SECTION I. EXECUTIVE SUMMARY

Irrigation is used to increase agricultural crop production, maintain landscapes, support re-vegetation of disturbed soils, preserve soil structure, suppress dust, and protect plants from cold or freeze damage. From the perspective of crop insurance, increased crop production and plant protection are the primary foci. For the purposes of this deliverable, the effect of differing levels of irrigation on crop production, and particularly the effect of reduction in water application relative to historical applications, is the focus.

In the production of agricultural crops, irrigation either supplements natural precipitation or replaces natural precipitation in areas with little or no rainfall. Irrigation supports greater evapotranspiration in a crop field than would occur if the crop were not irrigated. Evapotranspiration is responsible for the movement of nutrients throughout the plant, support for the movement of carbon dioxide into the plant for photosynthesis, and maintenance of the plant's temperature. All these contribute to the growth of the plant. In general, more growth of a crop plant means a greater yield potential.

Solicitation D13PS59998, Indefinite-Delivery/Indefinite-Quantity (IDIQ) Contractor for Insuring Irrigation, was issued by the United States (U.S.) Department of Interior (DOI) on behalf of the United States Department of Agriculture (USDA) Risk Management Agency (RMA). The solicitation identifies the objective of the IDIQ contract overall as “to conduct research and analysis regarding irrigation policy for potential crop insurance program development.”¹

The Solicitation for the second Task Order (TO 2)² of the IDIQ contract calls for a first deliverable focusing on data collection related to insurance of irrigated crops under Federal Crop Insurance Corporation (FCIC) yield-based plans of insurance (including yield-based revenue plans). TO 2 also calls for an outline of recommended policy and procedures modifications to those yield-based crop insurance products to appropriately address changes in the amount of irrigation water applied to insured irrigated acreage. This document represents the deliverable to fulfill these requirements.

From year to year, the amount of irrigation water applied to each acre of commercial irrigated cropland may vary substantially. The amount applied is affected by the crop being produced; the amount of natural precipitation; temperature and wind; changes in water supply; management practices (e.g., tillage practices and planting times); and the irrigation technology being used. The amount of water a producer chooses to apply is also affected by economic decisions the producer makes related to the cost of applying irrigation water (whether these costs are for the water itself or the delivery of the water) and the potential revenue from the crop produced.

The FCIC insurance documents do not define “irrigation.” They do, however, define “Irrigated Practice,” and frequently use this term in describing insurance offers and loss adjustment. An “Irrigated Practice” is defined in the Basic Provisions and the Crop Insurance Handbook (CIH) as:

¹ U.S. DOI, 2013, Solicitation Number D13PS59998, pages 1, 3, and 10.

² U.S. DOI, 2013, Solicitation D14PD00062 under IDIQ contract D13PC00032, pages 6, 8 and 9.

A method of producing a crop by which water is artificially applied during the growing season by appropriate systems and at the proper times, with the intention of providing the quantity of water needed to produce at least the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage planted to the insured crop.^{3,4}

The reader should note this definition does not require the producer to maximize the yield. The definition only requires the producer to follow management practices intended to achieve the insured yield by “providing the quantity of water needed to produce at least the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage planted to the insured crop.”

The Solicitation introduces two new definitions related to the effects of reducing the amount of irrigation on insurance for commercial crops which are grown under an irrigated practice. The definitions for “Efficient Irrigation” and “Limited Irrigation” refer respectively to applying less irrigation water to an insured crop than was historically applied that will “likely not result” and will “likely result” in lower actual yields than “the average yield for the irrigated practice for that location.” Another way to say this is “Efficient Irrigation” involves applying less irrigation water to an insured crop than was historically applied yet likely results in a yield at least equal to the average yield for the irrigated practice for that location. “Limited Irrigation” occurs when applying less irrigation water than was historically applied yet most likely results in a yield lower than the average yield for the irrigated practice for that location.

The distinction between Efficient and Limited Irrigation is especially important when considering policy and procedures modifications to crop insurance programs to address appropriately any changes a producer makes in the management practices used for insured irrigated acreage. In the first case, changes are not required other than those that recognize Efficient Irrigation as an acceptable management practice under the definition of Irrigated Practice. This may include refinement of the definition of Efficient Irrigation. In the case of Limited Irrigation, if the crop is to be insured as irrigated, changes are required first so that insurance of the crop with an Irrigated Practice is allowed and then so the crop is neither insured with a higher than appropriate liability nor with an incorrect trigger for an indemnity payment; which may necessitate adjustments to expected yield.

The Contractor considered publicly available data from government and private sources that could support appropriately modifying the policy and procedures for crop insurance for irrigated crops when the producer uses Efficient or Limited Irrigation. The publicly available data include in the USDA National Agricultural Statistics Service (NASS), RMA, state irrigation survey, and published research data. NASS data reviewed included aggregate data published in the NASS

³ USDA, RMA, 2013, 2014 Crop Insurance Handbook (FCIC 18010), page 512.

⁴ It should be noted that although there is a single definition for Irrigated Practice, for 2015, crops that are insured as irrigated are insured under 182 different practice codes. The different codes incorporate other elements of the management, such as the organic practice, tillage, and planting period.

2007 Census of Agriculture (Census)⁵ as well as data available from Quick Stats, and the Census Farm and Ranch Irrigation Survey (2008)⁶ (FRIS). The published research data are primarily useful in confirming the assumption that the amount of water available for evapotranspiration is correlated to the yield **as long as no other factors are limiting** production. Published data are useful in identifying locations where crops are produced under irrigation and identifying major commodity crops and yields of those crops from surveys. The only reports of the amount of water applied per acre are in the FRIS and in some state survey reports. However, the Contractor found no reports where both yield and amount of water applied were documented for production crops in a time series at any finer level than for whole states.

The Contractor reviewed and analyzed the RMA insurance experience data at the level of the insured to assess the potential contributions of these data to developing recommendations for modifications to policy and procedure. The focus of this research was on Type P11 (acreage reports), Type P15 (yield reports), and Type P21 (production loss reports).⁷ While the RMA data include information about the number and location (i.e., county) of insured irrigated acres as well as reports of irrigated yields, they contain no information about the amount of irrigation water applied. RMA data are the only data available to identify the states, counties, crops, and acreage of the **insured** irrigated crops. The Contractor's research on RMA data focused on crop years 2003 and 2008 (the crop years reported in the most recent FRIS reports), 2007 (the crop year reported in the most recent Census available for inclusion in this deliverable at the time the research effort was begun), and 2012 (the most recent crop year with a relatively complete insurance experience record). The RMA data show about 90 crops insured as irrigated, with slight variations in that number from year to year. Almost every state has at least one insured irrigated crop each year.

The Census reports 922,095,840 acres of land on U.S. farms. Of this land in farms, 406,424,909 acres (approximately 44 percent) are in cropland. A total of 317,013,499 acres were either harvested or had "failed or abandoned" crops. The remaining cropland acres were used for pasture, were idle, were in cover crops, or were in summer fallow. The Census reports that 56,599,305 irrigated acres were harvested in 2007, representing about 17.8 percent of the planted cropland that year (13.9 percent of total cropland acres).

The Census also reports 222,267,817 acres "enrolled" in FCIC insurance programs administered by RMA.⁸ The RMA database shows approximately 31 million acres insured under irrigated practice codes in 2007. Consequently, the cropland used to produce insured irrigated crops accounts for slightly less than 3.5 percent of the land on farms in the United States; about 8 percent of the total NASS-reported U.S. croplands; and less than 15 percent of the FCIC reported

⁵ The 2012 Census of Agriculture U.S. Summary and State Data and State and County Data Online Reports were released on May 2, 2014. The Contractor reviewed these reports to verify that the conclusions reached concerning the utility of the Census of Agriculture data were not changed. However, time constraints prevented updating all the Tables, Appendices, and files before the delivery date of this report.

⁶ USDA NASS, 2009, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008).

⁷ The Contractor includes records in the predecessor Type 11, 15, and 21 records when using this newer record naming system.

⁸ FCIC's Summary of Business reports 271.6 million net acres insured in 2007. The difference between the net acres reported by FCIC and the 222.3 million acres reported by the Census is due to insured acres of pasture and rangeland and inclusion of net acreage of insured trees and of the fruits of those trees separately in the RMA Summary of Business.

insured acreage. This implies a crop insurance participation rate for irrigated lands of approximately 55 percent.

The Contractor reviewed state irrigation surveys to see if these reports might provide useful information for developing modifications to crop insurance policy and procedure regarding Efficient and Limited Irrigation. The state surveys available are not particularly useful because of the infrequency of collection, limited sample size, and substantially different data collection methods between states and between years within a state. Few of the surveys have yield data. Most of the data are focused on extraction of water from reservoirs, rivers, and aquifers. These surveys focus on hydrology rather than agricultural production.

The FRIS reports on estimated yields for 18 irrigated crops and the estimated average amount of water applied to these crops by various irrigation systems at the state level.⁹ State-level data have a coarser level of granularity than the data that are normally used for establishing crop insurance parameters. The Contractor also assessed respondent-level (unpublished) data at the NASS Data Lab. These data were obtained by queries to the FRIS survey database documenting the survey responses. These data revealed no strong correlation between the amount of precipitation and the amount of irrigation water applied. Some producers apply more irrigation water per acre when there is more precipitation, especially in areas where surface waters are the primary source of water for irrigation. This behavior reflects a drive to maximize the potential production. Some producers apply less irrigation water per acre when there is more precipitation, especially in areas where ground waters are the primary source of water for irrigation. This behavior reflects a drive to reduce costs of producing the crop.

Between 2003 and 2008, there were relatively few substantive changes in the amounts of water applied per acre at the state level. There were substantially greater applications of water by efficient methods in 2008 than in 2003. Data for the 2013 FRIS survey should be available sometime in October 2014. Publication of these data was delayed by the 2013 government shutdown.

The Contractor explored precipitation data to understand better the relationship of annual precipitation to the amount of water used for irrigation. Most weather datasets are incomplete and many cover a relatively short period. Gridded precipitation values and cleaned, filled, data are available commercially. The Contractor used data extracted from a proprietary dataset built from National Oceanic and Atmospheric Administration (NOAA) data that is cleaned, filled, and backcast for analysis. Not surprisingly, the amount of precipitation in a given location varies from year to year. Geographically, that variability is itself quite variable (either as an empirical or relative value), as is the average precipitation.

Just as the amount of natural precipitation is highly variable from region to region, so is the amount of water applied for irrigation. This is evident in a review of the FRIS data. In some areas, when precipitation is abundant, the amount of water used for irrigation (generally from surface sources) is high. In other areas, particularly those with ground water sources for irrigation, when precipitation is high, the amount of applied irrigation water is lower. However,

⁹ Ibid. Tables 27 and 28.

these patterns are highly variable from crop to crop, from region to region, and even within a region. Testimony suggests that when water is limited, or when the cost of water is particularly high, the most valuable crops get watered first with remaining water going to lesser valued crops. In other words, producers behave as rational “economic” decision makers.

In gathering input from stakeholders, the Contractor identified 20 changes in irrigation management practices that would support Efficient Irrigation. Though not all can be applied concurrently, it is conceivable that a very substantial change in the amount of water needed to achieve the Approved Yield could be realized over the period required to establish an Approved Yield. As rational economic decision makers, many insureds who produce crops under an Irrigated Practice have been implementing changes as needed to achieve Efficient Irrigation. The USDA, extension offices, other state entities, seed companies, irrigation supply companies, and private consultants have provided educational material related to irrigation and water conservation for commercial producers.

Water Board records are not generally useful for a wide-ranging analysis of farm-level phenomena. Relatively few water rights are allocated at the crop insurance unit level. Most are allocated at the farm level. Some are allocated at the water board or district level. Consequently, the best data available for the purposes of analyzing water applied to a unit are those maintained by the producer. Some producers indicated they maintain these records only as long as required (i.e., three years under the Irrigated Practices Guidelines).¹⁰

The Irrigated Practices Guidelines provided to producers insuring crops on irrigated land outline the types of data a producer is required to maintain and the expected duration of the maintenance period. Data on irrigation water applied are maintained by the producer under these guidelines to support adjustment of insurance claims. Since the crop, soil characteristics, weather, and changes in technology (i.e., method of application, timing of application, etc.) all affect the amount of water required for an “Irrigated Practice,” an analysis of the yield per amount of applied water on a unit is only possible by using a combination of the yield data already in the RMA database and the data maintained by the producer under the Irrigated Practices Guidelines. Considering that many producers have already been practicing Efficient Irrigation, both the scale of an analysis along these lines and the lack of an approach to appropriately address the changes in irrigation technology already implemented make such an analysis infeasible. In addition, such an effort would require clearance by the Office of Management and Budget for the conduct of a survey. Even if this clearance were sought, the probabilities of a successful effort most likely are low because producers are required to keep records pertaining to the insured crop only for a period of three years after the end of the insured crop year. This period of time may not be sufficient to identify any trends or patterns.

However, the Contractor believes sufficient data are available in the RMA database, producer records, and weather datasets to construct a meaningful insurance approach to address Efficient Irrigation and Limited Irrigation. The simplest approach will be to use yield data for the irrigated crops from the annual yield reports entered into the Data Acceptance System (DAS) by the Approved Insurance Providers (AIPs), while providing the producer with additional guidance

¹⁰ USDA, RMA, 2013, Document and Supplementary Standards Handbook (FCIC-24040-02 (02-2013), page 146ff.)

on sufficient irrigation records so appropriate underwriting and loss adjustment for Efficient Irrigation and Limited Irrigation can be achieved. This must be done in a manner that does not impose greater respondent burden than the agency presently is allowed, or more respondent burden hours under the Paperwork Reduction Act will be required. The weather data are required to obtain a measure of how much water in total has been available to the crop historically and will be available to the crop under the Efficient Irrigation and Limited Irrigation scenarios.

To implement Efficient and Limited Irrigation policies and procedures, definitions for “Efficient Irrigation” and “Limited Irrigation” need to be provided in the CIH. The definition of Irrigated Practice must be refined to permit gradations of amounts of water applied relative to the amount applied to establish the insurance guarantee. Successful Efficient Irrigation requires changes in management practices. The Contractor proposes that such changes can be any of the Efficient Irrigation techniques identified in this report. These techniques were identified primarily in conversations with extension specialists and producers and in irrigation reports published by the National Institute of Food and Agriculture (NIFA)/Cooperative State Research, Education, and Extension Service (CSREES) supported extension programs. Some of these irrigation water conservation techniques are described by the Natural Resources Conservation Service (NRCS) on their website. Documentation by the producer of implementation of approved techniques to obtain Efficient Irrigation will be required by the underwriting. AIPs and insurance agents will need appropriate Efficient Irrigation underwriting guidelines.

However, some reductions in the amount of irrigation water available and/or intended to be applied to an acre are too large for Efficient Irrigation to be possible. The current insurance procedures provide the producer two options when the Irrigated Practice, as defined, cannot be followed for all the historically irrigated acreage: insure fewer acres as irrigated (applying the historical amount of water per acre to the reduced acreage) or insure the acreage as non-irrigated (if that option is available for the county) in spite of the fact that some irrigation water will be applied.

The Contractor believes a relatively simple, Limited Irrigation/reduced Approved Yield approach can be implemented. However, implementing this approach requires acceptance of several assumptions, including:

- Smaller changes in the amount of water applied to an acre can be offset by modifications in management practices to produce Efficient Irrigation;
- There is a limit to the efficiencies than can be realized by Efficient Irrigation; and
- Over an appropriate range of values of irrigation water applied, the reduction in yield under Limited Irrigation is linearly correlated to the proportion of the historical water available to the crop.

Consideration of any reduction in irrigation water available or anticipated to be applied too large to support the assumption of Efficient Irrigation will require additional work by the agent and AIP. However, the vast majority of the insured acreage is not irrigated. The vast majority of the insured irrigated acreage is irrigated as required under the Irrigated Practice definition. Some of this acreage will be irrigated with an amount of water essentially the same as the amounts applied historically. Some has been maintained under an Irrigated Practice by implementing

Efficient Irrigation. Consequently, recognizing Efficient Irrigation in RMA's policies and procedures will appropriately recognize current farming practices.

The offer of a Limited Irrigation approach then provides the small number of insureds who are faced with a substantially limited supply of irrigation water three options to address their risk management rather than the current two. These are:

- Irrigate and insure as managed under an Irrigated Practice a smaller number of acres than have been irrigated historically (sometimes with the possibility of receiving Prevented Planting indemnities for the acreage that is not irrigated that might otherwise have been);
- Insure the acreage that is irrigated with substantially less water than was used historically as non-irrigated (if the practice is accepted for the crop in the county); or
- Choose a Limited Irrigation Approved Yield to address the reduction in irrigation water anticipated to be available or to be applied to the irrigated acreage.

None of these options is intended to be punitive. Instead they are intended to provide an insured whose irrigation inputs are known to be limited at the time the insurance attaches alternatives in choosing the appropriate management practices for the operation and appropriate risk management tools, without creating opportunities for beneficial gain.

The Contractor believes properly addressing Efficient Irrigation along with the current procedures for addressing a reduced irrigation water supply will be the best approach. It is a change that will be accepted by insureds. It is a change that recognizes current farming practices. Furthermore, the current procedures allow a case by case decision to provide a reduced Approved Yield if that is the option the insured would prefer. Implementing Limited Irrigation nationwide for all crops is unlikely to resolve any issues that currently exist and is likely to create problems that do not now exist.

SECTION II. INTRODUCTION

On October 18, 2012, the U.S. DOI issued a combined synopsis/solicitation on behalf of the USDA RMA for an IDIQ contract addressing “research and analysis regarding irrigation policy for potential crop insurance program development.”¹¹ The solicitation provided background for the respondents. Some of that text is included below to provide the reader with context for this report.

Throughout the United States there are areas where the amount of irrigation water available to producers can vary from year to year.... Many producers already face reductions from their historical water use, or will in the future.... As a result, the RMA is evaluating the feasibility of establishing a limited irrigation guarantee for producers who apply less water than their irrigated guarantee is based on.

Current crop insurance policies and procedures require a producer to timely apply the quantity of water needed to produce 1) at least the yield used to establish their production guarantee or, 2) the amount of insurance for the irrigated acreage planted to the insured crop. Producers who intend to apply less water have the following options:

- *Apply the amount of water needed to produce the irrigated production guarantee or amount of insurance on a reduced number of acres and report the remaining acres as nonirrigated; or*
- *Apply less water to the total acreage and report the total acreage as non-irrigated.*

RMA has worked with several interested parties to develop a reliable estimate of the expected reduction in yield corresponding with the intended reduction of applied water used to reduce a producer’s fully irrigated production guarantee to a limited irrigation production guarantee, but still be consistent with an irrigated production practice.

This was intended to help growers better understand the potential trade-off they face between irrigation and production, and provide them with an additional tool for their crop management decisions. The model was developed only for corn and soybeans in a limited number of specified counties in Colorado, Kansas and Nebraska. [The model provided a basis for adjusting] the approved APH yield reflecting [language] in 3(h)(3) of the Common Crop Insurance Policy and Section 18E of the Crop Insurance Handbook.¹²

While irrigation is used to increase plant growth, maintain landscapes, help re-vegetate disturbed soils, protect plants from cold or freeze damage, preserve soil structure, and suppress erosion from wind, the focus of irrigation in this report is on its use to increase commercial crop production as compared to production that occurs without the application of water by the

¹¹ U.S. DOI, 2013, Solicitation Number D13PS59998, pages 1.

¹² U.S. DOI, 2013, Solicitation Number D13PS59998, pages 9-10.

producer. The Solicitation for TO 2 of the IDIQ contract calls for a report focusing on data collection related to insurance under FCIC yield-based plans of insurance for commercial crops grown under an irrigated practice. These plans include Yield Protection (01), Revenue Protection (02), Revenue Protection with Harvest Price Exclusion (03), and Actual Production History (90) (APH). TO 2 also calls for an outline of recommended policy and procedures modifications to those insurance programs to appropriately address changes in the amount of irrigation water applied to insured irrigated acreage.

The term “Irrigated Practice” is defined in the Common Crop Insurance Policy Basic Provisions as:

“A method of producing a crop by which water is artificially applied during the growing season by appropriate systems and at the proper times, with the intention of providing the quantity of water needed to produce at least the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage planted to the insured crop.”¹³

The Area Risk Protection Insurance Policy (ARPI) Basic Provisions contains a similar yet distinct definition of Irrigated Practice:

“A method of producing a crop by which water, from an adequate water source, is artificially applied in sufficient amounts by appropriate and adequate irrigation equipment and facilities and at the proper times necessary to produce at least the (1) yield expected for the area; (2) yield used to establish the production guarantee or amount of insurance/coverage on the irrigated acreage planted to the commodity; or (3) producer’s established Approved Yield, as applicable. Acreage adjacent to water, such as but not limited to a pond, lake, river, stream, creek or brook, shall not be considered irrigated based solely on the proximity to the water.”¹⁴

A primary difference between the two definitions is the recognition that ARPI insurance offers are not based on individual yields but rather on area yields. Hence, the requirement that sufficient water be applied to produce at least the yield expected for the area. In practical terms, if the irrigated ARPI offer is based on NASS data, this requires that the producer seek to achieve the county average yield. Conditions 2 and 3 apparently reflect introduction of the trend adjustment option, under which the “yield used to establish the production guarantee” and the “producer’s established Approved Yield” differ because the Approved Yield based on APH procedures is increased by the trend adjustment process. However, the definition does not state that the “higher of” applies. This definition presumably is the definition of Irrigated Practice that will be proposed whenever the current Basic Provisions (11-BR) is revised. The Contractor notes this definition does not differ in conceptual underpinnings relative to the definition currently contained in the Basic Provisions.

¹³ USDA, RMA, 2010, Common Crop Insurance Policy: Basic Provisions (11-BR), pp. 3-4, with the same language appearing in 05-BR for policies on crops harvested before the 2011 crop year.

¹⁴ Federal Register Volume 78, Number 123 (Wednesday, June 26, 2013).

The reader should note that neither definition of irrigated practice requires the producer to seek to maximize the yield. Thus, producer A might irrigate with the intention of providing the quantity of water needed to produce at least 200 bushels per acre (the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage), while his neighbor, producer B, might irrigate with the intention of providing the quantity of water needed to produce at least 180 bushels per acre (the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage). This difference could result from innumerable factors, including an economic decision by producer B that attempting to produce 180 bushels of production will provide higher net revenues than by attempting to produce a higher yield. The difference in expected yield for these similarly situated growers is explicitly considered in the determination of their premium rates.

FCIC crop insurance programs do not require what the scientific literature calls “full irrigation.” This term is used to describe the amount of irrigation needed to support maximum evapotranspiration. Full irrigation is applying sufficient irrigation water so a factor other than the amount of soil water limits the growth and productivity of the plant and therefore of the crop.

A producer insuring a crop grown under an Irrigated Practice is free to follow whatever management practices make the greatest economic sense in his/her situation. The requirement of the definition of Irrigated Practice is the producer must have the intention of providing irrigation sufficient to result in a yield at least equal to the yield on which the production guarantee is based. The Irrigated Practice Guidelines¹⁵ contained in the Document and Supplementary Standards Handbook, introduce the idea that the producer should have “reasonable expectations, at the time coverage begins, of receiving adequate water to carry out a good irrigation practice.” “Reasonable expectation” is then defined by excluding from a reasonable expectation: if “the insured knew or had reason to know that the amount of his/her irrigation water may be reduced before coverage begins.” Prevented planting indemnities are introduced as a potential risk management strategy for producers who have no reasonable expectation of receiving adequate water for irrigating the number of acres normally planted to produce an irrigated crop.

The Contractor noted the insurance documents do not always speak of “the” irrigated practice but rather of “an” irrigated practice. RMA insures crops grown under irrigated practices under 13 plans of insurance (Table 1). Of these plans, only the Yield Protection, Revenue Protection, Revenue Protection with Harvest Price Exclusion, and APH plans address a producer’s Approved Yield in establishing a guarantee, and if appropriate, an indemnity. Yield affects annual revenue used in the Actual Revenue History (ARH) insurance. In the 2014 insurance offers, 182 practice codes are included as Irrigated Practices (Appendix A, Tables A1 and A2). The Contractor considered the applicability of these practice codes by insurance plan, crop, and type. Yield Protection, Revenue Protection, Revenue Protection with Harvest Price Exclusion, and APH plans are the principal focus of the remainder of this report.

For 2014, RMA offers coverage for 75 crops grown under the Irrigated Practice and insured with one of the approved-yield-based plans (Table 2). RMA also offers coverage for 8 of these crops under other plans (Table 3) and as well as for 13 crops that are not covered under an approved-yield-based plan.

Table 2. Crops Grown under an Irrigated Practice and Insured under at Least One of the FCIC Approved-yield-based Plans of Insurance

Crop	Crop	Crop
Alfalfa Seed	Fresh Market Beans	Potatoes
All Other Grapefruit	Fresh Market Tomatoes	Processing Apricots
Almonds	Fresh Nectarines	Processing Beans
Apples	Grain Sorghum	Processing Cling Peaches
Avocados	Grapefruit	Processing Freestone
Barley	Grapes	Prunes
Blueberries	Grass Seed	Pumpkins
Buckwheat	Green Peas	Rice
Burley Tobacco	Late Oranges	Rio Red & Star Ruby
Cabbage	Lemons	Ruby Red Grapefruit
Canola	Macadamia Nuts	Rye
Corn	Mandarins/Tangerines	Safflower
Cotton	Millet	Sesame
Cotton Ex Long Staple	Mint	Silage Sorghum
Cucumbers	Mustard	Soybeans
Cultivated Wild Rice	Oats	Sugar Beets
Dry Beans	Olives	Sugarcane
Dry Peas	Onions	Sunflowers
Early & Midseason	Oranges	Sweet Corn
Oranges	Peaches	Sweet Potatoes
Figs	Peanuts	Table Grapes
Flax	Pears	Tangelos
Flue Cured Tobacco	Pistachios	Tomatoes
Forage Production	Plums	Walnuts
Fresh Apricots	Popcorn	Wheat
Fresh Freestone Peaches

¹ Crops in bold are also insured under at least one Approved-Yield-based plan.

In 2012, FCIC insured at least 1 irrigated crop in 49 of the 50 states (Appendix B). The remaining state, Rhode Island, had no insured irrigated crops in 2012, but has had insured irrigated crops in the past.

The Solicitation introduces two definitions addressing irrigation of commercial crops grown under an irrigated practice:

Efficient Irrigation - A method of producing a crop by which less water is artificially applied during the growing season by appropriate systems and at the proper times than the quantity of water that was used to establish the irrigated approved APH yield, that will likely not result in lower actual yields than the average yield for the irrigated practice for that location.

Limited Irrigation - A method of producing a crop by which less water is artificially applied during the growing season by appropriate systems and at the proper times than the quantity of water that was used to establish the irrigated approved APH yield, that will likely result in lower actual yields than the average yield for the irrigated practice for that location.¹⁶

Limited Irrigation was first proposed as a defined FCIC term in the IDIQ solicitation.¹⁷ The definitions for "Efficient Irrigation" and "Limited Irrigation" refer to applying less irrigation water to an insured crop than was historically applied that will "likely not result" and will "likely result" in lower actual yields than "the average yield for the irrigated practice for that location," respectively. The distinction between Efficient and Limited Irrigation is especially important when considering policy and procedures modifications to address appropriately changes in the management practices used for insured irrigated acreage. In the case of Efficient Irrigation, modifications to the policy and procedures are not required other than those that recognize Efficient Irrigation as an acceptable management practice under the definition of Irrigated Practice. In the case of Limited Irrigation, if the crop is to be insured as irrigated, changes are

¹⁶ U.S. DOI, 2014, Task Order D14PD00062 under IDIQ contract D13PC00032, Page 6.

¹⁷ U.S. DOI, 2013, Solicitation Number D13PS59998, on page 7 defines Limited irrigation as "A method of producing a crop by which less water is artificially applied during the growing season by appropriate systems and at the proper times than the quantity of water that was used to establish the irrigated production guarantee or amount of insurance on the irrigated acreage planted to the insured crop."

required so the crop is neither insured with a higher than appropriate liability nor with an incorrect trigger for an indemnity payment.

The background material provided by RMA in the IDIQ solicitation and cited at the beginning of this introduction shows existing policies and procedures do not address the differences in expectation between producing a crop under Efficient Irrigation and producing a crop under Limited Irrigation. Efficient Irrigation under the proposed definition could be construed as one form of management under the current definition of the Irrigated Practice. Limited Irrigation could not be interpreted this way.

Irrigation is used in the production of crops either to supplement natural precipitation or to replace natural precipitation in areas with little or no rainfall. Irrigation supports greater evapotranspiration than would occur if the land were not irrigated. Evapotranspiration is a measure of the loss of water from the surface of the Earth through a combination of evaporation from the soil and transpiration from plants. Evapotranspiration is responsible for movement of nutrients throughout the plant; support for the movement of carbon dioxide into the plant for photosynthesis; and maintenance of the plant's temperature. The movement of mineral nutrients throughout the plant supports both cellular metabolic processes and maintenance of turgor. The first is required for cell growth and cell division. The second is required to maintain the upright stature of the plant. Carbon dioxide is required for photosynthesis. Without an adequate supply of photosynthetic sugars, a plant will metabolize stored sugars. The result is a plant that shrinks rather than grows. Excessive temperatures have many deleterious effects on plant growth and metabolism. Thus, sufficient evapotranspiration is essential to plant growth and consequently to crop production.

Nonetheless, from year to year, the amount of irrigation water applied to each acre of commercial irrigated cropland may vary substantially. The amount applied is affected by the crop being produced; the amount of natural precipitation; temperature and wind; changes in water supply; management practices; and the irrigation technology being used. It is important to note all these parameters may affect a producer's decisions about the amount of water required to obtain an optimum economic outcome. These producer decisions in turn affect the actual yield realized that contributes to the development of an Approved Yield. The definition of Irrigated Practice accommodates the variability in the amount of irrigation water applied to each acre of commercial irrigated cropland each year. What is less well accommodated is the reduction in water intended to be applied under Efficient Irrigation.

The NASS 2007 Census of Agriculture (Census) reported 922,095,840 acres of land on U.S. farms. Of this land on farms, 406,424,909 acres were in cropland. The Census also reported 222,267,817 acres "enrolled" in FCIC insurance programs administered by USDA RMA. The RMA database shows 30,822,581 of those acres insured under irrigated practice codes in 2007. Consequently, the cropland used for insured irrigated crops accounts for about 8 percent of the total NASS reported U.S. croplands and slightly less than 3.5 percent of the land on farms in the United States.

From an examination of the FRIS data, the Contractor has concluded a very small proportion of cropland insured under an Irrigated Practice was likely managed under Efficient Irrigation during

any one of the years between 2003 and 2008. However, testimony from producers and extension specialists suggests that proportion was likely higher during the years between 2008 and 2013. NASS has distributed the FRIS survey questionnaires for 2013, but has not completed the analysis of the responses, so quantitative verification of this testimony cannot be made at this time. The Contractor estimates it is likely producers implement new Efficient Irrigation techniques on less than 3,000,000 acres of cropland insured under an Irrigated Practice in any given year. The number of acres affected by Limited Irrigation is undoubtedly much smaller. The strongest drivers of Limited Irrigation are administrative actions and disappearance of irrigation water supplies. In the listening sessions, producers expressed substantial concern about water rights for urban and suburban development taking precedence over long-standing rights for agriculture.

The IDIQ Solicitation identifies the “objective of the IDIQ [Indefinite Delivery/Indefinite Quantity] contract overall [as] to conduct research and analysis regarding irrigation policy for potential crop insurance program development.”¹⁸ The TO 2 Solicitation identifies the “objective of the second task order under the IDIQ as “to obtain a detailed report that [documents] further analysis of any issues/obstacles that need to be resolved in order for the Contractor to implement **nationwide for all crops** their recommended approach contained in option 3a from Watts’ Task Order 1, Deliverable 2.”¹⁹ Option 3a calls for maintaining the existing irrigation policy and procedures but changing the definition for the Irrigated Practice so the definition focuses on all management practices collectively [i.e., Efficient Irrigation] that are required to obtain the Approved Yield.

Furthermore, the TO 2 Solicitation calls for the Contractor to “explore the possibility of a limited irrigation break point where, within a range of reduced irrigation, there is the potential to not obtain the irrigated approved APH yield even with the reasonable utilization of other production management practices and there should be a yield reduction which would result in an approved APH yield less than the irrigated practice but greater than the non-irrigated practice yield.”²⁰ The Contractor is also asked to consider if Limited Irrigation should be a separate third practice and “consider Option 7 elements for yield reduction function modeling, or any other feasible yield reduction functions to adjust the irrigated approved APH yield for reduced irrigation.”²¹

The following sections address, in order: Section III. Regional Study Areas; Section IV. Stakeholder Input; Section V. Available Programs/Support; Section VI. Quantitative Data Collection Summary; Section VII. Irrigation Production Management Practices; Section VIII. Available Irrigation Water Use Records; Section IX. Risk Analyses; Section X. Outline of Proposed Modifications; and Section XI. Research Findings.

²⁰ Solicitation page 5 of 19.

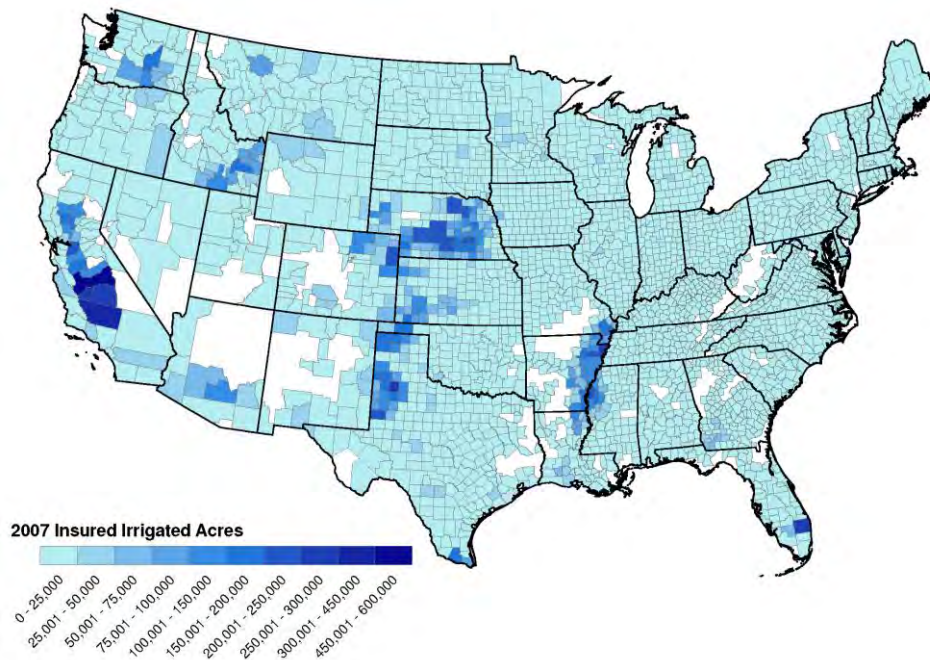

²¹ Solicitation page 5 of 19.

SECTION III. REGIONAL STUDY AREAS

This section of the report deals with the requirement in the Solicitation that: the “Contractor shall delineate regional areas of study and justify their selection.”²² The Solicitation requires: “a report that provides the analysis and results about insuring reduced irrigation nationwide for all crops.”²³ To the extent that quantitative data can be gathered nationwide, the United States has been the study area.

The Contractor also addressed issues for which data are not available for the entire country. An example of this is available irrigation educational resources. These resources are generally targeted at state-level audiences. To the extent these resources are available in a state, the state became the study region and all states with available resources were included in the study. The Contractor collected testimonial information from extension agents. Conversations were conducted with extension agents in all states that were responsive to the Contractor’s request. Finally, the Contractor collected testimonial information through listening sessions. The selection of locations for the listening sessions was based primarily on mapping of the insured irrigated acreage (Figure 1).

Figure 1. 2007 FCIC Insured Irrigated Acreage in the Contiguous 48 States²⁴

Source: W&A Underwriting Department after RMA insurance experience data.

While Alaska and Hawaii are not included in this map, insured irrigated acreage in Alaska and Hawaii is very limited. In Alaska a small amount of potato production is occasionally insured as having been produced under an Irrigated Practice. This insured irrigated potato production

²² DOI, 2013, Solicitation D14PD00062 under IDIQ contract D13PC00032, page 5

²³ *Ibid.*, page 5.

²⁴ This is a map of FCIC Insured Irrigated Acreage in the Contiguous 48 States and the table underlying the map is available on the RMA website.

represents much less than 1 percent of the potato production in Alaska and just more than $\frac{1}{4}$ of one percent of the acreage insured in Alaska. In Hawaii, macadamia trees and the production from those trees is insured as managed under the Irrigated Practice. Most of the macadamia production is in Hawaii County, Hawaii. About half the production is on the dry side of the island. For these operations, water is transported from the rainy side to the dry side. The macadamia operations represent almost $\frac{3}{4}$ of the \$102,670,452 FCIC insured liability in Hawaii in 2013.²⁵

The Contractor noted the map of insured irrigated acreage in the United States is basically similar to the map of all U.S. irrigated acreage published by NASS based on the Census (Figure 2).

Figure 2. 2007 Census Irrigated Acreage in the United States

http://www3.rma.usda.gov/apps/sob/current_week/stcrop2013.pdf, accessed May, 2014.

The specific locations for listening sessions were selected considering first the map of insured acreage managed under an Irrigated Practice. The Contractor identified nine clusters of counties with large amounts of acreage insured under an Irrigated Practice. The largest of these includes portions of Colorado, Kansas, and Nebraska. Listening sessions to gather stakeholder input from these three states were held under the first task order in Colby, Kansas, on March 13, 2013, and in Kearney, Nebraska, on March 14, 2013. Consequently under TO 2, listening sessions were scheduled in other locations. Stakeholder input from the Kansas and Nebraska sessions is available on the RMA website.²⁶

The FRIS reports nearly 56.6 million acres in the United States were irrigated in 2008. Furthermore, the FRIS identifies 20 Water Resources Regions NASS has designated for tracking water usage. The Solicitation limited the number of listening sessions under TO 2 to six. Consequently, the Contractor selected six locations for listening sessions providing the opportunity to gather information from producers and stakeholders in the largest number of additional Water Resources Regions.

The listening session in Tifton, Georgia provided stakeholders from the Tennessee and South Atlantic Water Resources Regions an opportunity to provide input regarding their nearly 2.6 million irrigated acres. The Contractor invited stakeholders from Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, and Tennessee to this listening session.

The listening session in Lubbock, Texas, provided opportunities to gather input from stakeholders in 8 states with nearly 4.6 million irrigated acres. The Water Resources Regions addressed through this listening session include the Arkansas-White-Red, the Rio Grande, and the Texas-Gulf regions. These regions encompass portions of Arkansas, Colorado, Kansas, Louisiana, Missouri, New Mexico, Oklahoma, and Texas.

California producers irrigate nearly 7.5 million acres. The listening session in Sacramento, California provided an opportunity to obtain stakeholder input from many of these producers and from the state and regional water regulatory leadership for the California Water Resources Region. The Water Resources Region encompasses portions of California, Nevada and Oregon.

The listening session in Monticello, Arkansas was located at the confluence of five Water Resources Regions: the Arkansas-White-Red, the Lower Mississippi, the Missouri, the Ohio, and the Upper Mississippi. These regions encompass portions of the states of Arkansas, Colorado, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Minnesota, Mississippi, Missouri, Montana, Nebraska, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Virginia, West Virginia, Wisconsin, and Wyoming. There are nearly 28.3 million irrigated acres in these Water Resources Regions.

Pocatello, Idaho was the location for a fifth listening session. The session provided opportunities to collect information from the Great Basin, Lower Colorado, Pacific Northwest, and Upper Colorado Water Resources Regions. These regions cover portions of Arizona, California,

²⁶ The Contractor for USDA, RMA, 2013, Insuring Irrigation Feasibility Report, www.rma.usda.gov/pubs/2013/insuringirrigationfeasibilityreport508.pdf, accessed May, 2014.

Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming. There are nearly 3.9 million irrigated acres in these Water Resources Regions.

A final listening session was held in the Tri-City area of Washington (Kennewick, Pasco, and Richland) where stakeholders from the Pacific Northwest Water Resources Region were invited to provide input. The Pacific Northwest Water Resources Region contains almost 7 million acres of irrigated land in seven states: Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming.

Consequently, stakeholders in 14 of the 20 NASS Water Resource Regions had an opportunity to participate in the listening sessions offered under the two task orders. Producers in these Water Resource Regions irrigate nearly 53.6 million acres of land. That represents nearly 95 percent of all irrigated acreage in the United States documented in the FRIS.

SECTION IV. STAKEHOLDER INPUT

This section of the report deals with the requirement in the Solicitation that:

The Contractor shall contact insurance providers, various producers, and leaders representing producers at the state and national levels to identify the following:

- *The issues/obstacles that are currently faced by insured producers with reduced irrigation including economic, physical, and regulatory water restrictions.*
- *The risks that producers encounter in their operations and the coverage that interests them.*
- *Their perceptions of any potential conflicts and difficulties. Describe the production activities of these producer(s).*
- *Review of actual water application records and the utilization of water metering.²⁷*

The Contractor gathered stakeholder input during discussions with producers, insurance industry representatives, educators, and government personnel in 6 listening sessions and in more than 150 one-on-one conversations. The listening sessions were conducted in Tifton, Georgia on February 18, 2014; Monticello, Arkansas on February 20, 2014; Sacramento, California on March 6, 2014; Lubbock, Texas on March 18, 2014; Pocatello, Idaho on March 20, 2014; and Pasco, Washington on March 28, 2014. The sessions were broadly advertised. On the advice of agricultural extension educators, the Contractor provided a press release (Appendix C, Exhibit 1) to newspapers serving the location where listening sessions were to be held. An advertisement (Appendix C, Exhibit 2) of the listening session was also prepared. Both the press release and the advertisements were reviewed by RMA before release. The press release was also sent to crop associations in the states where the sessions were being held, extension services offices in the counties where the sessions were conducted, and extension services offices in contiguous counties. Copies of the advertisements were provided to RMA Regional Offices (ROs). RMA distributed the press release to AIPs to recruit insurance industry stakeholders; insurance agencies were encouraged to extend invitations to key producers.

Listening session input was obtained from stakeholders from 6 states: Arkansas (at least 22 stakeholders), California (9 stakeholders), Georgia (2 stakeholders), Idaho (2 stakeholders), Texas (22 stakeholders), and Washington (3 stakeholders). Stakeholder input was solicited from at least one individual in each of the states not represented in the listening sessions. Most of those contacted were extension agents.

Sixty individuals (not including the Contractor's representatives) attended the listening sessions. Attendees included 29 producers. Some producers were also among the 21 insurance industry representatives and 11 grower association representatives attending. The remaining attendees included 10 extension educator/researchers, 2 state government officials representing offices with authority over irrigation water, and 2 RMA RO representatives. Additional follow-up conversations outside the listening session venues were held with RMA personnel, extension specialists, and insurance agents in the six locations where the listening sessions were held. The

²⁷ TO 2 Solicitation, page 5.

producers indicated their primary crops include corn, cotton, grain sorghum, potatoes, rice, soybeans, and wheat. Although substantial efforts were made to solicit participation at listening sessions from stakeholders with interests in Category C crops, none attended any of the sessions. Input from extension agents representing Category C crops were solicited when the listening sessions were completed.

Information was collected from stakeholder comments in compliance with the contract requirements regarding the Paperwork Reduction Act. The flow of the listening sessions was controlled by an agenda (Appendix C, Exhibit 3). The Contractor refrained from asking questions in any way that might be construed as a survey of the group; however individuals were queried to seek clarification of comments they made. Information obtained in this manner is qualitative and cannot be interpreted to represent a statistically valid sample. Nevertheless, the information gleaned from the voluntary comments of stakeholders provides substantial value concerning agricultural management techniques; risks, acceptance of the existing risk management products, and reaction to possible new risk management approaches like the proposed Limited Irrigation construct. Although the Contractor provided an email address for comments, no input was received through that channel.

Summary of Stakeholder Input

To preserve the anonymity of individual stakeholders, comments gathered at the six listening sessions are summarized collectively. Individual comments and categorical characterization of sources (i.e., producer, insurance agent, educator, etc.) are documented in Appendix C, Exhibit 4.

At each session, as much as half the input from stakeholders was in the form of questions about the existing insurance language regarding irrigation and how that language impacts insurance. After providing summary information reflecting the results of the Contractor's first deliverable under this IDIQ contract and addressing in very general terms some of the underpinnings of the policy language identified therein, the Contractor referred stakeholders to RMA RO personnel, policy and underwriting documents, and their insurance agents for answers to specific questions. From these questions it was clear many producers and insurance industry stakeholders were previously unaware of some of the policy language pertaining to irrigation and were concerned by the constraints current procedural language places on their options if the supply of irrigation water is reduced. The stakeholders expressed notable concern about two issues. The first was the insurance options available if knowledge of the reduction in irrigation water supply precedes the acreage reporting date. The second was how RMA and the AIPs would respond to a loss associated with a legislative body or regulatory authority removing access to necessary irrigation water. These comments from stakeholders indicate limited familiarity with current policy provisions. That limitation suggests a substantial educational effort will be needed to achieve an appropriate level of awareness if changes to irrigation procedures are made.

Producers indicated that from year to year, soil moisture at planting, heat units, wind, and many other factors including amount and timing of natural precipitation affect how much irrigation water is required to grow a crop. Furthermore, they confirmed that different crops require different amounts of irrigation water. From region to region, soil quality, slope, and the aspect of the slope (the direction the slope faces) also impact how much water is needed to have a good economic outcome.

Virtually all stakeholders in every category recognize and acknowledge the importance of irrigation to agricultural production and the changes in production under the irrigated practice that are likely to occur as irrigation water becomes more limited. Stakeholders at all six listening sessions corroborated what had previously been identified by producers from Colorado, Kansas, and Nebraska: reductions in water allocations have occurred, are currently occurring, and will continue to occur in the foreseeable future.

Another recurring theme during the listening sessions was that producers have responded and are likely to respond to changes in supply of irrigation water in accordance with their understanding of the crop and their farmland. Some have chosen to target their available water on fewer acres of higher revenue crops. Others are planting new crops. Many indicated they have implemented Efficient Irrigation techniques. None indicated they applied less irrigation water with an expectation of achieving a yield less than their Approved Yield. Insureds are very aware of their deductible and the effect on their net revenue when the Approved Yield is not achieved.

The Contractor identified 20 broad categories of technological innovations and/or management practices that have been adopted by producers to address reduced irrigation water access. In each session, the Contractor was presented with anecdotes of how producers have adapted their practices in an effort to maintain their yields. In one instance, a producer stated he had nearly tripled his cotton yield merely by changing his irrigation method from flood to pivot drip. In this case, the producer was using far less water for irrigation and achieving far greater yields. In another session, a potato consolidator indicated the yield and quality of potatoes are damaged by over-irrigation. Reductions of as much as 30 percent in water use could increase yields and provide even larger increases in revenue due to the better quality of the harvested product.

Producers, producer associations, and insurance industry personnel believe crop insurance is a vital risk management tool for producers. Crop insurance is further viewed as an essential tool for developing appropriate strategies to optimize economic outcomes. The current two options of reporting crops grown with reduced irrigation as non-irrigated (if allowed) or uninsurable are viewed as unfair. Additionally, creating a new practice for Limited Irrigation that encompasses Efficient Irrigation is not considered to be sensible. Producers voiced their support for the modification of policy language and procedures to address both Efficient and Limited Irrigation. Some voiced opposition to the creation of break points in amounts of water applied between irrigated and non-irrigated practices. Concern was expressed about unintended consequences of introducing Limited Irrigation. The impact of the timing of application of water was raised during these sessions. In Arkansas, producers are beginning to use cover crops to maintain soil moisture in an effort to reduce the need for pre-plant irrigation. Planting into the cover crop without tilling preserves soil moisture. However, in some instances, this approach is specifically prohibited for an insured crop.

Insurance industry personnel expressed concerns about how various management strategies could be addressed through modifications to the existing insurance, but expressed reluctance and trepidation when discussing the creation of a newly defined Limited Irrigation practice. These respondents noted that irrigation water is not metered in Georgia, Arkansas, Texas, Idaho, California, or Washington. In some of these states, Georgia and Arkansas in particular, the amount of water used for irrigation is estimated based on reviewing the power and fuel bills and

records of the producer in an attempt to substantiate that any loss on irrigated acres was not due to failure to apply the appropriate quantity of water.

Educators who attended the sessions were very vocal about the large number of variables that affect production. Educators encouraged the Contractor to consider very carefully the fact the producer's history encompasses all these variables and the effects of these variables are captured to some extent in the producer's Approved Yield. They noted as producers change their management practices to adapt to the amount of available water, changes in technology, changes in seed and hybrid technology, environmental changes, etc., the effects of all these changes will be incorporated into the Approved Yield over time.

The National Sorghum Producers representative attended the sessions in Kansas, Nebraska, and Texas. He indicated his association was quite concerned that the proposed Limited Irrigation approach for corn and soybeans would distort the markets for crops where sorghum is grown and allowing a Limited Irrigation practice to be insured might lead fewer producers to grow crops with low water requirements. He indicated the T-yields for irrigated sorghum and corn are already creating disincentives for switching from corn to sorghum, and adding Limited Irrigation insurance for corn would only exacerbate that situation.

As noted previously, the most notable themes in stakeholder input were:

- Reduced availability of irrigation water and higher costs for the application of irrigation water are currently problems for some producers;
- Reduced availability of irrigation water and higher costs for the application of irrigation water will continue to be issues for producers for the foreseeable future;
- Many (if not most) producers are changing management strategies to achieve Efficient Irrigation;
- Conserving water for all purposes is an appropriate public policy, even for agricultural production; and
- Addressing limited availability of water in the crop insurance program must be done with caution, with appropriate care to avoid unintended consequences.

SECTION V. AVAILABLE PROGRAMS/SUPPORT

This subtask is a continuation of data collection focused on the TO 2 Solicitation requirement that:

The Contractor shall list and summarize the provisions and benefits of all state and federal programs that currently support or subsidize these producers for irrigation. The Contractor shall also research and describe any private insurance program that is available to these producers. The Contractor shall note any gaps in coverage and constraints of the private insurance programs, if applicable.

Producers can avail themselves of a variety of support programs from the federal, state, and private sectors. Few of these programs specifically address risk; none specifically address risk inherent in applying less irrigation water. Many assist in risk management by providing information that allows the producer to make informed decisions.

Federal Programs

Federal programs in support of producers are offered primarily by agencies of the USDA.

Agricultural Marketing Service (AMS)

Producers benefit from general services of the AMS including the following programs:

- Promotion and Research,
- Marketing and Economic Research,
- Organic Standards, and
- Plant Variety Protection Act (PVPA).

AMS also provides support for extension research into disease prevention, including management of disease vectors which is generally applicable to crops. AMS standards applicable to organic crop production practices provide a mechanism to leverage certain production practices to gain a higher price.

Animal and Plant Health Inspection Service (APHIS)

APHIS is responsible for protecting and promoting U.S. agricultural health. APHIS has been tasked with responsibility for enforcing the obligations of the United States under phytosanitary rules such as the *Codex Alimentarius*, responding to plant health import requirements of other countries, and assisting in negotiating science-based trade restrictions. APHIS programs support export of most crops. APHIS documents, such as the “Export Program Manual”²⁸ provide useful information for producers about phytosanitary requirements.

National Institute of Food and Agriculture (NIFA, formerly Cooperative State Research, Education, and Extension Service (CSREES))

NIFA is the federal administrative authority that offers programs in research, extension, and education to provide important educational and consultancy resources for producers in all areas. The extension services also provide programs for consumers. State extension services have

²⁸ USDA, APHIS, 2010, Exports (08/2010-07), http://www.aphis.usda.gov/import_export/plants/manuals/domestic/downloads/xpm.pdf, accessed April, 2013.

produced research addressing the impact of irrigation on crop production. State extension services also provide support for research into disease prevention and disease vector management, which is broadly applicable to insured crops, including irrigated crops.

Economic Research Service (ERS)

ERS provides data and analysis on product supply and demand, as well as information on industry structure, pricing, trade, production policies, production systems, and processing.

Farm Service Agency (FSA)

FSA provides financial assistance to producers facing losses from natural disaster (i.e., drought, flood, fire, freeze, tornadoes, pest infestation, and others). FSA's Noninsured Crop Disaster Assistance Program (NAP) provides payments to producers of non-insurable crops when low yields, loss of inventory, or prevented planting occur due to a natural disaster. Eligible producers include landowners, tenants, and sharecroppers who share in the risk of producing an eligible crop. The average non-farm adjusted gross income of the producer cannot exceed \$500,000. A payment limitation of \$100,000 per individual or entity per crop year applies. The natural disaster causing the loss must occur before or during harvest and must directly affect the eligible crop. The specific rules for inclusion of production under the FSA programs are contained in 7 CFR 1437.303.²⁹

FSA also administers Conservation Reserve Enhancement Programs (CREP), which are federal-state cooperative conservation programs that address "targeted agricultural-related environmental concerns. CREP participants voluntarily enroll in 14- to 15-year Conservation Reserve Program (CRP) contracts with USDA's (FSA). Participants receive financial incentives to remove cropland and marginal pastureland from agricultural production." CREP has been used to "reduce irrigation water use, increase water quality, reduce soil erosion and sedimentation and increase wildlife populations."³⁰ Removing marginal irrigated acreage from production reduces the pressure on water supplies for other producers in an area.

Food Safety and Inspection Service (FSIS)

FSIS employees identify, assess, and define emerging and standing issues affecting procedures, policies, activities, or resources for food safety. They are responsible for identifying food safety concerns associated with production, transportation, and marketing. FSIS personnel are also responsible for outreach and liaison activities to develop and sustain risk reduction strategies regarding food safety in agricultural production.

Foreign Agricultural Service (FAS)

FAS maintains internet links to resources for producers. These links focus on sites that identify production practices and data, including the UN FAO import and export data. There are no links specifically targeting different irrigation production practices.

There are several FSA press releases about various CREP at <http://search.usa.gov/search?utf8=%E2%9C%93&affiliate=usdafarmserviceagency&query=irrigation>

National Agricultural Statistics Service (NASS)

NASS is the primary data collection and publication service of the USDA. Its data series are widely used by producers, businesses, and researchers. Data are collected as part of the Census of Agriculture and from surveys sent to sample producer populations.

Risk Management Agency (RMA)

RMA provides numerous products for insuring crops. Approximately 100 crops can be insured as managed under an Irrigated Practice. The insurance of these crops when the amount of water being applied is less than the amount applied during the development of an Approved Yield is the subject of this report.

Rural Development (RD, formerly Rural Business–Cooperative Service (RBS))

RD is a small agency with limited funding and staff whose purpose is to finance and facilitate development of small and emerging private business enterprises, and promote sustainable economic development in rural communities.³¹

State Government Programs

State programs and regulations affect crop production and crop risk management. Some states have regulations that replace or complement federal phytosanitary or environmental standards. The various regulations are similar to federal standards, often referencing them as minima. The purpose of these regulations is to reduce risks of diseases and the vectors that carry those diseases. States also provide support for the NIFA programs. State governments often are involved in the cooperative CREP administered by FSA.

Water Regulatory Programs

The Contractor identified scores of water regulatory authorities which have impacts on agricultural water use. Information about these authorities is documented in Appendix D and in the section of the report on Available Irrigation Water Use Records.

Private Insurance Inventory

Private insurance companies offer coverage to commercial crop operations; available coverage is described below.

Weather Insurance Coverage

Private weather insurance is available from a number of traditional and online insurance companies. These products are often reinsured by major reinsurance companies (e.g., Munich Re, Swiss Re, Renaissance Re, etc.). The policies are generally “one off” contracts, customized to reflect specific named perils identified by the insured. This insurance can be structured to cover any one weather event (e.g., extreme cold or excessive rainfall) or combinations of weather the producer chooses from available options. These policies have relatively high premiums and are not subject to premium subsidies. They cover losses only from the specific named perils. These products do not mirror the structure of any existing FCIC insurance. Instead these products focus on limited, producer-identified, named perils.

³¹ USDA, RD, 2011, Business, <http://www.rurdev.usda.gov/Business.html>, accessed May, 2011.

Crop-hail and fire coverage is an exception to the one-off nature of other weather insurance products. It is a more or less standardized product subject to state regulation. Variations among insurance companies can occur but the basic coverage is substantially the same. Crop-hail indemnities are based on the percent of damage to the vegetative structure of the plant and stage of growth. These factors are converted into a percent of loss of ultimate potential yield, not actual yield. The amount of loss is the amount of insurance purchased by the insured multiplied by the percent of loss. Fire coverage applies to mature fields that may be struck by lightning and set afire. Producers who purchase both additional coverage crop insurance policies and crop-hail can request that the premium for the multi-peril coverage be reduced by waiving the right to any indemnity from the multi-peril policy for hail or fire damage.

Basic Business Liability

Basic business liability insurance is available. Business liability coverage does not provide any insurance on a growing crop.

Employers Contingent Liability

Employers Contingent Liability is available with the ability to add employees as insureds. Contingent liability does not provide any coverage on a growing crop.

SECTION VI. QUANTITATIVE DATA COLLECTION SUMMARY

The Contractor examined publicly available data from government and private sources that might support appropriately modifying the policy and procedures for crop insurance for crops insured under an Irrigated Practice code when the insured uses Efficient or Limited Irrigation. The Contractor's efforts included research into weather, crop yield, and irrigation data. The focus was on identifying data that might be useful in implementing insurance procedures for all crops, nationwide. A longitudinal study of the impact of irrigation on yield requires farm-level data on the amount of irrigation water applied, the method of application, and the resulting yield. The Contractor examined publicly available data from NASS, National Climate Data Center (NCDC), RMA, and state irrigation surveys. The Contractor reviewed published research reports on the effects of irrigation at different levels to determine their potential contributions to implementation of Efficient and Limited Irrigation procedures. The Contractor also examined the potential for using unpublished data in both the NASS and RMA databases to determine if these data might be useful in addressing Efficient and/or Limited Irrigation. Finally, the Contractor explored the utility of private weather data as a potential source of information for implementation of Efficient and Limited Irrigation Procedures. This report addresses the weather data first because of the Contractor's use of weather data in analysis of the NASS FRIS unpublished producer-level data.

Weather Data

Irrigation is occasionally used to address extreme high and low temperatures. However, irrigation water is more often applied to address the water balance³² of the plant. Precipitation, which maintains water balance by providing soil moisture, therefore plays a more substantial role in the requirements for irrigation than does temperature. Precipitation directly impacts the amount of irrigation water required to produce a yield at least equal to the Approved Yield. With the exception of data on temperature and precipitation, weather data are rather spotty.³³ Furthermore, the Solicitation requires a simple approach to addressing Efficient and Limited Irrigation, not dependent on annual updating. Consequently, the focus of the Contractor's efforts on weather was on the precipitation available for crop growth and development. The Contractor examined available sources of precipitation data.

The National Climate Data Center (NCDC) is the principal government source for weather data. The National Oceanic and Atmospheric Administration (NOAA) of the U.S. Department of Commerce administer NCDC. NCDC maintains an extensive archive of weather data, including time series of temperature and precipitation data. NCDC's "Climate Data Online (CDO)" provides free access to NCDC's archive of historical weather and climate data in addition to station history information. These data include quality controlled daily, monthly, seasonal, and yearly measurements of temperature [and], precipitation... Customers can also order most of these data as certified hard copies for legal use."³⁴ Subscription services are also available to download NCDC weather data series.

Most weather data series in the NCDC archive are incomplete and many cover relatively short periods. Although the NCDC data are in an easy to handle format and data fields are adequately described in documentation provided by NCDC, the data contain holes and flags that need to be addressed. The NCDC datasets contain daily values for precipitation for most days. They also include flags to identify aberrant, suspect, and missing data. For analysis of average precipitation and the standard deviation of the precipitation for any block of consecutive days in a county, complete datasets are required for that block. Published weather data from the NCDC are not sufficient to complete this analysis. Gridded precipitation values³⁵ and cleaned, filled data³⁶ are available commercially.

The precipitation most logically affecting irrigation requirements is the precipitation that falls during the growing season. The growing season could be considered to include the days when pre-plant moisture is deposited in the soil. Furthermore, during ripening, precipitation often reduces the quality and/or quantity of a crop that can be harvested. Consequently, the growing season precipitation window varies from location to location, from crop to crop. It should not be defined as the period between planting and harvest. The Contractor notes growing season is not defined in the CIH or the Basic Provisions. Growing Season is defined in the Vegetative and Rainfall Index products as "a period of time designated in the Actuarial Documents during which the crop is planted."

The Solicitation requires a simple approach addressing all crops nationwide. The growing season is not well documented in all locations for all crops. Nonetheless, the Contractor believes there is useful information regarding irrigation risks in the precipitation statistics for a county, even using a "standard growing season." First, the amount of precipitation an insured expects affects any decision about how much water is sufficient to irrigate at the appropriate time with the appropriate equipment. Then, that decision of sufficiency is also affected by the variability of the amount of precipitation expected, which grows from the experience of variability in precipitation from year to year. The greater the variability, the more water must be held in reserve to address a particularly dry growing season.

³⁴ U.S. Department of Commerce, NOAA, NCDC, 2014, Climate Data Online, <http://www.ncdc.noaa.gov/cdo-web/>, accessed March, 2014.

³⁵ RMA has used gridded historical precipitation data in development of its Rainfall Index product. Climate Corporation is one commercial source of such data.

³⁶ Weather Source has cleaned and filled historical weather datasets. Weather Source lists the USDA ARS on its client list.

Consequently, the Contractor considered the period from April 1 through September 30 to represent the nominal growing season precipitation. While the crop being grown, the timing of the rainfall, the soil composition, and the slope and aspect of the field all affect how useful the precipitation is to plant growth, some measure of the average available precipitation, acted upon by a factor capturing the crop, timing, etc. will be used in establishing the irrigation protocol.

The Contractor therefore extracted for each crop year for each county in which production was insured under an Irrigated Practice code the amount of total precipitation during the nominal growing season window. The values by county were then averaged over the period 1950 to 2012. The Contractor calculated the standard deviation of the nominal growing season precipitation values by county. The Contractor then documented the average growing season precipitation and the standard deviation of that precipitation in each county counties in which crops are insured under an Irrigated Practice code (Appendix E). Sixteen of the 20 counties with the highest growing season precipitation are in Florida, with four in Louisiana (Table 4).

Table 4. The 20 Counties/Parishes in which Crops Are Insured under an Irrigated Practice Code with the Highest Average Growing Season (April through September) Precipitation

State	County/Parish	Average	Standard Deviation
Florida	Palm Beach	39.4	7.0
Florida	Hendry	38.0	6.0
Florida	Miami-Dade	37.9	9.4

The amount of precipitation in a given location varies from year to year. Geographically, that variability is itself quite variable (either as an empirical or relative value), as is the average precipitation. The 20 counties with the lowest growing season precipitation are all in the desert Southwest (Table 5).

Table 5. The 20 Counties in which Crops Are Insured under an Irrigated Practice Code with the Lowest Average Growing Season (April through September) Precipitation

State	County	Average	Standard Deviation
California	Imperial	0.6	0.7

Source: The Contractor's Research Department after cleaned, filled, and backcast NCDC data

When a crop generally receives ample growing season precipitation, irrigation is used primarily to supplement the precipitation during brief dry periods. Therefore, in areas with abundant precipitation, the variability of that precipitation from year to year is the parameter imposing the requirements for an adequate supply of irrigation water. The 20 counties with the highest standard deviation of the growing season precipitation all have on average more than 22 inches of rain during the growing season. Only Miami-Dade and Gulf counties in Florida and Terrebonne Parish in Louisiana are on both the maximum average growing season precipitation list and the maximum standard deviation of growing precipitation list. The reader should note, the high variability of rainfall in counties with abundant precipitation indicates that in some years, precipitation in these counties cannot support even 15 acre inches of evapotranspiration. This is one underlying cause of higher insurance rates for non-irrigated crops than for irrigated crops in counties that generally have ample rainfall to support an abundant harvest.

It is important to understand the impact of precipitation variability on irrigation requirements. Soybean requires approximately 20 inches of water for full evapotranspiration.³⁷ Harris and Matagorda counties in Texas and Greenwood County in Kansas all receive more than enough water on average during the growing season to support full evapotranspiration (Table 6). However, considering the standard deviation of the growing season precipitation in these counties, in some years maintaining an Approved Yield for a soybean crop grown under the Irrigated Practice will require having access to a substantial quantity of water for irrigation, even if the Approved Yield was achieved at evapotranspiration levels substantially lower than full evapotranspiration.

³⁷ Al-Kaisi, M., 2000, Crop water use or evapotranspiration, IC-484:84-86, <http://www.ipm.iastate.edu/ipm/icm/2000/5-29-2000/wateruse.html>, accessed May, 2014.

Table 6. The 20 Counties/Parishes in which Crops Are Insured under an Irrigated Practice Code with the Highest Standard Deviation of Growing Season (April through September) Precipitation

State	County/Parish	Standard Deviation	Average
Oklahoma	Johnston	11.4	32.7
Florida	Dixie	9.9	33.3
Texas	Chambers	9.6	27.5
Arizona	Cleveland	9.5	32.2
Kansas	Neosho	9.4	33.7

Texas	Orange	8.5	27.4
Kansas	Greenwood	8.5	23.8

Source: The Contractor's Research Department after cleaned, filled, and backcast NCDC data

When very limited growing season precipitation falls, irrigation is used primarily to replace rainfall rather than to supplement the rainfall. Therefore, in areas with very limited precipitation, the variability of that precipitation from year to year is unlikely to impose requirements for more irrigation water than is normally used. Instead, producers manage their crops to avoid overwatering when natural precipitation does fall. The 20 counties with the lowest variability in the standard deviation of the growing season precipitation all have less than 4 inches of rain on average during the growing season (Table 7). LaPaz County in Arizona; Imperial, Inyo, Kern, Kings, Merced, Riverside, San Bernardino, Stanislaus, and Yuma counties in California; and Clark County in Nevada all have very limited average growing season precipitation as well as very little variability in the amount of precipitation from year to year.

Table 7. The 20 Counties in which Crops Are Insured under an Irrigated Practice Code with the Lowest Standard Deviation of Growing Season (April through September) Precipitation

State	County	Standard Deviation	Average
California	Inyo	0.6	1.0

Source: The Contractor's Research Department after cleaned, filled, and backcast NCDC data

During the preparation of the second deliverable of the first Task Order under this IDIQ, a very important issue was raised concerning the period of natural precipitation that supports crop production. The issue was first raised in a conversation with an extension agent in northwestern Kansas. The agent and other stakeholders in the area reported the precipitation that falls in October is just as important to corn production the next calendar year as precipitation falling after planting, during emergence, or during the development of the ear. Since the general consensus on the window of precipitation that supports plant growth is that pre-plant moisture and growing season moisture through maturity are the two essential sources of moisture, these stakeholders were suggesting, in this area, pre-plant moisture was the moisture collected by the soil from October through planting.

The Contractor tested this suggestion by examining the correlation from 1972 to 2012 between planted yields for non-irrigated corn in Sheridan County, Kansas, and of the amount of precipitation falling during various periods (i.e., April through September, January through September, and October of the prior year through September of the crop year). The Contractor considered both total precipitation and weighted totals of the precipitation. The Contractor considered both a simple weighting approach (with the April through September precipitation weighted higher than precipitation that fell earlier and January through September moisture weighted higher than the moisture that fell earlier) and graded weighting (with earlier pre-plant precipitation weighted less than the precipitation falling nearer to planting).

The highest correlation for yields of non-irrigated corn to precipitation was for the un-weighted precipitation total from October through September of the crop year (0.49). This was also the period of strongest correlation between the irrigated corn yield and any period of precipitation

(0.08). However, because natural precipitation plays a limited role in the growth and development of irrigated crops, the correlations between precipitation and yield were much lower for irrigated corn than for non-irrigated corn. Discussions with extension agents in several locations about these unusual results led to the conclusion that the area in question must be underlain with a relatively impervious subsoil layer. Consequently, any moisture falling on the soil is banked for future evapotranspiration. In the absence of transpiration (i.e., after the crop has been harvested), the only loss of water from the soil is by evaporation from the surface.

This concept of “critical precipitation window” advanced by the Kansas extension service led the Contractor to inquire about the “critical precipitation window” for crops in other states. The intent was to understand better some of the limits of the construct “during the growing season ... at the proper times” in the definition of the Irrigated Practice.

The Contractor succeeded in discussing this concept with extension agents in 40 states. For simplicity the focus was on growing season, an extended pre-plant period and growing season, and from the end of harvest one year through maturity the next. Most considered the April to September (i.e., an arbitrary “growing season”) to be the most crucial period for precipitation (Appendix F), with a limited period of pre-plant moisture contributing to production. Extension specialists representing New Hampshire, Oklahoma, and the eastern half of Kansas indicated that any precipitation after the beginning of the calendar year was crucial to crop productivity. In the remaining 13 states (Table 8), according to testimony, the precipitation from harvest one year through the maturation of the crop the following year is the best measure of the available water for crop production.

Table 8. States Where the Total Precipitation from the Preceding Harvest through the End of the Harvest was Identified as Crucial for Crop Production

Arizona	North Dakota
California	Oregon
Idaho	South Dakota
Kansas - West	Utah
Nebraska - West	Washington
Nevada	Wyoming - Northwest
New Mexico	

Source: The Contractor’s Research Department after discussion with state extension specialist

The Contractor is not suggesting irrigation of a harvested field is irrigating “during the growing season ... at the proper times”. Instead the lesson from this effort is that well-informed producers who understand their soil’s moisture holding capacity are likely to change their irrigation approach from year to year to address appropriately the available soil moisture. Furthermore, deep soil moisture in some areas will play a substantially greater role than in other locations. The appropriate granularity of the requisite information about soil moisture holding capacity is not at the state level and not likely at the county level. Within a county, and even on an enterprise, soil differences are an important element of identifying what can be accomplished with Efficient Irrigation. Consequently, a simple approach, not requiring annual updating, to address Efficient and Limited Irrigation will need to allow decisions that represent good management practices without restricting the management decisions of the most knowledgeable producers.

Finally, recognizing that a healthy plant is essential to the production, by perennials, of their fruit and nut crops, the entire year's precipitation is important for these Category C crops. This is true even for Category C crops grown under irrigation. An extended dry period in any part of the year can damage the growing points of woody species. If a drought is severe enough, it can even damage dormant buds. Consequently, having sufficient irrigation water to supplement natural precipitation throughout the year is crucial to maintenance of an Approved Yield for Category C crops insured under an Irrigated Practice code. The producers of these crops understand this requirement. It was evident in comments at listening sessions and in discussions with extension agents. The literature published by extension offices provides good evidence that producers of these perennial crops have been among the pioneers in the development of Efficient Irrigation techniques.³⁸

NASS

NASS data are useful in identifying locations where crops are produced under irrigation. NASS conducts surveys and prepares reports covering a wide range of topics concerning U.S. agriculture. The Contractor reviewed NASS aggregate data published in the Census as well as data available from Quick Stats and the FRIS. NASS is especially conscientious about documenting their sampling methods and reporting the methods used to develop results estimated from samples. NASS survey reports identify major irrigated commodity crops and estimated yields of those crops. The only USDA reports of the amount of water applied per acre are in the FRIS, a follow-up survey to the Census of Agriculture, and in evaluations of the FRIS datasets by the ERS³⁹ and ARS.⁴⁰ The Contractor found no reports from NASS where both yield and amount of irrigation water applied at any finer level than for whole states were published.

NASS Census Data

NASS conducts a Census of Agriculture every five years. The Census of Agriculture is unusual among NASS data collection instruments in that NASS distributes census questionnaires to the complete list of farms NASS maintains. For the purpose of the Census of Agriculture NASS defines a farm as "any place that produced and sold, or normally would have sold, \$1,000 or more of agricultural products during the Census year."⁴¹ Most NASS surveys other than the Census of Agriculture are distributed to limited samples of total potential respondent populations.

⁴⁰ See, for example: USDA, ARS, 2001, Irrigation and Drainage, <http://www.ars.usda.gov/is/np/irrigationdrainage/IrrigDrainBro.pdf>, accessed May, 2014.

⁴¹ USDA, NASS, 2102, Census of Agriculture: Your Voice, Your Future, Your Responsibility, http://www.agcensus.usda.gov/Partners/Brochures/2012_Census_Brochure_FINAL_ENGLISH.pdf, accessed April, 2014.

The Census of Agriculture provides the only source of detailed agricultural data for every county in the United States. NASS collects these data using a uniform and consistent methodology, carefully documenting changes in the form and analytical methods from one census to the next. At the same time, NASS is required by law to preserve producer confidentiality. Title 7, U.S. Code, Section 2276 and the Confidential Information Protection and Statistical Efficiency Act prohibit public disclosure of individual information. Personal information, including personally reported data, is protected from legal subpoena and Freedom of Information Act requests. NASS identifies confidentiality and data security as their top priorities.

The 2007 Census reports 922,095,840 acres of land on U.S. farms. Of this land on farms, 406,424,909 acres are in cropland. The Census also reports 222,267,817 acres “enrolled” in FCIC insurance programs administered by USDA RMA. The RMA database shows approximately 31 million of those acres insured under irrigated practice codes in 2007. Consequently, the cropland used to produce insured irrigated crops accounts for slightly less than 3.5 percent of the land on farms in the United States; about 8 percent of the total NASS-reported U.S. croplands; and slightly less than 14 percent of the FCIC insured acreage. Table 36 of the 2012 Census of Agriculture Census (Table 32 of the 2007 Census) documents the yield per acre of 26 crops grown with and without Irrigation (Table 9). These aggregate yields provide an overview of the benefits of irrigation, but provide no useful information about the effects of the amount of irrigation water applied.

Table 9. Yield per Acre of 26 Crops Grown With and Without Irrigation

Crop (unit for the crop)	Irrigated Yield	Non-irrigated Yield
Barley for grain (bushels)	100.7	55.8
Corn for grain (bushels)	171.1	111.1
Corn for silage or greenchop (tons)	23.8	13.5
Cotton, all (bales)	2.3	1.6
Upland cotton (bales)	2.2	1.6
Pima cotton (bales)	3.1	-
Dry edible beans, excluding limas (cwt)	22.8	17.8
Oats for grain (bushels)	87.1	59.4
Peanuts for nuts (pounds)	4,362.0	3,875.1
Rice (cwt)	74.3	-
Sorghum for grain (bushels)	80.7	47.7
Soybeans for beans (bushels)	49.4	37.6
Sugar beets for sugar (tons)	32.8	26.2
Sugarcane for sugar (tons)	35.7	34.7
Tobacco (pounds)	2,616.1	2,153.8
Wheat for grain, all (bushels)	81.8	42.9
Winter wheat for grain (bushels)	76.8	44.3
Durum wheat for grain (bushels)	96.0	32.9
Other Spring wheat for grain (bushels)	89.1	40.8
Alfalfa hay (tons, dry)	4.6	2.2
Small grain hay (tons, dry)	3.3	1.8
Tame hay other than alfalfa, small grain, and Wild hay (tons, dry)	2.6	1.8
Wild hay (tons, dry)	1.2	1.3
Haylage or greenchop from alfalfa or alfalfa mixtures (tons, green)	7.5	6.4
All other haylage, grass silage, and greenchop (tons, green)	10.7	4.1

Source: The Contractor's Research Department the 2012 Census of Agriculture, Volume 1, Table 36, page 26.

The remaining information on irrigation in the census is of limited use for assessing the appropriate approach for addressing Efficient and Limited Irrigation. Table 37 of the 2012 Census documents U.S. farm numbers and acreage with irrigated production of camelina, canola, dry peas, flaxseed, hops, lentils, pineapples, popcorn, rye, safflower, and sunflower seed of various types. There is no information on yields or on the amount of irrigation water required. Table 1 of the 2012 Census state level summaries reports the number of farms with irrigation and the number of irrigated acres in each state for the crops identified in Table 9. Table 10 of the 2012 Census state level summarizes reports on these parameters by size of operation and by state. Table 25 of the 2012 Census state level summaries documents the number of farms and acreage with irrigated production for nine additional crops: buckwheat, cowpeas, emmer and spelt (one crop), mustard seed, rape seed, sugar beets for seed, sugar beets for seeds, triticale, and wild rice. Table 26 of the 2012 Census state level summaries reports the number of farms and acreage with irrigated production for grass and field seed. Tables 27 through 29 of the 2012 Census state level summaries report number of farms and acreage with irrigated production for other crops (from dill to taro), vegetable, and orchards respectively, while Table 32 addresses berries.

As stated previously, these data are useful in identifying major irrigated crops. For the major commodity crops it would be possible to mine the respondents' data to establish yield under

irrigated and non-irrigated practices, but not using the insurance definition of Irrigated Practice. However, since NASS conducts a census only once every five years, these producer-level yield data would represent a very limited time series. Furthermore, the NASS confidentiality requirements would reduce the number of counties for which yields could be reported.

NASS Quick Stats

The NASS agricultural database for the United States is enormous. NASS developed Quick Stats (http://www.nass.usda.gov/Quick_Stats/) as a research tool for extraction of relevant data from the database. The Quick Stats database contains almost 31 million records of aggregated parameters derived from the census data and from analysis of survey responses. Each record addresses 39 parameters (http://quickstats.nass.usda.gov/param_define). No producer-level data is available through Quick Stats, but NASS supports research visits to analyze the unpublished data if such analysis can be completed without violating the requirements of Title 7, U.S. Code, Section 2276 and the Confidential Information Protection and Statistical Efficiency Act. The Contractor reviewed the Quick Stats summary data to understand better any value that might be obtained from research of producer-level responses to NASS surveys. NASS describes its general survey methodology as follows:

Most of the [NASS] estimates are based on data collected from a sample of a given population. The samples are designed so that the chance, or probability, of including a particular operation in the sample is known before the survey is carried out. The sample data can be used to measure how much the survey estimates could differ from the population values. This measure of variability, due to selecting a sample rather than conducting a census is ... the sampling error.

The data from a probability-based sample can then be used to make precise inferences about the population. This survey technique has distinct advantages over a census; it takes less time, costs less, and can actually be more accurate because fewer errors are made in reporting and handling the smaller quantities of data. Also, the results of the survey stand alone; they do not depend on relationships to other sets of data, such as the Census of Agriculture.⁴²

Quick Stats provides reports on 29 crops that are insured under an Irrigated Practice code (Table 10). Harvested acreage is reported for all 29 crops, but not for all counties where the crops are produced commercially. NASS documents harvested acreage from both the census reports and estimates of harvested acreage based on analysis of survey results. NASS only publishes production and yield estimates in Quick Stats from their survey analyses. These values likely have more limited value to the insurance of Efficient and Limited Irrigation because of the errors associated with the sampling and analyses.

NASS publishes production data for some crops at the state level in the census reports⁴³ and yield data are documented in the census reports for a number of crops and states as noted above. However, except for data on harvested acres, many of these data are not mined by the Quick Stats algorithms. Corn is by far the best documented crop in the dataset. The Contractor has extracted the data for acreage, production, and yield for irrigated corn for 2012. Tables 11 and 12 are included to illustrate the limits of these Quick Stats data.

⁴³ See, for example: USDA, NASS, 2014, 2012 Census Publications, <http://www.agcensus.usda.gov/Publications/2012/>, accessed May, 2014.

¹ Survey² Census

Source: The Contractor's Research Department after USDA, NASS 2012 Census of Agriculture and surveys accessed through Quick Stats, May, 2014.

The Contractor notes first that the estimates for planted acres, yields, and production derived from the surveys are all rounded to address significance of the sample data used in the calculations. The Contractor is reminded by this rounding that these NASS figures are evidence-based estimates. Furthermore, limitation on reports for irrigated corn in some counties in both the Census of Agriculture (Appendix G, Table G1) and Quick Stats (Appendix G, Table G2), illustrates the challenges of using NASS Quick Stats survey data to address Efficient and Limited Irrigation even for a major commodity crop. The 2012 Census documents corn for grain irrigated acres harvested for 1,852 counties in 46 states. The Quick Stats Survey data for 2012 document corn for grain irrigated planted acreage in only 116 named counties and only 4 states. The Contractor has been asked to identify a simple approach not requiring frequent updating for all irrigated crops nationwide that are insured under a yield-based plan. With these disparities in reporting, the additional Quick Stats data on yield provide very limited useful information for addressing Efficient and Limited Irrigation as a construct for crop insurance.

Examination of the Quick Stats Survey data for peanuts, a specialty crop with substantial production, further illustrates the barrier to using Quick Stats data, or its underlying producer-level dataset, to develop an approach to support implementation of Efficient and Limited Irrigation procedures. The 2007 Census documents peanut production in 237 counties in 15 states (Appendix G, Table G3). The most recent surveys for peanuts (2007) document irrigated planted acreage, harvested acreage, production, and yield in only 4 named counties and only in Texas (Appendix G, Table G4).

NASS FRIS

Over time, the U.S. government has collected substantially more data addressing on-farm irrigation. The 11th U.S. Census in 1890 included questions about agricultural practices, including Irrigation. In 1894, the Department of Interior Bureau of the Census issues a report on irrigated agriculture almost a thousand pages long.⁴⁴ The collection of agriculture statistics remained the purview of the Bureau of the Census until 1997. They conducted special quinquennial FRIS from 1979 through 1994. The Bureau of Census transferred responsibility for agricultural census activities to the USDA NASS in 1997. The 1998 FRIS was the first survey to collect and publish data for irrigation in each of the 50 States. Prior to that, NASS collected data for leading irrigation states.

The 2008 FRIS is the seventh survey devoted entirely to collecting on-farm irrigation data for the United States. For the first time, irrigation data for horticultural specialty operations with sales of \$10,000 or greater were included in the survey. The 2008 FRIS provides data that supplement the basic irrigation data collected from all farm and ranch operators in the 2007 Census of Agriculture. The summary of irrigation data collected in this survey provides the most complete and detailed profiles of irrigation in the United States. NASS focuses the data collection effort for FRIS to complement the census dataset and allow meaningful estimates of a wide range of parameters for U.S. irrigation. Almost 207,000 farms were irrigating in 2008, with almost 55 million acres irrigated using just more than 91 million acre feet of water.

FRIS reports on estimated yields for 16 irrigated crops and the estimated average amount of water applied to these crops at the state level (Table 13).⁴⁵ State-level data are more granular than the data that are normally used for crop insurance analyses.

¹ Acre-weighted average for these 15 crops and crop groupings.

Source: The Contractor's Research Department after USDA, NASS, 2009, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008).

For some crops, the number of farms irrigating changed dramatically between 2003 and 2008 (Table 14). These changes reflect producer decisions about which crops to plant and which crops to irrigate. They also capture the growth of larger farms and the disappearance of smaller farms. Furthermore, they reflect changes in technologies that allow production without irrigation (e.g., drought tolerant varieties and changes in tillage). Although the total number of farms irrigating for these 22 crops/crop groupings increased by 1 percent, the total number of farms irrigating in the United States decreased 1.6 percent from 2003 to 2008.

**Table 14. Percent Change between 2003 and 2008 by Crop
in the Numbers of U.S. Farms Irrigating**

Crop	Farms	Crop	Farms
Wheat for grain or seed	20.3	Corn for grain or seed	4.2
Peanuts for nuts	19.9	Land in orchards, vineyards, and nut trees	-1.1
Potatoes	19.2	Tomatoes	-2.7
All berries	13.3	Barley for grain or seed	-6.8
Soybeans for beans	9.3	Corn for silage or greenchop	-9.7
All other hay	7.7	Rice	-23.0
Lettuce and romaine	7.4	Cotton - Pressure Systems	-23.3
Sweet corn	7.1	Sorghum for grain or seed	-32.9
Land in vegetables	5.9	Sugarbeets for sugar	-36.3
Beans, Dry Edible	5.6	Tobacco, all types	-46.2
Other small grains	5.3	Cotton - Low-flow Systems	-48.3
Alfalfa and alfalfa mixtures	4.6	Total United States	1.0

Source: The Contractor's Research Department after USDA, NASS, 2009, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008).

NASS estimates the total farmland acreage irrigated, including pastures, increased by 4.6 percent between 2003 and 2008. The total cropland acreage irrigated for 13 named crops/crop groupings increased by 7.4 percent between 2003 and 2008, with changes in acreage ranging from an increase of almost 32 percent for soybeans to a decrease of about the same amount for sugar beets and tobacco. Once again, these changes reflect producer decisions on which crops to plant and which crops to irrigate.

NASS reported in the FRIS that about 75,000 farms made changes to reduce their energy costs or to conserve water between 2003 and 2008. Almost 60 percent of these respondents indicated they used less water. Consequently, approximately a fifth of the farms irrigating in 2008 had practiced Efficient Irrigation as a result of the changes made to reduce their energy costs or to conserve water. However, the reader should remember the FRIS is only conducted every five years. Furthermore, because it is a survey and because of its frequency, the FRIS provides at best a snapshot of U.S. irrigation practices.

Perhaps the most interesting data in the FRIS from the perspective of addressing Efficient and Limited irrigation for crop insurance are the changes made for 13 named crops/crop groupings between 2003 and 2008 in the amount of irrigation water applied and the resultant yields achieved. For eight crops, the average irrigation water applied decreased, while the average yield only decreased for one of these eight crops. That crop was wheat, whose percent decrease in yield was much less than the percent decrease in irrigation water applied. Only hay (of all types) showed poorer yields although additional irrigation water was applied. Such a pattern might be expected if the hay were grown primarily in areas with adequate precipitation in 2003, but under drought conditions in 2008 (Table 15). The distribution of hay production in the United States and the drought conditions across the nation those two years support this hypothesis.

Table 15. Percent Change in U.S. Irrigated Acres, Irrigation Water Applied per Acre, and Yields between 2003 and 2008 by Crop

Crop	Irrigated Acres Harvested	Average Acre-Feet Applied	Average Yield
Corn for grain or seed (bushels)	23.0	-16.7	1.7
Soybeans for beans (bushels)	31.8	-12.5	2.1
Beans, Dry Edible (cwt)	-5.9	-12.5	4.3
Sorghum for grain or seed (bushels)	-6.0	-10.0	2.7
All cotton (lbs, lint)	-23.3	-7.1	10.9
Wheat for grain or seed (bushels)	25.7	-6.7	-1.3
Corn for silage or greenchop (tons, green)	24.5	-4.5	0.0
Sugarbeets for sugar	-31.9	-3.7	3.4
Barley for grain or seed (bushels)	-23.1	0.0	4.2
Rice (cwt)	-10.4	0.0	1.4
Tobacco, all types (pounds)	-32.6	0.0	9.2
Alfalfa and alfalfa mixtures (dry hay, greenchop, and silage) (tons, dry)	-0.3	4.3	-10.0
All other hay (dry hay, greenchop, and silage) (tons, dry)	3.3	5.9	0.0
Total United States	7.4	-3.6	N/A

FRIS Unpublished Data⁴⁶

The Contractor also assessed respondent-level (unpublished) data provided in response to the FRIS at the NASS Data Lab. The target population for the 2008 FRIS was all farms in the United States irrigating in the reference year 2008. Reporting irrigated acreage in response to the Census in 2007 was required to be considered among all farms in the United States irrigating in the reference year 2008. This includes some operations in the target population who irrigated in 2007 but not in 2008. NASS corrects for this sampling error. It also excludes operations which did not report irrigation in the Census. These fall mainly into three categories: Those who irrigated in 2008 who did not irrigate in 2007; those who did not respond to the Census by choice; and those whose operations are so small that they are not included in the Census target population. All three categories likely include some limited resource producers. There is no mechanism to correct for this sampling error.

NASS identified 217,604 records in the 2007 Census having irrigation activity on their farm or ranch. The population was divided into those with irrigated horticultural production and those without. NASS selected a final sample for the FRIS of 23,089 operations. NASS expected a final response rate of 70 percent, taking the expected responses to about 7.5 percent of the target population. The responses are then handled to eliminate forms that have not addressed queries appropriately (e.g., misinterpreted questions or answered inconsistently between related questions). The survey instrument is available for review as Appendix B on pages B-11 through B-26 of the FRIS summary report.⁴⁷ The final FRIS unpublished data included 14,503 records (reports from producers), with more than 100 attributes reported for each record.

The Contractor was excited by the possibility that these data could support quantitative models for addressing benchmarks for Efficient Irrigation and adjustments to Approved Yield for Limited Irrigation. The FRIS Survey Overview notes, “FRIS is the most comprehensive source of information on irrigation water use throughout the agricultural industry and results are reported not only on the national and state levels, but by water resources regions.”^{48,49} The survey analysis accounts for 97.1 percent of all land reported as irrigated in the 2007 Census of Agriculture. The survey parameters address the crucial irrigation characteristics associated with that land. However, the Contractor notes the association with the land is the focus, with association with crops receiving less attention.

The confidentiality requirement for NASS survey data require that all unpublished data research be conducted in a secure USDA NASS data facility. The Contractor sent two analysts to the NASS Data Lab in Washington, D.C. The first day of work was spent gaining familiarity with the database structure and its relationship to the survey instrument. Thereafter, the analysts

⁴⁶ The Contractor would like to thank Robert Hunt and Jim Burt of the USDA NASS Data Lab for their warm welcome and their efforts in preparing the FRIS data for the Contractor’s queries.

⁴⁷ USDA, NASS, 2010, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008), http://www.agcensus.usda.gov/Publications/2007/Online_Highlights/Farm_and_Ranch_Irrigation_Survey/fris08.pdf, accessed May, 2014.

⁴⁸ The 20 NASS defined Water Resources Regions each include at least parts of multiple states and in most cases, multiple states. They reflect primarily surface water resources.

⁴⁹ USDA, NASS, 2010, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008) fact sheet, http://www.agcensus.usda.gov/Publications/2007/Online_Highlights/Fact_Sheets/Practices/fris.pdf, accessed May, 2014.

mined the data to understand the extent to which these data would inform an analysis of irrigation activities at the state and county levels.

The Contractor's initial analysis focused on obtaining an understanding of the relative proportion of the 14,503 records which could be used to assess county-level irrigation practices. Since Efficient and Limited Irrigation address changes in management, the Contractor sought to identify counties that had at least 5 respondents in 2003 (the previous FRIS) and 2008. The Contractor was surprised that only 351 of the 3,144 counties (or county-like entities) in the United States had data that could support irrigation comparisons between surveys at the county level (Table 16). Even considering that only about two thirds of these counties and county-like entities have insured irrigated production, the utility of the FRIS unpublished data in addressing Efficient and/or Limited Irrigation became a concern.

Table 16. Number of Counties with 10 or More 2008 FRIS Respondents, by State

The Contractor then examined the potential for the FRIS data to be of use at the crop, rather than the county level. If enough counties could be mined for a crop, a crop specific pattern of irrigation might be discerned. So for example, if corn irrigation and precipitation together generally resulted in 30 acre inches of water being available to the corn crop, then the mining of weather data could be used as a proxy. The Contractor sought to identify the number of counties

that had at least 10 respondents in 2003 (the previous FRIS) and 2008 for each of the 16 named crops in the survey (Table 17).

Table 17. Number of Counties with 10 2008 FRIS Respondents, by Crop

NASS FRIS unpublished data.

There are some crop/county combinations that have especially rich data. To illustrate the limitations of these data-rich counties to be useful in addressing Efficient and Limited Irrigation, all county/crop combinations with more than 50 respondents are provided in Table 18. The data for all county/crop combinations are provided in Appendix G, Table G5.

Table 18. Crop County Combinations with More than 50 Respondents

State	County	Crop	Number of Respondents
Washington	Grant	Wheat	95

Oklahoma	Texas	Wheat	51
Minnesota	Dakota	Corn for Grain	50

Source: The Contractor's Research Department after USDA, NASS FRIS unpublished data.

To understand if there was a possibility of bridging between precipitation data and amount of irrigation water applied, the Contractor examined the correlation between the amount of water applied to irrigated crops per acre in a county from the FRIS unpublished data and the natural precipitation falling on the county (Table 19). The Contractor first looked at correlations at the county level and then at the Crop Reporting District (CRD) level. As these correlations showed no discernible pattern, the Contractor continued to an even coarser granularity. Correlation coefficients are reported in Table 19 at the state level. The reader should note the wide range of both positive and negative correlations. In conversations, Texas producers express an opinion that the positive correlations might reflect states with primarily surface water supplies, the negative correlations might represent states with primarily ground water supplies, and the weak correlations might represent states with a wide mix of water supplies. This is an interesting hypothesis, but not relevant to the current analysis of data that might be of use to an insurance approach to address Efficient and Limited Irrigation.

Table 19. Correlations of the Amount of Irrigation Water used for Irrigation in a County and the Amount of Growing Season Precipitation: Top 25 Counties¹

State	Correlation Coefficient	State	Correlation Coefficient

The Contractor used a similar approach to examine the correlation between the amount of water applied to irrigated crops per acre and the natural precipitation falling on the crops (Table 20).

Table 20. Correlations of the Amount of Irrigation Water used for a Crop and the Amount of Growing Season Precipitation: Top 10 Crops²

These data revealed that there is no strong correlation between the amount of precipitation and the amount of irrigation water applied. It appears some producers apply more irrigation water per acre when there is more precipitation, especially in areas where surface waters are the primary source of water for irrigation. It appears some producers apply less irrigation water per acre when there is more precipitation, especially in areas where ground waters are the primary source of water for irrigation. Between 2003 and 2008, there were negligible changes in the

amounts of water applied per acre nationwide.⁵⁰ Nonetheless, Table 15 of this report shows evidence of the effects of Efficient Irrigation. The FRIS provides the opportunity to map the distribution of those efforts by county (Figure 3).

Figure 3. Map of the Proportion of the Respondents in each County Indicating Implementation of Improvements in their Irrigation Systems Based on Question 1 of Section 18 of the FRIS for Operations without Horticultural Production⁵¹

Source: The Contractor's Research Department after USDA, NASS FRIS unpublished data.

The FRIS also provides useful information about sources of irrigation information producers use (Table 21). Knowledge of these sources and the distribution of their use by producers will be particularly useful in drafting underwriting language if RMA implements Efficient and/or Limited Irrigation. Data to establish these sources are reported at the state level in the FRIS and may be mined at the county level from FRIS unpublished data for many major agricultural counties.

⁵⁰ USDA, NASS, 2010, 2007 Census of Agriculture: Farm and Ranch Irrigation Survey (2008), Table 8, http://www.agcensus.usda.gov/Publications/2007/Online_Highlights/Farm_and_Ranch_Irrigation_Survey/fris08.pdf, accessed May, 2014.

If the FRIS were a census, rather than a survey, the unpublished data would provide a basis for better analysis of the effects of application of different amounts of irrigation water. A census attempts to obtain data from the entire target population, while the survey samples from the population. Furthermore, if this hypothetical irrigation census were offered every year or every other year, the data time series would be more useful in analyzing the impacts of changes in irrigation amounts and the effects of weather on producer decisions about irrigation. Since the data for precipitation can be known at the county level, and if the FRIS were an annual census, it would then be possible to know the average total water available to a crop (in acre inches). This would involve nothing more difficult than adding the average precipitation at the county level to the average irrigation water applied at the county level. Regrettably, the survey nature of the FRIS and the interval between surveys severely limits the utility of the FRIS unpublished data in addressing Efficient and Limited Irrigation. Nonetheless, data for the 2013 FRIS survey should be available sometime in October 2014. It seems likely the 2013 FRIS report will document an even greater effort to achieve efficient irrigation.

RMA Unpublished Data

The Contractor reviewed and analyzed the RMA insurance experience data at the level of the insured to assess the potential contributions of these data to developing recommendations for modifications to policy and procedure. The focus of this research was on Type P11 (acreage reports), Type P15 (yield reports), and Type P21 (production loss reports).⁵² While the RMA data include information about the number and location of insured irrigated acres as well as reports of irrigated yields, they contain no information about the amount of irrigation water applied. RMA data are the only data available to identify the states, counties, crops, and acreage of the **insured** irrigated crops. The research on RMA data focused on crop years 2003 and 2008 (the crop years reported in the most recent FRIS reports), 2007 (the crop year reported in the most recent Census when the research was begun),⁵³ and 2012 (the most recent crop year with a relatively complete insurance experience record). These data were selected because they facilitate analysis in context with the NASS census data and other available datasets. The RMA data show about 90 crops insured as irrigated, with slight variations in that number from year to year. Almost every state has at least one insured irrigated crop each year (Appendix H).

⁵² The Contractor includes records in the predecessor Type 11, 15, and 21 records when using this newer record naming system.

⁵³ As noted earlier, the 2012 Census of Agriculture U.S. Summary and State Data and State and County Data Online Reports were released on May 2, 2014. The Contractor reviewed these reports to verify that the conclusions reached concerning the utility of the Census of Agriculture data were not changed.

State Survey

The Contractor reviewed state irrigation surveys to see if they might provide useful information for developing modifications to crop insurance policy and procedure regarding Efficient and Limited Irrigation. The Contractor was able to identify surveys on irrigation from 13 states. (Table 22, Appendix I). These state surveys are not particularly useful because of the infrequency of data collection, limited sample size, and substantially different data collection methods between states and between years within a state. Most of the data are focused on extraction of water from reservoirs, rivers, and aquifers. These surveys focus on hydrology rather than on agricultural production.

Research Reports

The published academic research data are useful primarily in confirming the assumption that the amount of water available for evapotranspiration is correlated to the yield as long as no other factors are limiting production. Deficit irrigation is defined in the academic literature as irrigation that supplies less than the water required for full evapotranspiration. In this respect, for the plant physiologist and agronomist, deficit irrigation is an equivalent construct in relation to full irrigation as Limited Irrigation is to the amount of irrigation water applied to achieve the Approved Yield. However, they are in no way synonymous, since the Irrigated Practice does not require full irrigation. Full irrigation should not be used as a term defining the amount of water required to produce the Approved Yield. The analysis of scientific research in search of insight about Limited Irrigation is confounded by the scientists emphasis on the only limiting factor being the irrigation water applied. That is certainly the case for the initial reductions in applied irrigation water if the producer is expecting to get a production potential not less than the Approved Yield. However, if the expectation is a lesser amount of production, and if the producer reduces other inputs, then one of those other inputs could become limiting.

The Contractor did not attempt to duplicate the work commissioned by the RMA from the University of Nebraska regarding yields from plants whose productivity is limited by the available water supply.⁵⁴ The essential conclusion from this work is that, over some reasonable

⁵⁴ Procedures for Adjusting APH when Implementing a Deficit Irrigation Insurance Practice.

range of amounts of water applied for irrigation, when water is limiting, the yield for corn and soybean in three states increases linearly with the increase in available water. While this has not been documented for every crop, the partitioning of water by the crop plant between that required for vegetative growth and that required for reproductive growth makes it generally reasonable to accept the linearity of the relationship. The Contractor identified no primary research reports or reviews that examined time series effects of Efficient, Limited or deficit irrigation.

SECTION VII. IRRIGATION PRODUCTION MANAGEMENT PRACTICES

Producer production decisions are driven by many factors. Producers consider input costs such as the costs of seed, fertilizer, energy, rent, and water used for irrigation. They also consider revenue factors such as which crop is likely to bring the highest net revenue per acre at harvest and the opportunity costs of storing production. Many producers make their decision regarding which crop to plant based primarily on personal histories and experiences.

Producers cannot have perfect knowledge about the availability of water for production prior to planting. They cannot know how much natural precipitation will fall. Consequently, they cannot know how much water they will need to apply. Producers dependent on surface water for their irrigation water supply cannot know the rate at which snowpack will melt. Adding to this uncertainty is the recent trend of state and local governmental entities making determinations about available water for irrigation at the legislative level. These administrative actions may not come prior to the planting date. These statements are not intended to imply that producers never know when water available for crop production may be limited. Some limitations can be known in advance, but the nature of information available and its timing can be expected to vary widely.

Producers in many states have been proactively seeking ways to improve or at least maintain their yields using techniques for irrigation that require less water applied to each irrigated acre. In those states where “banking” water is offered, some producers are using Efficient Irrigation to allow them to set aside a portion of their water allocation for future use. In other states, implementing the Efficient Irrigation techniques identified below has allowed an increase in the acreage managed under irrigation, an ability to address more severe natural precipitation shortfalls, a way to decrease input costs, or a way to deal with the actions of administrative bodies which control the amount of water available for irrigation.

From an economic perspective, the potential for emergence of market-driven allocation of water, whether it be in the form of salable allotments, credits for reduced application, or other potential market-based incentives for investment in improved irrigation techniques, can be expected to have positive impacts on water usage overall. The implications on crop insurance, however, are not obvious. Some growers may indeed realize increases in expected yield or reductions in variability (both of which would contribute to reduced losses and therefore rates) as a result of increased investment in irrigation technologies. Others may change their crop mix or find alternative markets for the available water, with unpredictable results.

VII.A. Efficient Irrigation Techniques

The Contractor learned of some of these techniques through input during the listening sessions. The Contractor also contacted extension specialists in each state to discuss techniques being used by producers to apply less water to a crop while maintaining yields. It became apparent that while producers are using various means to address limitations in water availability, in many cases they are not using a single technique. Based on input from extension specialists and producers, the Contractor developed descriptions of 20 techniques currently used by producers to limit the amount of irrigation water required to maintain yields and 2 techniques that may result in Efficient Irrigation. The descriptions follow.

Changing the Irrigation Method

The United States Geological Survey (USGS) defines 9 primary methods to control the “application of water for agricultural purposes through manmade systems to supply water requirements not satisfied by rainfall.”⁵⁵ These methods, in general order of increasing water use efficiency, are:

- Gravity: Irrigation in which the water is not pumped but flows and is distributed by gravity.
- Flood: The application of irrigation water where the entire surface of the soil is covered by ponded water.
- Furrow: A partial surface flooding method of irrigation normally used with clean-tilled crops where water is applied in furrows or rows of sufficient capacity to contain the designed irrigation system.
- Surface: Irrigation where the soil surface is used as a conduit, as in furrow and border irrigation as opposed to sprinkler irrigation or sub-irrigation.
- Traveling Gun: Sprinkler irrigation system consisting of a single large nozzle that rotates and is self-propelled. The name refers to the fact that the base is on wheels and can be moved by the irrigator or affixed to a guide wire.
- Center-Pivot: Automated sprinkler irrigation achieved by automatically rotating the sprinkler pipe or boom, supplying water to the sprinkler heads or nozzles, as a radius from the center of the field to be irrigated. Water is delivered to the center or pivot point of the system. The pipe is supported above the crop by towers at fixed spacings and propelled by pneumatic, mechanical, hydraulic, or electric power on wheels or skids in fixed circular paths at uniform angular speeds. Water is applied at a uniform rate by progressive increase of nozzle size from the pivot to the end of the line. The depth of water applied is determined by the rate of travel of the system. Single units are ordinarily about 1,250 to 1,300 feet long and irrigate about a 130-acre circular area.
- Drip: A planned irrigation system in which water is applied directly to the Root Zone of plants by means of applicators (orifices, emitters, porous tubing, perforated pipe, etc.) operated under low pressure with the applicators being placed either on or below the surface of the ground.
- Sprinkler: A planned irrigation system in which water is applied by means of perforated pipes or nozzles operated under pressure so as to form a spray pattern.
- Sub-irrigation: Applying irrigation water below the ground surface either by raising the water table within or near the root zone or by using a buried perforated or porous pipe system that discharges directly into the root zone.

The USGS includes in their list, two methods of control that affect the amount of water used, but not the efficiency of the irrigation.

- Rotation: A system by which irrigators receive an allotted quantity of water, not a continuous rate, but at stated intervals.
- Supplemental: Irrigation to ensure increased crop production in areas where rainfall normally supplies most of the moisture needed.⁵⁶

⁵⁵ <https://water.usgs.gov/edu/irquicklook.html>

⁵⁶ *Ibid*

Switching to a more sophisticated distribution technique generally results in Efficient Irrigation. However, producers consider the capital costs when changing their irrigation approach. For example, when changing from flood irrigation to center pivot, the producer exchanges the cost of labor for managing the distribution of the water for the cost of machinery to distribute the water. The producer must decide if the opportunity for greater yields under the pivot irrigation system and the lower labor costs will, over time, offset the substantial costs of machinery and power to operate the center pivot system. The Contractor heard substantial testimony about producers realizing greater yields with less irrigation water following a change to a more efficient irrigation method. In short, the producers used less water with a more modern irrigation method and achieved larger yields than their Approved Yield. However, the data supporting this testimony are anecdotal or based on very limited field trials.

Computerizing Irrigation

The cost of irrigation is substantial. Inefficient use of irrigation can destroy a farming business. Since the onset of personal computers in the early 1970s, producers have been using personal computer applications to monitor irrigation and schedule its timing. Agricultural specialists have developed tools for use by producers to help them get the most value from irrigation water. These tools range from simple spreadsheets to interactive applications for smart phones. Sophisticated computerized scheduling of irrigation can use a wide range of inputs including weather history, average historical evapotranspiration rates for the specific crop being irrigated, heat units, humidity levels, soil moisture monitoring devices, etc. The outputs are highly customized irrigation schedules. Furthermore, most recently-installed mechanical irrigation systems support wireless control of the machinery. Therefore, a producer can set the irrigation schedule and let a computer manage the plan with minimal oversight.

Some state regulatory agencies have been given the authority to monitor and even take control of these computerized irrigation systems. In Nebraska, the Natural Resources Districts have the authority and ability to turn off active pivot irrigation systems. In Colorado, state water resources personnel operate the opening and closing of irrigation canal gates from computers in their offices, thereby effectively managing when and the quantity of water to which a producer has access during the growing season.

Using an Automated Variable Rate Irrigation Systems

Traditional pivot irrigation systems water the covered area using a uniform water application rate. Due to topography and soil type differences within the field, a uniform application of water to an entire field may leave some areas of the field too dry while inundating other areas.⁵⁷ This leads to inefficiencies in water use and reduced yields in parts of the field. Variable rate irrigation systems address these inefficiencies. Variable rate irrigation systems use technology, including producer set control modules, to adjust water application rates based on the soil type, topography of the field, and individual crop water requirements. The variable rate irrigation system adjusts, at the level of individual sprinkler heads, the amount of water being applied to different portions of a field. Correctly engineered, this system ensures crops receive the appropriate amount of water for production while limiting the amount of water to only that amount necessary for that crop, soil type, and soil moisture level. An automated variable rate

⁵⁷ <http://edis.ifas.ufl.edu/pdffiles/AE/AE49000.pdf>

irrigation system may also enable a producer to practice Efficient Irrigation by reducing the inefficiencies inherent in the ability of a traditional pivot irrigation system to address microclimate variable.

Limiting Cultivation

Cultivation is “loosening and breaking up (tilling) of the soil. The soil around existing plants is cultivated (by hand using a hoe, or by machine using a cultivator) to destroy weeds and promote growth by increasing soil aeration and water infiltration. Soil being prepared for the planting of a crop is cultivated by a harrow or plow.”⁵⁸ In the context of irrigation, limiting cultivation (the number of times the soil is mechanically disturbed by the producer) decreases the loss of soil water to evaporation. The University of Nebraska identifies six primary tillage approaches: Plow, Chisel, Disk, Ridge Plant, Strip-till, and No-till.⁵⁹ Plow, Chisel and Disk tillage result in relatively high soil moisture losses.⁶⁰ In Ridge Plant, Strip-till, and No-till systems, the number of times the soil is disturbed and the amount of disturbance decreases and the soil moisture retention increases. Soil type and slope play a substantial role when a producer chooses a tillage system. However, many extension experts indicated the producers in their state are more frequently choosing a tillage system which allows them to disturb the soil less frequently, thereby increasing the soil moisture retention. The Contractor received substantial testimony about producers limiting cultivation in an effort to improve soil water retention. No till and limited tillage systems have been adopted by producers practicing Efficient Irrigation.

Tiling

Tiling was originally used to drain soil for industrial and agricultural uses. Substantial portions of Midwestern agricultural land from Ohio to Minnesota and from Michigan to Missouri are drained by tiles. Producers in North Dakota are currently tiling fields to control runoff and to capture that run-off for later irrigation. Furthermore, the tile may be used as a conduit for sub-irrigating the crop, thereby reducing evaporation of the soil water. By capture, storage, and sub-irrigation, producers enhance the efficiency of the irrigation process, reducing the amount of surface or ground water that is required for maintaining yields.

Using Soil Moisture Monitors

Soil moisture monitors can be used to assess many parameters regarding soil moisture. The most common are overall soil moisture, changing soil moisture status, and the “wetting front” location as water moves down through the root zone. Some monitors require manual reading and recording of information while others are connected to data recording devices. Soil moisture monitors which have been integrated into the irrigation schedule enable producers to selectively target when and where they use their water allocation for best resource allocation.⁶¹ Soil probes can be used by a producer to collect small soil samples from multiple locations in the field. The soil characteristics can be used to estimate the samples’ moisture based on physical characteristics (e.g., compaction, friability). Soil water sensors can measure soil moisture using water tension, electrical resistance, or soil capacitance to estimate actual available water in the

⁵⁸ <http://www.merriam-webster.com/dictionary/cultivation>

⁵⁹ <http://cropwatch.unl.edu/tillage>

⁶⁰ <https://cropwatch.unl.edu/tillage/advdissadv>

⁶¹ <http://www.growingproduce.com/uncategorized/soil-moisture-based-irrigation-scheduling/>

soil profile. A tensiometer uses a vacuum pressure gauge placed into the soil at a desired depth (usually within with the root zone) to register the drying of the soil. “Electrical resistance sensors consist of a formed block ... that contains a water absorption material like sand or gypsum in which electrodes to measure the electrical conductivity of the solution are embedded. Electrical resistance between the electrodes varies with the soil water content, and this has been related to soil water tension.”⁶² Capacitance sensors estimate volumetric water content in the soil. Sensors that are left in the field for the entire growing season generally monitor soil water status in annual crops better than those monitors that are placed and removed each time a measurement is taken.⁶³ The additional information available from soil moisture meters allows the producer to limit the irrigation to the most appropriate times and control the amount of irrigation so as to not overwater.

Using Natural Precipitation Schedules

The Contractor received input from extension specialists about irrigation efficiencies being realized by timing of planting so peak water requirements of the crop are better coordinated with peak periods of natural precipitation. This is essentially the technique used for crops in developing countries with monsoon and dry periods. Very few agricultural areas in the United States have a monsoon/dry period pattern. Even fewer have growing season temperatures that would support substantial changes in planting dates. However, when an insured can document successful use of this strategy, it should be recognized as Efficient Irrigation as defined for the crop insurance.

Using Evapotranspiration Schedules

Estimation of evapotranspiration rates is important in planning irrigation schemes.⁶⁴ In many states, extension specialists report producers using simple evapotranspiration schedules to schedule irrigation and determine the amount of irrigation water required for their fields. For most crops in most areas, most of the irrigation water applied to the crop ends up in the atmosphere through evapotranspiration. There are many models used to estimate evapotranspiration rates in row crops. In general, evapotranspiration rates differ during the various growth stages of a crop. Most moisture loss in early stages of production is from evaporation from the soil. As the crop matures and more of the ground is shaded by the leaves of the crop, most moisture loss is from transpiration of the plants. Extension specialists in major agricultural states have been educating producers about the benefits of understanding evapotranspiration rates and using that understanding to achieve Efficient Irrigation.

Using Crop Water-use Calculators

More sophisticated evapotranspiration models are incorporated into crop water-use calculators. These tools are primarily developed by extension offices. The calculators indicate when a crop needs water and how much is needed based on the growth stages of the crop. Water application estimates used in the calculators may be based on a proxy crop for that region. Furthermore, crop water use is impacted by several factors, including crop species, soil type, available soil

⁶² <http://hightunnels.cfans.umn.edu/files/2012/11/10-Irrigation.pdf>

⁶³ *Ibid*

⁶⁴ <http://www.merriam-webster.com/dictionary/evapotranspiration>

moisture, prevailing weather conditions, and growth stage of the crop.⁶⁵ Nonetheless, if properly constructed, crop water-use calculators can support Efficient Irrigation.

Using Irrigation Charts

Irrigation charts provide an alternative view of the information in evapotranspiration schedules or the output from crop water-use calculators. If generic regional charts are used, the producer sacrifices accuracy for simplicity. Online or stand-alone charting applications developed by universities have included inputs as diverse as crop species, soil type, available soil moisture, weather, solar radiance, degree days, and number of rainy days per month. Properly constructed irrigation charts provide an alternate view of the information provided by crop water-use calculators.

Using Evapotranspiration Monitors

The primary factors affecting evapotranspiration rates are weather conditions (wind speed, air temperature, relative humidity, and sun light), plant type, soil conditions (chemistry and salinity), and geographic location.⁶⁶ “An [evapotranspiration] station consists of weather sensors, a data logger, a solar panel to provide electric power and radio telemetry. The radio telemetry communicates the weather data in real time back to a computer where a program calculates the reference evapotranspiration. The typical sensors included on an [evapotranspiration] station are an anemometer for wind speed and direction, a relative humidity sensor, air temperature sensor, pyrometer for solar radiation measurements, a barometer, and rain gauge.”⁶⁷ By using evapotranspiration monitors, producers are able to schedule their irrigation applications more efficiently. Many extension specialists have been encouraging the use of evapotranspiration monitors in conjunction with soil moisture monitors to help producers develop sophisticated, customized irrigation schedules.

Use of Water Flow Meter

“Measuring irrigation flow helps producers better manage and schedule irrigation. Measuring flow also is a tool for estimating irrigation water use.”⁶⁸ In some states (e.g., Kansas), metering water is required for all non-exempt diversions.⁶⁹ In other states, water usage is not metered and not monitored. Producers who choose to install a meter are adding data to the processes they are using for making irrigation management decisions. In many cases, meters are added to monitor energy costs associated with irrigation. However, an added benefit is that the data may support the use of less irrigation water per acre.

Mulching

Mulching is used by vegetable growers to control soil moisture; provide weed control; reduce fertilizer leaching, soil rot, soil compaction, and root pruning; and improving plant growth generally. Mulching materials can be either organic or inorganic. Using plastic mulch to warm soils early in the growing season can accelerate the harvest of those crops by up to two weeks.

⁶⁵ *Ibid*

⁶⁶ <http://www.stevenswater.com/articles/etbasics.aspx>

⁶⁷ *Ibid*

⁶⁸ <http://www.lsuagcenter.com/NR/rdonlyres/780D6F0A-61DE-4D45-8B8F-4926E093F3F6/53894/IrrigationFlowMeasurementpub3082.pdf>

⁶⁹ <http://agriculture.ks.gov/divisions-programs/dwr/water-appropriation/water-flowmeters>

Shorter growing periods may require less water. Mulching materials also offer opportunity for regulating soil moisture by providing a ready environment for draining excessive precipitation when needed and limiting opportunity for moisture loss through soil evaporation during times of low precipitation. This latter benefit, coupled with subsurface irrigation or targeted drip irrigation, allows the producer to use dramatically less irrigation water on the same acreage and maintain or exceed historical yields. Some mulches help to cool soils during the summer. Less water will evaporate from cooler soils.⁷⁰

Using Soil Amendments that Increase the Soil's Water Holding Capacity

There are three main factors which influence the ability of a plant to extract moisture from the soil. These are infiltration, water holding capacity, and the plant root system. Infiltration, the movement of the water into the soil, affects the amount of run-off. This in turn affects the ability of the soil to capture moisture from precipitation and/or irrigation. Water holding capacity refers to the ability of soil to retain moisture. The plant root system impacts the efficiency with which plants retrieve the stored moisture provided by the soil.⁷¹ The number of branch roots, the depth of the roots, the presence of root hairs, and the presence of mycorrhizal fungi all influence the efficiency of a root system.

Soil amendments are materials added to improve the physical or biological properties of a soil. Unlike mulches which are used primarily on the surface of the soil, soil amendments are mixed into the soil. Amendments are generally organized into organic or inorganic categories. Organic amendments are materials that were once alive or living material like inocula for mycorrhizae or nitrogen fixing symbioses. Organic amendments increase the organic matter in soil which, over time, improves the soils' water infiltration characteristics and water holding capacity.⁷² Both these soil characteristics are beneficial to a producer trying to maximize available irrigation water. Inorganic amendments are generally mined (e.g., vermiculite made from mica). Producers generally consult an extension specialist when choosing the appropriate amendment for their region and soil type. The Contractor documented incorporation of soil amendments as an Efficient Irrigation technique through input primarily by state extension specialists.

Leveling Cropland

According to the USDA Natural Resources Conservation Service, irrigated land leveling is the practice of "reshaping the surface of irrigated land to planned grades."⁷³ In practice, this is the systematic relocation of soil from high spots in a field to low spots in an effort to obtain a uniformly graded surface area. The practice assists the producer to apply irrigation water to the planted crop more efficiently and uniformly while limiting soil erosion and also limiting damage due to waterlogging to the soil and crops. The most sophisticated leveling systems use machinery guided by a global positioning system (GPS) and laser transit/levels to ensure uniformity of the leveled field. Large scale land leveling generally involves specialists including civil engineers. In the state of Washington, producers reported that the top soil was so thin that

⁷⁰ <http://pods.dasnr.okstate.edu/docushare/dsweb/Get/Document-1099/F-6034%20web.pdf>

⁷¹ <http://www.fao.org/docrep/009/a0072e/a0072e07.htm#bm07.2>

⁷² <http://www.ext.colostate.edu/pubs/garden/07235.html>

⁷³ http://www.nrcs.usda.gov/Internet/FSE_DOCUMENTS/nrcs143_026413.pdf

efforts to achieve Efficient Irrigation by leveling could destroy the soil structure and render the agricultural land useless for decades.

Terracing

A terrace is “a flat area created on the side of a hill and used especially for growing crops.”⁷⁴ Terracing then is the practice of reshaping the surface of the land to accommodate agriculture, particularly steeply sloped land. The primary benefits associated with terracing are: adding land suitable for cultivation; reducing soil erosion; protecting water quality by capturing run-off; and improving soil quality and productivity.⁷⁵ Terracing enables a producer to irrigate land in ways previously impractical because the land was too steep to efficiently retain the applied water. Some producers are terracing land they previously used for dry-land forage production and repurposing the land for row crop production. In some cases, producers are terracing land so they can switch from one form of irrigation to another, more efficient form. Correctly terraced fields may produce higher yields with less irrigation water. Terraces may allow greater infiltration of natural precipitation, thereby reducing the demand for artificially applied water. Finally, the soil structure of a terraced field may also improve, so more water is retained.

High Tunnel Production

“A high tunnel is a low-cost version of a standard greenhouse... The definition of a high tunnel is a freestanding or gutter-connected covered structure, without heating or electrical power, using passive ventilation for air exchange and cooling, and an irrigation system for crop production.”⁷⁶ High tunnel farming is used primarily on vegetable and nursery crops. Producers are able to extend their growing season through the use of these structures by being able to plant earlier and harvest later. The high tunnel creates a micro-climate wherein the producer controls virtually all the inputs for the crop. The producer has some control over the plants’ exposure to direct sunlight, access of pests to the crop, relative humidity within the structure, and evapotranspiration rates throughout the growing season. Producers adopting this technique are able to apply irrigation water when and where it is needed within the controlled environment. They are better able to monitor the efficacy of the water application. Furthermore, producers have reported building these structures with a water retention and collection system. This allows the producer to capture runoff from irrigation and condensation from evapotranspiration. This water can then be reused for irrigation. High tunnels are not conducive to traditional row crop production, but have been used for production of high value specialty crops.

Targeted Crop Selection Based on Soil Mapping and Soil Type

Producers understand that different crops grow better in different soil types. Furthermore, producers understand that many fields contain different soil types. Several state extension services offer soil mapping services for producers. Some producers have begun selectively planting crops based on the soil type most suited to that crop. This practice benefits the producer by potentially increasing the yield of the crop best suited to that soil type while decreasing the amount of water applied by targeting the irrigation for that particular crop/soil combination.

⁷⁴ <http://www.merriam-webster.com/dictionary/terrace>

⁷⁵ <http://www.mda.state.mn.us/protecting/conservation/practices/terrace.aspx>

⁷⁶ <http://msucare.com/crops/hightunnels/>

Using Varieties Requiring Less Water for Evapotranspiration

Seed companies are developing and producers are planting varieties of crops that fare better during times of reduced natural precipitation. This has been particularly important to dry land farmers. However, with recent legislative attention focused on availability of water for municipalities, producers who have traditionally irrigated crops have been buying more of these drought resistant varieties. According to Kansas State University agronomist Kraig Roozeboom, the new drought resistant varieties of corn tend to have bigger roots which absorb more water and smaller tassels that save the plant's energy and water.⁷⁷ Agricultural companies such as Monsanto, DuPont Pioneer, and Syngenta have started releasing varieties with claims of higher yields under drought conditions. These companies have been conducting research to develop and/or select drought-resistant varieties through targeted selection and through genome manipulation. As producers who irrigate lose access to water for irrigation, these drought-resistant varieties offer the possibility of maintaining yields under Efficient Irrigation. Many drought-resistant varieties are being marketed for corn, wheat, and soybeans.

Reusing Runoff as an Irrigation Water Supply

The practice of building reservoirs or holding ponds to collect run-off for later use in irrigation goes back before recorded history. In the United States, using captured run-off as an irrigation water supply is overseen by the Environmental Protection Agency (EPA) at the federal level and by various state agencies (Departments of Agriculture and Water Quality Departments). For example, in Colorado, this practice is strictly monitored by the state and prohibited without appropriate licensing and state approval. Producers in other states can collect spring runoff water for irrigation without constraint or regulation except under the EPA guidelines. By itself, collecting run-off may reduce the amount of ground or surface water that is required for irrigation. However, it may only result in Efficient Irrigation if the water would otherwise have been lost to the crops.

VII.B. Techniques that May Result in Efficient Irrigation

The Contractor identified several techniques which result in Efficient Irrigation some of the time. Unlike the techniques described previously, more careful underwriting will be required when an insured proposes these techniques as an Efficient Irrigation strategy. Local good practices and input from extension agents or other disinterested third-party experts may be required before the technique is accepted as meeting the requirements for Efficient Irrigation.

Planting into a Cover Crop

The literature regarding water requirements and cover crops is diverse and full of conflicting results. Planting into a cover crop is used primarily for soil conservation. The benefits of a cover crop can include: "reduced soil erosion; improved soil quality; reduced weed pressure; [and] reduced insect, nematode and other pest problems."⁷⁸ Cover crops can reduce evaporation, but increase transpiration. Cover crops can also increase the amount of soil organic material.

⁷⁷ Kraig Roozeboom, 2012, Midwest Drought Allows Farmers to Test Drought-resistant Crops, <http://www.realscience.us/2012/08/16/midwest-drought-allows-farmers-to-test-drought-resistant-crops/>, accessed February, 2014.

⁷⁸ http://www.covercrops.msu.edu/pdf_files/covercrop.pdf

One pound of soil organic matter can absorb 18 – 20 pounds of water.⁷⁹ Producers who have the soil type to take advantage of this additional available water gain the benefit of reducing the amount of irrigation water they need to apply. Consequently, in some regions, for some crops, planting into a cover crop is also a logical water conservation practice. In other regions, and for other crops, a cover crop has been shown to reduce the available water for the cash crop. A study conducted in Illinois using perennial ryegrass, red clover, white clover, and canola as cover crops resulted in reduced yields of okra and peppers. The authors of the study attributed this reduction in yield to the moisture competition the living mulch introduced. However, the authors opined that the use of targeted drip irrigation for the cash crop might reverse the outcome.⁸⁰ RMA currently restricts planting into cover crops in many areas and for many crops. This technique should only be allowed to support Efficient Irrigation when sufficient local experience is available to support an appropriate decision. The interaction of existing policy constraints on cover crops and the desire to support Efficient Irrigation creates confusion for producers⁸¹ as well as a research question beyond the scope of this effort.

Changing Cropping Sequence in the Crop Rotation

Crop rotation is “the practice of growing different crops in succession on the same land chiefly to preserve the productive capacity of the soil.”⁸² As producers plan crop rotation schedules, they consider fertility, soil structure, insects, disease, weeds, and pesticide requirements.⁸³ Producers also consider irrigation requirements. For example, if the historical rotation pattern was corn-corn-soybeans-corn-soybeans, a change to corn-soybeans-soybeans-corn-soybeans will reduce the water requirements overall. This approach is especially useful to producers in states such as Kansas where some local water districts are allocating water on a multi-year basis. They are also useful in areas where irrigators have the ability to “bank” their water (e.g., northern Texas). While this technique improves the overall efficiency of the producer’s irrigation, it only supports Efficient Irrigation if the new rotational practice changes the soil characteristics sufficiently to require less water in every year of the rotation. The impact on profitability of the farming operation also is a factor since corn would be grown only two of every five years under the alternative rotation.

VII.C. Techniques that Reduce the Requirements for Irrigation Water on an Operation without Supporting Limited Irrigation

The Contractor identified several techniques which reduce the irrigation requirements of an operation or decrease the peak irrigation requirements of an operation. These do not reduce the amount of water required to maintain the crop yield and are consequently not Efficient Irrigation techniques under the definition proposed by RMA for the crop insurance program.

Targeted Irrigation of High Revenue Crops/Reduce Number of Irrigated Acres

Irrigation decisions, like other production related decisions, are rooted in economics. Upon receiving notice that their water allocation has been reduced, producers decide how to use that

⁷⁹ http://ohioline.osu.edu/anr-fact/pdf/Using_Cover_crops.pdf

⁸⁰ <http://www.entomology.wisc.edu/mbcn/misc506.html>

⁸¹ http://www.agriculture.com/crops/cover-crop-complications_135-ar22779

⁸² <http://www.merriam-webster.com/dictionary/crop%20rotation>

⁸³ <http://www.agannex.com/production/crop-rotation-considerations>

water most economically. In many cases, a producer will use the water on the crop that is expected to bring the most net revenue at harvest. If the notice comes after planting but before the acreage reporting date for insurance, the producer may only have the option of reducing the number of acres irrigated. The producer's options for use of irrigation water become more limited the later the notice of a reduction in available water is delivered. Several extension specialists indicated producers tend to combine strategies to reduce the number of irrigated acres and plant those irrigated acres to a higher revenue producing crop. Even in combination, these techniques do not result in Efficient Irrigation as defined for the insurance.

Changing Crop Species in Crop Rotation

The producer may add or remove a crop from the rotation in an effort to lower the overall use of irrigation water over time. For example: if a producer who typically did a corn-corn-soybeans-corn-soybeans rotation under historical irrigation water levels may consider adding grain sorghum, alfalfa, or pearl millet to the rotation to conserve water. Once again, this approach is of special interest to producers in states where irrigation water can be "banked" or is being allocated on a multi-year basis and where there is a market for the alternative crop. In these areas, a producer may change the crop species in their cropping sequence by planting a drought resistant crop. The irrigation water saved that year can then be used when they are producing a less drought resistant crop on another portion of their land. However, this approach does not result in Efficient Irrigation as defined for the insurance.

Staging Crop Maturity

A producer initially may plant one half of a field with a crop and later plant the second half of the field to the same crop. The two halves of the field then likely require different amounts of water at different times. A pivot can be set so the two sides are irrigated at appropriate rates to address water requirements based on maturity of the plants in each portion of the field. While this can be used to limit peak irrigation volume requirements, it does not reduce the overall irrigation water requirements. Consequently, this approach does not result in Efficient Irrigation as defined for crop insurance.

Split Field Planting

A producer may plant one half of a field with one crop and the second half of the field with a different crop. If the crops are chosen appropriately, the two halves of the field will require different amounts of water at different times. A pivot can be set so the two sides are irrigated at appropriate rates to address the crops' needs. While this may limit peak irrigation volumes, it does not reduce the overall irrigation water requirements for each crop. Consequently, this approach does not result in Efficient Irrigation as defined for the insurance.

SECTION VIII. AVAILABLE IRRIGATION WATER USE RECORDS

This section of the report deals with the requirement in the Solicitation that, “The Contractor shall investigate the availability and review of irrigation water use records, as well as information available for water restrictions.”

VIII.A. Water Use Records

Federal management of water resources is primarily assigned to the Environmental Protection Agency. Agency rules and regulations are controlled by both law and Executive Order. The relevant laws include the Federal Water Pollution Control Act as amended by the Clean Water Act of 1977, the Safe Drinking Water Act, and the Resource Conservation and Recovery Act. Numerous Executive orders have influenced the actions of the EPA. Some curbing of agriculture water use has resulted from cases brought under the Endangered Species Act and other federal conservation and environmental programs. However, neither the federal acts themselves nor the regulations provide sources of useful records for evaluating crop production under an Irrigated Practice or Efficient Irrigation.

Water extraction from ground and surface water is controlled primarily at the state level. The principles, laws and regulations controlling water rights vary enormously. Furthermore, recent state-level legislative action has upset some long-standing principles, as urban development (i.e., drinking water requirements) and industrial uses have been given higher priority for water rights than agricultural production. Links to the voluminous state water laws and regulations are documented in Appendix J.

The Contractor identified two forms that assist in understanding agricultural water use at the state level. First are applications for water extraction and/or use. Second are annual reports of use submitted to state agencies or water districts. Twenty-eight states require a producer to indicate the number of acres to be irrigated when an initial application for surface water diversion or well drilling is made (Table 23). Hawaii, Montana, Oklahoma, and Oregon require separate applications for surface and ground water extractions. According to producer testimony, California requires applications only for surface water.

Louisiana,⁸⁴ Maryland, West Virginia,⁸⁵ and Wisconsin⁸⁶ exempt agricultural users from any application requirements for extraction of surface or ground water. In Kentucky, row crop producers are exempt from application requirements, but specialty crop and nursery crop producers are not. In Rhode Island, any user anticipating extraction of less than 153 acre feet of water is exempt from application requirements. Based on Census and FRIS data, only about one quarter of Rhode Island farms irrigate. Furthermore, the average Rhode Island farm size is 56 acres and the typical irrigation application is less than 1 acre-foot per acre. Consequently, application records for irrigation water extraction are incomplete for Rhode Island. Wyoming water use permits require limited information about the purpose of the extraction and the location of the water source. In spite of numerous attempts to discuss water use applications with regulators in Illinois, the Contractor was unable to determine the content of applications for that

The other state-level documentation useful for understanding water used for irrigation are annual (or in some cases monthly) water use reports. The Contractor documented reporting requirements in 47 states, but was unable to locate a source for report documents from Delaware. Arizona, Florida, Kansas, and Nebraska require reports to water districts rather than to a state authority. Kentucky, Louisiana, and Wyoming do not require reporting. Utah requires reports “as requested.” Only 15 states require information in the reports on the number of acres irrigated (Table 24). Information about the crop irrigated and yield are not components of these reports. Only parts of Nebraska and Texas require reports from meters on center pivot irrigation systems. Even in those two states, the well-level reporting is not required in every water district.

Additional information documented on water use applications, but less relevant to the assessment of the Irrigated practice and Efficient Irrigation is included in Appendix K, Table K2. The Contractor is supplying RMA with a disc containing images of the reporting forms that were used in developing Table 24 and Appendix K.

VIII.B. Water Use Restrictions

State regulatory agencies have the authority to limit access to water. Generally water extraction is loosely monitored. However, as water becomes a limited resource, mechanisms to enforce restrictions are becoming more sophisticated. The Nebraska Natural Resources Districts have the authority and ability to shut down active pivot irrigation systems remotely. In Colorado, state water resources personnel can operate the opening and closing of irrigation canal gates from computers in their offices. In Idaho, irrigation companies remotely operate gates for canals linked to surface water sources, while groundwater sources in Idaho are essentially unmonitored. In Georgia, the state water resources personnel have the authority to turn irrigation pumps off. However, according to producer testimony, they do not have the ability to shut down these pumps remotely.

Testimony from extension officers in most states suggested that trends toward greater enforcement actions and toward more technological control of access are likely to continue. Producers expressed the greatest concerns about these trends in states under drought conditions. Extension experts were more generally concerned that producers will face more limited supplies of irrigation water in most parts of the United States. Even where water will not be limiting for producers with the most senior water rights, junior right holders are likely to be faced with restrictions. This disparity between restrictions placed on junior and senior water rights holders will need to be addressed in the underwriting for Efficient and Limited Irrigation scenarios, since producers in any one area may have substantially different outcomes because of the access to irrigation water.

SECTION IX. RISK ANALYSES

This section of the report deals with the solicitation requirement that:

The Contractor shall define the economic risks; collect data to identify and quantify any risks that the producers face when applying less than their historical average of irrigation water; identify any data that is available regarding irrigation application; identify any areas that data availability is considered a problem for the development of this program; identify any unavailable data, but necessary, to quantify these risks; estimate the frequency and severity of the risks that currently are uninsured, classify each of the perils as insurable or uninsurable and justify the classification of the risk. The Contractor shall also identify man made or created perils that can restrict water availability and describe when and how these perils can occur.⁸⁷

The economic risks associated with Efficient Irrigation and Limited Irrigation can be defined by two fundamental questions:

- Has the management of an Irrigated Practice using Efficient Irrigation introduced any risks that are not already identified and appropriately covered in the FCIC insurance offers?
- If a Limited Irrigation insurance offer is made, are any risks that are not already identified and appropriately covered in the FCIC insurance offers introduced?

If the answer to either of those questions is “yes,” then additional risk analysis is required.

Testimony from producers and extension officers indicates that regardless of the incorporation of the “Efficient Irrigation” term in the crop insurance lexicon, producers have been managing their Irrigated Practices using Efficient Irrigation for years, if not decades. The underlying yield-based insurance constructs identify the risks, classify them as insurable or non-insurable, and capture the frequency of these risks appropriately in the rating. The Contractor identified no data, quantitative or testimonial, which suggested Efficient Irrigation introduces new risks. The actual yields of producers managing their Irrigated Practices with Efficient Irrigation have been used by RMA in the updating of insurance rates. To the extent that the rates already address producer differences in risk based on rate yields, any added or decreased risk associated with Efficient Irrigation is addressed by the existing rating functions. If the existing rating functions do not address these differences in producer risk, there are no data to support the introduction of a new rating approach to address Efficient Irrigation.

It is not as easy to be unequivocal about the impact of Limited Irrigation on risk. There is literature addressing the increased susceptibility of plants to disease and insects if they are water stressed.⁸⁸ While these effects are not well documented for every species for which an offer of insurance is made for production under the Insured Practice, there is a recurring theme that stress

⁸⁷ U.S. DOI, 2013, Solicitation D14PD00062 under IDIQ contract D13PC00032, page 9.

⁸⁸ See, for example, Dutky, E.M., 2006, How Drought Stress Predisposes Trees and Shrubs to Diseases <http://www.bgohio.org/departments/public-works-department/arborist/files/droughtstr.pdf>, accessed March, 2014; Longstroth, M., 2012, Drought Stress Symptoms in Blueberries, <http://blueberries.msu.edu/uploads/files/Blueberry%20Drought%20Symptoms.pdf>, accessed April, 2014; Pearson, K., 2005, How and When Does Water Stress Impact Plant Growth and Development?, http://waterquality.montana.edu/docs/irrigation/a9_bauder.shtml, accessed April, 2014.

increases the susceptibility to losses from other causes. This then introduces a corollary to the fundamental question about Limited Irrigation: If a Limited Irrigation insurance offer is made, and the mechanism to address the Limited Irrigation is an adjustment of actual yield and rate yields, do the rates and the guarantee reflecting the new parameters appropriately address the risks introduced by the decrease in irrigation water applied?

Plants exhibit water stress when the water supply to the roots becomes limiting or when the rate of transpirational water loss exceeds the rate at which water may be taken up by the plant.⁸⁹ With the exception of plants grown hydroponically, most crop plants undergo periods of mild water stress, alternating with periods when water is not the factor limiting their growth. Plants have evolved to tolerate fluctuations in available water and to recover normal function after water stress. These processes contribute to the maintenance of high yield under cyclic dry and wet periods (e.g., immediately following irrigation and just prior to irrigation).⁹⁰ In fact, exposure to excess moisture also creates suboptimal conditions for plant growth. Consequently, the yield response to different levels of water stress is an essential issue in the analysis of risks associated with Limited Irrigation.

The Contractor will not attempt to duplicate the work commissioned by the RMA from the University of Nebraska regarding yields from plants whose productivity is limited by the available water supply.⁹¹ The essential conclusion from this work is that, over some reasonable range of amounts of water applied for irrigation, when water is limiting, the yield increases linearly with the increase in available water. While this has not been documented for every crop, the partitioning of water between that required for vegetative growth and that required for reproductive growth makes it generally reasonable to accept the linearity of the relationship.

The problem then becomes defining the starting and ending point for a “reasonable range” of amounts of water applied for irrigation. In areas where non-irrigated production is appropriate, it is logical to assume the endpoint of the beneficial effect of irrigation, and consequently of the linear yield response is when no irrigation water is applied. The yield at that point will be the unit’s non-irrigated yield if one is documented. Otherwise it could be the non-irrigated reference yield, or better yet, the non-irrigated reference yield multiplied by a factor that reflects the producer’s experience with the crop compared to the experiences of all the producers in the county (i.e., the Approved Yield / the county reference yield).

Establishing a starting point for the reduction in yield resulting from a reduction in applied irrigation water is more challenging. The simplest assumption is to use the insured’s rate yield and the simple average of the amount of water applied during the period to establish the parameters of the starting point. This implicitly assumes there are no additional Efficient Irrigation management practices that can be implemented. If the producer makes no other changes than applying less irrigation water, this is in fact an appropriate starting point. However, if the insured implements additional Efficient Irrigation management practices at the same time

⁸⁹ Blum, A., 1988, Plant Breeding for Stress Environments. CRC Press, Baco Raton, Florida; Rahman, I.M.M., and H. Hasegawa, 2012, Water Stress, In Tech, Rijeka, Croatia.

⁹⁰ Blum, A., 1996, Crop responses to drought and the interpretation of adaptation, Plant Growth Regulation.20:135-148.

⁹¹ Procedures for Adjusting APH when Implementing a Deficit Irrigation Insurance Practice.

Limited Irrigation is implemented, some reduction in the amount of water required needs to be incorporated into the Limited Irrigation Approved Yield calculations.

The Contractor has not identified any data that can be used to address simultaneous implementation of Efficient Irrigation techniques and Limited Irrigation. In the absence of a data-based establishment of the required amount of water to trigger a Limited Irrigation reduction in Approved Yield, use of any value other than a producer's estimate of the historic amount of water applied for irrigation will have no objective basis. Nonetheless, if during the establishment of that yield Efficient Irrigation was implemented, using the full irrigation history for the Approved Yield is unfair to the insured. Consequently, the Contractor recommends using only that portion of the irrigation history that has followed the implementation of Efficient Irrigation techniques that have already been implemented.

It is less clear how to address the simultaneous implementation of Efficient Irrigation techniques and Limited Irrigation. If RMA chooses to implement a Limited Irrigation alternative to the existing approaches available to an insured, the Contractor proposes RMA uses the standard deviation of the natural precipitation as a basis to adjust for the beneficial effects of the Efficient Irrigation technique(s) affected at the time Limited Irrigation is also implemented. In areas where little natural precipitation falls, using this value would "start" the yield reduction at a smaller relative change to the amount of water applied, whereas in regions with substantial natural precipitation, which varies substantially, the yield reduction imposed on the producer would reflect both the larger chance that an Approved Yield would be achieved and the less critical role the irrigation water plays in many years.

The underlying yield-based insurance identifies the risks, classifies them as insurable or not insurable, and captures the frequency and severity of these risks in the rating for crops produced under an Irrigated Practice. The Contractor identified no data to suggest Efficient Irrigation introduces risks, including the risks incumbent in water stress, that are not already addressed in the rating for crops grown under an Irrigated Practice. The actual yields of producers applying different amounts of irrigation water have been used by RMA in the updating of insurance rates for crops grown under the Irrigated Practices and insured under an Irrigated Practice code. To the extent that the rates already address producer differences in risk based on rate yields, any added risk associated with Efficient Irrigation should be addressed by the existing rating functions. If the existing rating functions do not address these differences in producer risk, there are no data to support the introduction of a new rating approach to address Limited Irrigation.

In this data limited environment, there are three approaches that can be taken regarding the rating. The first is to assume the rating for crops grown under the Irrigated Practice captures sufficient information to address any production under Limited Irrigation. In cases where the irrigation applied is reduced substantially, this may not be the case. The academic studies often use irrigation rates down to one quarter of the full irrigation. A producer may have already been irrigating at much less than full irrigation. Furthermore, these studies are comparing production within a year and not between years. Finally, these studies have focused primarily on major commodity crops, while scores of plants under hundreds of Irrigated Practice management scenarios are insured. A decision to accept the current rates for an irrigated practice code seems excessive. The Contractor cannot recommend this course for all crops in all states nationwide.

At the least, crops grown in counties where the non-irrigated practice is not allowed should be excluded from having this option. In these counties, too large a reduction in the amount of irrigation water applied will result in an attempt at production under water stress conditions that have never been attempted in the county before.

The second approach is to assume the rating for crops grown under the Irrigated Practice captures sufficient information to address production under Limited Irrigation for a particular level of reduction of irrigation water applied. For example, it is reasonable to accept that a reduction of 25 percent will be captured by the existing rating data for the top 50 percent of producers by the amount of irrigation water they apply. From an actuarial perspective, looking only at the predicted performance of the insurance, an arbitrary limit such as the 25 percent might be allowed so sufficient insurance experience can be gathered to fine tune the rate structure. The most likely outcome of this approach will be a slight rise in rates over time so the irrigators applying the most water, who are most likely to achieve the best yields, have smaller increases in their premiums than those who implement the largest reduction. This might work where a crop is represented by a large population of producers, each of whom is implementing Limited Irrigation with a range of changes in the amount of irrigation water applied. It is less likely to be effective in counties where there is a more limited number of producers or counties where water restrictions cause the whole population to reduce their irrigation by a comparable amount. In these cases, the rating adjustment process may be poorly equipped to deal with the distribution of the data. Furthermore, this will not support an approach with limited requirements for updating.

The final is to assume the rating for crops grown under the Irrigated Practice does not capture sufficient information to address production under Limited Irrigation. In cases where the irrigation applied is reduced below Efficient Irrigation levels, this is not an unreasonable hypothesis. Since the academic studies use full irrigation as their starting point and producers do not necessarily (and most likely do not) irrigate their crops fully, it is challenging to imagine any mechanism that does not place enormous faith in the current rating and rate updating paradigms that would bridge the gap between the data in the academic studies and actual production of scores of crops grown under an Irrigated Practice code in any county where that insurance is allowed. This would require accepting the linear reduction in production under Limited Irrigation for all crops under all Irrigated Practice codes. While it is defensible to say that is the best available approach, it is less defensible to say it is the course to follow. The Contractor finds it less easy to accept the universal applicability of the Limited Irrigation construct than to accept the universality of the Efficient Irrigation construct.

SECTION X. OUTLINE OF PROPOSED MODIFICATIONS

This section of the report deals with the requirement in the Solicitation that states:

The report shall identify what issues/obstacles need consideration when modifying the current policies and procedures. RMA [seeks] to understand how the modifications for reduced irrigation will work best for insured producers and for RMA.

The reader should note, per the Solicitation, this outline does not delineate specific modifications to the underwriting procedures, rates, loss adjustment procedures, data reporting requirements, CIH, LAM, Appendix III (Manual 13), insurance policies, or loss adjustment standards handbooks. If RMA exercises its options under the Contract, those details will be addressed in the optional Draft Program Modifications Package and the optional Final Program Modifications Package.

Instead, as directed by the Solicitation, this section of the report focuses on:

- Issues and obstacles to addressing both Efficient Irrigation and Limited Irrigation in the FCIC yield-based crop insurance programs;
- Issues and obstacles specific to addressing Efficient Irrigation;
- How addressing Efficient Irrigation will work best for insured producers;
- How addressing Efficient Irrigation will work best for RMA;
- Issues and obstacles specific to addressing Limited Irrigation;
- How addressing Limited Irrigation will work best for insured producers; and
- How addressing Limited Irrigation will work best for RMA.

In order for the Contractor to address issues, obstacles and benefits of implementing defined Efficient Irrigation and Limited Irrigation as part of the yield-based FCIC insurance programs, certain assumptions must be made about the changes that will be implemented. Based on language in the Solicitation, the Contractor assumes implementation of “option 3a from Watts, Task Order 1, Deliverable 2... nationwide for all crops”⁹². Option 3a calls for “maintain[ing] existing irrigation policy and procedures but change[ing] the definition for Irrigated Practice.”⁹³ The changes to the definition of Irrigated Practice incorporate the concept of Efficient Irrigation into currently allowed crop management under an Irrigated Practice. Efficient Irrigation is: “a method of producing a crop by which less water is artificially applied during the growing season by appropriate systems and at the proper times than the quantity of water that was used to establish the irrigated approved APH yield, that will likely not result in lower actual yields than the average yield for the irrigated practice for that location.”⁹⁴

The Contractor believes incorporating the definition of Efficient Irrigation into acceptable management activities under an Irrigated Practice requires objective standards for “the quantity of water that was used to establish the irrigated approved APH yield” (i.e., the historical quantity of irrigation water applied) and “less water... that will likely not result in lower actual yields

⁹² U.S. DOI, 2013, Solicitation D14PD00062 under IDIQ contract D13PC00032, p. 3.

⁹³ Watts and Associates, Inc., 2013, Task Order 1: Limited Irrigation Analysis & Evaluation, Deliverable 2: Limited Irrigation Feasibility Report, p. 71, www.rma.usda.gov/pubs/2013/insuringirrigationfeasibilityreport508.pdf, accessed May, 2014.

⁹⁴ U.S. DOI, 2013, Solicitation D14PD00062 under IDIQ contract D13PC00032, p. 3.

than the average yield for the irrigated practice for that location” (i.e., the minimum amount of water to be applied under Efficient Irrigation).

The only data to establish the historical quantity of irrigation water are those that might be kept by the producer.⁹⁵ The amount of water actually applied to an acre of land insured under an Irrigated Practice code differs from year to year, depending on a large number of factors. The Contractor proposes a lower limit on the amount of water available for and intended to be applied for the upcoming crop year be established. This limit would be a percentage of the historical water use by the producer. Its purpose is to define a point at which additional underwriting considerations begin. The Contractor believes, based on the literature, some minimum reduction in water use will not significantly affect the yield relative to the Approved Yield. The lower limit would be established by modeling the yield impact for selected crops (e.g., corn, cotton, and tomatoes) at various reductions in applied water. Such a model could incorporate natural precipitation values, “full” evapotranspiration values where available, and actual crop yield experiences to show the potential change in all areas where irrigation is common for these crops.

The Contractor proposes, subject to analysis of impacts described below, any negative deviation in available irrigation water for an insured acre managed under an Irrigated Practice that is greater than a defined percent of the simple average of water applied per acre during the development of the Approved Yield (based on the insured’s records) should require specific underwriting procedures. This defined percent would be established during the second option of the Task Order should the Government choose to implement that option. It is important to understand the Contractor is simply defining a point at which added underwriting considerations begin. However, given the general improvements in yields seen under lower irrigation levels in the FRIS data, selecting some value other than zero seems logical. Furthermore this approach would eliminate some paperwork without imposing substantial increased risk on the insurer. If the implementation option is exercised, the Contractor will model the extent of the risk for the insurer for certain sample crops (e.g., corn, cotton, and tomatoes) to show the deductible makes the risk to the insurer *de minimus*. Such a model may incorporate natural precipitation values, “full” evapotranspiration values where available, and actual crop yield experiences to show that for all areas where these crops are heavily irrigated, a limited change in irrigation water applied would not reduce the yield meaningfully unless some other cause of loss was involved.

A second underwriting step for Efficient Irrigation is intended to limit the paperwork burden on the insured and the insurer. This will focus on the irrigation management practices the insured used historically to increase the efficiency of the irrigation or decrease the amount of water required for irrigation. If techniques to increase the efficiency of irrigation have been implemented, and if the average actual yields for the period after that implementation are equal to or greater than the Approved Yield, then the historical quantity of irrigation water can be based on the average of the period after the implementation rather than the average during the entire period used to establish the Approved Yield. Again this should not add substantial risk on

⁹⁵ The Contractor notes that the producer is required to maintain records of the insured crop for three years after the end of the crop year. Hence, if records of applied water are available, those records may not include the entire production history included in an APH database.

the insurer, not only because the yields after implementation were equal to the Approved Yield, but also because the deductible assigns the initial risk to the insured.

The third underwriting step for Efficient Irrigation is to consider techniques the insured will be using **for the first time** during the forthcoming crop year to increase the efficiency of irrigation. There are no precise data to quantify the gains in efficiency that can be realized by any one of the Efficient Irrigation techniques. Furthermore, it is possible that more than one Efficient Irrigation technique will be implemented in the same year, depending on the producer's management decisions. When more than one technique is implemented, the gains in efficiency might be additive, synergistic, or might together produce a smaller gain than gains realized if a single technique were employed. The potential gains differ by many factors, including crop, soil type, slope, etc. In the absence of a set of values for efficiencies realized by the improved irrigation techniques, the Contractor believes that allowing a small (e.g., 5 to 10 percent) reduction in the historical quantity of irrigation water provides the insured recognition of the improved efficiency to be realized, without creating significant risk for the insurer. If the implementation option is exercised, as stated previously, the Contractor will model the extent of the risk for the insurer of varying percent reductions for several sample crops to determine the correct value that appropriately limits the risk to the insurer.

The final underwriting step for Efficient Irrigation is to allow the producer to maintain the Approved Yield with an even larger reduction in the amount of water to be applied relative to their historical quantity of irrigation water. If the insured can provide documentation from a disinterested third party that supports obtaining the Approved Yield even with a greater reduction in the available water than the amount established under the third underwriting procedure, the insurer will maintain the Approved Yield without revision. This will allow practices that have been demonstrated locally to provide substantially greater efficiencies in irrigation to be considered a good management practice under an Irrigated Practice. Requiring documentation from an appropriate disinterested third party would limit fraud, waste, and abuse based on losses associated with reduction in irrigated water available or applied.

X.A. Issues and Obstacles to Addressing Efficient and Limited Irrigation

The definition of Irrigated Practice contains many terms. Some of these terms, such as "artificial means" and "appropriate systems" have objective meanings. Other terms, such as "appropriate time" to irrigate and "intention," are more subjective. However, the reader should note the definition of Irrigated Practice has been included in the Basic Provisions since the 1998-BR. The definition was introduced in a proposed rule dated August 12, 1997 (FR 43236) and adopted in the final rule published December 10, 1997. The Contractor is unaware of any issues regarding the suitability of the definition, in spite of the elements of subjectivity in its interpretation. That being said, the addition of Efficient Irrigation and Limited Irrigation definitions must improve the insurance available for an Irrigated Practice and not introduce any barriers to implementation of a crop insurance product identified in RMA's feasibility requirements.

Consequently, irrigation with less water than historically applied is an Irrigated Practice as long as the: "water is artificially applied during the growing season by appropriate systems and at the proper times, with the intention of providing the quantity of water needed to produce at least the yield used to establish the irrigated production guarantee or amount of insurance on the irrigated

acreage planted to the insured crop.” As long as the crop insurance procedures and regulations are followed, the insured producer has the flexibility to follow whatever practices make the greatest economic sense in his/her situation. The only requirement is that the producer must follow the practice of providing irrigation intended to be sufficient to result in a yield at least equal to the yield on which the production guarantee is based. The addition of definitions of Efficient Irrigation and Limited Irrigation provides a subjective measure of the intention (e.g., “that will likely not result in lower actual yields than the average yield for the irrigated practice for that location.”). However, the Contractor notes “likely” is a subjective term.

It will be important to refine the Efficient Irrigation and Limited Irrigation definitions to clarify the meaning of “location.” The Contractor assumes the intention in development of this definition was to refer to a unit. If that is the case, then Efficient Irrigation and Limited Irrigation can only be established when sufficient records are available to establish an “average” of actual yields. Alternatively, if the intention were to allow T-yields under an Irrigated Practice to be used (i.e., if the intention is that “location” is on the scale of a county), then establishing the amount of irrigation required to establish the T-yield is much more challenging. T-yields reflect a wide range of different irrigation management practices.

There is some logic to not allowing a new irrigator to change the management practices used to establish the Approved Yield under the Irrigated Practice too rapidly. However, the essence of individual Approved Yields is to capture sufficient producer-specific information so differences in the success of a particular producer are reflected in the insurance the producer can purchase. The flexibility offered by the definition of Irrigated Practice allows changes to the management practices used to establish the Approved Yield. The addition of the Efficient Irrigation and Limited Irrigation definitions should decrease rather than increase any ambiguity in the underlying Irrigated Practice definition. Therefore, if the implementation option is exercised, the Contractor will consider ways the definitions of Efficient Irrigation and Limited Irrigation can be refined to further decrease the possibility of misinterpretation in the definition of Irrigated Practice.

Generally producers do not irrigate to obtain full evapotranspiration. Instead, as pointed out in earlier reports, producers use irrigation management practices to optimize economic outcomes. Due to the many differences between operations, even if they are located in close proximity to one another, the producers’ perceptions of an optimum economic outcome for a particular crop are likely to be quite different. This is one reason the continuous rating functions address the producer’s actual average historical yields relative to the reference yield for the county. This allows the rates to be customized to reflect the particular outcome of the producer’s management decisions. In many cases, producers who are neighbors have obtained very different Approved Yields under the same Irrigated Practice code. Any attempt to address Efficient Irrigation and Limited Irrigation must allow management decisions to continue to be made by the insureds and take into account the outcomes of the insured’s decisions in establishing the Approved Yield.

As noted in the first deliverable of TO 1, there are inconsistencies in the language in the policies and procedural documents. In establishing Efficient Irrigation and Limited Irrigation procedures, it will be important to eliminate potential misunderstandings that might arise because terms such as “irrigated acreage” are used without definition and because terms such as “Irrigation Water

Supply” are defined in the CIH and again in the Irrigated Practices Guidelines rather than in the policy. The definition does not address aquifers, but appears to focus on surface waters. “Adequate Irrigation Facilities” is not defined in the Basic Provisions, but is defined in the Irrigated Practices Guidelines. In developing procedures to deal with Efficient Irrigation and Limited Irrigation, it will be essential to eliminate as many of these inconsistencies as possible, first by including additional definitions in the Basic Provisions and then by a careful expansion of the Irrigated Practices Guidelines (which is provided to insureds and potential insureds).

The Data Acceptance System does not currently require or accept information on amount of irrigation water applied. This is not seen by the Contractor as a barrier to addressing Efficient and Limited Irrigation constructs. The proposed modifications can use the data required by the Irrigation Practices Guidelines on water applied to the crop grown under an Irrigated Practice. Heretofore those data on the amount of water applied to a crop grown under an Irrigated Practice have been used during loss adjustment to determine if an uninsured cause of loss appraisal should be made. As described previously, the proposed modifications will use data from both the yield histories and the insured’s irrigation records in establishing break points and in establishing an Approved Yield under Limited Irrigation. This change in the timing of the use of the data is likely to create logistic problems. Producers have indicated they maintain their irrigation records for only a few years, and are required to maintain records pertaining to the insured crop for only three years after the end of the insured crop year. Therefore, both producers and insurance industry personnel will need to be educated about this change and about mechanisms to address sparse data situations.

Reports to water boards generally do not incorporate all the information needed to establish water applied under an Irrigated Practice at the unit level. These reports are not required in every region. Even where these reports are required, often only the total water use by an entity must be reported. Data to document water applications at the unit level may only be in the hands of the producer. Consequently, simple and generally applicable procedures for Efficient and Limited Irrigation will need to utilize an insured’s data. This is no different than the approach used for other inputs such as fertilizer or pest management chemicals. Therefore, while it will require development of additional underwriting guidelines, the general approach will be familiar to both the insurance industry and insureds.

When producers have more than one source of irrigation water, maintaining records for application to different crops/types/practices may be especially challenging. One producer with surface water rights and a legal, but undocumented, well had indicated that when water prices were high, water from the well could be sold, while Prevented Planting could be claimed on a crop not planted because of restrictions on the use of the surface water. Care will need to be taken to assure that implementation of Efficient and Limited Irrigation do not create moral hazards that encourage this sort of fraudulent activity.

The Contractor is aware that present policy and procedure for Irrigated Practices are the result of many years of dealing primarily with the issue of fluctuating water supplies, i.e., changes from year to year that affect availability. It is becoming evident that more permanent restrictions on water availability for individual insured producers may be the norm, at least in some areas.

Production practices that prevailed when more plentiful supplies were available may and likely will no longer be possible.

X.B. Efficient Irrigation

Many producers have already implemented changes to irrigation management practices to realize Efficient Irrigation. The producer's Approved Yield reflects the changes they have already made. Procedures to unravel the historical changes in management practices used to maintain an Irrigated Practice could be very complex. Anecdotally, a reduction of 30 percent in the amount of applied irrigation per acre in one case resulted in Efficient Irrigation (i.e., the Approved Yield was realized). Based on comments from extension educators and producers other than the one claiming a successful Efficient Irrigation with a 30 percent reduction in applied water, the Contractor believes most changes in irrigation management practices will result in smaller reductions in the amount of water required to have a reasonable expectation for Efficient Irrigation. That is the basis for the third and final underwriting suggestions proposed for Efficient Irrigation.

Recognizing and defining Efficient Irrigation will correct an information asymmetry that exists between the insured and the insurer under the existing Irrigated Practice definition and procedures. The existing insurance has accepted substantial variation in the quantity of irrigation water applied to an insured crop from year to year. Introducing Efficient Irrigation and Limited Irrigation will help to assure that good communication between the insured and insurer occurs. It will also help to assure there are no surprises on either side during loss adjustment about the amount of water that was available to be applied to a field insured under an Irrigated Practice code. However, documentation of amounts of irrigation applied has been required only in the case of a loss. Introducing the Efficient Irrigation concept will encourage documentation of improvements made to the irrigation management practices. It will assist in the insurer and the insured having the same understanding about the amount of water that is required to be available and/or applied when the insurance attaches. This will improve the performance of the crop insurance program and make it more responsive to current developments in the agricultural industry.

X.C. Limited Irrigation

The Solicitation requires the Contractor to “consider option 7 elements for yield reduction function modeling, or any other feasible yield reduction functions to adjust the irrigated approved APH yield for reduced irrigation”⁹⁶ in identifying issues and obstacles to addressing Limited Irrigation. Option 7 is using “the [RMA] suggested Limited Irrigation insurance approach, but replace the yield reduction tables with a formula based on average annual rainfall for the county and the insured’s historic and expected irrigation amounts.”⁹⁷

There are not sufficient data to support a yield reduction curve for each insured irrigated crop. The linearity of the yield reduction is documented for the few crops in limited locations where sufficient data are available to establish a yield reduction function. The linear function applies

⁹⁶ *Ibid.*, p. 5.

⁹⁷ Watts and Associates, Inc., 2013, Task Order 1: Limited Irrigation Analysis & Evaluation, Deliverable 2: Limited Irrigation Feasibility Report, p. 72, www.rma.usda.gov/pubs/2013/insuringirrigationfeasibilityreport508.pdf, accessed May, 2014.

only where water is the limiting growth factor. Nonetheless, the Contractor proposes using a linear Approved Yield reduction function when the insured chooses Limited Irrigation as the approach to address a decrease in available irrigation water supply. In other words, if unable to meet the Efficient Irrigation underwriting standards, an insured would have the choice of reducing irrigated acreage or insuring under the Limited Irrigation construct.

In areas allowing production without irrigation, the starting point for the linear reduction will be the Approved Yield and the historical quantity of irrigation water. As with Efficient Irrigation, if techniques to increase the efficiency of irrigation have been implemented and if the average actual yields for the period after that implementation are equal to or greater than the Approved Yield, then the average of those yields will be the starting point for the linear reduction function, along with the amount of water applied. If the insured has an Approved Yield for the crop and type managed under the non-irrigated practice in the area, then the end point will be zero water applied and the insured's non-irrigated yield for the crop and type. If the producer does not have a non-irrigated Approved Yield for the crop and type even though the non-irrigated practice is allowed in the area, then the end point would be zero water applied and the non-irrigated transitional yield for the crop and type. The Limited Irrigation Approved Yield would be extrapolated between these two points based on the amount of irrigation water available under the Limited Irrigation scenario relative to the historical quantity of irrigation water.

The Solicitation requires: "Any yield reduction function ... to be simple, applicable nationwide for all crops, and not reliant on updated data maintenance."⁹⁸ The Contractor's proposed function takes into account the linear patterns seen in the limited number of location-specific, crop-specific studies that do look at the effects of reducing the amount of irrigation water when the available amount of irrigation water is the limiting factor. It provides limits on the extent of the reduction that reflect both the producer's experience and differences in locations. It provides a mechanism to address all crops nationwide. Furthermore, a simple tool (Appendix L) can be constructed to return a value for the Limited Irrigation Approved Yield. Thus, while the description of the approach cannot be said to be extremely simple, the math itself is simple. Furthermore, the calculations of a Limited Irrigation Approved Yield can be established using the producer's irrigation records, the producer's APH database and a limited set of data (i.e., the non-irrigated transitional yield, the average precipitation for the county, and the standard deviation of the precipitation for the county) that can be supplied either in the Special Provisions or as a look-up table behind the "Limited Irrigation Approved Yield Calculator." The Limited Irrigation Approved Yield can be used in cases where the available or applied irrigation water is reduced for a single year. It can be used to populate a Limited Irrigation database in the case where a reduction in available or applied irrigation water is permanent. In areas that do not allow the crop and type to be managed under the non-irrigated practice, Limited Irrigation, if implemented, should not be allowed.

SECTION XI. RESEARCH FINDINGS

The most comprehensive data on production, yield, and risks for plants grown under an Irrigated Practice are the data in the RMA Type P11 (acreage, formerly Type 11), Type P15 (yield, formerly Type 15) and Type P21 (indemnity, formerly Type 21) databases. Collectively, these records document the acreage irrigated, the production and yield from that irrigated acreage and the causes of loss when a loss occurs. These data do not provide a perfect basis for implementing Efficient Irrigation and Limited Irrigation procedures for the scores of crops that are insured as irrigated. However the imperfections of the data are no greater for implementing these procedures than for implementing the FCIC crop insurance program in general.

There are three elements missing from these RMA data that are required to conclude whether a decrease in the amount of irrigation water applied will result in Efficient Irrigation or Limited Irrigation. The first of these is the amount of irrigation water applied historically. The producer's own records provide the only consistent source of information about the historical application of irrigation water. These records can be expected to be sparse and highly variable. Water authority records are not generally collected in a way that provides the information required. They can be used to support the producer's records. In the cases where the water authority records do include requisite information (e.g., in the cases where water authorities require pivot well-head meters), the meter records are part of the producer's irrigation documentation as required under the crop insurance Irrigation Practices Guidelines. However, it is much more common that water authorities monitor water extraction facilities, total farm-level extraction, or point of diversion extraction. In these cases, the only records which capture unit-level irrigation are those maintained by the insured.

The second missing element in the RMA databases is the historical precipitation in the location of the insured acreage. While some producers are beginning to maintain farm-level precipitation records, those records are generally too short to capture the historical mean precipitation and variability in the precipitation. The Contractor believes an understanding of the extent to which the water for crop evapotranspiration comes from precipitation is essential to evaluating whether a lesser application of irrigation water is likely to result in Efficient or Limited Irrigation. The variability of the precipitation provides a measure of whether the application of smaller amounts of irrigation water will increase the risk to the crop from natural causes.

The final element missing in the RMA databases is the characterization of changes in management practices that justify identifying a reduced application of irrigation water as Efficient Irrigation. The Contractor has identified 20 changes in irrigation techniques that contribute to Efficient Irrigation. Of these, those that are appropriate for a particular farm cannot be determined by research such as that documented in this report. Appropriate Efficient Irrigation techniques are influenced by numerous factors including crop, variety, soil type, weather, air quality, slope, and aspect. In making decisions about how to irrigate efficiently, the producer uses production experiences within the locale, the condition of the soil, the cost of the irrigation water, the cost of delivering the irrigation water, the specific crop being grown, and the cost of the changes to the irrigation system to determine if one or more of the Efficient Irrigation techniques should be implemented.

Still, the Contractor believes implementation of at least one of the Efficient Irrigation techniques identified in this report or of an Efficient Irrigation strategy approved by a local or regional disinterested authority is required for Efficient Irrigation. In the absence of such changes in the irrigation techniques, reducing the amount of irrigation water applied will, on average, result in a reduced yield if the amount of water has been a limiting factor for the crop production. Consequently, when a producer has advance knowledge that less irrigation water will be available either the current policies and procedures should be required, or the production should be insured, if possible, under a Limited Irrigation practice.

The Contractor has identified numerous references to irrigation in the Common Crop Insurance Basic Provisions, the crop provisions, the special provisions, the CIH, and the LAM. Some of these will require modification to address Limited Irrigation if the practice is accepted as insurable. Most of the language in RMA documents is not fundamentally affected by Efficient Irrigation, provided this term is properly defined. Changes to the Irrigated Practice Guidelines will provide a mechanism to address details concerning Efficient Irrigation without requiring changes to every document that address the concept of irrigation. However, using irrigation terminology consistently in the Common Crop Insurance Basic Provisions, the crop provisions, the CIH, and the LAM, will simplify communication about Efficient Irrigation as an appropriate management practice for crops insured under an Irrigated Practice code.

While the introduction of the Efficient Irrigation concept is likely to simplify the insurance of irrigated crops by recognizing the evolving management techniques used for irrigation, introducing Limited Irrigation will complicate insurance of irrigated crops. The Contractor believes three complications require special attention in the decision about adding Limited Irrigation as a construct in the FCIC insurance. First, and foremost, although it is possible to propose a relatively simple system for assigning a Limited Irrigation Approved Yield, the calculation of this assigned Approved Yield requires acceptance of several assumptions that could be called into question by insureds and AIPs. This introduces the potential for substantial increases in the burden on RMA and the insurer.

Secondly, while some insureds may need to insure under Limited Irrigation for one year (e.g., a producer in the Sheridan 6 Local Enhanced Management Area (LEMA) who has used more than 80 percent of the assigned five year water allocation), others will be starting a permanent Limited Irrigation practice (producers whose water allocation has been permanently reduced as a result of legislative or legal or administrative action). This disparity makes decisions about RMA yield history databases particularly difficult. If Limited Irrigation is implemented at all, it should be implemented for one or the other of these cases. The remaining situation can be addressed through the mechanisms already in place that allow an RO to assign an Approved Yield under unusual circumstances.

Finally, one barrier to insuring fewer acres under an Irrigated Practice than were insured historically is being addressed by irrigation technologies. The change from flood irrigation to pivot circles seemed to make the circle the smallest unit that could be irrigated. It is now possible to irrigate portions of a circle. Consequently, if there is a reduction in the supply of water available for irrigation, fewer acres can be irrigated and the amount of the decrease in acreage is technologically manageable.

The benefit of adding a Limited Irrigation practice is providing an additional option for producers facing limits in the supply of available water. While many producers were not happy that they might be required to irrigate fewer acres with a limited water supply, none indicated they would prefer to water the same number of acres with less water per acre and a reduced Approved Yield.

The Contractor believes properly addressing Efficient Irrigation along with the current procedures for addressing a reduced irrigation water supply will be the best approach. It is a change that will be accepted by insureds. It is a change that recognizes current farming practices. Furthermore, the current procedures allow a case by case decision to provide a reduced Approved Yield if that is the option the insured would prefer. Implementing Limited Irrigation nationwide for all crops is unlikely to resolve any issues that currently exist and is likely to create problems that do not now exist.

Exhibit 1. Press Release

PRESS RELEASE:

Growers and Other Stakeholders Invited to Listening Session on Federal Insurance for Crops Produced under Irrigation

Farmers know better than most people that fresh water is a precious commodity. In some areas, major crops are generally irrigated, while in other areas irrigation is used primarily to supplement natural rainfall. Each state has unique systems for determining who gets water and how much they get. Throughout the United States there are areas where the amount of irrigation water available to producers can vary from year to year, and can be significantly impacted by drought. In some areas, this means less water is available for agricultural use, particularly in recent years.

Because some farmers are required to use less water while others are offered alternative approaches to their water allocations, production of irrigated crops is changing. Many producers already face reductions from their historical water use; others will in the future. These reductions come from a variety of reasons including reduced well capacity, compliance with interstate river compacts, and water right administration policies. The reduction in the supply of irrigation water creates challenges for the farmers who use the water, the organizations that manage water use, and the public/private sector programs that insure farmers' yields or revenues.

As a result, the United States Department of Agriculture (USDA), Risk Management Agency (RMA) is evaluating how Federal Crop Insurance currently addresses producers intending to apply reduced irrigation. Furthermore, RMA is evaluating a limited irrigation guarantee for producers who apply less water than they may have historically applied to their irrigated acreage. As a result of this USDA initiative, RMA issued a contract to study initially the impacts of "limited irrigation" on crop insurance for all crops in all states.

As part of the contract study, six listening sessions are being held to gather input from interested stakeholders. One will be at the [*Insert Location and Address*]. The session will start at [*Insert Time and Date*]. Grower, insurance industry representatives, and other interested stakeholders are encouraged to attend and share their concerns and feedback about limited irrigation and ideas to address the crop insurance consequences of the changing irrigation water situation in future years.

For more information contact:

Randy Landgren

Project Manager

Watts and Associates, Inc. under contract to USDA RMA

rlandgren@wattsandassociates.com

Exhibit 2. Sample Newspaper Advertisement

Woodland Democrat, California

Watts and Associates (W&A) will be conducting a listening session for the **USDA Risk Management Agency on the impact of reduced irrigation on risk management through FCIC crop insurance**. W&A seeks input from stakeholders (farmers, insurance agents and companies, extension agents and faculty, irrigation suppliers, water board representatives, etc.). While this is an open forum, W&A is particularly interested in obtaining the following information: input on strategies to reduce the amount of irrigation water required, effects of the reduced irrigation on production, and the effects of reduced irrigation on crop insurance.

The listening session will be at the
Heidrick Ag History Center
1962 Hays Lane, Woodland, CA

The session will start at 9 A.M., March 6, 2014

All are welcome

Exhibit 3. Listening Session Agenda

Crop Insurance and Reduced Irrigation Listening Session Agenda

- Introductions
 - Watts and Associates, Inc.
 - Attendees
- Purpose
 - Gather stakeholder input
 - Learn about how irrigation has been changing
 - W&A is to make recommendation to USDA insuring the irrigated practice
- Background
 - FCIC Insurance
 - Insured irrigated crops
 - The “Irrigated Practice”
 - “Limited Irrigation”
 - Challenges of reduced irrigation
- Input
 - Strategies to reduce the amount of irrigation water required,
 - Effects of the reduced irrigation on production, and
 - The effects of reduced irrigation on crop insurance
- Questions

Exhibit 4. Stakeholder Comments (sorted by theme¹)

¹ Comments were made by producers unless marked with an (a) to identify a comment made by a producer association representative, an (i) to identify a comment made by an insurance industry stakeholder, an (e) to identify an educator. The Contractor believes many insurance industry representatives who made comments are also producers.

Comments addressing whether producers have knowledge of the existing crop insurance program language pertaining to irrigated vs non-irrigated practices:

We separate dryland from irrigated in regard to the non-irrigated corners of our fields.

We are not covered on our full APH and the worst thing we can do is overplant, because that costs us money.

The APH will take care of your coverage if you don't take care of it yourself.

A lot of the producers did not know they have choices when irrigation problems arise under the current crop insurance system. (a)

The language specifically says that you have to employ the practice that established your guarantee. (i)

Comments addressing irrigation water related risk management needs:

Irrigation issues are varied and depend on not just irrigation but also heat units received and soil type.

State has authority to stop producers from irrigating (i)

State authorities placed flow meters on well heads and have a key to turn the well off.

State laws and enforcement need to be addressed in the insurance language. (i)

May get a flood on the east side of the county and not get a drop on the west side of the county. (e)

Water not the only factor that impacts yield. (e)

Yields on a lot of farms are based on the structure of the farm, like land leveling. (e)

The day is coming when regulators will step in and adjust the availability of water for your irrigation practices so start now getting your irrigation practices in line to achieve the maximum non-irrigated yields or some hybrid of the two. (i)

I see a real challenge with perennial crops because if you have a yield this year and a dry year and another dry year, that will really reduce yields. (i)

That is the challenge of the perennials because what you do this year doesn't only affect this years crop, but the next years crop and potential beyond. (i)

Here, we don't have the problem of supplemental rain. If it doesn't rain, you turn the irrigators on. (i)

Comments addressing willingness to participate in a crop insurance program

Resource definitions limiting participation.

Until the problems surrounding the "general to the area" phrase in the policy are address, a lot of producers are not going to feel they have a true safety net in insurance.

Insurance doesn't fit for irrigated crops in this area.

The management decision needs to be kept as close to the producer as possible. (a)

We need to make sure you've thought through all the unintended consequences are considered when you make your recommended changes.

The system seems to be working here.

Comments addressing irrigation related management practices and techniques:

There are producers who report their land as dryland and irrigate. (i)

Capacity of an individual pivot must also be taken into account.

Varieties and other crops which need less water are being planted in the rotations. (p)

There are numerous government programs designed to help producers use less water to grow crops, such as the Phaucet Program. (e)

Heat reduces our yields in this area.

We need to get the government to agree to re-investigate the advisability of planting into cover crops in this region. There is a tremendous amount of water retained in the soil when you use a cover crop.

Need to allow for practices recommended by local experts to be used and still covered by the insurance. (e)

Make sure you document any changes you make to your irrigation practices so your yields are verified when the regulators come.

If we can increase our organic matter from 1.5% to 3 or 4%, that would be a great help to our production activities.

Here the water usage is recorded. I cannot just turn on the water whenever I want.

What about perennial crops? Growers change their methodology of how they irrigate, going to more efficient systems.

Where is a cotton/almond grower going to put his water? To his trees.

We've been managing this irrigation issue for years and years. Irrigation is a self-managing problem. (a)

Producers change their crop rotations or the amount of acres they irrigate during times of limited water availability.

Determining whether a farmer irrigated adequately or not falls under the Good Farming Practice clause. (i)

Canal company sends out letters that need to discuss the natural cause of the reduction in irrigation water. (i)

Comments addressing potential underwriting requirements:

Producers are responsible for proving the cause of loss in any case (i)

The general crop provision language is problematic in and of itself. (i)

State laws and enforcement need to be addressed in the insurance language. (i)

How are you going to address crops planed in the previous year and harvested this year?

It gets back to the rating on the history of that particular piece of dirt. (i)

The phrase "General to the area" can be problematic, it allows for too much subjectivity on the part of the loss adjustor and review board. (e)

Whatever language is changed or added to the documents needs to address cool versus warm season crops, double cropping practices, etc...

Even after you make changes to the language, there needs to be a way to address issues at a sub-regional level based on geographic formations. (e)

Typically, your data for insurance comes from the scam artists or the really good producers, neither of which provide the data which is applicable to everyone. (e)

Using local CSP type processes and reporting might help with tracking irrigation water usage.

It seems to make some sense to provide broad language by perennial versus annual crops or fruits and vegetables versus field versus tree. (a)

The producers APH itself has a self-regulating nature.

We do not have state monitored pumps on our wells. (a)

Some districts put a limit on the amount of groundwater a producer can pull and the producers pay a penalty if they use more than allowed.

We can bank some of our water in wet years.

Our APH is not only based on the average irrigation over the last ten years but also the average precipitation.

It takes time to build our APH so it should also be given the same amount of time to go down.

You cannot compare us with Nebraska. We do not have governmental regulations where the government can come in a shut off our water.

We turn in our power records to support our loss claims.

My association believes changes to irrigation language should be done by the individual RMA regional office like they are doing in Kansas. (a)

Water Boards need to document the cause of water restriction. (i)

You'll never be able to create irrigation language without opening loopholes that people will find to game the system.

Comments addressing what type of risk management insurance would be appropriate for Limited Irrigation:

Third practice called, maybe, Supplemental Water. (i)

Seek an approach where the producer is not going to lose 2/3rds of their irrigated yield when they lose access to some of their water.

The plan needs to take into account the imperfections of the program based on a national crop program.

Overhead heat needs to be accounted for in any changes.

Sometimes there is not enough water to overcome the effects of weather like high heat and winds combined.

If they are going to talk about reducing APH because of irrigation, let's up it. I have 600 pounds APH trying to raise a crop of 1800 pounds because I changed how I irrigate so I don't have near enough coverage.

Appendix D

State-level Irrigation Reporting Requirements and Information Collected by the State

Table D1. Reporting Requirements

State	Registration	Monitoring
Alabama	100,000 gallons of water or more per day for irrigation	
Alaska	500 gallons per day	
Arizona	Any amount, groundwater has time limit	Arizona has a database for all users whose groundwater withdrawal rate exceeds 35 gpm in five areas (Phoenix, Tucson, Pinal Prescott and Santa Cruz)
Arkansas	Registration involves reporting water use for the past water year	
California	withdrawal of surface water is by permit	There is no comprehensive permit process for groundwater use.
Colorado	by permit regardless of amount	
Connecticut	50,000 gpd	
Delaware	50,000 gpd; special permit >100,000gpd	
Florida	1,000,000 gpd and for wells greater than six inches in diameter.	Water use data are reported monthly, quarterly or annually, depending on the management district
Georgia	100,000 gpd on a monthly average	Data is not gathered and complied for irrigation
Hawaii	more than 25,000 gpm	
Idaho	Any use	
Illinois	100,000 gpd capacity	
Indiana	more than 100,000 gpd	
Iowa	over 25,000 gpd	An annual water use report form
Kansas	>1,000,000 gallons	An annual water use report
Kentucky	10,000 gpd	may not have a reporting requirement
Louisiana	Groundwater registration	more than 1,000,000 gpd report withdrawal information quarterly, all other facilities receive a questionnaire every five years
Maine	all significant groundwater withdrawals	reports of surface and groundwater withdrawals for agricultural use
Maryland	All withdrawals with additional registration procedures for withdrawals over 10,000 gpd	periodic reporting

State	Registration	Monitoring
Massachusetts	in excess of 100,000 gpd or 9,000,000 gallons in any three month period	water meters
Michigan	over 2,000,000 gpd must be permitted	over 100,000 gpd must be reported
Minnesota	10,000 gallons in any one day or 1,000,000 gallons in a year	new water withdrawals must be equipped with a flow meter
Mississippi	New uses after 1985 in excess of 20,000 gpd	water use is reported annually on a voluntary basis
Missouri	over 100,000 gpd	report withdrawals annually
Montana	in excess of 35 gpm	
Nebraska	All surface water and some groundwater extraction requires permits	may be required to submit a report
Nevada	New use after 1905	the right holder is required to file proof once water has been put to beneficial use
New Hampshire	Groundwater >57,600 gallons over any 24-hour period over	
New Jersey	100,000 gpd	
New Mexico	New uses after 1907	maintains water-use databases
New York	No comprehensive program	
North Carolina	1,000,000 gallons of water a day or more renewed every 5 years	Annual reporting of withdrawals for surface and ground water users of more than 10,000 gpd
North Dakota	>12.5 acre-feet per year	“reports”
Ohio	100,000 gpd except in stressed area where every withdrawal may require a permit	annual reports
Oklahoma	2 acre feet per year or based on yield studies	The amount of unappropriated water must be documented
Oregon	any new use	irrigation districts report water use annually
Pennsylvania	10,000, 20,000 and 100,000 gpd depending on source	periodic reports for some sources
Rhode Island	50,000,000 gallons per year	
South Carolina	3,000,000 gallons per month	Annual report
South Dakota	>18 gpm	
Tennessee	Agriculture exempt from permitting	Encouraged to report withdrawal

State	Registration	Monitoring
Texas	Any new use	
Utah	all withdrawals of surface and groundwater are permitted	One time file of proof of quantity etc.
Vermont	No comprehensive program	Farms using more than 57,600 gpd
Virginia	300,000 gallons per month or more in a declared management area	
Washington	Any use since 1917 (5,000 gpd exception for irrigation)	no mandatory reporting or monitoring of withdrawals
West Virginia	no water withdrawal regulation	
Wisconsin	New groundwater withdrawals over 100,000 gpd	groundwater withdrawals over 100,000 gpd, however surface water withdrawals for agricultural or irrigation purposes do not require a permit
Wyoming	Some groundwater extraction since 1947	State Engineer may require water use reports

Table D4. Information Collected on Water Usage Reporting Forms by State

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
Alabama	Withdrawal Name				X			X	Million Gallons/Day - Monthly Use reporting
Alaska	Source Name/Meter Reading							X	
Arizona	Withdrawal Location/DWR Well Registration							X	Online Reporting available, two short forms available- one for Santa Cruz AMA, another for all other areas.
Arkansas	X	X					X	X	
California	Source and Diversion Works Name, Section/Township	X			X			X	Measurement Description on Form, Yearly Reporting
Colorado								X	
Connecticut	Diversion Name							X	Gallons pumped/Day- Monthly Use reporting
Delaware									
Florida									Water use is reported to the districts and then to the State, but water permits are through the State itself.

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
		X					X	Multiple Water Reporting Forms depending on conditions of permit, with Annual, Periodic, and Summary Forms available.	
							X	Reporting form unavailable	
							X	Monthly Water Use Reporting	
							X	Online Reporting for registered users, screenshots unavailable	
							X	Yearly Reporting	
Georgia	Reporting from Aquifer or Multiple Aquifers					X		Daily/Monthly Reporting	
Hawaii	Ground: State Well Number/Name, Surface: Gage ID/Name						X	Monthly Reporting for both Surface/Ground	
Idaho	Diversion Name and Site Tag Number			X			X	Yearly reporting, typically submitted by Water Master rather than Producer unless requested	
Illinois	Well/intake/Township information						X	Water Use Breakdown by Self-Supplied and Purchased, Online reporting available	
Indiana	Well/intake information, Source ID,						X	Monthly/Annual Reporting for Ground/Surface, Online Submission	
Iowa	Name and Type of Water Source	X		X			X	Monthly/Annual Reporting	
Kansas	Section/Township/Range	X					X	Annual Reporting - Total use by Gallon, forms are mailed to water rights holders	

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
Kentucky									Agricultural water users are exempt from Reporting due to Chapter 22, Article 26 of the newest Legislature.
Louisiana	DOTD Well Number/Parish							X	Reporting not required
Maine	Water Source info, If Groundwater Well, Distance from/identification of Nearest Surface Water Body. Municipality and Township							X	Gallons per Hour/Day, Daily and Monthly Predictions/Actuals for Year
Maryland		X		X					Required to be submitted 30 days after form received. Monthly Reporting for Year.
Massachusetts	Withdrawal Point and Location							X	Annual Reporting, separate forms for reporting water use for growing cranberries and for other crops.
Michigan	Pump ID, Location, capacity, Water Source Information	X		X	X			X	Monthly Reporting for Year
Minnesota		X						X	Received screenshots of online process from Sean Hunt on 4/30

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
Mississippi								Water reporting records are taken during permitting process and voluntary reporting	
Missouri	Water Use Information: Withdrawal/Intake ID Number, Well Cert#, Water Body Name, etc	X			X			X	Monthly Reporting for Year, online reporting available-permitting for new users and reporting is on the same form
Montana	Location and Type of Device Used				X			X	Annual Reporting, Multiple Reporting Forms available- Flow Meter, Hour Meter, Open Channel, Staff Gage, Static Level, Watt Hour Meter can be used. Not all Water Districts required to submit reports and some reporting information is obtained via meters, those that are will be sent in by producers in the form of a spreadsheet or written statement with few exceptions. These exceptions vary from one district to another. Some districts also participate in Adjacent State Transfers.
Nebraska									Reporting required Yes, in sub-areas, have form Volunteer Reports Reporting not required Yes, for all District required flow meters (sub areas) Yes, in sub-areas, have form Yes, in sub-areas, have form

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes

New Jersey	Source Name , Well/Intake Information	X					X		Quarterly or Annual Online Reporting Process
New Mexico	Location of Well, Number, Subdivision/Township (for Ground) also USGS Coordinates and Lat/Long (for Surface), Source Information	X			X				Separate Forms for Ground and Surface Water
New York	Source Name/Type						X		Monthly Reporting Due March 31 of Each Year. General Map (USGS) and Interbasin Diversions (if any) also required Application and Reporting on the same form
North Carolina	Source and Well ID Numbers, Lat/Long						X		
North Dakota	N/A	X			X				Online Reporting
Ohio	Facility Well ID (Ground) or Intake ID (Surface), Source/Well Number						X		Annual Reporting
Oklahoma	Pump/Diversion Point kept on file	X			X				Water is Pre-Allocated, Report is only to verify
Oregon	Facility Report ID	X			X		X		October through September of following year (Annual) reporting
Pennsylvania							X		Online Annual Reporting from Jan to Dec, Unable to acquire screenshots, but have sample Subfacility Report

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
Rhode Island								X	Only major water suppliers (50million gallons/year or more) are required to report. Agricultural needs are pre-estimated and privately verified by consumers *See email in State file*
South Carolina	Source(ground), name of well or wells utilized							X	Actual Reporting Forms mailed strictly to water-rights holders, but requirements visible in other documents.
South Dakota		X		X			X		Monthly/Annual Reporting due by December 2 of each year
Tennessee	Source/Intake Information							X	Daily Averages Annual Report due by March 1 of each year
Texas	Aquifer/Source/Well Information for Purchased and Self-Supplied Water							X	Municipal Water Use Survey due December 31 of each year. Forms for Ground/Surface/Purchased/Self-Supplied available.
Utah	Source/Well Information		X		X		X	X	Annual Online Reporting when requested. Water is allocated and monitored.
Vermont	Facility ID (Water Source)							X	Daily/Monthly forms Annually submitted
Virginia	Well Number							X	Online Reporting available, Montly/Annual Withdrawal Amounts. Excess over 10,000 gallons/day is required to be reported, below that is voluntary
Washington	Only Meter Type				X			X	Online Reporting available. Reporting due by January 31 each year

State	Location of Pump/Diversion Point Description	Acres Irrigated	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
			Unit	Crop	Farm	Unit	Crop	Farm	
West Virginia									Farmers and Irrigators are exempt from filling out both an application/permit and reporting water use in West Virginia Annual Reporting due March 1 for previous year, majority of information that would supplement the actual permitting process as is typical in most States is taken from the water reporting form instead. Reporting not required
Wisconsin	Source Name, Well Number, Public Water System ID (if applicable)						X		
Wyoming	N/A								

Appendix E

Historical Precipitation by State and County

Kansas	Jackson	Corn, Grain, Irrigated - Acres Harvested	318
Kansas	Jackson	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kansas	Jefferson	Corn, Grain, Irrigated - Acres Harvested	2,240
Kansas	Jefferson	Corn, Grain, Irrigated - Operations With Area Harvested	18
Kansas	Leavenworth	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Leavenworth	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kansas	Marshall	Corn, Grain, Irrigated - Acres Harvested	1,961
Kansas	Marshall	Corn, Grain, Irrigated - Operations With Area Harvested	13
Kansas	Nemaha	Corn, Grain, Irrigated - Acres Harvested	753
Kansas	Nemaha	Corn, Grain, Irrigated - Operations With Area Harvested	9
Kansas	Pottawatomie	Corn, Grain, Irrigated - Acres Harvested	11,801
Kansas	Pottawatomie	Corn, Grain, Irrigated - Operations With Area Harvested	45
Kansas	Riley	Corn, Grain, Irrigated - Acres Harvested	1,482
Kansas	Riley	Corn, Grain, Irrigated - Operations With Area Harvested	12
Kansas	Wyandotte	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Wyandotte	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kansas	Cheyenne	Corn, Grain, Irrigated - Acres Harvested	29,498
Kansas	Cheyenne	Corn, Grain, Irrigated - Operations With Area Harvested	77
Kansas	Decatur	Corn, Grain, Irrigated - Acres Harvested	8,188
Kansas	Decatur	Corn, Grain, Irrigated - Operations With Area Harvested	41
Kansas	Graham	Corn, Grain, Irrigated - Acres Harvested	6,525
Kansas	Graham	Corn, Grain, Irrigated - Operations With Area Harvested	32
Kansas	Norton	Corn, Grain, Irrigated - Acres Harvested	9,186
Kansas	Norton	Corn, Grain, Irrigated - Operations With Area Harvested	35
Kansas	Rawlins	Corn, Grain, Irrigated - Acres Harvested	12,142
Kansas	Rawlins	Corn, Grain, Irrigated - Operations With Area Harvested	52
Kansas	Sheridan	Corn, Grain, Irrigated - Acres Harvested	49,852
Kansas	Sheridan	Corn, Grain, Irrigated - Operations With Area Harvested	144
Kansas	Sherman	Corn, Grain, Irrigated - Acres Harvested	65,478
Kansas	Sherman	Corn, Grain, Irrigated - Operations With Area Harvested	121
Kansas	Thomas	Corn, Grain, Irrigated - Acres Harvested	57,009
Kansas	Thomas	Corn, Grain, Irrigated - Operations With Area Harvested	112
Kansas	Barber	Corn, Grain, Irrigated - Acres Harvested	3,421
Kansas	Barber	Corn, Grain, Irrigated - Operations With Area Harvested	11
Kansas	Comanche	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Comanche	Corn, Grain, Irrigated - Operations With Area Harvested	8
Kansas	Edwards	Corn, Grain, Irrigated - Acres Harvested	57,210
Kansas	Edwards	Corn, Grain, Irrigated - Operations With Area Harvested	92
Kansas	Harper	Corn, Grain, Irrigated - Acres Harvested	590
Kansas	Harper	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kansas	Harvey	Corn, Grain, Irrigated - Acres Harvested	22,765
Kansas	Harvey	Corn, Grain, Irrigated - Operations With Area Harvested	83
Kansas	Kingman	Corn, Grain, Irrigated - Acres Harvested	9,126
Kansas	Kingman	Corn, Grain, Irrigated - Operations With Area Harvested	32
Kansas	Kiowa	Corn, Grain, Irrigated - Acres Harvested	21,855
Kansas	Kiowa	Corn, Grain, Irrigated - Operations With Area Harvested	34
Kansas	Pawnee	Corn, Grain, Irrigated - Acres Harvested	32,977
Kansas	Pawnee	Corn, Grain, Irrigated - Operations With Area Harvested	80

State	County	Data Item	Value
Kansas	Pratt	Corn, Grain, Irrigated - Acres Harvested	45,619
Kansas	Pratt	Corn, Grain, Irrigated - Operations With Area Harvested	118
Kansas	Reno	Corn, Grain, Irrigated - Acres Harvested	19,567
Kansas	Reno	Corn, Grain, Irrigated - Operations With Area Harvested	86
Kansas	Sedgwick	Corn, Grain, Irrigated - Acres Harvested	19,758
Kansas	Sedgwick	Corn, Grain, Irrigated - Operations With Area Harvested	74
Kansas	Stafford	Corn, Grain, Irrigated - Acres Harvested	36,134
Kansas	Stafford	Corn, Grain, Irrigated - Operations With Area Harvested	117
Kansas	Sumner	Corn, Grain, Irrigated - Acres Harvested	5,762
Kansas	Sumner	Corn, Grain, Irrigated - Operations With Area Harvested	20
Kansas	Allen	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Allen	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kansas	Bourbon	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Bourbon	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kansas	Butler	Corn, Grain, Irrigated - Acres Harvested	2,399
Kansas	Butler	Corn, Grain, Irrigated - Operations With Area Harvested	11
Kansas	Cherokee	Corn, Grain, Irrigated - Acres Harvested	660
Kansas	Cherokee	Corn, Grain, Irrigated - Operations With Area Harvested	4
Kansas	Cowley	Corn, Grain, Irrigated - Acres Harvested	1,186
Kansas	Cowley	Corn, Grain, Irrigated - Operations With Area Harvested	10
Kansas	Crawford	Corn, Grain, Irrigated - Acres Harvested	707
Kansas	Crawford	Corn, Grain, Irrigated - Operations With Area Harvested	5
Kansas	Greenwood	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Greenwood	Corn, Grain, Irrigated - Operations With Area Harvested	2
Kansas	Labette	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Labette	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kansas	Montgomery	Corn, Grain, Irrigated - Acres Harvested	1,848
Kansas	Montgomery	Corn, Grain, Irrigated - Operations With Area Harvested	6
Kansas	Wilson	Corn, Grain, Irrigated - Acres Harvested	676
Kansas	Wilson	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kansas	Clark	Corn, Grain, Irrigated - Acres Harvested	750
Kansas	Clark	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kansas	Finney	Corn, Grain, Irrigated - Acres Harvested	80,695
Kansas	Finney	Corn, Grain, Irrigated - Operations With Area Harvested	153
Kansas	Ford	Corn, Grain, Irrigated - Acres Harvested	31,966
Kansas	Ford	Corn, Grain, Irrigated - Operations With Area Harvested	67
Kansas	Grant	Corn, Grain, Irrigated - Acres Harvested	39,187
Kansas	Grant	Corn, Grain, Irrigated - Operations With Area Harvested	84
Kansas	Gray	Corn, Grain, Irrigated - Acres Harvested	54,041
Kansas	Gray	Corn, Grain, Irrigated - Operations With Area Harvested	123
Kansas	Hamilton	Corn, Grain, Irrigated - Acres Harvested	5,574
Kansas	Hamilton	Corn, Grain, Irrigated - Operations With Area Harvested	14
Kansas	Haskell	Corn, Grain, Irrigated - Acres Harvested	54,420
Kansas	Haskell	Corn, Grain, Irrigated - Operations With Area Harvested	79
Kansas	Hodgeman	Corn, Grain, Irrigated - Acres Harvested	(D)
Kansas	Hodgeman	Corn, Grain, Irrigated - Operations With Area Harvested	55
Kansas	Kearny	Corn, Grain, Irrigated - Acres Harvested	21,312
Kansas	Kearny	Corn, Grain, Irrigated - Operations With Area Harvested	50
Kansas	Meade	Corn, Grain, Irrigated - Acres Harvested	86,136

State	County	Data Item	Value
Kansas	Meade	Corn, Grain, Irrigated - Operations With Area Harvested	121
Kansas	Morton	Corn, Grain, Irrigated - Acres Harvested	23,082
Kansas	Morton	Corn, Grain, Irrigated - Operations With Area Harvested	54
Kansas	Seward	Corn, Grain, Irrigated - Acres Harvested	44,826
Kansas	Seward	Corn, Grain, Irrigated - Operations With Area Harvested	61
Kansas	Stanton	Corn, Grain, Irrigated - Acres Harvested	43,137
Kansas	Stanton	Corn, Grain, Irrigated - Operations With Area Harvested	62
Kansas	Stevens	Corn, Grain, Irrigated - Acres Harvested	97,886
Kansas	Stevens	Corn, Grain, Irrigated - Operations With Area Harvested	81
Kansas	Gove	Corn, Grain, Irrigated - Acres Harvested	12,664
Kansas	Gove	Corn, Grain, Irrigated - Operations With Area Harvested	63
Kansas	Greeley	Corn, Grain, Irrigated - Acres Harvested	12,025
Kansas	Greeley	Corn, Grain, Irrigated - Operations With Area Harvested	31
Kansas	Lane	Corn, Grain, Irrigated - Acres Harvested	5,919
Kansas	Lane	Corn, Grain, Irrigated - Operations With Area Harvested	21
Kansas	Logan	Corn, Grain, Irrigated - Acres Harvested	6,049
Kansas	Logan	Corn, Grain, Irrigated - Operations With Area Harvested	26
Kansas	Ness	Corn, Grain, Irrigated - Acres Harvested	702
Kansas	Ness	Corn, Grain, Irrigated - Operations With Area Harvested	11
Kansas	Scott	Corn, Grain, Irrigated - Acres Harvested	15,644
Kansas	Scott	Corn, Grain, Irrigated - Operations With Area Harvested	56
Kansas	Trego	Corn, Grain, Irrigated - Acres Harvested	2,375
Kansas	Trego	Corn, Grain, Irrigated - Operations With Area Harvested	17
Kansas	Wallace	Corn, Grain, Irrigated - Acres Harvested	38,243
Kansas	Wallace	Corn, Grain, Irrigated - Operations With Area Harvested	56
Kansas	Wichita	Corn, Grain, Irrigated - Acres Harvested	25,423
Kansas	Wichita	Corn, Grain, Irrigated - Operations With Area Harvested	75
Kentucky	Bath	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Bath	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kentucky	Boyle	Corn, Grain, Irrigated - Acres Harvested	90
Kentucky	Boyle	Corn, Grain, Irrigated - Operations With Area Harvested	3
Kentucky	Fleming	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Fleming	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kentucky	Garrard	Corn, Grain, Irrigated - Acres Harvested	42
Kentucky	Garrard	Corn, Grain, Irrigated - Operations With Area Harvested	4
Kentucky	Harrison	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Harrison	Corn, Grain, Irrigated - Operations With Area Harvested	4
Kentucky	Jessamine	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Jessamine	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kentucky	Lincoln	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Lincoln	Corn, Grain, Irrigated - Operations With Area Harvested	2
Kentucky	Madison	Corn, Grain, Irrigated - Acres Harvested	20
Kentucky	Madison	Corn, Grain, Irrigated - Operations With Area Harvested	7
Kentucky	Mason	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Mason	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kentucky	Nicholas	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Nicholas	Corn, Grain, Irrigated - Operations With Area Harvested	1
Kentucky	Scott	Corn, Grain, Irrigated - Acres Harvested	(D)
Kentucky	Scott	Corn, Grain, Irrigated - Operations With Area Harvested	5

State	County	Data Item	Value
Kentucky	Shelby	Corn, Grain, Irrigated - Acres Harvested	(D)

Wyoming	Platte	Corn, Grain, Irrigated - Operations With Area Harvested	39

Table G2. 2013 NASS Survey Data for Corn

State	County	Data Item	Value
Colorado	Cheyenne	Corn, Grain, Irrigated - Acres Harvested	14,400.0
Colorado	Cheyenne	Corn, Grain, Irrigated - Production, Measured In Bu	2,782,000.0
Colorado	Cheyenne	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	193.2
Colorado	Cheyenne	Corn, Irrigated - Acres Planted	14,700.0
Colorado	Kit Carson	Corn, Grain, Irrigated - Acres Harvested	78,900.0
Colorado	Kit Carson	Corn, Grain, Irrigated - Production, Measured In Bu	12,847,000.0
Colorado	Kit Carson	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	162.8
Colorado	Kit Carson	Corn, Irrigated - Acres Planted	83,900.0
Colorado	Other (Combined) Counties	Corn, Grain, Irrigated - Acres Harvested	241,500.0
Colorado	Other (Combined) Counties	Corn, Grain, Irrigated - Production, Measured In Bu	46,811,000.0
Colorado	Other (Combined) Counties	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	193.8
Colorado	Other (Combined) Counties	Corn, Irrigated - Acres Planted	257,400.0
Colorado	Phillips	Corn, Grain, Irrigated - Acres Harvested	60,200.0
Colorado	Phillips	Corn, Grain, Irrigated - Production, Measured In Bu	11,680,000.0
Colorado	Phillips	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	194.0
Colorado	Phillips	Corn, Irrigated - Acres Planted	64,000.0
Delaware	Sussex	Corn, Grain, Irrigated - Acres Harvested	55,900.0
Delaware	Sussex	Corn, Grain, Irrigated - Production, Measured In Bu	10,380,000.0
Delaware	Sussex	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	185.7
Delaware	Sussex	Corn, Irrigated - Acres Planted	57,000.0
Kansas	Barton	Corn, Grain, Irrigated - Acres Harvested	16,300.0
Kansas	Barton	Corn, Grain, Irrigated - Production, Measured In Bu	2,945,000.0
Kansas	Barton	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	180.7
Kansas	Barton	Corn, Irrigated - Acres Planted	16,700.0
Kansas	Brown	Corn, Grain, Irrigated - Acres Harvested	3,000.0
Kansas	Brown	Corn, Grain, Irrigated - Production, Measured In Bu	660,000.0
Kansas	Brown	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	220.0
Kansas	Brown	Corn, Irrigated - Acres Planted	3,100.0
Kansas	Cloud	Corn, Grain, Irrigated - Acres Harvested	11,700.0
Kansas	Cloud	Corn, Grain, Irrigated - Production, Measured In Bu	2,162,000.0
Kansas	Cloud	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	184.8
Kansas	Cloud	Corn, Irrigated - Acres Planted	11,800.0
Kansas	Decatur	Corn, Grain, Irrigated - Acres Harvested	5,800.0
Kansas	Decatur	Corn, Grain, Irrigated - Production, Measured In Bu	911,000.0
Kansas	Decatur	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	157.1
Kansas	Decatur	Corn, Irrigated - Acres Planted	6,000.0
Kansas	Doniphan	Corn, Grain, Irrigated - Acres Harvested	2,400.0
Kansas	Doniphan	Corn, Grain, Irrigated - Production, Measured In Bu	463,000.0
Kansas	Doniphan	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	192.9
Kansas	Doniphan	Corn, Irrigated - Acres Planted	2,500.0
Kansas	Edwards	Corn, Grain, Irrigated - Acres Harvested	61,500.0
Kansas	Edwards	Corn, Grain, Irrigated - Production, Measured In Bu	12,464,000.0
Kansas	Edwards	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	202.7
Kansas	Edwards	Corn, Irrigated - Acres Planted	61,800.0
Kansas	Geary	Corn, Grain, Irrigated - Acres Harvested	2,400.0
Kansas	Geary	Corn, Grain, Irrigated - Production, Measured In Bu	443,000.0
Kansas	Geary	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	184.6
Kansas	Geary	Corn, Irrigated - Acres Planted	2,500.0

State	County	Data Item	Value
Kansas	Gove	Corn, Grain, Irrigated - Acres Harvested	10,500.0
Kansas	Gove	Corn, Grain, Irrigated - Production, Measured In Bu	1,572,000.0
Kansas	Gove	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	149.7
Kansas	Gove	Corn, Irrigated - Acres Planted	11,000.0
Kansas	Harvey	Corn, Grain, Irrigated - Acres Harvested	20,600.0
Kansas	Harvey	Corn, Grain, Irrigated - Production, Measured In Bu	3,470,000.0
Kansas	Harvey	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	168.4
Kansas	Harvey	Corn, Irrigated - Acres Planted	20,800.0
Kansas	Kiowa	Corn, Grain, Irrigated - Acres Harvested	30,500.0
Kansas	Kiowa	Corn, Grain, Irrigated - Production, Measured In Bu	5,983,000.0
Kansas	Kiowa	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	196.2
Kansas	Kiowa	Corn, Irrigated - Acres Planted	30,600.0
Kansas	Marion	Corn, Grain, Irrigated - Acres Harvested	1,400.0
Kansas	Marion	Corn, Grain, Irrigated - Production, Measured In Bu	224,000.0
Kansas	Marion	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	160.0
Kansas	Marion	Corn, Irrigated - Acres Planted	1,500.0
Kansas	Mcperson	Corn, Grain, Irrigated - Acres Harvested	17,800.0
Kansas	Mcperson	Corn, Grain, Irrigated - Production, Measured In Bu	2,753,000.0
Kansas	Mcperson	Corn, Grain, Irrigated - Yield, Measured In Bu / Acre	154.7
Kansas	Mcperson	Corn, Irrigated - Acres Planted	18,900.0
Kansas	Mitchell	Corn, Grain, Irrigated - Acres Harvested	4,600.0
Kansas	Mitchell	Corn, Grain, Irrigated - Production, Measured In Bu	775,000.0

Table K1. Water Rights Application and Usage Reporting Forms Information Gathered by State Combined (Continued)

State	Estimation Method	Acres Irrigated from Source	Avg Inch/year applied	Number of Months Irrigate	Irrigate Days/Month	Water Usage Intent	Chemical Application through Diversion?	Map of Diversion Points	NOTES
Alabama	X	X	X	X	X				
Alaska			X	X		X			
Arizona									
Arkansas		X		X		X			
California	X	X		X		X		X	
Colorado		X				X		X	
Connecticut				X	X				Permitting involves both an application and a documentation attachment that contains further information on the location, source, and diversion methods.
Delaware		X				X	X-see notes	X	Attach documentation/pumping test reports and well information with form, attach information regarding treatment (chemical?) of water prior to use
Florida		X				X		X	Different Application for each of the five water districts. Some currently under revision and some examples are unavailable. Water Rights are applied for primarily on the State level while reporting is done at the district level and then to the State. Information in table required on North West WD permit, as example. Well Permits are acquired through a State-wide process.
Georgia		X				X	X	X	
Hawaii		X		X		X		X	Separate applications for Ground and Surface Water
Idaho		X		X	X	X		X	Also have Temporary Appropriation Form
Illinois									
Indiana						X		X	
Iowa		X		X	X	X		X	
Kansas						X	X	X	

Use or disclosure of information or data contained on this sheet is subject to the restrictions on the title page of this report.

State	Estimation Method	Acres Irrigated from Source	Avg Inch/year applied	Number of Months Irrigate	Irrigate Days/Month	Water Usage Intent	Chemical Application through Diversion?	Map of Diversion Points	NOTES
Kentucky		X	X	X	X	X		X	Row crop/grain operations are exempt from needing to both apply for and report water usage. Produce and nursery are not. Have application for when exemption does not apply
Louisiana									Water permits not required, permits for wells only required for large industrial projects.
Maine		X				X		X	Wells appear to be uncommon in Maine, with ponds or diverting from streams much more frequently used. A pre-acceptance meeting must occur before actual permitting can be approved.
Maryland		X				X			Application for Agricultural Purposes does not inquire about quantity of water needed, but separate application for non-ag irrigation does. We also have a copy of this form as well.
Massachusetts		X							Acreage for cranberry growers, Permit transfer included in Registration.
Michigan				X		X			
Minnesota	X	X	X	X		X		X	Minnesota requires a preliminary application to construct a well in the case of ground water withdrawal before an actual permit to use the water can be filled out or approved. Some of this information is requested on the pre-application and others on the actual application
Mississippi		X				X		X	
Missouri		X		X	X	X			
Montana		X		X	X	X		X	Ground and Surface Applications are separate, Groundwater Permit requires additional attachments such as Aquifer Testing Report

State	Estimation Method	Acres Irrigated from Source	Avg Inch/year applied	Number of Months Irrigate	Irrigate Days/Month	Water Usage Intent	Chemical Application through Diversion?	Map of Diversion Points	NOTES
Nebraska		X				X		X	Any diversion of surface water is permitted on a district and individual basis, some may require special hearings to get a permit. Surface water is appropriated by the State, Ground is by NRD's
Nevada		X		X	X	X			
New Hampshire						X			
New Jersey					X	X	X	X	
New Mexico		X	X			X			
New York						X		X	Permitting process includes Application and Joint-Application together
North Carolina				X	X	X		X	
North Dakota				X	X	X			
Ohio						X		X	
Oklahoma		X				X		X	Separate forms for Ground and Surface/Stream Withdrawal Permits. Also have temporary 90 day permits for Ground and Surface available.
Oregon		X				X		X	
Pennsylvania						X		X	Only major water users (50 mgly or more) need to fill out an application or report
Rhode Island									
South Carolina		X				X		X	
South Dakota		X		X		X		X	
Tennessee				X	X	X		X	
Texas		X				X		X	
Utah		X		X		X			
Vermont						X		X	

State	Estimation Method	Acres Irrigated from Source	Avg Inch/year applied	Number of Months Irrigate	Irrigate Days/Month	Water Usage Intent	Chemical Application through Diversion?	Map of Diversion Points	NOTES
Virginia		X	X			X			New Groundwater Withdrawal Permit currently being revised. Information taken from Existing Users form
Washington West Virginia				X	X	X		X	Farmers and Irrigators are exempt from filling out both an application/permit and reporting water use in West Virginia. Permitting is only required in the Great Lakes Basin and is simply a letter with an pre-approved amount. Any user who is using under 100k gallons in a 30-day period are exempt. Tied to ownership of property instead of source. Forms are generated for each permittee and signed on an individual basis.
Wisconsin									
Wyoming						X		X	

Table K2. Water Regulatory Divisions for Reporting Purposes and Information Required by State

State	Water District	Special Use Area	Water Owner (Name or Permit Number)	Location of Pump/Diversion Point Description	Acres Irrigated	Management District ID	County	Pump Rate	Irrigation System Code	Energy ID
Alabama			Owner Name and Certificate of Use Number	Withdrawal Name						
Alaska			Water User Name/Water Right Number	Source Name/Meter Reading						
			Owner Name and Right/Permit Number	Withdrawal Location/DWR Well Registration						
Arizona	Phoenix AMA Pinal AMA Prescott AMA Tuscon AMA Santa Cruz AMA									
Arkansas			Owner Name/ID	X	X		X			
California			Claimant Name	Source and Diversion Works Name, Section/Township	X		X

Table K2. Water Regulatory Divisions for Reporting Purposes and Information Required by State (Continued)

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
Alabama	X			X			X	Million Gallons/Day - Monthly Use reporting
Alaska							X	
	X						X	Online Reporting available, two short forms available- one for Santa Cruz AMA, another for all other areas.
Arizona								
Arkansas	X					X	X	
California	X			X			X	Measurement description on form, yearly reporting
Colorado							X	
Connecticut							X	Gallons pumped/day- monthly use reporting
Delaware								
								Water use is reported to the districts and then to the State, but water permits are through the State itself.
Florida							X	
							X	Multiple water reporting forms depending on conditions of permit, with Annual, Periodic, and Summary Forms available.
							X	
							X	No form available, developing automated monitoring of groundwater withdrawals
								Monthly water use reporting

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
Georgia					X			Online Reporting for registered users, screenshots unavailable
Hawaii							X	Yearly reporting
Idaho	X			X				Daily/Monthly reporting
Illinois							X	Monthly reporting for both surface/ground
Indiana	X						X	Yearly reporting, typically submitted by water master rather than producer unless requested
Iowa				X			X	Water use breakdown by self-supplied and purchased, Online reporting available
	X					X		Monthly/Annual reporting for ground/surface, online submission
Kansas								Monthly/Annual Reporting
						X		Annual reporting - total use by gallons, forms are mailed to water rights holders
Kentucky								Agricultural water users are exempt from Reporting due to Chapter 22, Article 26 of the newest Legislature.
Louisiana							X	Reporting not required

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
Maine							X	Gallons per Hour/Day, Daily and Monthly Predictions/Actuals for Year
Maryland			X					Required to be submitted 30 days after form received. Monthly Reporting for Year.
Massachusetts							X	Annual Reporting, separate forms for reporting water use for growing cranberries and for other crops.
Michigan			X	X		X	X	Monthly Reporting for Year
Minnesota							X	Received screenshots of online process from Sean Hunt on 4/30
Mississippi								Water reporting records are taken during permitting process and voluntary reporting
Missouri				X			X	Monthly Reporting for Year, online reporting available- permitting for new users and reporting is on the same form
Montana	X			X			X	Annual Reporting, Multiple Reporting Forms available- Flow Meter, Hour Meter, Open Channel, Staff Gage, Static Level, Watt Hour Meter can be used.
								Not all Water Districts required to submit reports and some reporting information is obtained via meters, those that are will be sent in by producers in the form of a spreadsheet or written statement with few exceptions. These exceptions vary from one district to another.
								Some districts also participate in Adjacent State Transfers.
Nebraska			X					Reporting required
								Reporting not required, Plan in development
								Volunteer Reports, have form
								Reporting not required
								Yes, for all District required flow meters (sub areas), given information and expecting form
	X		X					Yes, in sub-areas, have form
			X					Yes, in sub-areas, have form

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
			X					Volunteer Reports
			X					Reporting required, provided by meters, called Friday, May 9th, information verified May 20th
			X					Reporting required, provided by meters, called Friday, May 9th,
			X					Yes, in sub-areas
			X					Reporting required, provided by meters read on site
			X					Reporting required, provided by meters read on site
			X					Reporting required, provided by meters read on site, called Friday, May 9th
								Reporting not required
			X					Reporting required, provided by meters read on site, information obtained May, 9th
			X					Reporting required, provided by meters read on site
			X					Reporting not required, but information can be included in form for soil/fertilizer use.
				X			X	Reporting required, provided by meters read on site, Groundwater only
			X					Reporting required, provided by meters read on site
				X				Reporting required, some through flow meters and others with pumping hours reported with acre-inches then calculated from that information. Working to get flow meters universally required within district
			X					Reporting required, provided by meters read on site
			X					Reporting required, provided by meters read on site, called Friday, May 9th
Nevada								
New Hampshire							X	Monthly Online Reporting Process
New Jersey								Quarterly or Annual Online Reporting Process

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
New Mexico				X				Separate Forms for Ground and Surface Water
New York							X	Monthly Reporting Due March 31 of Each Year. General Map (USGS) and Interbasin Diversions (if any) also required
North Carolina							X	Application and Reporting on the same form
North Dakota				X				Online Reporting
Ohio							X	Annual Reporting
Oklahoma				X				Water is Pre-Allocated, Report is only to verify
Oregon	X			X			X	October through September of following year (Annual) reporting
Pennsylvania							X	Online Annual Reporting from Jan to Dec, Unable to acquire screenshots, but have sample Subfacility Report
Rhode Island							X	Only major water suppliers (50million gallons/year or more) are required to report. Agricultural needs are pre-estimated and privately verified by consumers *See email in State file*
South Carolina							X	Actual Reporting Forms mailed strictly to water-rights holders, but requirements visible in other documents.
South Dakota			X				X	Monthly/Annual Reporting due by December 2 of each year
Tennessee							X	Daily Averages Annual Report due by March 1 of each year
Texas							X	Municipal Water Use Survey due December 31 of each year. Forms for Ground/Surface/Purchased/Self-Supplied available.
Utah		X		X	X		X	Annual Online Reporting when requested. Water is allocated and monitored.
Vermont							X	Daily/Monthly forms Annually submitted

State	Reporting Entity Water Rights Owner	Irrigation Usage (acre inches)			Irrigation Usage (Gallons used)			Notes
		Unit	Crop	Farm	Unit	Crop	Farm	
Virginia	X						X	Online Reporting available, Monthly/Annual Withdrawal Amounts. Excess over 10,000 gallons/day is required to be reported, below that is voluntary
Washington	X			X			X	Online Reporting available. Reporting due by January 31 each year
West Virginia								Farmers and Irrigators are exempt from filling out both an application/permit and reporting water use in West Virginia
Wisconsin	X						X	Annual Reporting due March 1 for previous year, majority of information that would supplement the actual permitting process as is typical in most States is taken from the water reporting form instead.
Wyoming								Reporting not required

Appendix L

Sample Limited Irrigation Approved Yield Calculator

Inputs

State/County	Name/name	Sheridan/Kansas
State County FIPS	Code	20179
Irrigated Crop	Name	corn
Policy	XXXXXXXXXX	635297G
Unit	NNNN	1
Average rainfall from SPOI (inches)	num ₁	20.00
SD of rainfall from SPOI (inches)	num ₂	1.10
Irrigated reference yield from SPOI	num ₃	125
Non-irrigated reference yield from SPOI	num ₄	120
<i>Water applied to obtain APH historical values*</i>		
irrigation water applied previous harvest year (inches)	num ₅ *	8.0
irrigation water applied previous year-1 (inches)	num ₆ *	10.0
irrigation water applied previous year-2 (inches)	num ₇ *	9.0
irrigation water applied previous year-3 (inches)	num ₈ *	12.0
irrigation water applied previous year-4 (inches)	num ₉ *	12.0
irrigation water applied previous year-5 (inches)	num ₁₀ * or blank	13.0
irrigation water applied previous year-6 (inches)	num ₁₁ * or blank	13.0
irrigation water applied previous year-7 (inches)	num ₁₂ * or blank	
irrigation water applied previous year-8 (inches)	num ₁₃ * or blank	
irrigation water applied previous year-9 (inches)	num ₁₄ * or blank	
Approved yield from APH History in appropriate units	num ₁₅ *	180
Water to be applied this year (inches)	num ₁₇ *	6.5
Other Changes to irrigation practices list:	enter yes or no enter changes already implemented in irrigation practices other than amount of water applied	yes Lowered sprinkler heads into canopy, Changed timing of application, Changed variety to drought tolerant
Qualified changes to irrigation practices	check against approved list and enter yes or no	yes
Acceptable documentation of irrigation water applied	check against standards and enter yes or no	yes

*best estimate if necessary or blank

Outputs

Count of irrigation records	returns count	7
average irrigation water applied (inches)	returns average	11
Keep irrigated approved yield without changes	returns yes or no	no
Limited Irrigation Approved Yield	returns value or " "	154
Change practice to non-irrigated	returns yes or " "	
Approved yield for non-irrigated	returns value or " "
