calls the template version must be written.

If we were to decide that the templates could be used for this purpose, there would be no way for a user to request that the implicitly generated function should be used in place of the template.

Version added: 15
Version updated: 15

8.10 Question: What kind of entity can appear in a template friend declaration?

Status: Open

The purpose of this issue is to clarify the rules regarding the matching of a template friend declaration with a prior declaration of a template.

Answer: A template friend declaration that refers to a member function template must match the previous declaration of the template. It is not possible to have a "partial friend" declaration in which some of the template parameters are bound to specific types.

```
template <class T> struct A {
        template <class T2> void f(T2);
};

template <class U> class B {
        template <class T>
        template <class T2> friend void A<T>::f(T2); // okay

        template <class T>
        template <class T2> friend void A<T2>::f(T); // error

        template <>
```

```
        template <class T2> friend void A<U>::f(T2); // error

        template <>
        template <class T2> friend void A<int>::f(T2); // error
};
```

Version added: 17
Version updated: 17

8.11 Clarification of conversion template instance names and using-declarations.

Status: Open

Answer: The purpose of this issue is to clarify that, although an instance of a conversion template can be named in a call, an explicit instantiation, and an explicit specialization, that such usage is not permitted in a using-declaration.

7.3.3 [namespace.udecl] paragraph 4 says:

> *A using-declaration used as a member-declaration shall refer to a member of a base class of the class being defined ...*

In the example below, class A has no member `operator int`, so the declaration is ill-formed.

```
struct A {
        template <class T> operator T();
};

A a;
int j = a.operator int();  // okay

struct B : public A {
        using A::operator int;  // ill-formed
};
```
