Figure 7-82. Symbols for AES Encryption

The following description applies to all KMA-GCM-AES functions. A sequence of operations is performed, depending on the flags and function code in general register 0, as follows:

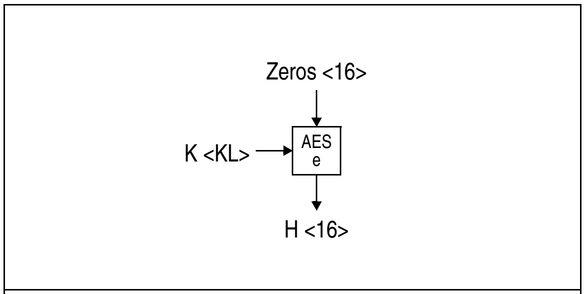
Wrapping-Key Verification: For the KMA-GCM-encrypted-AES functions (function codes 26-28), the contents of the 32-byte $\mathrm{WK_aVP}$ field are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of the key field of the parameter block are deciphered using the AES wrapping key to obtain the cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-431 for details.)

For the KMA-GCM-AES functions that do not use encrypted keys (codes 18-20), wrapping-key verification is not performed.

Computing the Hash Subkey: A hash subkey is used in the GHASH processing to produce the resulting message-authentication tag. GHASH processing is described in Reference [17.] on page xxx.

For KMA-GCM-AES functions (function codes 18-20), the following applies:

- When the hash-subkey-supplied flag (HS, bit 53 of general register 0) is zero, a block of 128 binary zeros is encrypted using the AES algorithm described in Reference [14.] on page xxx. The AES algorithm uses the key (K) field from the parameter block, as shown in Figure 7-83, below.



Symbol	Explanation
<n>	Length of item in bytes
H	Hash subkey.
K	Key value.
KL	Key length (see Figure 7-79).

Figure 7-83. Encrypting the Hash Subkey

The resulting 128-bit hash subkey is placed into the H field of the parameter block, and the HS flag is set to one in general register 0.

- When the HS flag is one, the H field in the parameter block is used as the hash subkey. In this case, the H field and HS flag are not altered.

For KMA-GCM-encrypted-AES functions (function codes 26-28), the HS flag is ignored. A block of 128 binary zeros is always encrypted using the AES algorithm as shown in Figure 7-83, using the decrypted key (K). In this case, the H field of the parameter block and the HS flag are not altered.

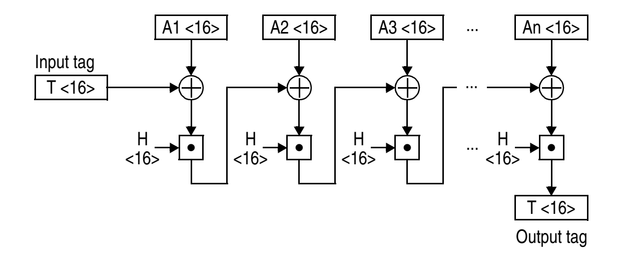
Additional-Authenticated-Data (AAD) Hashing: AAD hashing is not performed when either of the following conditions apply. In either of these conditions, general registers R_3 and R_3+1 are not modified, and it is model dependent whether the T field in the parameter block is fetched and stored back unmodified.

- The third-operand length in general register R_3 + 1 is initially less than 16, and the last-AAD flag (LAAD, bit 54 of general register 0) is zero. In this case, the instruction completes by setting condition code 2.

- The third-operand length is initially zero, and the LAAD flag is one. In this case, processing continues as described in “Ciphering and Hashing” on page 7-85.

When the third-operand length in general register R_3 + 1 is nonzero, additional-authenticated-data hashing is performed. In this case, general register R_3 contains the address of a storage location containing data from which a message-authentication tag is computed using the GHASH algorithm described in Reference [17.] on page xxx. In addition to the blocks of the third operand, the GHASH function uses the hash subkey (described above) and the tag field in the parameter block as input values.

The result is obtained as if processing starts at the left end of the third operand and proceeds to the right, block by block. When one or more full 16-byte blocks of AAD remain, the processing is illustrated in Figure 7-84.



Symbol	Explanation
<n>	Length of item in bytes
An	Block n of additional authenticated data (third operand).
H	Hash subkey
T	Message-authentication tag (in the parameter block).

Figure 7-84. GHASH Processing of Full Blocks.

The AAD-hashing process ends when any of the following is true:

- A CPU-determined number of blocks that is less than the length of the third operand has been processed. In this case, the message-authentication tag computed thus far is placed into the T field of the parameter block, general register R_3 is incremented by the number of third-operand bytes processed, general register R_3 + 1 is decremented by the same amount, and the instruction completes by setting condition code 3.

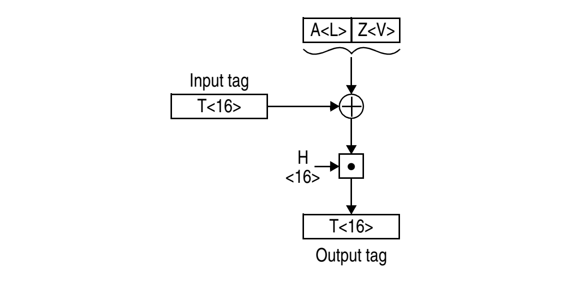
- The last-AAD flag (LAAD, bit 54 of general register 0) is zero, and number of bytes remaining in the third operand is less than 16. In this case, the message-authentication tag computed thus far is placed into the T field of the parameter block, general register R_3 is incremented by the number of third-operand bytes processed (if any), general register R_3 + 1 is decremented by the same amount, and the instruction completes by setting condition code 2.

- The LAAD flag is one, and the number of bytes remaining in the third operand is between 1 and 15. In this case, the following is performed:

  – A copy of the remaining short block is padded on the right with sufficient binary zeros to form a full block that is hashed using GHASH.

  – General register R_3 is incremented by the number of third-operand bytes processed, and the third-operand length in general register R_3 + 1 is set to zero.

Processing of the last block of the third operand is illustrated in Figure 7-85.



Symbol	Explanation
<n>	Length of item in bytes
A	Last (short) block of additional authenticated data (in the third operand).
H	Hash subkey
L	Length of last 3rd-operand block in bytes (between 1 and 15).
T	Message-authentication tag (in the parameter block).
V	Number of bytes of zeros to pad the last block: 16 – L.
Z	Zeros.

Figure 7-85. GHASH Processing of Last (Short) Block

- The LAAD flag is one and the number of bytes remaining in the third operand is zero.

For either of the above two cases (when the LAAD flag is one), it is model dependent whether the instruction completes with condition code 3, or processing continues with the ciphering and hashing of the second operand, as described below.

Ciphering and Hashing: The ciphering-and-hashing process is not performed when either of the following conditions apply. In either of these conditions, general registers R_1, R_2, and R_2+1 are not modified, and it is model dependent whether the CV and T fields in the parameter block are fetched and stored back unmodified.

- The second-operand length in general register R_2 + 1 is initially less than 16, and the last-plaintext/ciphertext flag (LPC, bit 55 of general register 0) is zero. In this case, the instruction completes by setting condition code 2.
- The second-operand length is initially zero, and the LPC flag is one. In this case, processing continues as described in “Last Message-Authentication-Tag Hashing and Encryption” on page 7-87.

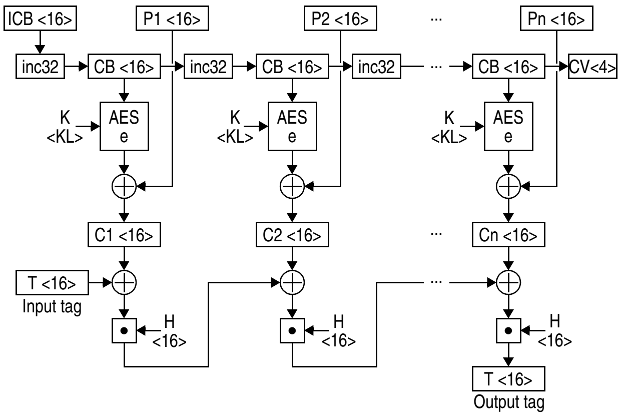
Depending on the M bit (bit 56 of general register 0), each block of the second operand is either encrypted or decrypted using the GCTR function described in Reference [17.] on page xxx. The respective encrypted or decrypted result is placed at the first-operand location, and the encrypted operand is hashed using the GHASH function. The combination of the GCTR and GHASH processing is described as the GCM function in Reference [17.] on page xxx.

Conceptually, the result is obtained as if processing starts at the left end of the first and second operands and proceeds to the right, block by block, as illustrated in Figure 7-86 and Figure 7-87. However, depending on the model, a unit of operation may process multiple blocks of the first and second operands in parallel; thus, the blocks may not necessarily be accessed in left-to-right order. Furthermore, multiple accesses may be made to a block, and in the case of the encryption operation, a first-operand block may be re-fetched after it is stored.

The GCTR function uses a 16-byte initial-counter block (ICB) formed from the concatenation of the leftmost 12 bytes of the initial-counter-value (J_0) on the left with the four-byte counter value (CV) on the right. GCTR also uses the key field (either directly from the parameter block for the KMA-GCM-AES functions, or the decrypted key for the KMA-GCM-encrypted-AES functions). For each block that is ciphered by GCTR, the counter value (CV) is incremented by one; a carry out of bit position 0 of the counter value is ignored. The GCTR function then uses a 16-byte counter block (CB) formed from the leftmost 12 bytes of J_0 concatenated with the incremented counter value.

The GHASH function uses the encrypted data (that is, the encrypted first-operand result when M is 0 or the second operand when M is one), the tag (T) field from either the parameter block or from the preceding step, and the hash subkey.

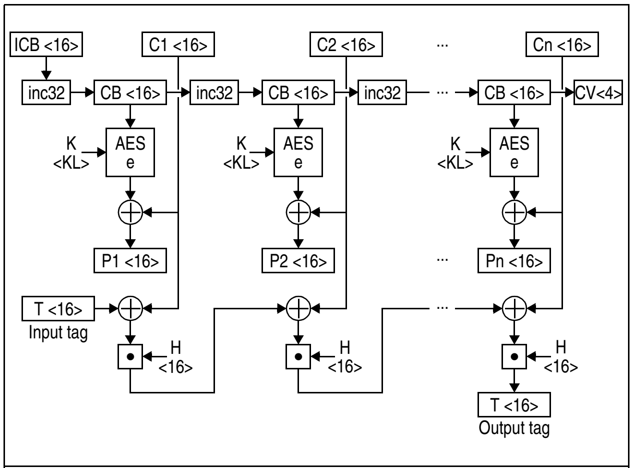
When the M bit is zero (that is, when the second operand is being encrypted), GCM processing of full blocks is illustrated in Figure 7-86.



Symbol	Explanation
<n>	Length of item in bytes
CB	Counter block formed from the concatenation of the leftmost 12 bytes of J_0 with the incremented counter value (CV)
Cn	Block n of the ciphertext (first operand).
CV	Counter value stored into the parameter block.
H	Hash subkey.
ICB	Initial counter block comprising the leftmost 12 bytes of the initial-counter value (J_0) concatenated with the 4-byte counter value (CV).
inc32	Incrementing of the 32-bit counter value (CV); a carry out of the leftmost bit position is ignored.
K	Key value.
KL	Key length (see Figure 7-79).
Pn	Block n of the plaintext (second operand).
T	Message-authentication tag (in the parameter block).

Figure 7-86. Combined Ciphering and Hashing of Full Blocks for Encryption

When the M bit is one (that is, when the second operand is being decrypted), GCM processing of full blocks is illustrated in Figure 7-87.



Explanation

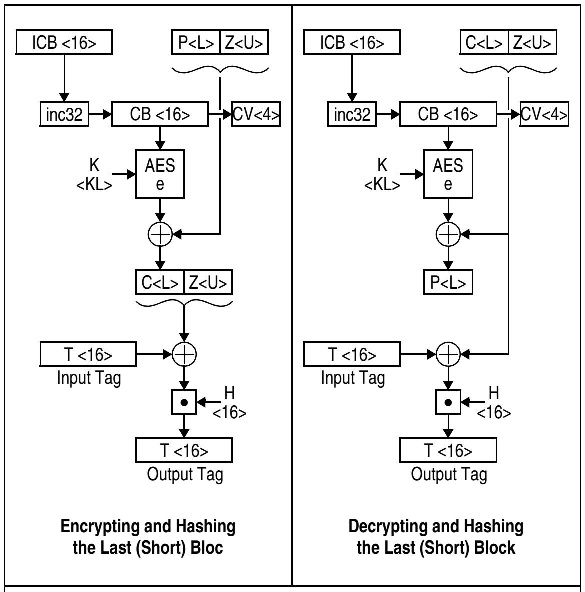
Cn Block n of the ciphertext (second operand).
Pn Block n of the plaintext (first operand).
Other symbols are the same as in Figure 7-86.

Figure 7-87. Combined Ciphering and Hashing of Full Blocks for Decryption

The ciphering-and-hashing process for either encryption or decryption continues until any of the following is true:

- A CPU-determined number of blocks that is less than the length of the second operand has been processed. In this case, the current counter value is placed into the CV field of the parameter block, the message-authentication tag computed thus far is placed into the T field of the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed, general register $R_2 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 3.
- The last-plaintext/ciphertext flag (LPC, bit 55 of general register 0) is zero, and number of bytes remaining in the second operand is less than 16. In this case, the current counter value is placed into the CV field of the parameter block, the message-authentication tag computed thus far (if any) is placed into the T field of the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed (if any), general register $R_2 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 2.
- The LPC flag is one, and the number of bytes remaining in the second operand is between 1 and 15. In this case, the following is performed:
  - A copy of the remaining bytes of the second operand is padded on the right with sufficient binary zeros to form a full block that is ciphered using the GCTR algorithm, and the leftmost bytes of the resulting encrypted or decrypted block are placed at the first-operand location. The number of bytes placed at the first-operand location is the same as the number of bytes remaining in the second operand (that is, less than 16).
  - The GHASH algorithm is then applied to the ciphertext. When M is zero, the input to the GHASH algorithm consists of a copy of the short block stored into the first-operand location, padded on the right with sufficient binary zeros to form a full block. When M is one, the input to the GHASH algorithm is the same as the input to the GCTR algorithm (that is, a copy of the remaining bytes of the second operand, padded on the right with sufficient binary zeros to form a full block).
  - The current counter value is placed into the CV field of the parameter block, the resulting tag value is placed in the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed, and general register $R_2 + 1$ is set to zero.

GCM processing of the last block of the second operand is illustrated in Figure 7-88.



Symbol	Explanation
<n>	Length of item in bytes
CB	Counter block formed from the concatenation of the leftmost 12 bytes of J_0 with the incremented counter value (CV)
C	Last (short) block of the ciphertext (first operand when M=0, second operand when M=1).
CV	Counter value (in the parameter block)
H	Hash subkey
ICB	Initial counter block comprising the leftmost 12 bytes of the initial-counter value (J_0) concatenated with the 4-byte counter value (CV).
inc32	Incrementing of the 32-bit counter value (CV); a carry out of the leftmost bit position is ignored.
K	Key value.
KL	Key length (see Figure 7-79).
L	Length of last second-operand block in bytes (between 1 and 15).
P	Last (short) block n of the plaintext (second operand when M=0, first operand when M=1).
T	Message-authentication tag (in the parameter block).
U	Number of bytes of zeros to pad the last block: 16 – L.
Z	Zeros.

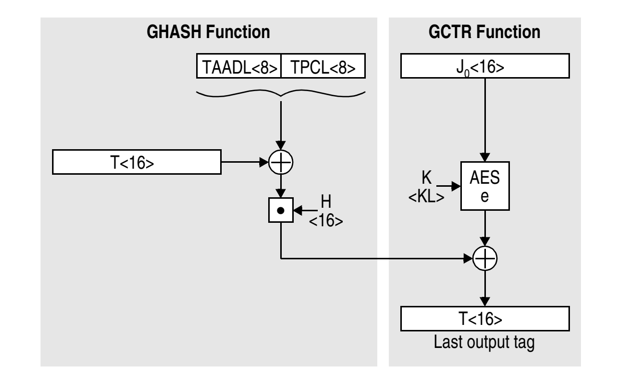
Figure 7-88. Ciphering and Hashing of the Last (Short) Block.

- The LPC flag is one, and the number of bytes remaining in the second operand is zero.

For either of the above two cases (when the LPC flag is one), it is model dependent whether the instruction completes with condition code 3 or continues processing with the last message-authentication-tag hashing and encryption, as described below.

Last Message-Authentication-Tag Hashing and Encryption: A 128-bit value comprising the concatenation of the 64-bit total-AAD-length (TAADL) and total-plaintext-or-ciphertext-length (TPCL) fields from the parameter block is hashed using the GHASH function. The GHASH function uses the concatenated lengths field, the tag (T) field as computed in the ciphering-and-hashing operation, and the hash subkey.

The resulting 128-bit output of GHASH is then processed by the GCTR algorithm. Note, unlike the ciphering-and-hashing operation, the input counter to GCTR is the initial-counter-block (J_0) field from the parameter block. The resulting 128-bit value replaces the tag (T) field in the parameter block, and the instruction completes with condition code 0. Figure 7-89 illustrates the hashing and encryption of the last tag value.



Symbol	Explanation
<n>	Length of item in bytes
H	Hash subkey
J_0	Initial counter value (from the parameter block)
K	Key value.
KL	Key length (see Figure 7-79).
T	Message-authentication tag (in the parameter block).
TAADL	Total length of the message’s additional-authenticated data (AAD) in bits (from the parameter block).
TPCL	Total length of the message’s plaintext or ciphertext in bits (from the parameter block).

Figure 7-89. Hashing and Encrypting the Last Tag

Common Operation: The detection of conditions resulting in condition code 3 depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The results are unpredictable if either of the following is true:

- The third operand overlaps destructively with any portion of the parameter block that may be updated during AAD processing.
- The LAAD flag is one, and any of the following is true:
  - The second operand overlaps destructively with any portion of the parameter block that may be updated during ciphering and hashing.
  - The first operand overlaps destructively with any portion of the parameter block that may be accessed during ciphering and hashing.
  - The first operand overlaps destructively with the second operand, but the operands do not designate the same location.

Operands are said to overlap destructively when a location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right.

Figure 7-90 illustrates the various condition codes set by the instruction, and the resulting second- and third-operand lengths based on the LAAD and LPC flags.

Condition Code	LAAD	LPC	3rd-operand length	2nd-operand length
0	1	1	0	0
1	—	—	Unchanged†	Unchanged†
2	0	—	< 16	Unchanged
	1	0	0	< 16
3	0	—	>= 16	Unchanged
	1	0	0	>= 16
	1 ‡	1 ‡	0 ‡	0 ‡

Explanation:

— Not applicable

† Also, first-, second-, and third-operand addresses in general registers R_1, R_2, and R_3 are unchanged

‡ It is model dependent whether CC3 is set for these conditions (which are identical to the CC0 conditions).

LAAD Last-additional-authenticated-data flag, bit 54 of general register 0

LPC Last-plaintext/ciphertext flag, bit 55 of general register 0

Figure 7-90. Condition Codes and Resulting Operand Lengths, based on LAAD and LPC

Store-type access exceptions may be recognized for any location in the parameter block, even though only the CV, T, and H fields are actually stored by the instruction.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first-, second-, and third-operand locations and for the parameter block (including the reserved field of the parameter block). When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

It is unpredictable how many bytes of the first-, second-, or third-operand locations has been processed when a PER storage-alteration event is recognized for the parameter block. When a storage-alteration PER event is recognized for the first-operand location, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the third-operand length is initially zero, the third operand is not accessed, and the third-operand address and third-operand length in general registers R_3 and $R_3 + 1$, respectively, are not changed. When the second-operand length is initially zero, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. However, the parameter block may be accessed even when the second- and third-operand lengths are both zero.

When the contents of the R_1 and $R_{2,}$ fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by a multiple of the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers to reflect the last unit of the first, second, and third operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage; and the portion of the first and third operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first, second, and third operands when the comparison results in a mismatch and respective operand's length is nonzero.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Special Conditions for KMA

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 $R_{2,}$ or R_3 field designates an odd-numbered register or general register 0.
3. The R_3 field designates the same register as either the R_1 or R_2 fields.
4. The function code is nonzero, and the LPC flag is one (indicating that the last blocks of plaintext or ciphertext are being processed), but the LAAD flag is zero (indicating that not all AAD has been processed).

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Incomplete processing (remaining third-operand length is less than 16 when the LAAD flag is zero, or remaining second-operand length is less than 16 when the LPC flag is zero)
3 Partial completion (model-dependent limit exceeded)

Program Exceptions:

- Access (fetch, operand 2, operand 3, parameter block fields; store, operand 1, counter value, hash subkey, tag)
- Operation (if the message-security-assist extension 8 is not installed)
- Specification
- Transaction constraint

1.-7.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to LPC flag being one when the LAAD flag is zero (applicable only when the function code is nonzero).
10.A.1	Access exceptions for an access to the parameter block.
10.A.2.	Condition code 1 due to verification-pattern mismatch.
10.B	Access exceptions for an access to the first, second, or third operand.
11.	Condition code 3 due to partial processing of the third operand.
12.	Condition code 2 due to the remaining third-operand length being less than 16 when the LAAD flag is zero.
13.	Condition code 3 due to partial processing of the second operand.
14.	Condition code 2 due to remaining second-operand length being less than 16 when the LPC flag is zero.
15.	Condition code 0 due to normal completion.

Figure 7-91. Priority of Execution: KMA

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a

function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

3. When processing an individual message, the program should initially set the following fields in the parameter block and not alter these fields until the instruction completes with condition code 0; otherwise, the results will not conform to the GCM standard, as described in Reference [17.] on page xxx.

   a. *Counter Value (CV):* The CV field should be initialized with the rightmost 4 bytes of the initial-counter-value (J_0) field.

   b. *Tag (T):* The tag field should be initialized to zeros.

   c. *The Hash Subkey (H):* For KMA-GCM-AES functions (codes 18-20), the following applies:

      - When the HS flag is one, the program supplies a pre-computed hash subkey in the H field. The subkey comprises 16 bytes of zeros, encrypted using the AES algorithm.

      - When the HS flag is zero, the CPU encrypts 16 bytes of zeros using the AES algorithm and key field in the parameter block, stores the results in the H field, and sets the HS flag to one.

      For KM-GCM-encrypted-AES functions (codes 26-28), the CPU always calculates the hash subkey, and the H field and HS flags are not altered.

   d. *Initial-Counter Value (J_0):* The initial-counter value is derived from an initialization vector (IV) provided by the program. If the program uses a 96-bit IV (as recommended in Reference [17.] on page xxx), then it should store the IV into the leftmost 12 bytes of the J_0 field, and store 00000001 hex in the rightmost bytes of the J_0 field. If the program uses an IV having a different length, then it must supply a 16-byte hashed value of the IV in the J_0 field using the GHASH algorithm (as described in Reference [17]).

   e. *Key Value (K) and Wrapping-Key Verification Pattern (WK_aVP):* For proper ciphering of an individual message, the key must be the same for all executions of the instruction. For KM-encrypted-AES functions, the wrapping-key-verification-pattern field must also remain unchanged.

4. When processing the last plaintext or ciphertext block(s) (that is, when the LPC flag is one), the total-AAD-length (TAADL) and total-plaintext/ciphertext-length (TPCL) fields in the parameter block should contain the total length in bits of the respective AAD and plaintext or ciphertext for the entire message.

5. The program is responsible for comparing the hashed tag of a decrypted message with that of the message when it was encrypted to ensure authenticity of the message.

6. The LAAD and LPC flags provide the means by which a message can be ciphered and hashed when not all components of the message are available for a single execution of the instruction. For example, if the plaintext or ciphertext portion of a message spans multiple disk or tape records, and not all blocks of the message have been read into storage, the program can process the earlier blocks of the message by issuing the instruction with the LPC flag set to zero. When the final plaintext or ciphertext blocks of the message are available, the program can then complete the message ciphering by issuing the instruction with the LPC flag set to one.

   When condition code 2 is set due to either or both the LAAD or LPC flag being zero, the general registers containing the operand addresses and lengths, and the parameter block are updated to indicate the progress thus far. However, unlike condition code 3 (where the program can simply branch back to the instruction to continue the operation), the program is responsible for updating the operand addresses and lengths, and the LAAD and LPC flags, as necessary, before branching back to the instruction. If the program simply branches back to the instruction in response to condition code 2, a nonproductive program loop will result.

7. When condition code 3 is set, the general registers containing the operand addresses and lengths, and the parameter block, are usually updated such that the program can simply branch back to the instruction to continue the operation.

CIPHER MESSAGE WITH CIPHER FEEDBACK

KMF R_1,R_2 [RRE]

'B92A'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are ignored.

Bit positions 32-39 of general register 0 contain the length of cipher feedback in bytes (LCFB, also known as “s”), and bit positions 57-63 of general register 0 contain the function code. Figure 7-92 shows the assigned function codes for CIPHER MESSAGE WITH CIPHER FEEDBACK. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. Bits 0-31 and 40-55 of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH CIPHER FEEDBACK are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size[1] (bytes)
0	KMF-Query	16	—
1	KMF-DEA	16	8
2	KMF-TDEA-128	24	8
3	KMF-TDEA-192	32	8
9	KMF-Encrypted-DEA	40	8
10	KMF-Encrypted-TDEA-128	48	8
11	KMF-Encrypted-TDEA-192	56	8
18	KMF-AES-128	32	16
19	KMF-AES-192	40	16
20	KMF-AES-256	48	16
26	KMF-Encrypted-AES-128	64	16
27	KMF-Encrypted-AES-192	72	16
28	KMF-Encrypted-AES-256	80	16

Explanation:

[1] The size of ciphertext and plaintext segments (s) range from 1 to the data-block size, depending on the value of the LCFB in bits 32-39 of general register 0.

— Not applicable

Figure 7-92. Function Codes for CIPHER MESSAGE WITH CIPHER FEEDBACK

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and an initial chaining value in the parameter block, and the result is placed in the first-operand location. The chaining value is updated as part of the operation.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first and second operands is specified by the contents of the R_1 and R_2 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$ and must be a multiple of the cipher-feedback length in bits 32-39 of general register 0; otherwise, a specification exception is recognized. The first operand is the same length as the second operand.

As part of the operation, the addresses in general registers R_1 and R_2 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1 and R_2, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, and $R_2 + 1$, always remain unchanged.

Figure 7-93 on page 7-92 shows the contents of the general registers just described.

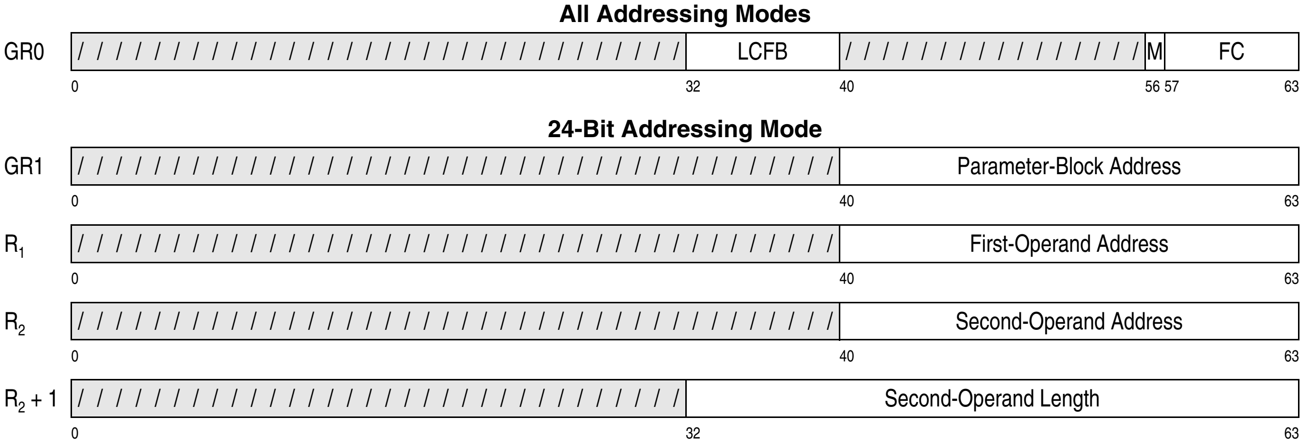


Figure 7-93. General Register Assignment for KMF (Part 1 of 2)

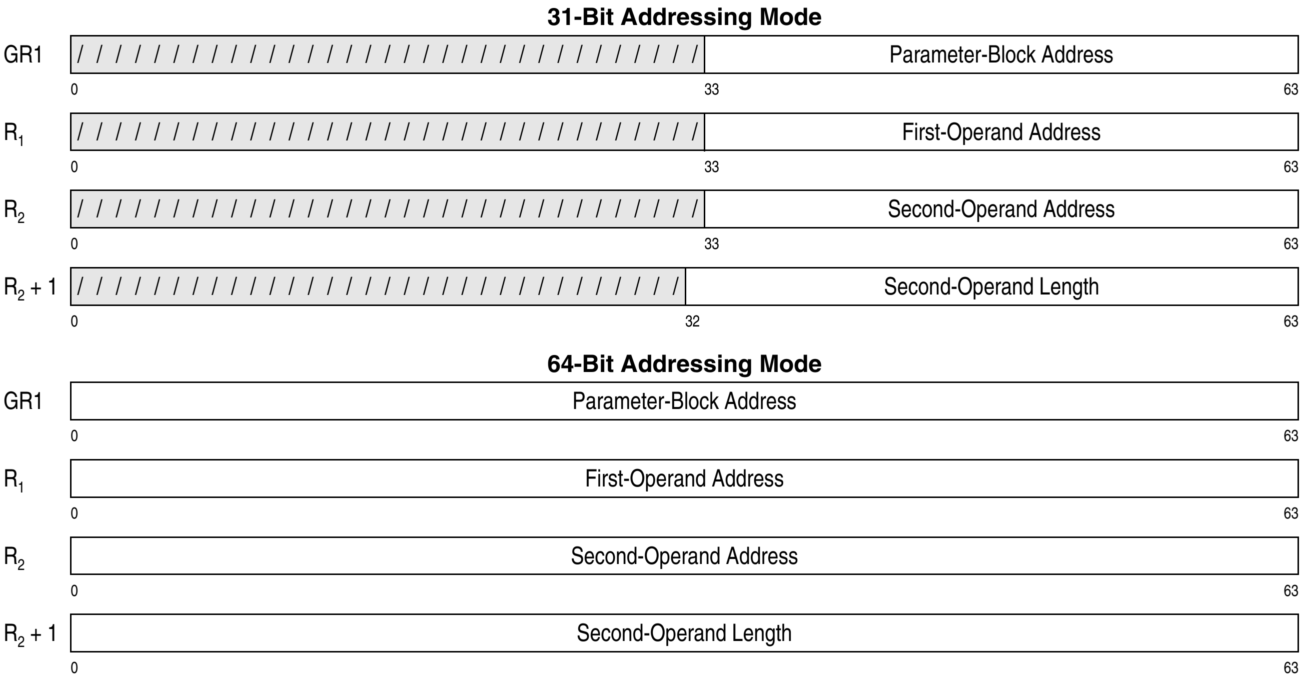

Figure 7-93. General Register Assignment for KMF (Part 2 of 2)

In the access-register mode, access registers 1, R$_1$, and R$_2$ specify the address spaces containing the parameter block, first, and second operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The operation is ended when the number of bytes in the second operand as specified in general register R$_2$ + 1 have been processed and placed at the first-operand location (called normal completion) or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The results in the first-operand location and the chaining-value field are unpredictable if any of the following situations occur:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The chaining-value field overlaps any portion of the first operand or the second operand.
3. The first and second operands overlap destructively. Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in R$_2$ + 1 is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in R$_2$ + 1 is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- and second-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the parameter block, first, and second operands are not accessed, general registers R_1, R_2, and $R_2 + 1$ are not changed, and condition code 0 is set.

When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by twice the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers and chaining value to reflect the last unit of the first and second operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH CIPHER FEEDBACK functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxx. Further description of the AES standard may be found in Reference [14.] on page xxx. Further description of the cipher-feedback mode of encryption and decryption may be found in Reference [16.] on page xxx.

KMF-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-93 on page 7-92.

The parameter block used for the function has the following format:

0	Status Word
8	
	0 63

Figure 7-99. Parameter Block for KMF-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH CIPHER FEEDBACK instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMF-Query function completes; condition codes 1 and 3 are not applicable to this function.

In the following function descriptions, the term *input block* refers to the 8- or 16-byte input to the DEA or AES algorithms, respectively. Similarly, the term *output block* refers to the 8- or 16-byte results from the respective algorithms. The term *segment* refers to the s-byte portions of the first and second operands.

KMF-DEA (Function Code 1)

KMF-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-93 on page 7-92.

The parameter block used for the KMF-DEA function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key (K)
	0 63

Figure 7-100. Parameter Block for KMF-DEA

For the KMF-DEA function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMF-Encrypted-DEA function has the following format:

0	Chaining Value (CV)
8	Encrypted Cryptographic Key (WK$_d$(K))
16	DEA Wrapping-Key Verification Pattern (WK$_d$VP)
24	
32	
	0 63

Figure 7-101. Parameter Block for KMF-Encrypted-DEA

For the KMF-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-431 for details.)

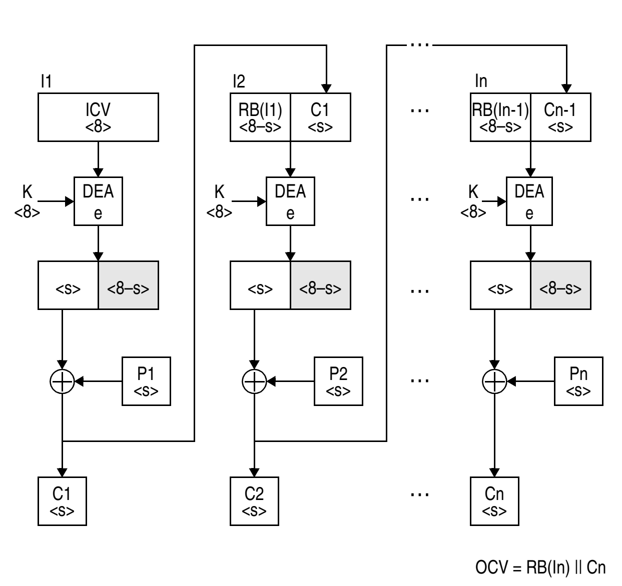
The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes (LCFB).

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-102.



Symbol	Explanation
||	Concatenation
Ij	Input block j to DEA
RB(Ij)	Rightmost (8-s) bytes of input block j
Note:	The rightmost (8–s) bytes of the output block from the DEA-encipher operation are ignored.

Figure 7-102. KMF-DEA Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-103.

Note:	The rightmost (8–s) bytes of the output block from the DEA-decipher operation are ignored.

Figure 7-103. KMF-DEA Decipher Operation

KMF-TDEA-128 (Function Code 2)

KMF-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-93 on page 7-92.

The parameter block used for the KMF-TDEA-128 function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key 1 (K1)
16	Cryptographic Key 2 (K2)

0 63

Figure 7-104. Parameter Block for KMF-TDEA-128

For the KMF-TDEA-128 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMF-Encrypted-TDEA-128 function has the following format:

0	Chaining Value (CV)
8 16	Encrypted Cryptographic Key (WK_d(K))
24 32 40	DEA Wrapping-Key Verification Pattern (WK_dVP)

0 63

Figure 7-105. Parameter Block for KMF-Encrypted-TDEA-128

For the KMF-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-106.

Figure 7-118. KMF-AES-192 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 192-bit cryptographic key and the 128-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (16 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (16 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-119.

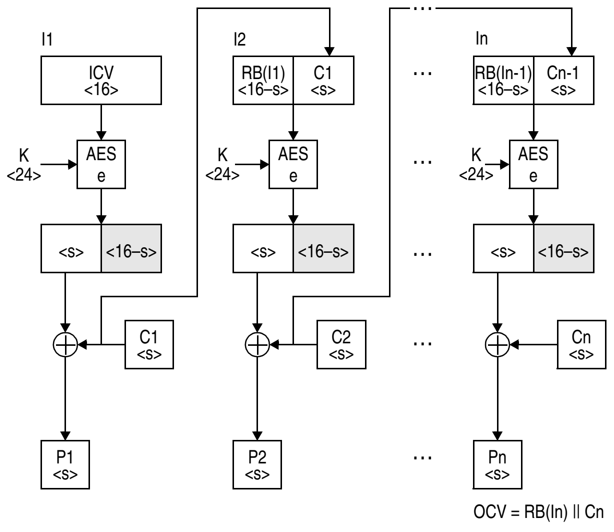

Figure 7-119. KMF-AES-192 Decipher Operation

Symbol	Explanation
||	Concatenation
Ij	Input block j to AES
RB(Ij)	Rightmost (16-s) bytes of input block j
Note:	The rightmost (16–s) bytes of the output block from the AES-decipher operation are ignored.

Figure 7-119. KMF-AES-192 Decipher Operation

KMF-AES-256 (Function Code 20)

KMF-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-93 on page 7-92.

The parameter block used for the KMF-AES-256 function has the following format:

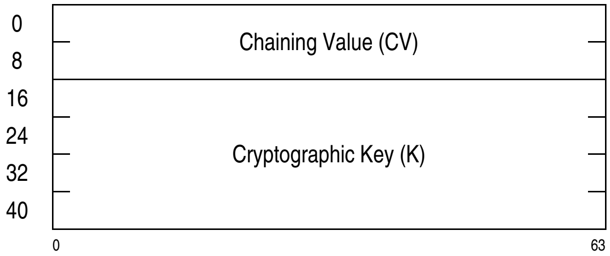

Figure 7-120. Parameter Block for KMF-AES-256

For the KMF-AES-256 function, the chaining value is in byte offset 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMF-Encrypted-AES-256 function has the following format:

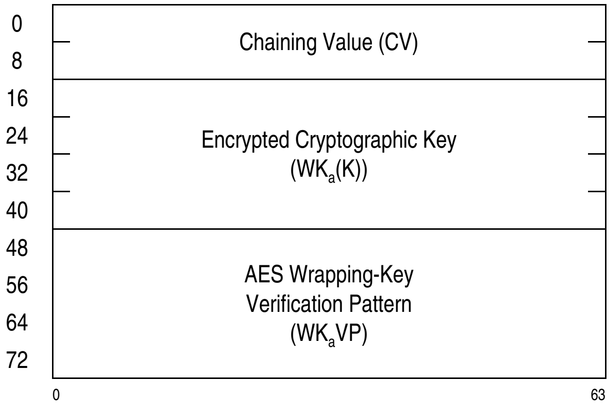

Figure 7-121. Parameter Block for KMF-Encrypted-AES-256

For the KMF-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

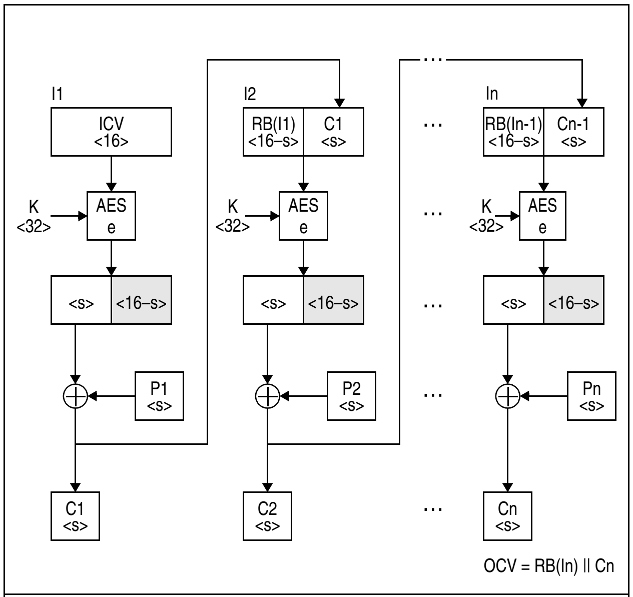
The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (16 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (16 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block.The operation is shown in Figure 7-122.



Symbol	Explanation
||	Concatenation
Ij	Input block j to AES
RB(Ij)	Rightmost (16-s) bytes of input block j
Note:	The rightmost (16–s) bytes of the output block from the AES-encipher operation are ignored.

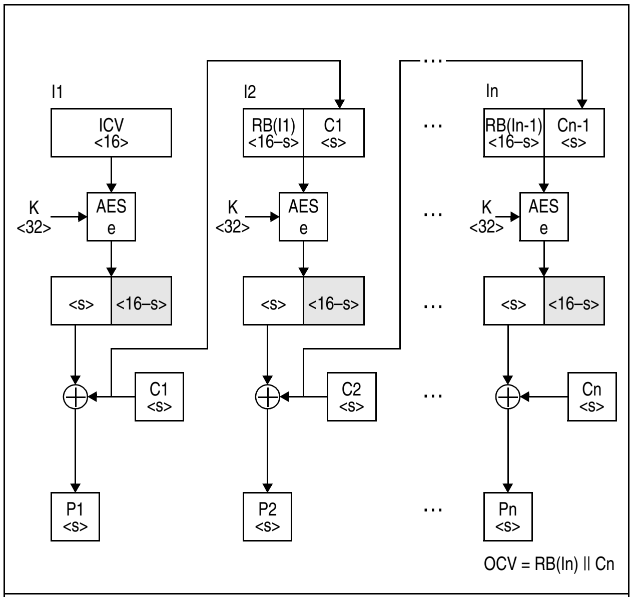
Figure 7-122. KMF-AES-256 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (16 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (16 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-123.



Symbol	Explanation
||	Concatenation
Ij	Input block j to AES
RB(Ij)	Rightmost (16-s) bytes of input block j
Note:	The rightmost (16–s) bytes of the output block from the AES-decipher operation are ignored.

Figure 7-123. KMF-AES-256 Decipher Operation

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. For DEA or TDEA functions, bits 32-39 of general register 0 specify a value that is zero or greater than 8.
2. For AES functions, bits 32-39 of general register 0 specify a value that is zero or greater than 16.
3. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
4. The R_1 or R_2 field designates an odd-numbered register or general register 0.
5. The second operand length is not a multiple of the length of cipher feedback. This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; store, operand 1; fetch and store, chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Condition code 0 due to second-operand length originally zero.
11.A.1	Access exceptions for an access to the parameter block.
11.A.2.	Condition code 1 due to verification-pattern mismatch.
11.B	Access exceptions for an access to the first, or second operand.
12.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).
13.	Condition code 3 due to partial completion (second-operand length still nonzero).

Figure 7-124. Priority of Execution: KMF

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. See the programming notes for CIPHER MESSAGE WITH CHAINING.

3. In earlier versions of the architecture, CIPHER MESSAGE WITH CIPHER FEEDBACK was known as CIPHER MESSAGE WITH CFB.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CIPHER MESSAGE WITH COUNTER

KMCTR R_1,R_3,R_2 [RRF-b]

‘B92D’	R_3	////	R_1	R_2
0	16	20	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 20-23 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-125 shows the assigned function codes for CIPHER MESSAGE WITH COUNTER. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH COUNTER are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMCTR-Query	16	—
1	KMCTR-DEA	8	8
2	KMCTR-TDEA-128	16	8
3	KMCTR-TDEA-192	24	8
9	KMCTR-Encrypted-DEA	32	8
10	KMCTR-Encrypted-TDEA-128	40	8
11	KMCTR-Encrypted-TDEA-192	48	8
18	KMCTR-AES-128	16	16
19	KMCTR-AES-192	24	16
20	KMCTR-AES-256	32	16
26	KMCTR-Encrypted-AES-128	48	16
27	KMCTR-Encrypted-AES-192	56	16
28	KMCTR-Encrypted-AES-256	64	16

Explanation:

— Not applicable

Figure 7-125. Function Codes for CIPHER MESSAGE WITH COUNTER

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, $R_2 + 1$, and R_3 are ignored for the query function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and counter values, and the result is placed in the first-operand location.

The R_1 and R_3 fields each designate a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first, second, and third operands is specified by the contents of the R_1, $R_{2,}$ and R_3 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand and the third operand are the same length as the second operand.

As part of the operation, the addresses in general registers $R_{1,}$ $R_{2,}$ and R_3 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers $R_{1,}$ $R_{2,}$ and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers $R_{1,}$ R_2, and R_3, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1, $R_{2,}$ and R_3 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers $R_{1,}$ R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers $R_{1,}$ R_2, and R_3, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers $R_{1,}$ $R_{2,}$ and R_3 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers $R_{1,}$ $R_{2,}$ and R_3 constitute the addresses of the first, second, and third operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers $R_{1,}$ R_2, and R_3, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first, second, and third operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first, second, and third operands; the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, $R_2 + 1$, and R_3 always remain unchanged.

Figure 7-126 on page 7-108 shows the contents of the general registers just described.

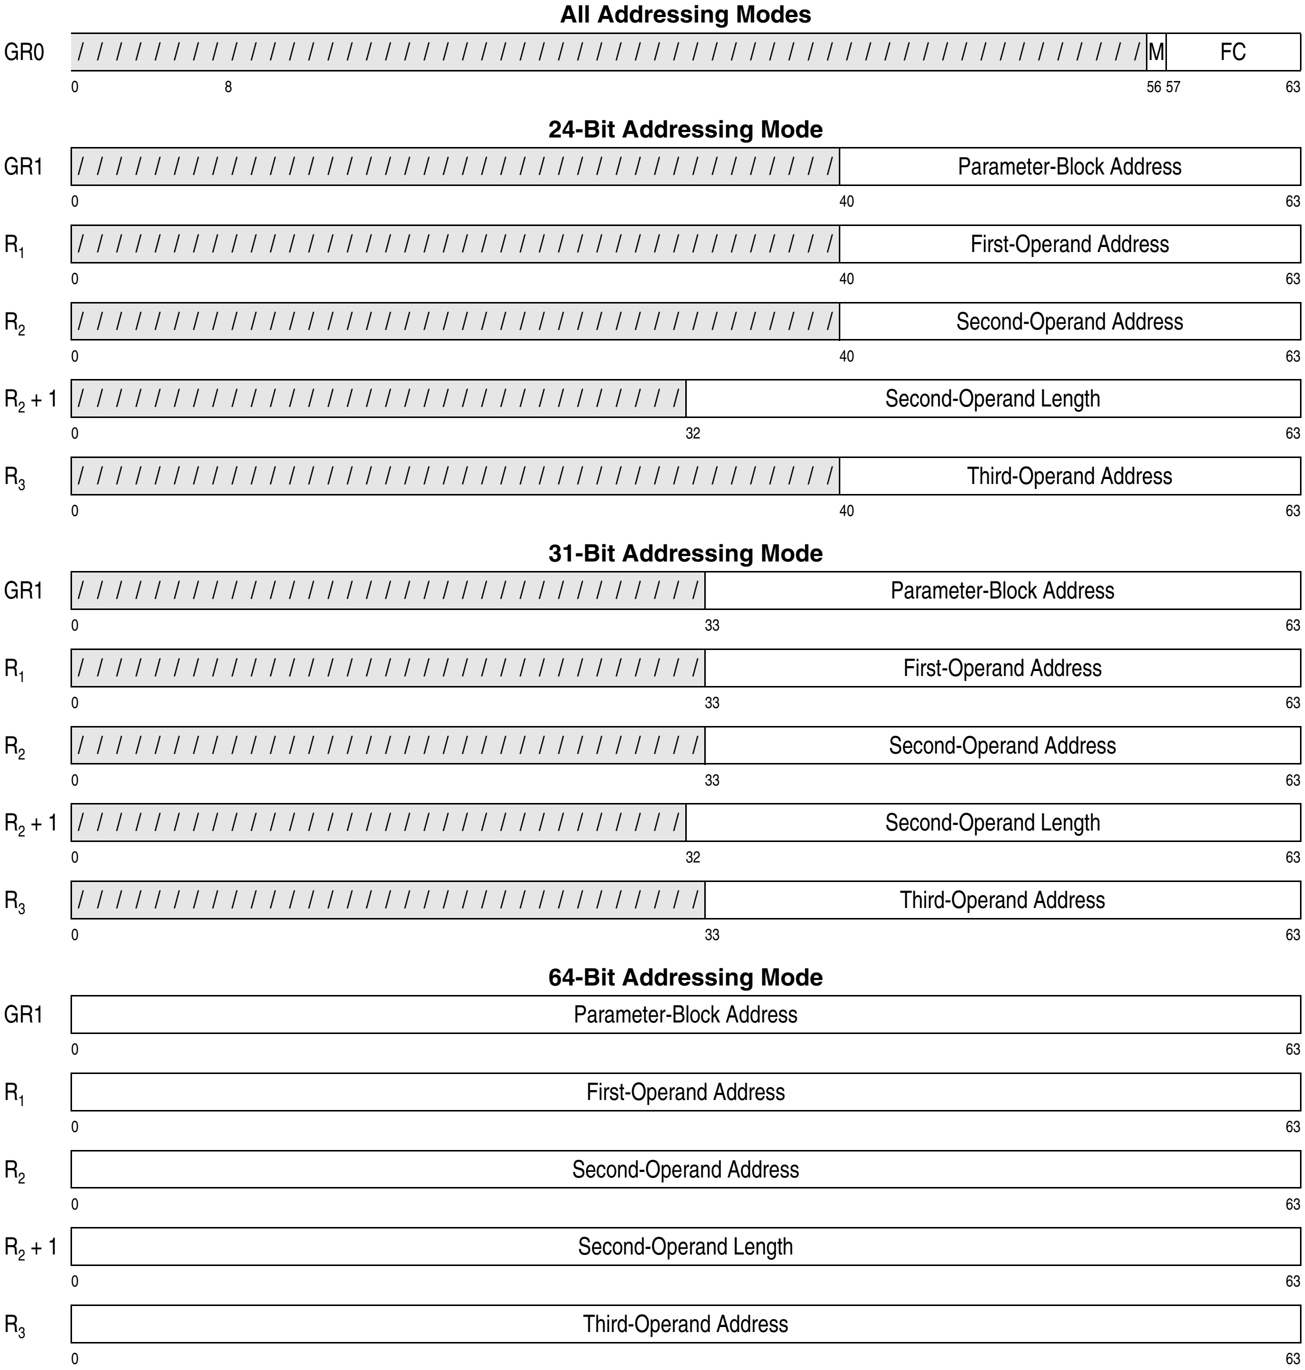


Figure 7-126. General Register Assignment for KMCTR

In the access-register mode, access registers 1, R_1, R_2, and R_3 specify the address spaces containing the parameter block, first, second, and third operands, respectively.

The result is obtained as if processing starts at the left end of the first, second, and third operands and proceeds to the right, block by block. The operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location (called normal completion) or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The results in the first-operand location are unpredictable if any of the following situations occurs:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The first and second operands overlap destructively.
3. The first and third operands overlap destructively.

Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- , second-, and third-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the parameter block, first, second, and third operands are not accessed, general registers R_1, R_2, $R_2 + 1$, and R_3 are not changed, and condition code 0 is set.

When the contents of any two or all three of the R_1, $R_{2,}$ and R_3 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by a multiple of the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers to reflect the last unit of the first, second, and third operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage; and the portion of the first and third operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first, second, and third operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH COUNTER functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxx. Further description of the AES standard may be found in Reference [14.] on page xxx. Further description of the counter mode of encryption and decryption may be found in Reference [16.] on page xxx.

KMCTR-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the function has the following format:

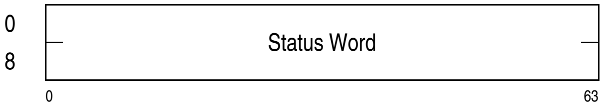

Figure 7-132. Parameter Block for KMCTR-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH COUNTER instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMCTR-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMCTR-DEA (Function Code 1)

KMCTR-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the KMCTR-DEA function has the following format:

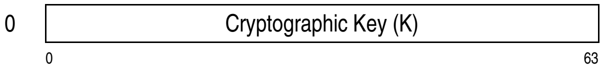

Figure 7-133. Parameter Block for KMCTR-DEA

For the KMCTR-DEA function, the cryptographic key is in byte offsets 0-7 of the parameter block.

The parameter block used for the KMCTR-Encrypted-DEA function has the following format:

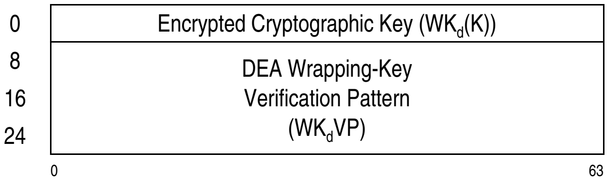

Figure 7-134. Parameter Block for KMCTR-Encrypted-DEA

For the KMCTR-Encrypted-DEA function, the contents of byte offsets 8-31 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-7 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA algorithm with the 64-bit cryptographic key and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-135.

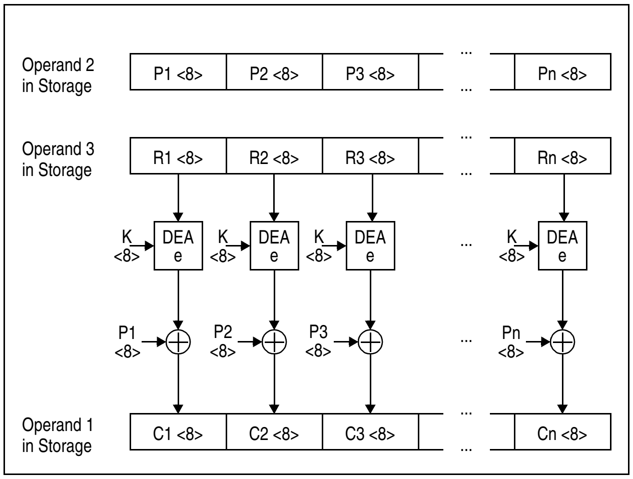

Figure 7-135. KMCTR DEA Encipher Operation Using 64-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA algorithm with the 64-bit cryptographic key and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-136.

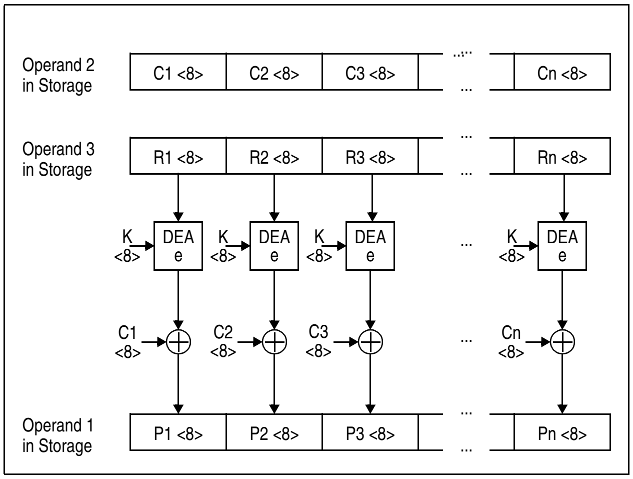

Figure 7-136. KMCTR DEA Decipher Operation Using 64-Bit Key

KMCTR-TDEA-128 (Function Code 2)

KMCTR-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the KMCTR-TDEA-128 function has the following format:

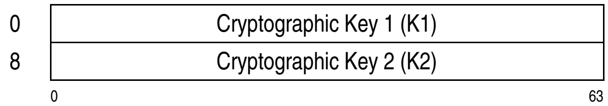

Figure 7-137. Parameter Block for KMCTR-TDEA-128

For the KMCTR-TDEA-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block.

The parameter block used for the KMCTR-Encrypted-TDEA-128 function has the following format:

Encrypted Cryptographic Key (WK$_d$(K))
DEA Wrapping-Key Verification Pattern (WK$_d$VP)
0
63

Figure 7-138. Parameter Block for KMCTR Encrypted-TDEA-128

For the KMCTR-Encrypted-TDEA-128 function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K = K1 || K2, where K1 is the leftmost 64 bits of K and K2 is the rightmost 64 bits of K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA (triple DEA) algorithm with the two 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-139.

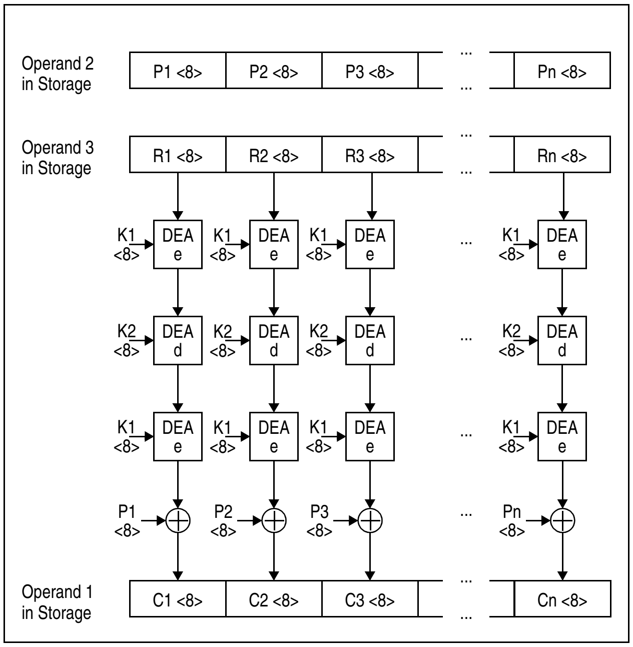

Figure 7-139. KMCTR TDEA Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the two 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-140.

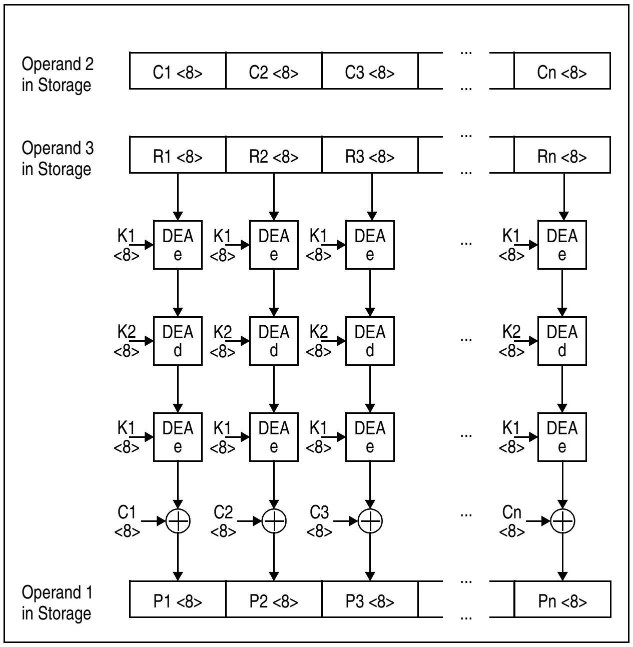

Figure 7-140. KMCTR TDEA Decipher Operation Using 128-Bit Key

KMCTR-TDEA-192 (Function Code 3)

KMCTR-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the KMCTR-TDEA-192 function has the following format:

0	Cryptographic Key 1 (K1)
8	Cryptographic Key 2 (K2)
16	Cryptographic Key 3 (K3)
	0 63

Figure 7-141. Parameter Block for KMCTR-TDEA-192

For the KMCTR-TDEA-192 function, the cryptographic key is in byte offsets 0-23 of the parameter block.

The parameter block used for the KMCTR-Encrypted-TDEA-192 function has the following format:

0 8 16	Encrypted Cryptographic Key ($WK_d(K)$)
24 32 40	DEA Wrapping-Key Verification Pattern (WK_dVP)
	0 63

Figure 7-142. Parameter Block for KMCTR-Encrypted-TDEA-192

For the KMCTR-Encrypted-TDEA-192 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K = K1 || K2 || K3, where K1 is the leftmost 64 bits of K, K2 is the middle 64 bits of K, and K3 is the rightmost 64 bits of K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA algorithm with the three 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-143.

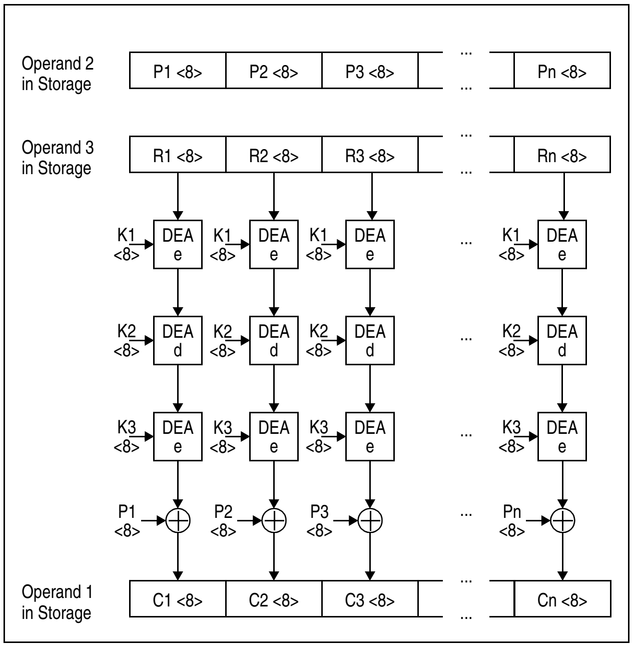

Figure 7-143. KMCTR TDEA Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the three 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-144.

If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 128-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-147.

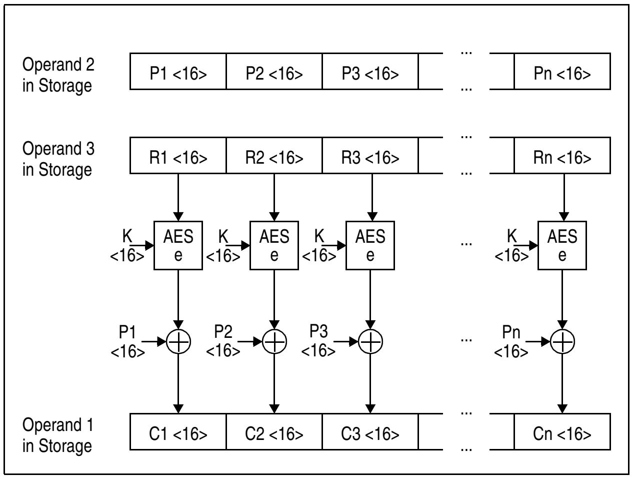

Figure 7-147. KMCTR AES Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 128-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-148.

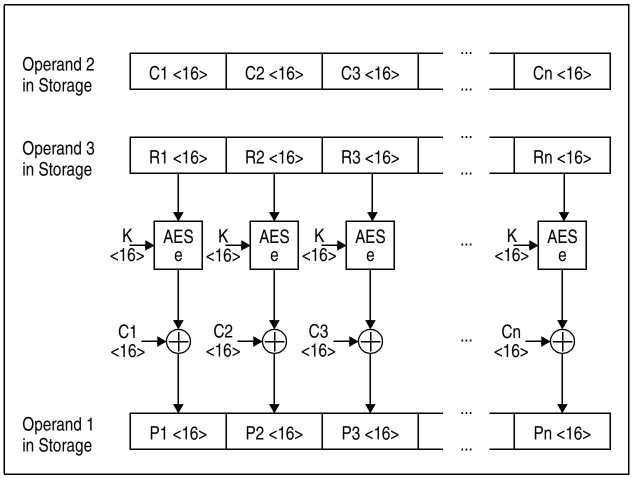

Figure 7-148. KMCTR AES Decipher Operation Using 128-Bit Key

KMCTR-AES-192 (Function Code 19)

KMCTR-Encrypted-AES-192 (Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the KMCTR-AES-192 function has the following format:

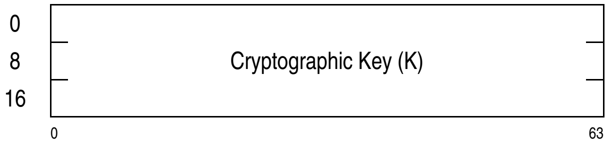

Figure 7-149. Parameter Block for KMCTR-AES-192

For the KMCTR-AES-192 function, the cryptographic key is in byte offsets 0-23 of the parameter block.

The parameter block used for the KMCTR-Encrypted-AES-192 function has the following format:

Figure 7-150. Parameter Block for KMCTR-Encrypted-AES-192

For the KMCTR-Encrypted-AES-192 function, the contents of byte offsets 24-55 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-23 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 192-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-151.

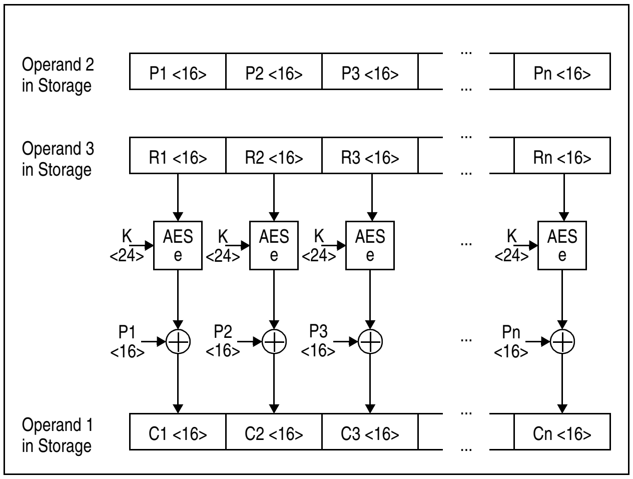

Figure 7-151. KMCTR AES Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 192-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown Figure 7-152.

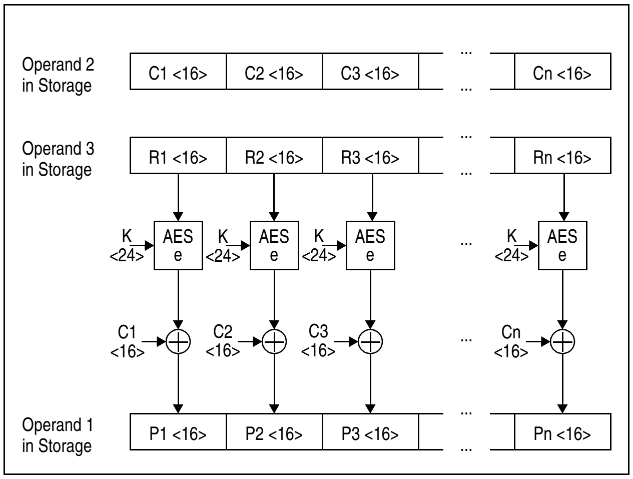

Figure 7-152. KMCTR AES Decipher Operation Using 192-Bit Key

KMCTR-AES-256 (Function Code 20)

KMCTR-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-126 on page 7-108.

The parameter block used for the KMCTR-AES-256 function has the following format:

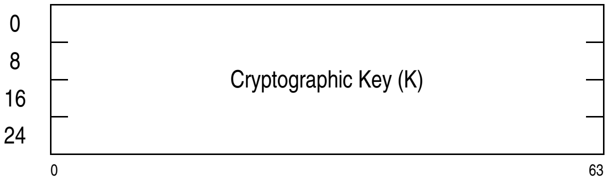

Figure 7-153. Parameter Block for KMCTR-AES-256

For the KMCTR-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block.

The parameter block used for the KMCTR-Encrypted-AES-256 function has the following format:

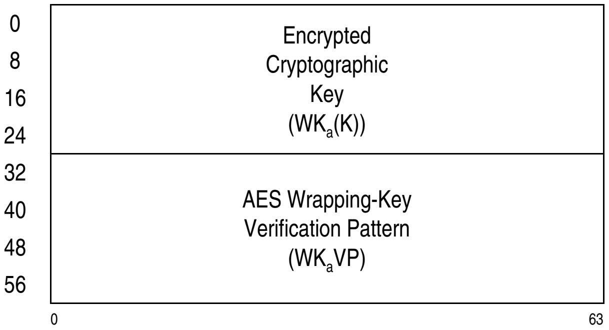

Figure 7-154. Parameter Block for KMCTR-Encrypted-AES-256

For the KMCTR-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 256-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-155.

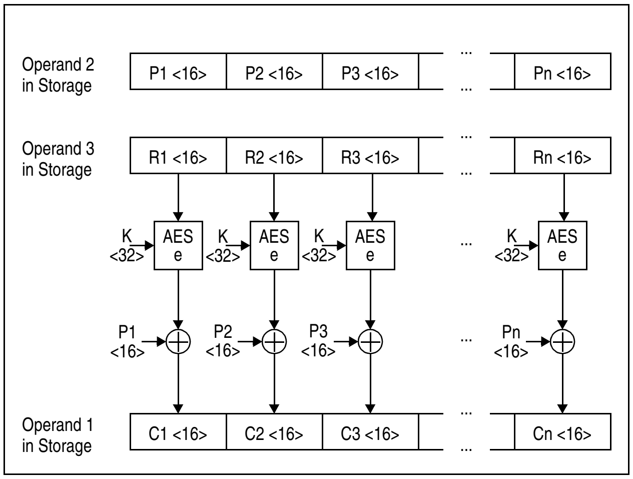

Figure 7-155. KMCTR AES Encipher Operation Using 256-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 256-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-156.

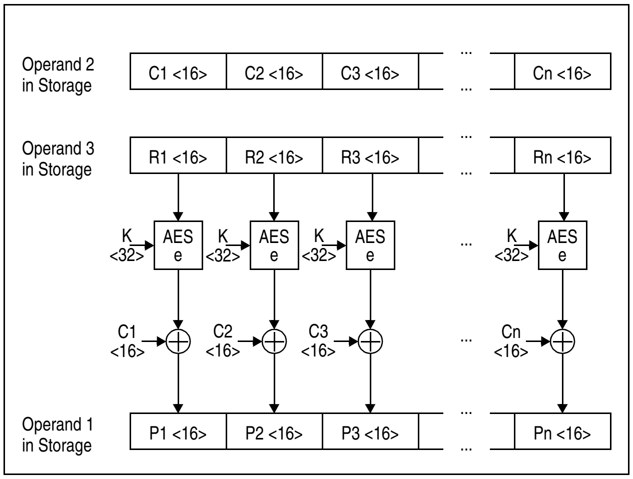

Figure 7-156. KMCTR AES Decipher Operation Using 256-Bit Key

Special Conditions for KMCTR

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

2. The R_1 $R_{2,}$ or R_3 field designates an odd-numbered register or general register 0.

3. The second operand length is not a multiple of the data block size of the designated function (see Figure 7-125 on page 7-107 to determine the data block sizes for CIPHER MESSAGE WITH COUNTER functions).This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, operand 3, cryptographic key, and wrapping-key verification pattern; store, operand 1)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Condition code 0 due to second-operand length originally zero.
11.A.1	Access exceptions for an access to the parameter block.

Figure 7-157. Priority of Execution: KMCTR

11.A.2.	Condition code 1 due to verification-pattern mismatch.
11.B	Access exceptions for an access to the first, second, or third operand.
12.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).
13.	Condition code 3 due to partial completion (second-operand length still nonzero).

Figure 7-157. Priority of Execution: KMCTR (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CIPHER MESSAGE WITH OUTPUT FEEDBACK

KMO R_1,R_2 [RRE]

'B92B'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-158 shows the assigned function codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMO-Query	16	—
1	KMO-DEA	16	8
2	KMO-TDEA-128	24	8
3	KMO-TDEA-192	32	8
9	KMO-Encrypted-DEA	40	8
10	KMO-Encrypted-TDEA-128	48	8
11	KMO-Encrypted-TDEA-192	56	8
18	KMO-AES-128	32	16
19	KMO-AES-192	40	16
20	KMO-AES-256	48	16
26	KMO-Encrypted-AES-128	64	16
27	KMO-Encrypted-AES-192	72	16
28	KMO-Encrypted-AES-256	80	16
Explanation:			
—	Not applicable		

Figure 7-158. Function Codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and an initial chaining value in the parameter block, and the result is placed in the first-operand location. The chaining value is updated as part of the operation.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first and second operands is specified by the contents of the R_1 and R_2 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand is the same length as the second operand.

As part of the operation, the addresses in general registers R_1 and R_2 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1 and R_2, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, and $R_2 + 1$, always remain unchanged.

Figure 7-159 on page 7-121 shows the contents of the general registers just described.

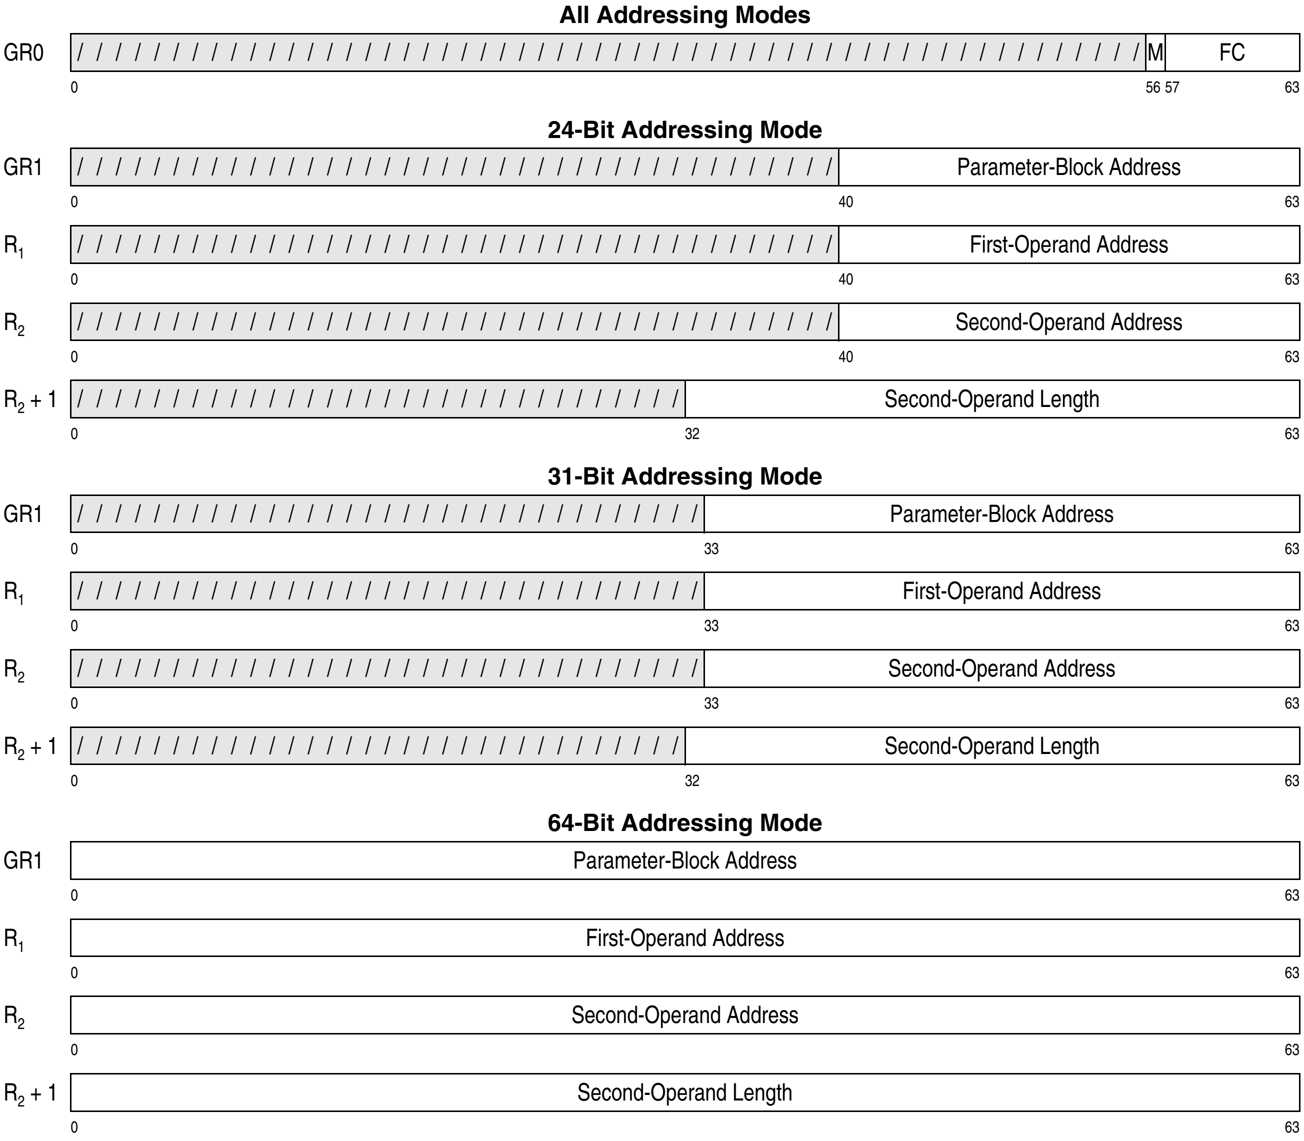

Figure 7-159. General Register Assignment for KMO

In the access-register mode, access registers 1, R_1, and R_2 specify the address spaces containing the parameter block, first, and second operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location (called normal completion) or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The results in the first-operand location and the chaining-value field are unpredictable if any of the following situations occur:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.

2. The chaining-value field overlaps any portion of the first operand or the second operand.

3. The first and second operands overlap destructively. Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- and second-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the parameter block, first, and second operands are not accessed, general registers R_1, R_2, and $R_2 + 1$ are not changed, and condition code 0 is set.

When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by twice the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers and chaining value to reflect the last unit of the first and second operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH OUTPUT FEEDBACK functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxx. Further description of the AES standard may be found in Reference [14.] on page xxx. Further description of the output-feedback mode of encryption and decryption may be found in Reference [16.] on page xxx.

KMO-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the function has the following format:

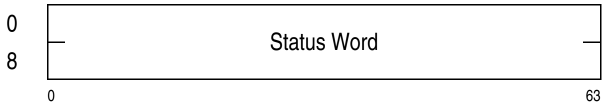

Figure 7-165. Parameter Block for KMO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH OUTPUT FEEDBACK instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMO-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMO-DEA (Function Code 1)

KMO-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the KMO-DEA function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key (K)
	0 63

Figure 7-166. Parameter Block for KMO-DEA

For the KMO-DEA function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMO-Encrypted - DEA function has the following format:

0	Chaining Value (CV)
8	Encrypted Cryptographic Key (WK_d(K))
16 24 32	DEA Wrapping-Key Verification Pattern (WK_dVP)
	0 63

Figure 7-167. Parameter Block for KMO-Encrypted-DEA

For the KMO-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-168.

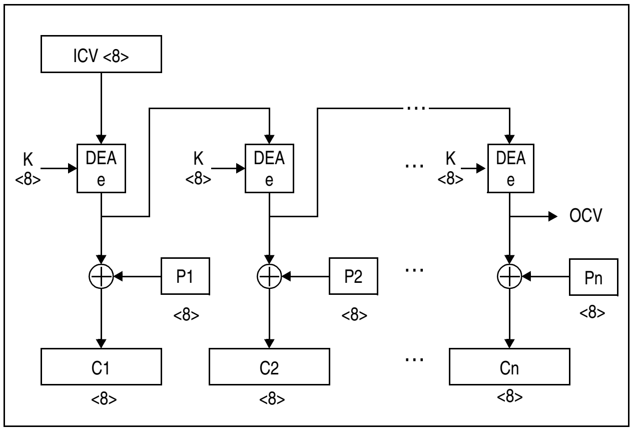

Figure 7-168. KMO-DEA Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-169.

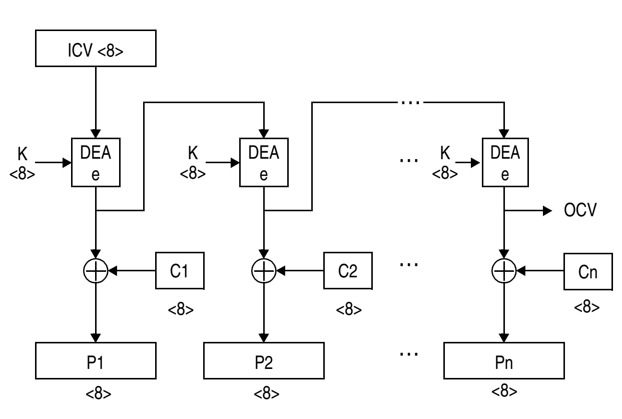

Figure 7-169. KMO-DEA Decipher Operation

KMO-TDEA-128 (Function Code 2)

KMO-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the KMO-TDEA-128 function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key 1 (K1)
16	Cryptographic Key 2 (K2)
	0 63

Figure 7-170. Parameter Block for KMO-TDEA-128

For the KMO-TDEA-128 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMO-Encrypted-TDEA-128 function has the following format:

0	Chaining Value (CV)
8 16	Encrypted Cryptographic Key (WK_d(K))
24 32 40	DEA Wrapping-Key Verification Pattern (WK_dVP)
	0 63

Figure 7-171. Parameter Block for KMO-Encrypted-TDEA-128

For the KMO-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-

value field of the parameter block. The operation is shown in Figure 7-172.

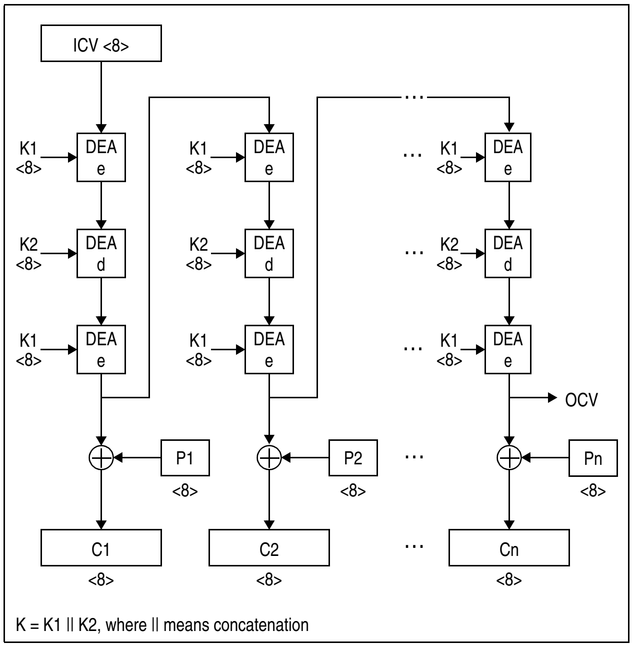

Figure 7-172. KMO-TDEA-128 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-173.

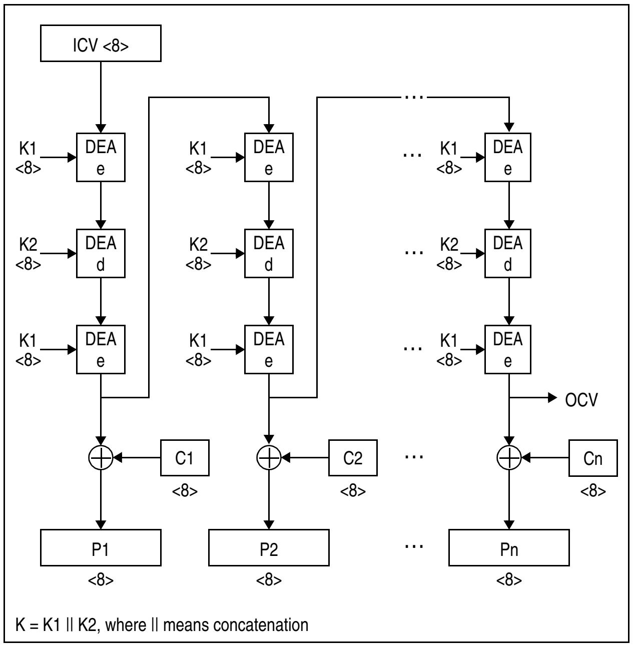

Figure 7-173. KMO-TDEA-128 Decipher Operation

KMO-TDEA-192 (Function Code 3)

KMO-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the KMO-TDEA-192 function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key 1 (K1)
16	Cryptographic Key 2 (K2)
24	Cryptographic Key 3 (K3)
	0 63

Figure 7-174. Parameter Block for KMO-TDEA-192

For the KMO-TDEA-192 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.

The parameter block used for the KMO-Encrypted-TDEA-192 function has the following format:

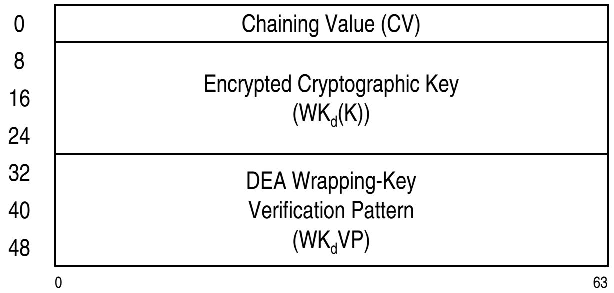

Figure 7-175. Parameter Block for KMO-Encrypted-TDEA-192

For the KMO-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 192-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is The operation is shown in Figure 7-176.

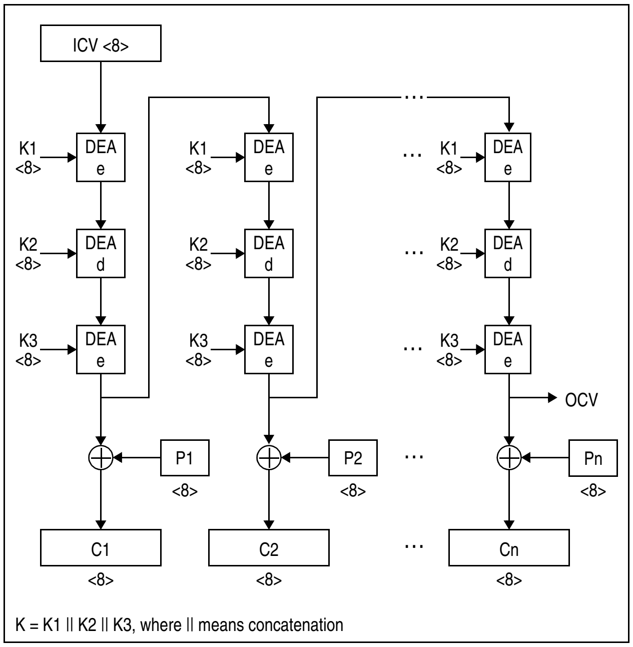

Figure 7-176. KMO-TDEA-192 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA-encryption algorithm with the 192-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-

value field of the parameter block. The operation is shown in Figure 7-177.

KMO-AES-128 (Function Code 18)

KMO-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the KMO-AES-128 function has the following format:

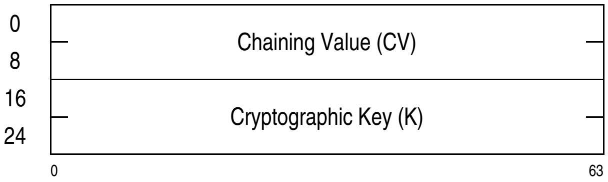

Figure 7-178. Parameter Block for KMO-AES-128

For the KMO-AES-128 function, the chaining value is in byte offset 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31 of the parameter block.

The parameter block used for the KMO-Encrypted-AES-128 function has the following format:

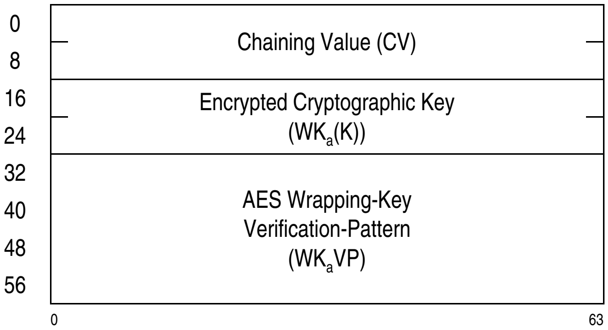

Figure 7-179. Parameter Block for KMO-Encrypted-AES-128

For the KMO-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the chaining value, and the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-180.

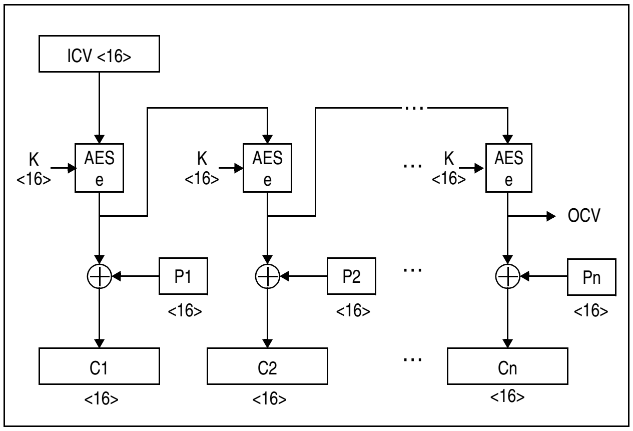

Figure 7-180. KMO-AES-128 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. value field of the parameter block. The operation is shown in Figure 7-185.

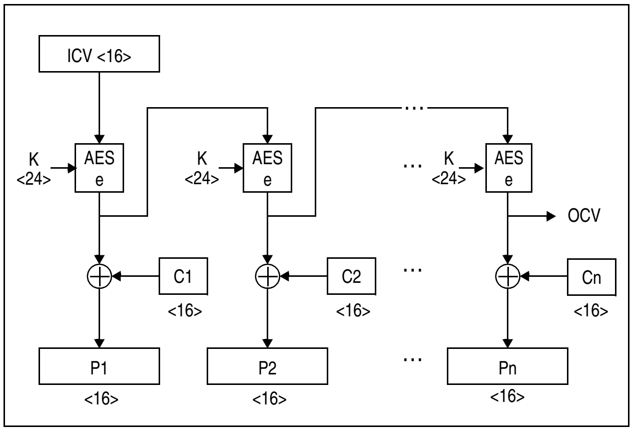

Figure 7-185. KMO-AES-192 Decipher Operation

KMO-AES-256 (Function Code 20)

KMO-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-159 on page 7-121.

The parameter block used for the KMO-AES-256 function has the following format:

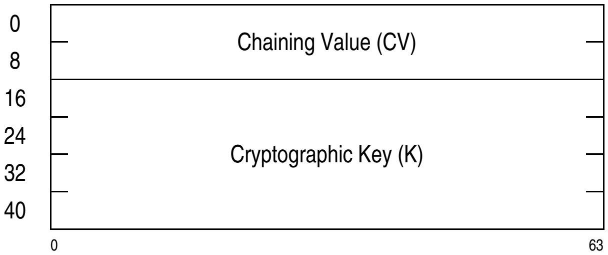

Figure 7-186. Parameter Block for KMO-AES-256

For the KMO-AES-256 function, the chaining value is in byte offset 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMO-Encrypted-AES-256 function has the following format:

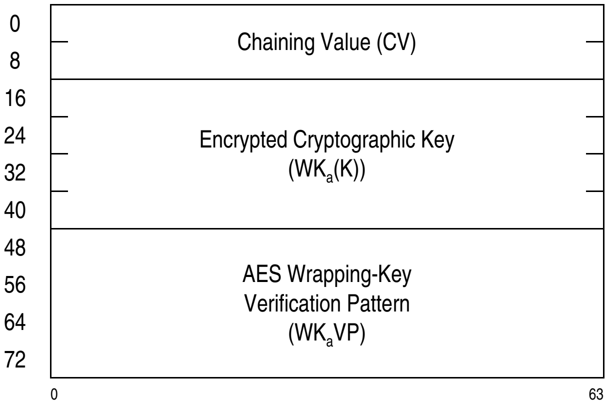

Figure 7-187. Parameter Block for KMO-AES-256

For the KMO-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-188.

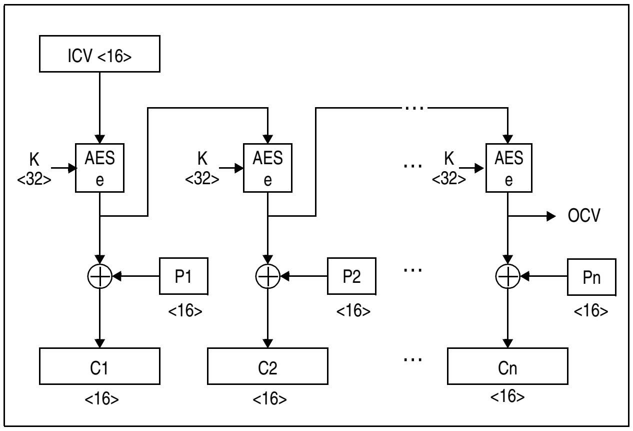

Figure 7-188. KMO-AES-256 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-189.

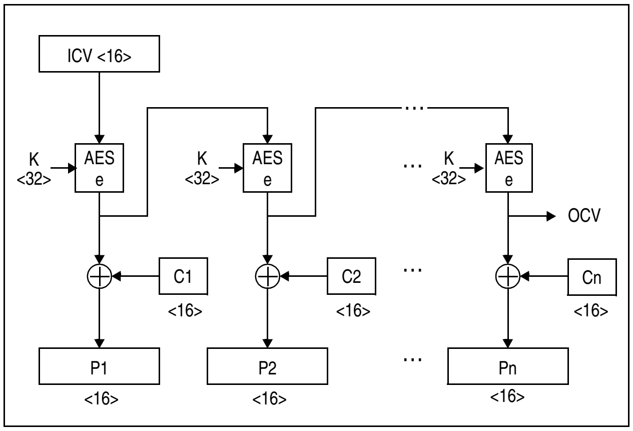

Figure 7-189. KMO-AES-256 Decipher Operation

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 or R_2 field designates an odd-numbered register or general register 0.
3. The second operand length is not a multiple of the data block size of the designated function (see Figure 7-158 on page 7-120 to determine the data block sizes for CIPHER MESSAGE WITH OUTPUT FEEDBACK functions). This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; store, operand 1; fetch and store, chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification

- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Condition code 0 due to second-operand length originally zero.
11.A.1	Access exceptions for an access to the parameter block.
11.A.2.	Condition code 1 due to verification-pattern mismatch.
11.B	Access exceptions for an access to the first or second operand.
12.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).
13.	Condition code 3 due to partial completion (second-operand length still nonzero).

Figure 7-190. Priority of Execution: KMO

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. See the programming notes for CIPHER MESSAGE WITH CHAINING.

3. In earlier versions of the architecture, CIPHER MESSAGE WITH OUTPUT FEEDBACK was known as CIPHER MESSAGE WITH OFB.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

COMPARE

Register-and-register formats:

CR R_1,R_2 [RR]

'19'	R_1	R_2
0	8	12 15

CGR R_1,R_2 [RRE]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'30'
0	8	12	16	20	32	40 47

COMPARE IMMEDIATE

CFI R_1,I_2 [RIL-a]

'C2'	R_1	'D'	I_2
0	8	12	16 47

CGFI R_1,I_2 [RIL-a]

'C2'	R_1	'C'	I_2	
0	8	12	16	47

COMPARE RELATIVE LONG

CRL R_1,RI_2 [RIL-b]

'C6'	R_1	'D'	RI_2	
0	8	12	16	47

CGRL R_1,RI_2 [RIL-b]

'C6'	R_1	'8'	RI_2	
0	8	12	16	47

CGFRL R_1,RI_2 [RIL-b]

'C6'	R_1	'C'	RI_2	
0	8	12	16	47

The first operand is compared with the second operand, and the result is indicated in the condition code.

For COMPARE (CR, C, CY), COMPARE IMMEDIATE (CFI), and COMPARE RELATIVE LONG (CRL), the operands are treated as 32-bit signed binary integers. For COMPARE (CGR, CG) and COMPARE RELATIVE LONG (CGRL), they are treated as 64-bit signed binary integers. For COMPARE (CGFR, CGF), COMPARE IMMEDIATE (CGFI), and COMPARE RELATIVE LONG (CGFRL), the second operand is treated as a 32-bit signed binary integer, and the first operand is treated as a 64-bit signed binary integer.

The displacement for COMPARE (C) is treated as a 12-bit unsigned binary integer. The displacement for COMPARE (CY, CG, and CGF) is treated as a 20-bit signed binary integer.

For COMPARE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For COMPARE RELATIVE LONG (CRL, CGFRL), the second operand must be aligned on a word boundary, and for COMPARE RELATIVE LONG (CGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (operand 2 of C, CY, CG, CGF, CRL, CGRL, and CGFRL only)
- Operation (CY, if the long-displacement facility is not installed; CFI and CGFI, if the extended-immediate facility is not installed; CGFRL, CGRL, and CRL, if the general-instructions-extension facility is not installed)
- Specification (CGFRL, CGRL, and CRL only)

Programming Notes:

1. For COMPARE RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.

2. When COMPARE RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

COMPARE AND BRANCH

CRB R_1,R_2,M_3,D_4(B_4) [RRS]

0	8	12	16	20	32	36	40	47

COMPARE AND BRANCH RELATIVE

CRJ R_1,R_2,M_3,RI_4 [RIE-b]

'EC'	R_1	R_2	RI_4	M_3	////	'76'	
0	8	12	16	32	36	40	47

CGRJ R_1,R_2,M_3,RI_4 [RIE-b]

'EC'	R_1	R_2	RI_4	M_3	////	'64'	
0	8	12	16	32	36	40	47

COMPARE IMMEDIATE AND BRANCH

CIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

'EC'	R_1	M_3	B_4	D_4	I_2	'FE'	
0	8	12	16	20	32	40	47

CGIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

'EC'	R_1	M_3	B_4	D_4	I_2	'FC'	
0	8	12	16	20	32	40	47

COMPARE IMMEDIATE AND BRANCH RELATIVE

CIJ R_1,I_2,M_3,RI_4 [RIE-c]

'EC'	R_1	M_3	RI_4	I_2	'7E'	
0	8	12	16	32	40	47

CGIJ R_1,I_2,M_3,RI_4 [RIE-c]

'EC'	R_1	M_3	RI_4	I_2	'7C'	
0	8	12	16	32	40	47

The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, the instruction address in the current PSW is replaced by the branch address specified by the fourth operand; otherwise, normal instruction sequencing proceeds with the updated instruction address.

For COMPARE AND BRANCH (CRB), COMPARE AND BRANCH RELATIVE (CRJ), COMPARE IMMEDIATE AND BRANCH (CIB) and COMPARE IMMEDIATE AND BRANCH RELATIVE (CIJ), the first operand is treated as a 32-bit signed binary integer. For COMPARE AND BRANCH (CGRB), COMPARE AND BRANCH RELATIVE (CGRJ), COMPARE IMMEDIATE AND BRANCH (CGIB) and COMPARE IMMEDIATE AND BRANCH RELATIVE (CGIJ), the first operand is treated as a 64-bit signed binary integer.

For COMPARE AND BRANCH (CRB) and COMPARE AND BRANCH RELATIVE (CRJ), the second operand is treated as a 32-bit signed binary integer. For COMPARE AND BRANCH (CGRB) and COMPARE AND BRANCH RELATIVE (CGRJ), the second operand is treated as a 64-bit signed binary integer. For COMPARE IMMEDIATE AND BRANCH and COMPARE IMMEDIATE AND BRANCH RELATIVE, the second operand is treated as an 8-bit signed binary integer.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE AND BRANCH and COMPARE IMMEDIATE AND BRANCH, the fourth-operand address is used as the branch address. For COMPARE AND BRANCH RELATIVE and COMPARE IMMEDIATE AND BRANCH RELATIVE, the contents of the RI_4 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed).
- Transaction constraint

Programming Notes:

1. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a branch always occurs.

2. When COMPARE AND BRANCH RELATIVE or COMPARE IMMEDIATE AND BRANCH RELATIVE are the target of an execute-type instruction, the branch is relative to the target address. See “Branch-Address Generation” on page 5-12.

3. The high-level assembler (HLASM) provides extended-mnemonic formats for all of the multiple-operation instructions which perform a compare (arithmetic or logical) followed by a branch or trap. In the extended-mnemonic format, the mask field is not explicitly coded; rather the branch mask is implicitly indicated by the extended mnemonic.

   The extended-mnemonic names are formed by concatenating the base mnemonic, followed by one of the suffix characters, as shown below.

Suffix Chars	Meaning	Mask Field
E	Equal	8
H	First operand high	2
L	First operand low	4
NE	Not equal	6
NH	First operand not high	12
NL	First operand not low	10

   Consider the following example of a COMPARE IMMEDIATE AND BRANCH RELATIVE (CGIJ) instruction that is coded using an extended mnemonic:

   ```
           CGIJNE 10,-123,SKIP
            ⋮
   SKIP    DS      0H     (128 bytes past CGIJNE)
   ```

   The implied mask field corresponding to the mnemonic suffix (NE) is 6, thus the generated code is ECA60040857C hex.

COMPARE AND FORM CODEWORD

CFC D$_2$(B$_2$) [S]

'B21A'	B$_2$	D$_2$
0	16	20 31

General register 2 contains an index, which is used along with contents of general registers 1 and 3 to designate the starting addresses of two fields in storage, called the first and third operands. The first and third operands are logically compared, and a codeword is formed in general register 2 for use in sort/merge algorithms.

The second-operand address is not used to address data. Bits 49-62 of the second-operand address, with one rightmost and one leftmost zero appended, are used as a 16-bit index limit. Bit 63 of the second-operand address is the operand-control bit; the operand-control bit is applicable when the first and third operands are unequal. When bit 63 is zero, the codeword is formed from the one's complement of the high operand; when bit 63 is one, the codeword is formed from the low operand. The remainder of the second-operand address is ignored.

General registers 1 and 3 contain the base addresses of the first and third operands. Bits 48-63 of general register 2 are used as an index for addressing both the first and third operands. General registers 1, 2, and 3 must all initially contain even values; otherwise, a specification exception is recognized.

In the access-register mode, access register 1 specifies the address space containing the first and third operands.

The size of the units by which the first and third operands are compared, the size of the resulting codeword, and the participation of bits 0-31 of general registers 1, 2, and 3 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, the comparison unit is two bytes, the codeword is four bytes, and bits 0-31 of the registers are ignored and remain unchanged. In the 64-bit addressing mode, the comparison unit is six bytes, the codeword is eight bytes, and bits 0-31 of the registers are used in and may be changed by the operation.

Operation in the 24-Bit or 31-Bit Addressing Mode

The operation consists in comparing the first and third operands halfword by halfword and incrementing the index until an unequal pair of halfwords is found or the index exceeds the index limit. This proceeds in units of operation, between which interruptions may occur.

At the start of a unit of operation, the index, bits 48-63 of general register 2, is logically compared with the index limit. If the index is larger, the instruction is completed by placing bits 32-63 of general register 3, with bit 32 set to one, in bit positions 32-63 of general register 2, and by setting condition code 0.

If the index is less than or equal to the index limit, the index is applied to the first-operand and third-operand base addresses to locate the current pair of halfwords to be compared. The index, with 48 leftmost zeros appended, and bits 32-63 of general register 1, with 32 leftmost zeros appended, are added to form a 64-bit intermediate value. A carry out of bit position 32, if any, is ignored. The address of the current first-operand halfword is generated from the intermediate value by following the normal rules for operand address generation. The address of the current third-operand halfword is formed in the same manner by adding bits 32-63 of general register 3 and the index.

The current first-operand and third-operand halfwords are logically compared. If they are equal, the contents of general register 2 are incremented by 2, and a unit of operation ends.

If the compare values are unequal, the contents of general register 2 are incremented by 2 and then shifted left logically by 16 bit positions. The shifting occurs only within bit positions 32-63. If the operand-control bit is zero, (1) the one's complement of the higher halfword is placed in bit positions 48-63 of general register 2, and (2) if operand 1 was higher, bits 32-63 of general registers 1 and 3 are interchanged. If the operand-control bit is one, (1) the lower halfword is placed in bit positions 48-63 of general register 2, and (2) if operand 1 was lower, bits 32-63 of general registers 1 and 3 are interchanged. Condition code 2 is set if general registers 1 and 3 are interchanged; otherwise, condition code 1 is set.

For the purpose of recognizing access exceptions, operand 1 and operand 3 are both considered to have a length equal to 2 more than the value of the index limit minus the index.

Operation in the 64-bit Addressing Mode

The operation consists in comparing the first and third operands in units of six bytes at a time and incrementing the index until an unequal pair of six-byte units is found or the index exceeds the index limit. This proceeds in units of operation, between which interruptions may occur.

At the start of a unit of operation, the index, bits 48-63 of general register 2, is logically compared with the index limit. If the index is larger, the instruction is completed by placing bits 0-63 of general register 3, with bit 0 set to one, in bit positions 0-63 of general register 2, and by setting condition code 0.

If the index is less than or equal to the index limit, the index is applied to the first-operand and third-operand base addresses to locate the current pair of six-byte units to be compared. The index, with 48 leftmost zeros appended, and bits 0-63 of general register 1 are added to form the 64-bit address of the current first-operand six-byte unit. A carry out of bit position 0, if any, is ignored. The address of the current third-operand six-byte unit is formed in the same manner by adding bits 0-63 of general register 3 and the index.

The current first-operand and third-operand six-byte units are logically compared. If they are equal, the contents of general register 2 are incremented by 6, and a unit of operation ends.

If the compare values are unequal, the contents of general register 2 are incremented by 6 and then shifted left logically by 48 bit positions. If the operand-control bit is zero, (1) the one's complement of the higher six-byte unit is placed in bit positions 16-63 of general register 2, and (2) if operand 1 was higher, bits 0-63 of general registers 1 and 3 are interchanged. If the operand-control bit is one, (1) the lower six-byte unit is placed in bit positions 16-63 of general register 2, and (2) if operand 1 was lower, bits 0-63 of general registers 1 and 3 are interchanged. Condition code 2 is set if general registers 1 and 3 are interchanged; otherwise, condition code 1 is set.

For the purpose of recognizing access exceptions, operand 1 and operand 3 are both considered to have a length equal to 6 more than the value of the index limit minus the index. However, depending on the model, access exceptions may or may not be recognized for the portion of a storage operand to the right of the first unequal byte when the operand is not needed to form the codeword in general register 2.

Specifications Independent of Addressing Mode

The condition code is unpredictable if the instruction is interrupted.

When the index is initially larger than the index limit, access exceptions are not recognized for the storage operands. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the byte being processed. Access exceptions are not recognized when a specification-exception condition exists.

If the B_2 field designates general register 2, it is unpredictable whether or not the index limit is recomputed; thus, in this case the operand length is unpredictable. However, in no case can the operands exceed 2^{15} bytes in length.

Resulting Condition Code:

0 Operands equal
1 Operand-control bit zero and operand 1 low, or operand-control bit one and operand 3 low
2 Operand-control bit zero and operand 1 high, or operand-control bit one and operand 3 high
3 --

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of COMPARE AND FORM CODEWORD is given in “Sorting Instructions” in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The offset of the halfword or six-byte unit (depending on the addressing mode) of the first and third operands at which comparison is to begin should be placed in bit positions 48-63 of general register 2 before executing COMPARE AND FORM CODEWORD. The index limit derived from the second-operand address should be the offset of the last halfword or six-byte unit of the first and third operands for which comparison can be made. When the operands do not compare equal, the leftmost 16 bits of the codeword formed in general register 2 (bits 32-47 of the register in the 24-bit or 31-bit addressing mode, or bits 0-15 in the 64-bit addressing mode) by the execution of COMPARE AND FORM CODEWORD gives the offset of the first halfword or six-byte unit not compared. If the codewords compare equal in an UPDATE TREE operation, bit positions 32-47 of general register 2 in the 24-bit or 31-bit addressing mode, or bit positions 0-15 in the 64-bit addressing mode, will contain the offset at which another COMPARE AND FORM CODEWORD should resume comparison for breaking codeword ties. Operand-control-bit values of zero or one are used for sorting operands in ascending or descending order, respectively. Refer to “Sorting Instructions” on page A-53 for a discussion of the use of codewords in sorting.

3. The condition code indicates the results of comparing operands up to 32,768 bytes long. Equal operands result in a negative codeword in bit positions 32-63 of general register 2 in the 24-bit or 31-bit addressing mode, or in bit positions 0-63 in the 64-bit addressing mode. A negative codeword also results in the 24-bit or 31-bit mode when the index limit is 32,766 and the operands that are compared differ in only their last two bytes, or in the 64-bit mode when the limit is 32,762 and the operands differ in only their last six bytes. If this latter codeword is used by UPDATE TREE, an incorrect result may be indicated in general registers 0 and 1. Therefore, the index limit should not exceed 32,764 in the 24-bit or 31-bit mode, or 32,760 in the 64-bit mode, when the resulting codeword is to be used by UPDATE TREE.

4. Special precautions should be taken if COMPARE AND FORM CODEWORD is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

5. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” in Chapter 5, “Program Execution.”

6. The storage-operand references of COMPARE AND FORM CODEWORD may be multiple-access references. (See “Storage-Operand Consistency”.)

7. Figure 7-191 on page 7-139 and Figure 7-192 on page 7-140 contain summaries of the operation in the 24-bit or 31-bit addressing mode, and Figure 7-193 on page 7-141 and Figure 7-194 on page 7-142 contain summaries of the operation in the 64-bit addressing mode.

'EB'	R_1	R_3	B_2	DL_2	DH_2	'31'
0	8	12	16	20	32	40 47

CDSG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'3E'
0	8	12	16	20	32	40 47

The first and second operands are compared. If they are equal, the third operand is stored at the second-operand location. If they are unequal, the second operand is loaded into the first-operand location. The result of the comparison is indicated in the condition code.

For COMPARE AND SWAP (CS, CSY), the first and third operands are 32 bits in length, with each operand occupying bit positions 32-63 of a general register. The second operand is a word in storage.

For COMPARE AND SWAP (CSG), the first and third operands are 64 bits in length, with each operand occupying bit positions 0-63 of a general register. The second operand is a doubleword in storage.

For COMPARE DOUBLE AND SWAP (CDS, CDSY), the first and third operands are 64 bits in length. The first 32 bits of an operand occupy bit positions 32-63 of the even-numbered register of an even-odd pair of general registers, and the second 32 bits occupy bit positions 32-63 of the odd-numbered register of the pair. The second operand is a doubleword in storage.

For COMPARE DOUBLE AND SWAP (CDSG), the first and third operands are 128 bits in length. The first 64 bits of an operand occupy bit positions 0-63 of the even-numbered register of an even-odd pair of general registers, and the second 64 bits occupy bit positions 0-63 of the odd-numbered register of the pair. The second operand is a quadword in storage.

When an equal comparison occurs, the third operand is stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

When the result of the comparison is unequal, the second operand is loaded at the first-operand location, and the second-operand location remains unchanged. However, on some models, the contents may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

The displacement for CS and CDS is treated as a 12-bit unsigned binary integer. The displacement for CSY, CSG, CDSY, and CDSG is treated as a 20-bit signed binary integer.

The second operand of COMPARE AND SWAP (CS, CSY) must be designated on a word boundary. The second operand of COMPARE AND SWAP (CSG) and COMPARE DOUBLE AND SWAP (CDS, CDSY) must be designated on a doubleword boundary. The second operand of COMPARE DOUBLE AND SWAP (CDSG) must be designated on a quadword boundary. The R_1 and R_3 fields for COMPARE DOUBLE AND SWAP must each designate an even-numbered register. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by third operand
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (CSY and CDSY, if the long-displacement facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Several examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. Some of the following notes are worded, with respect to operand size, for CS, CSY, CDS, and CDSY. Similar notes, worded for a larger operand size, would apply to CSG and CDSG.

3. COMPARE AND SWAP can be used by CPU programs sharing common storage areas in either a multiprogramming or multiprocessing environment. Two examples are:

   a. By performing the following procedure, a CPU program can modify the contents of a storage location even though the possibility exists that the CPU program may be interrupted by another CPU program that will update the location or that another CPU program may simultaneously update the location. First, the entire word containing the byte or bytes to be updated is loaded into a general register. Next, the updated value is computed and placed in another general register. Then COMPARE AND SWAP is executed with the R_1 field designating the register that contains the original value and the R_3 field designating the register that contains the updated value. If the update has been successful, condition code 0 is set. If the storage location no longer contains the original value, the update has not been successful, the general register designated by the R_1 field of the COMPARE AND SWAP instruction contains the new current value of the storage location, and condition code 1 is set. When condition code 1 is set, the CPU program can repeat the procedure using the new current value.

   b. COMPARE AND SWAP can be used for controlled sharing of a common storage area, including the capability of leaving a message (in a chained list of messages) when the common area is in use. To accomplish this, a word in storage can be used as a control word, with a zero value in the word indicating that the common area is not in use and that no messages exist, a negative value indicating that the area is in use and that no messages exist, and a nonzero positive value indicating that the common area is in use and that the value is the address of the most recent message added to the list. Thus, any number of CPU programs desiring to seize the area can use COMPARE AND SWAP to update the control word to indicate that the area is in use or to add messages to the list. The single CPU program which has seized the area can also safely use COMPARE AND SWAP to remove messages from the list.

4. COMPARE DOUBLE AND SWAP can be used in a manner similar to that described for COMPARE AND SWAP. In addition, it has another use. Consider a chained list, with a control word used to address the first message in the list, as described in programming note 3.b above. If multiple CPU programs are to be permitted to delete messages by using COMPARE AND SWAP (and not just the single CPU program which has seized the common area), there is a possibility the list will be incorrectly updated. This would occur if, for example, after one CPU program has fetched the address of the most recent message in order to remove the message, another CPU program removes the first two messages and then adds the first message back into the chain. The first CPU program, on continuing, cannot easily detect that the list is changed. By increasing the size of the control word to a doubleword containing both the first message address and a word with a change number that is incremented for each modification of the list, and by using COMPARE DOUBLE AND SWAP to update both fields together, the possibility of the list being

incorrectly updated is reduced to a negligible level. That is, an incorrect update can occur only if the first CPU program is delayed while changes exactly equal in number to a multiple of 2^{32} take place *and* only if the last change places the original message address in the control word.

5. To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference (the section “Interlocked-Update References” on page 5-124 lists the instructions that perform an interlocked-update reference). For example, in a configuration where the interlocked-access facility 2 is not installed, if one CPU executes OR IMMEDIATE and another CPU executes COMPARE AND SWAP to update the same byte, the fetch by OR IMMEDIATE may occur either before the fetch by COMPARE AND SWAP or between the fetch and the store by COMPARE AND SWAP, and then the store by OR IMMEDIATE may occur after the store by COMPARE AND SWAP, in which case the change made by COMPARE AND SWAP is lost.

6. For the case of a condition-code setting of 1, COMPARE AND SWAP and COMPARE DOUBLE AND SWAP may or may not, depending on the model, cause any of the following to occur for the second-operand location: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exception exists, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

7. The performance of CDSG on some models may be significantly slower than that of CSG. When quadword consistency is not required by the program, alternate code sequences should be used.

COMPARE AND SWAP AND STORE

CSST $D_1(B_1),D_2(B_2),R_3$ [SSF]

'C8'	R_3	'2'	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The first operand is compared with the third operand. If they are equal, the replacement value is stored into the first-operand location, and subsequently, the store value is placed into the second-operand location. If they are not equal, then the first operand is loaded into the third-operand location, and the second operand is not changed. The result is indicated by the condition code.

The size of the first and third operands, the size of the replacement value, and the alignment of the first operand are determined by the contents of a function code (FC) in bits 56-63 of general register 0. The assigned function codes are as follows:

- When the function code is 0, the operands are 32 bits in length. The first operand is a word in storage, and the third operand is in bits 32-63 of general register R_3. The replacement value is in bytes 0-3 of the parameter list.

- When the function code is 1, the operands are 64 bits in length. The first operand is a doubleword in storage, and the third operand is in bits 0-63 of general register R_3. The replacement value is bytes 0-7 of the parameter list.

- When the function code is 2 and the compare-and-swap-and-store facility 2 is installed, the operands are 128 bits in length. The first operand is a quadword in storage, and the third operand is in bits 0-63 of general registers R_3 and $R_3 + 1$. The replacement value is in bytes 0-15 of the parameter list.

The size of the store value and the alignment of the second operand are determined by a store characteristic (SC) in bits 48-55 of general register 0. The store characteristic is expressed as a power of two; the assigned store characteristics are 0, 1, 2, and 3. An SC of 0 means that one byte is stored on a byte boundary; an SC of 1 means that two bytes are stored on a halfword boundary, an SC of 2 means that four bytes are stored on a word boundary, and an SC of 3 means that eight bytes are stored on a doubleword boundary. When the CSST facility 2 is installed, an SC of 4 is also assigned; an SC of 4 means that sixteen bytes are stored on a quadword boundary. The store value begins at byte 16 of the parameter list.

Bits 0-31 of general register 0 are ignored. Bits 32-47 of general register 0 and bits 60-63 of general register 1 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 1 contains the logical address of a parameter list that contains the replacement value and the store value. The parameter list is on a quadword boundary. In the access-register mode, access register 1 specifies the address space containing the parameter list.

The handling of the parameter-list address is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-59 of general register 1, with four zeros appended to the right, constitute the address, and bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-59 of the register, with four zeros appended to the right, constitute the address, and bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-59 of the register, with four zeros appended to the right, constitute the address.

Figure 7-195 illustrates contents of the registers and parameter list just described.

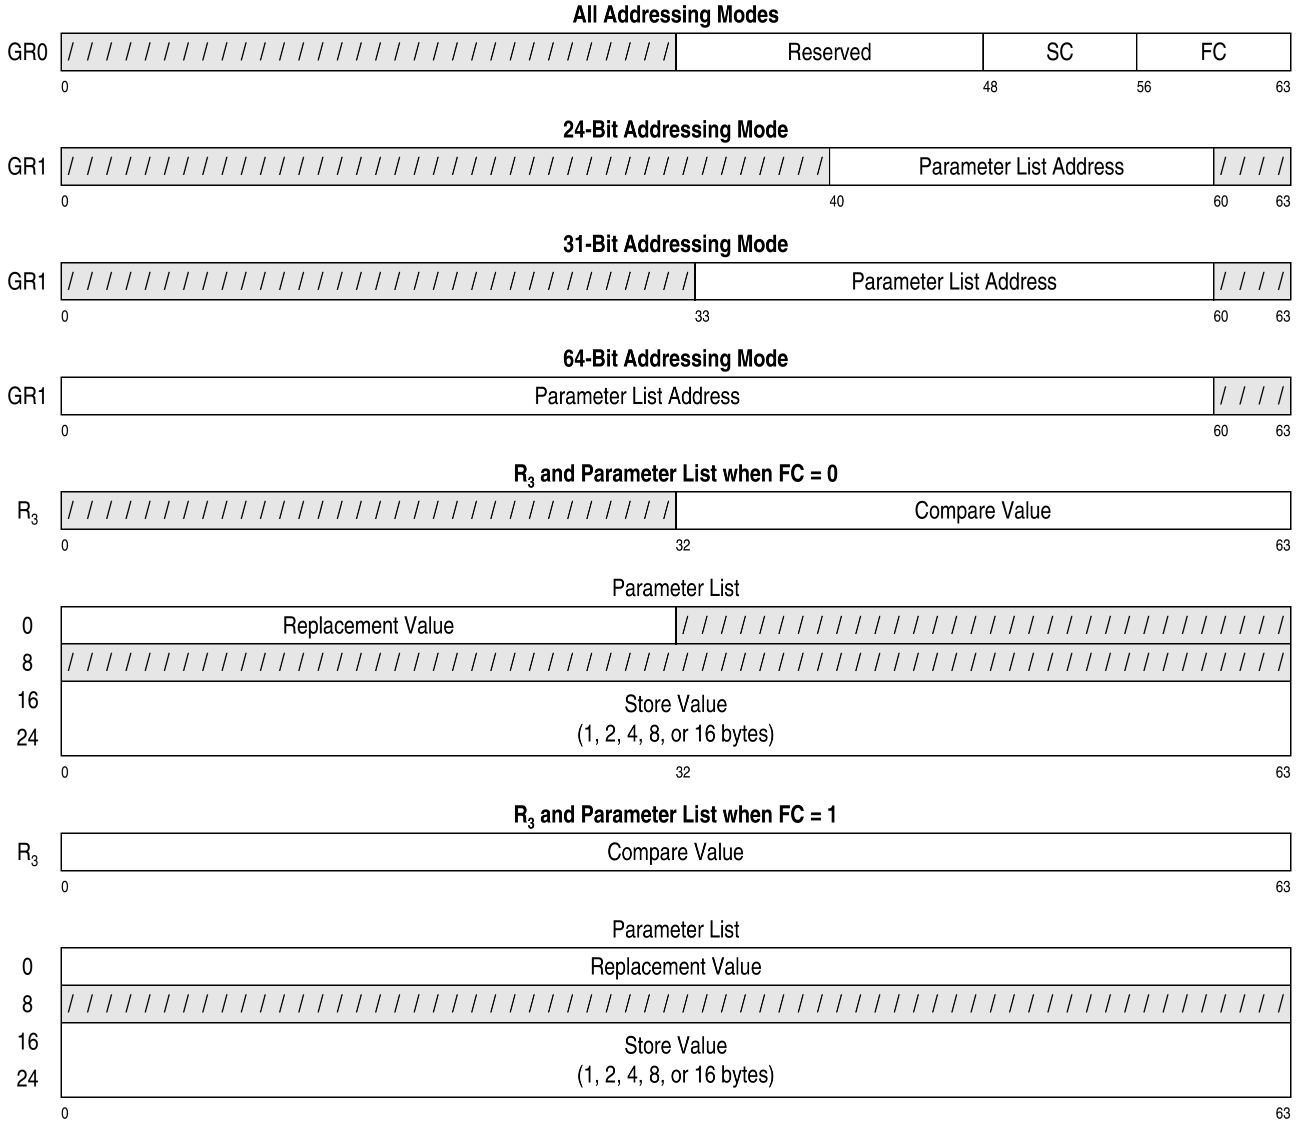

Figure 7-195. Register Contents for COMPARE AND SWAP AND STORE

When an equal comparison occurs, the replacement value is stored at the first-operand location, and the store value is stored at the second-operand location. The fetch of the first operand for purposes of comparison, and the store of the replacement value into the first-operand location, both appear to be a block-concurrent interlocked-update reference as observed by other CPUs. The store of the store value appears to be block-concurrent as observed by other CPUs.

When the result of the comparison is unequal, the first operand is loaded into the third-operand location, and the first operand remains unchanged. However, on some models, the contents of the first operand may be fetched and subsequently stored back unchanged at the first-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

As observed by this CPU and by other CPUs, all fetches appear to occur before all stores, and the store into the first operand appears to occur before the store into the second operand. Access-exception conditions are recognized for the entire 32-byte parameter list and for the second operand, regardless of whether the first and third operands are or are not equal. For the second operand, PER storage-alteration and zero-address-detection events are recognized, and a change bit is set, only if a store occurs.

A serialization function is performed before the operation begins and again after the operation is completed.

Special Conditions

A specification exception is recognized for any of the following conditions:

- The function code specifies an unassigned value.
- The store characteristic specifies an unassigned value.
- The function code is 0, and the first operand is not designated on a word boundary.
- The function code is 1, and the first operand is not designated on a doubleword boundary.
- The function code is 2, and any of the following is true:
  - The compare-and-swap-and-store facility 2 is not installed.
  - The first operand is not designated on a quadword boundary.
  - The R_3 field does not designate the even-numbered register of an even-odd register pair.
- The second operand is not designated on an integral boundary corresponding to the size of the store value.

For all of the above conditions, and for all addressing and protection exceptions, the operation is suppressed.

Resulting Condition Code:

0 First and third operands equal; first operand replaced by replacement value, and second operand replaced by store value
1 First and third operands unequal; third operand replaced by first operand
2 --
3 --

Program Exceptions:

- Access (fetch, parameter list; fetch and store, operand 1; store, operand 2)
- Operation (if the compare-and-swap-and-store facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. COMPARE AND SWAP AND STORE may be used in conjunction with other COMPARE AND SWAP or COMPARE DOUBLE AND SWAP instructions to manipulate locks, queue pointers, or other fields that require interlocked updates.

2. COMPARE AND SWAP AND STORE should not be used to manipulate fields that are also manipulated by PERFORM LOCKED OPERATION.

3. The store value is intended to provide a separate “footprint” of the interlocked-update operation in a location apart from the first operand in a single unit of operation.

4. The performance of COMPARE AND SWAP AND STORE may be significantly slower than the that of separate COMPARE AND SWAP, BRANCH ON CONDITION, and STORE instructions.

5. COMPARE AND SWAP AND STORE should only be used when an interruption between the compare-and-swap operation and the store operation cannot be tolerated, and other means of disabling for interruptions are not practical.

COMPARE AND TRAP

CRT R_1,R_2,M_3 [RRF-c]

'B972'	M_3	////	R_1	R_2
0	16	20	24	28 31

CGRT R_1,R_2,M_3 [RRF-c]

'B960'	M_3	////	R_1	R_2
0	16	20	24	28 31

COMPARE IMMEDIATE AND TRAP

CIT R_1,I_2,M_3 [RIE-a]

'EC'	R_1	////	I_2	M_3	////	'72'
0	8	12	16	32	36	40 47

CGIT R_1,I_2,M_3 [RIE-a]

'EC'	R_1	////	I_2	M_3	////	'70'
0	8	12	16	32	36	40 47

The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, a compare-and-trap-instruction data exception is recognized, and the operation is completed; otherwise, normal instruction sequencing proceeds with the updated instruction address.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE AND TRAP (CRT) and COMPARE IMMEDIATE AND TRAP (CIT), the first operand is treated as a 32-bit signed binary integer. For COMPARE AND TRAP (CGRT) and COMPARE IMMEDIATE AND TRAP (CGIT), the first operand is treated as a 64-bit signed binary integer.

For COMPARE IMMEDIATE AND TRAP, the second operand is treated as a 16-bit signed binary integer.

For COMPARE AND TRAP (CRT), the second operand is treated as a 32-bit signed binary integer. For COMPARE AND TRAP (CGRT), the second operand is treated as a 64-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data
- Operation (if the general-instructions-extension facility is not installed)

Programming Notes:

1. Possible uses of COMPARE AND TRAP and COMPARE IMMEDIATE AND TRAP include checking for pointers containing zero (null pointer), or array range checking.

2. On most models, when a data exception is not recognized, the performance of COMPARE AND TRAP and COMPARE IMMEDIATE AND TRAP is typically similar to other COMPARE instructions. When a data exception is recognized, the instruction may be significantly slower than an equivalent COMPARE instruction followed by a BRANCH ON CONDITION instruction.

3. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a data exception is always recognized.

4. When a data exception is recognized, the compare-and-trap data-exception code (DXC FF hex) is stored, as described in “Data Exception” on page 6-25.

5. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH on page 7-136 also applies to the compare-and-trap instructions.

COMPARE HALFWORD

CH $R_1,D_2(X_2,B_2)$ [RX-a]

'49'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

CHY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'79'
0	8	12	16	20	32	40 47

CGH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'34'
0	8	12	16	20	32	40 47

COMPARE HALFWORD IMMEDIATE

Register-and-immediate formats:

CHI R_1,I_2 [RI-a]

'A7'	R_1	'E'	I_2
0	8	12	16 31

CGHI R_1,I_2 [RI-a]

'A7'	R_1	'F'	I_2
0	8	12	16 31

Storage-and-immediate formats:

CHHSI $D_1(B_1),I_2$ [SIL]

'E554'	B_1	D_1	I_2
0	16	20	32 47

CHSI $D_1(B_1),I_2$ [SIL]

'E55C'	B_1	D_1	I_2
0	16	20	32 47

CGHSI $D_1(B_1),I_2$ [SIL]

'E558'	B_1	D_1	I_2
0	16	20	32 47

COMPARE HALFWORD RELATIVE LONG

CHRL R_1,RI_2 [RIL-b]

'C6'	R_1	'5'	RI_2
0	8	12	16 47

CGHRL R_1,RI_2 [RIL-b]

'C6'	R_1	'4'	RI_2
0	8	12	16 47

The first operand is compared with the second operand, and the result is indicated in the condition code. The second operand is two bytes in length and is treated as a 16-bit signed binary integer.

For COMPARE HALFWORD IMMEDIATE (CHHSI), the first operand is treated as a 16-bit signed binary integer. For COMPARE HALFWORD (CH, CHY), COMPARE HALFWORD IMMEDIATE (CHI and CHSI), and COMPARE HALFWORD RELATIVE LONG (CHRL), the first operand is treated as a 32-bit signed binary integer. For COMPARE HALFWORD (CGH), COMPARE HALFWORD IMMEDIATE (CGHI and CGHSI), and COMPARE HALFWORD RELATIVE LONG (CGHRL), the first operand is treated as a 64-bit signed binary integer.

The displacement for COMPARE HALFWORD (CH) and for COMPARE HALFWORD IMMEDIATE (CGHSI, CHHSI, CHSI) is treated as a 12-bit unsigned binary integer. The displacement for COMPARE HALFWORD (CHY, CGH) is treated as a 20-bit signed binary integer.

For COMPARE HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 1 of CGHSI, CHHSI, and CHSI only; fetch, operand 2 of CGH, CGHRL, CH, CHRL, CHY only)
- Operation (CHY, if the long-displacement facility is not installed; CGH, CHRL, CGHRL, CGHSI, CHHSI, and CHSI, if the general-instructions-extension facility is not installed)

Programming Notes:

1. An example of the use of the COMPARE HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For COMPARE HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.
3. When COMPARE HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

COMPARE HIGH

Register-and-register formats:

CHHR R_1,R_2 [RRE]

'B9CD'	////////	R_1	R_2
0	16	24	28 31

CHLR R_1,R_2 [RRE]

'B9DD'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage format:

CHF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'CD'
0	8	12	16	20	32	40 47

COMPARE IMMEDIATE HIGH

CIH R_1,I_2 [RIL-a]

'CC'	R_1	'D'	I_2
0	8	12	16 47

The first operand is compared with the second operand, and the result is indicated in the condition code.

The operands are treated as 32-bit signed binary integers. The first operand is in bit positions 0-31 of general register R_1; bit positions 32-63 of the register are ignored. For COMPARE HIGH (CHHR), the second operand is in bit positions 0-31 of general register R_2; bit positions 32-63 of the register are ignored.

For COMPARE HIGH (CHLR), the second operand is in bit positions 32-63 of general register R_2; bit positions 0-31 of the register are ignored.

The displacement for CHF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (operand 2 of CHF only)
- Operation (if the high-word facility is not installed)

COMPARE LOGICAL RELATIVE LONG

CLRL R_1,RI_2 [RIL-b]

'C6'	R_1	'F'	RI_2
0	8	12	16 47

CLGRL R_1,RI_2 [RIL-b]

'C6'	R_1	'A'	RI_2
0	8	12	16 47

CLGFRL R_1,RI_2 [RIL-b]

'C6'	R_1	'E'	RI_2
0	8	12	16 47

CLHRL R_1,RI_2 [RIL-b]

'C6'	R_1	'7'	RI_2
0	8	12	16 47

CLGHRL R_1,RI_2 [RIL-b]

'C6'	R_1	'6'	RI_2
0	8	12	16 47

The first operand is compared with the second operand, and the result is indicated in the condition code.

The lengths of the operands are as follows:

- For COMPARE LOGICAL (CLR, CL, CLY), COMPARE LOGICAL IMMEDIATE (CLFI), and COMPARE LOGICAL RELATIVE LONG (CLRL), the operands are treated as 32 bits.
- For COMPARE LOGICAL (CLGR, CLG) and COMPARE LOGICAL RELATIVE LONG (CLGRL), the operands are treated as 64 bits.
- For COMPARE LOGICAL (CLGFR, CLGF), COMPARE LOGICAL IMMEDIATE (CLGFI), and COMPARE LOGICAL RELATIVE LONG (CLGFRL), the first operand is treated as 64 bits, and the second operand is treated as 32 bits with 32 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLHHSI), the operands are treated as 16 bits.
- For COMPARE LOGICAL IMMEDIATE (CLFHSI) and COMPARE LOGICAL RELATIVE LONG (CLHRL), the first operand is treated as 32 bits, and the second operand is treated as 16 bits with 16 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLGHSI) and COMPARE LOGICAL RELATIVE LONG (CLGHRL), the first operand is treated as 64 bits, and the second operand is treated as 16 bits with 48 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLI, CLIY), the operands are treated as 8 bits.
- For COMPARE LOGICAL (CLC), the first and second operands have the same length, in the range of one to 256 bytes.

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the fields is reached. For COMPARE LOGICAL (CL, CLY, CLG, CLGF, CLC), COMPARE LOGICAL IMMEDIATE (CLFHSI, CLGHSI, CLHHSI) and COMPARE LOGICAL RELATIVE LONG, access exceptions may or may not be recognized for the portion of a storage operand to the right of the first unequal byte.

The displacements for CL, CLI, CLFHSI, CLGHSI, CLHHSI, and both operands of CLC are treated as 12-bit unsigned binary integers. The displacement for CLY, CLG, CLGF, and CLIY is treated as a 20-bit signed binary integer.

For COMPARE LOGICAL RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For COMPARE LOGICAL RELATIVE LONG (CLRL, CLGFRL), the second operand must be aligned on a word boundary, and for COMPARE LOGICAL RELATIVE LONG (CLGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 2, CL, CLC, CLG, CLGF, CLGFRL, CLGHRL, CLGRL, CLHRL, CLRL, and CLY; fetch, operand 1, CLC, CLFHSI, CLGHSI, CLHHSI, CLI, and CLIY)
- Operation (CLY and CLIY, if the long-displacement facility is not installed; CLFI and CLGFI, if the extended-immediate facility is not installed; CLFHSI, CLGFRL, CLGHSI, CLGHRL, CLGRL, CLHHSI, CLHRL, and CLRL, if the general-instructions-extension facility is not installed)
- Specification (CLRL, CLGFRL, CLGRL)
- Transaction constraint (CLC)

Programming Notes:

1. Examples of the use of the COMPARE LOGICAL instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. COMPARE LOGICAL treats all bits of each operand alike as part of a field of unstructured logical data. For COMPARE LOGICAL (CLC), the comparison may extend to field lengths of 256 bytes.

3. For COMPARE LOGICAL RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.

4. When COMPARE LOGICAL RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

COMPARE LOGICAL AND BRANCH

CLRB $R_1,R_2,M_3,D_4(B_4)$ [RRS]

'EC'	R_1	R_2	B_4	D_4	M_3	////	'F7'

0	8	12	16	32	36	40 47

COMPARE LOGICAL IMMEDIATE AND BRANCH

CLIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

'EC'	R_1	M_3	B_4	D_4	I_2	'FF'
0	8	12	16	20	32	40 47

CLGIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

'EC'	R_1	M_3	B_4	D_4	I_2	'FD'
0	8	12	16	20	32	40 47

COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE

CLIJ R_1,I_2,M_3,RI_4 [RIE-c]

'EC'	R_1	M_3	RI_4	I_2	'7F'
0	8	12	16	32	40 47

CLGIJ R_1,I_2,M_3,RI_4 [RIE-c]

'EC'	R_1	M_3	RI_4	I_2	'7D'
0	8	12	16	32	40 47

The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, the instruction address in the current PSW is replaced by the branch address specified by the fourth operand; otherwise, normal instruction sequencing proceeds with the updated instruction address.

For COMPARE LOGICAL AND BRANCH (CLRB), COMPARE LOGICAL AND BRANCH RELATIVE (CLRJ), COMPARE LOGICAL IMMEDIATE AND BRANCH (CLIB), and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE (CLIJ), the first operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND BRANCH (CLGRB), COMPARE LOGICAL AND BRANCH RELATIVE (CLGRJ), COMPARE LOGICAL IMMEDIATE AND BRANCH (CLGIB), and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE (CLGIJ), the first operand is treated as a 64-bit unsigned binary integer.

For COMPARE LOGICAL AND BRANCH (CLRB) and COMPARE LOGICAL AND BRANCH RELATIVE (CLRJ), the second operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND BRANCH (CLGRB) and COMPARE LOGICAL AND BRANCH RELATIVE (CLGRJ), the second operand is treated as a 64-bit unsigned binary integer. For COMPARE LOGICAL IMMEDIATE AND BRANCH and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE, the second operand is treated as an 8-bit unsigned binary integer. When the size of the second operand is smaller than the size of the first operand, the second operand is extended on the left with zeros to match the size of the first operand.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE LOGICAL AND BRANCH and COMPARE LOGICAL IMMEDIATE AND BRANCH, the fourth operand is used as the branch address. For COMPARE LOGICAL AND BRANCH RELATIVE and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE, the contents of the RI_4 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed).
- Transaction constraint

Programming Notes:

1. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a branch always occurs.

2. When COMPARE LOGICAL AND BRANCH RELATIVE or COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE are the target of an execute-type instruction, the branch is relative to the target address. See “Branch-Address Generation” on page 5-12.

3. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH on page 7-136 also applies to the compare-logical-and-branch instructions.

COMPARE LOGICAL AND TRAP

Register-and-register formats:

CLRT R_1,R_2,M_3 [RRF-c]

'B973'	M_3	////	R_1	R_2
0	16	20	24	28 31

CLGRT R_1,R_2,M_3 [RRF-c]

'B961'	M_3	////	R_1	R_2
0	16	20	24	28 31

Register-and-storage formats:

CLT $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB	R_1	M_3	B_2	DL_2	DH_2	'23'
0	8	12	16	20	32	40 47

CLGT $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'2B'
0	8	12	16	20	32	40 47

COMPARE LOGICAL IMMEDIATE AND TRAP

CLFIT R_1,I_2,M_3 [RIE-a]

'EC'	R_1	////	I_2	M_3	////	'73'	
0	8	12	16	32	36	40	47

CLGIT R_1,I_2,M_3 [RIE-a]

'EC'	R_1	////	I_2	M_3	////	'71'	
0	8	12	16	32	36	40	47

The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, a compare-and-trap-instruction data exception is recognized, and the operation is completed; otherwise, normal instruction sequencing proceeds with the updated instruction address.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE LOGICAL AND TRAP (CLRT, CLT) and COMPARE LOGICAL IMMEDIATE AND TRAP (CLFIT), the first operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLGRT, CLGT) and COMPARE LOGICAL IMMEDIATE AND TRAP (CLGIT), the first operand is treated as a 64-bit unsigned binary integer.

For COMPARE LOGICAL IMMEDIATE AND TRAP, the second operand is treated as a 16-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLRT, CLT), the second operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLGRT, CLGT), the second operand is treated as a 64-bit unsigned binary integer. When the size of the second operand is smaller than the size of the first operand, the second operand is extended on the left with zeros to match the size of the first operand.

For COMPARE LOGICAL AND TRAP (CLT, CLGT), when bit positions 0-2 of the M_3 field contain either 000 or 111 binary, it is model dependent whether an access exception is recognized for the second-operand location; if accessible, it is model dependent whether a PER zero-address-detection event is recognized for the location.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2, CLT, CLGT)
- Data
- Operation (CLRT, CLGRT, CLFIT, CLGIT, if the general-instructions-extension facility is not installed; CLT, CLGT if the miscellaneous-instruction-extensions facility 1 is not installed)

Programming Notes:

1. Possible uses of COMPARE LOGICAL AND TRAP and COMPARE LOGICAL IMMEDIATE AND TRAP include checking for pointers containing zero (null pointer), or array range checking.

2. On most models, when a data exception is not recognized, the performance of COMPARE LOGICAL AND TRAP and COMPARE LOGICAL IMMEDIATE AND TRAP is typically similar to other COMPARE LOGICAL instructions. When a data exception is recognized, the instruction may be significantly slower than an equivalent COMPARE LOGICAL instruction followed by a BRANCH ON CONDITION instruction.

3. For CLFIT, CLGIT, CLGRT, and CLRT, when bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. This NOP characteristic may not apply to CLGT and CLT.

   When bit positions 0-2 of the M_3 field contain 111 binary, a data exception is always recognized.

4. When a data exception is recognized, the compare-and-trap data-exception code (DXC FF hex) is stored, as described in “Data Exception” on page 6-25.

5. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH

on page 7-136 also applies to the compare-logical-and-trap instructions.

COMPARE LOGICAL CHARACTERS UNDER MASK

CLM $R_1,M_3,D_2(B_2)$ [RS-b]

'BD'	R_1	M_3	B_2	D_2
0	8	12	16	20 31

CLMY $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'21'
0	8	12	16	20	32	40 47

CLMH $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'20'
0	8	12	16	20	32	40 47

The first operand is compared with the second operand under control of a mask, and the result is indicated in the condition code.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R_1. For COMPARE LOGICAL CHARACTERS UNDER MASK (CLM, CLMY), the four bytes to which the mask bits correspond are in bit positions 32-63 of general register R_1. For COMPARE LOGICAL CHARACTERS UNDER MASK (CLMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The byte positions corresponding to ones in the mask are considered as a contiguous field and are compared with the second operand. The second operand is a contiguous field in storage, starting at the second-operand address and equal in length to the number of ones in the mask. The bytes in the general register corresponding to zeros in the mask do not participate in the operation.

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the fields is reached.

When the mask is not zero, exceptions associated with storage-operand access are recognized for no more than the number of bytes specified by the mask. Access exceptions may or may not be recognized for the portion of a storage operand to the right of the first unequal byte. When the mask is zero, access exceptions are recognized for one byte at the second-operand address.

The displacement for CLM is treated as a 12-bit unsigned binary integer. The displacement for CLMY and CLMH is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Operands equal, or mask bits all zeros
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 2)
- Operation (CLMY, if the long-displacement facility is not installed)

Programming Note: An example of the use of the COMPARE LOGICAL CHARACTERS UNDER MASK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

COMPARE LOGICAL HIGH

Register-and-register formats:

CLHHR R_1,R_2 [RRE]

'B9CF'	////////	R_1	R_2
0	16	24	28 31

COMPARE LOGICAL IMMEDIATE HIGH

CLIH R$_1$,I$_2$ [RIL-a]

'CC'	R$_1$	'F'	I$_2$
0	8	12	16 47

The first operand is compared with the second operand, and the result is indicated in the condition code.

The operands are treated as 32-bit unsigned binary integers. The first operand is in bit positions 0-31 of general register R$_1$; bit positions 32-63 of the register are ignored. For COMPARE LOGICAL HIGH (CLHHR), the second operand is in bit positions 0-31 of general register R$_2$; bit positions 32-63 of the register are ignored. For COMPARE LOGICAL HIGH (CLHLR), the second operand is in bit positions 32-63 of general register R$_2$; bit positions 0-31 of the register are ignored.

The displacement for CLHF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (operand 2 of CLHF only)
- Operation (if the high-word facility is not installed)

COMPARE LOGICAL LONG

CLCL R$_1$,R$_2$ [RR]

'0F'	R$_1$	R$_2$
0	8	12 15

The first operand is compared with the second operand, and the result is indicated in the condition code. The shorter operand is considered to be extended on the right with padding bytes.

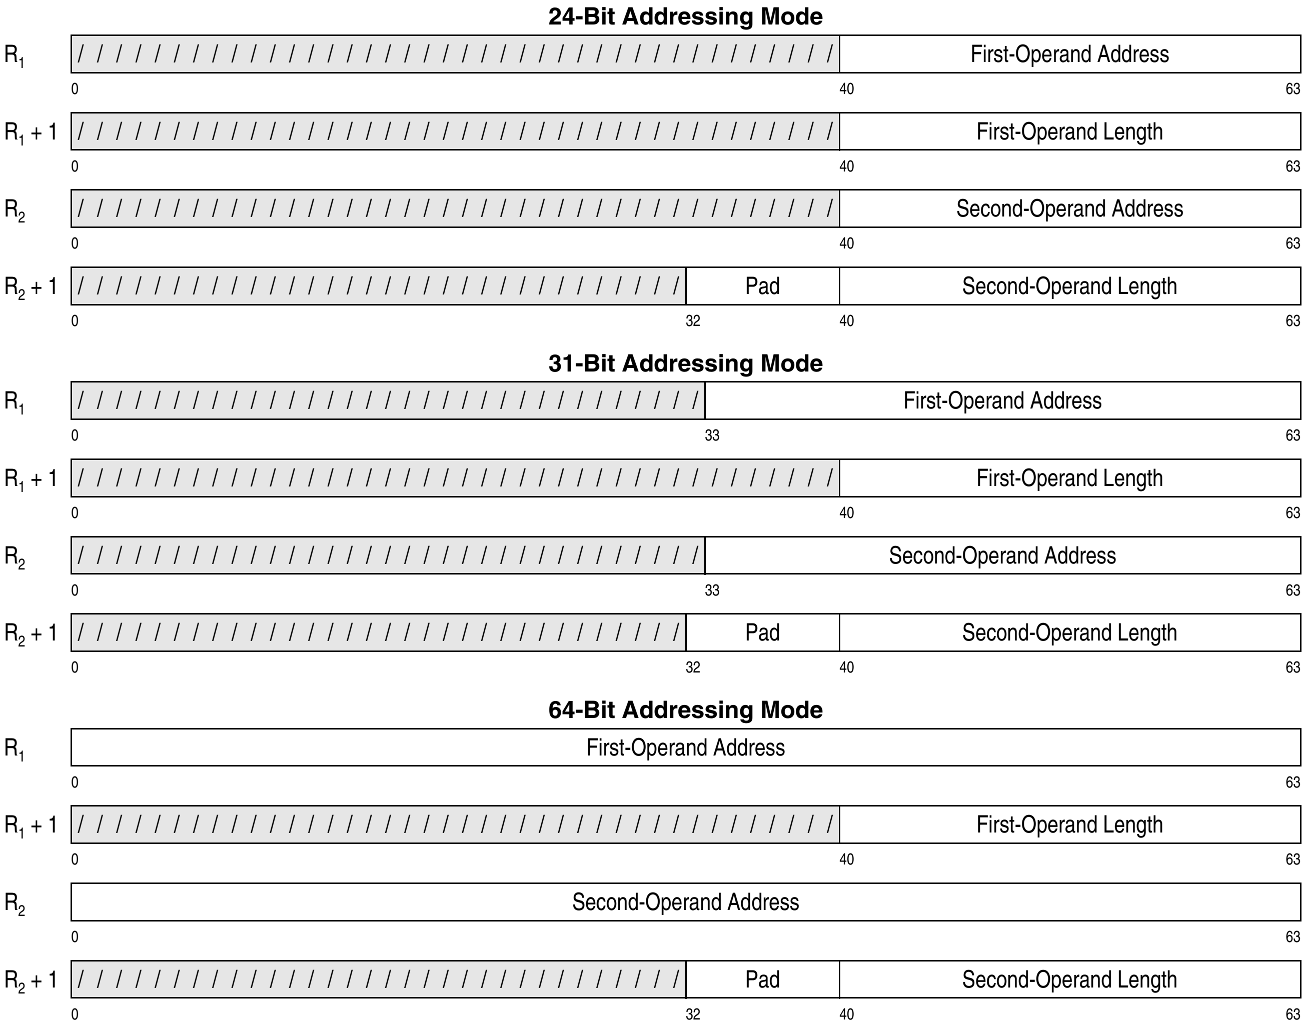
The R$_1$ and R$_2$ fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R$_1$ and R$_2$, respectively. The number of bytes in the first-operand and second-operand locations is specified by unsigned binary integers in bit positions 40-63 of general registers R$_1$ + 1 and R$_2$ + 1, respectively. Bit positions 32-39 of general register R$_2$ + 1 contain the padding byte. The contents of bit positions 0-39 of general register R$_1$ + 1 and of bit positions 0-31 of general register R$_2$ + 1 are ignored.

The handling of the addresses in general registers R$_1$ and R$_2$ is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R$_1$ and R$_2$ constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-196.



24-Bit Addressing Mode
R1 / / / / First-Operand Address 0 40 63
R1 + 1 / / / / First-Operand Length 0 40 63
R2 / / / / Second-Operand Address 0 40 63
R2 + 1 / / / / Pad Second-Operand Length 0 32 40 63
31-Bit Addressing Mode
R1 / / / / First-Operand Address 0 33 63
R1 + 1 / / / / First-Operand Length 0 40 63
R2 / / / / Second-Operand Address 0 33 63
R2 + 1 / / / / Pad Second-Operand Length 0 32 40 63
64-Bit Addressing Mode
R1 First-Operand Address 0 63
R1 + 1 / / / / First-Operand Length 0 40 63
R2 Second-Operand Address 0 63
R2 + 1 / / / / Pad Second-Operand Length 0 32 40 63

Figure 7-196. Register Contents for COMPARE LOGICAL LONG

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the longer operand is reached. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If both operands are of zero length, the operands are considered to be equal.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the lengths in general registers R_1 + 1 and R_2 + 1 are decremented by the number of bytes compared, and the addresses in general registers R_1 and R_2 are incremented by the same number, so that the instruction, when reexecuted, resumes at the point of interruption. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, and the contents of bit positions 0-31 remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers R_1 + 1 and R_2 + 1 remain unchanged, and the condition code is unpredictable. If the operation is interrupted after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and its address is updated accordingly.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_2 at completion identify the first unequal byte in each operand. The lengths in bit positions 40-63 of general registers $R_1 + 1$ and $R_2 + 1$ are decremented by the number of bytes that were equal, unless the inequality occurred with the padding byte, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_2 are incremented by the amounts by which the corresponding length fields were reduced.

If the two operands, including the padding byte, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values.

At the completion of the operation, in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, even when one or both of the initial length values are zero. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

Access exceptions for the portion of a storage operand to the right of the first unequal byte may or may not be recognized. For operands longer than 2K bytes, access exceptions are not recognized more than 2K bytes beyond the byte being processed. Access exceptions are not indicated for locations more than 2K bytes beyond the first unequal byte.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Operands equal, or both zero length
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the COMPARE LOGICAL LONG instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the R_1 and R_2 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by the number of bytes compared, not by twice the number of bytes compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, condition code 0 is set. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed.
3. Special precautions should be taken when COMPARE LOGICAL LONG is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.
4. Other programming notes concerning interruptible instructions are included in “Interruptible Instructions” in Chapter 5, “Program Execution.”
5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE LOGICAL LONG EXTENDED

CLCLE $R_1,R_3,D_2(B_2)$ [RS-a]

'A9'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

The first operand is compared with the third operand until unequal bytes are compared, the end of the longer operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with padding bytes. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The second-operand address is not used to address data; instead, the rightmost eight bits of the second-operand address, bits 56-63, are the padding byte. Bits 0-55 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-197.

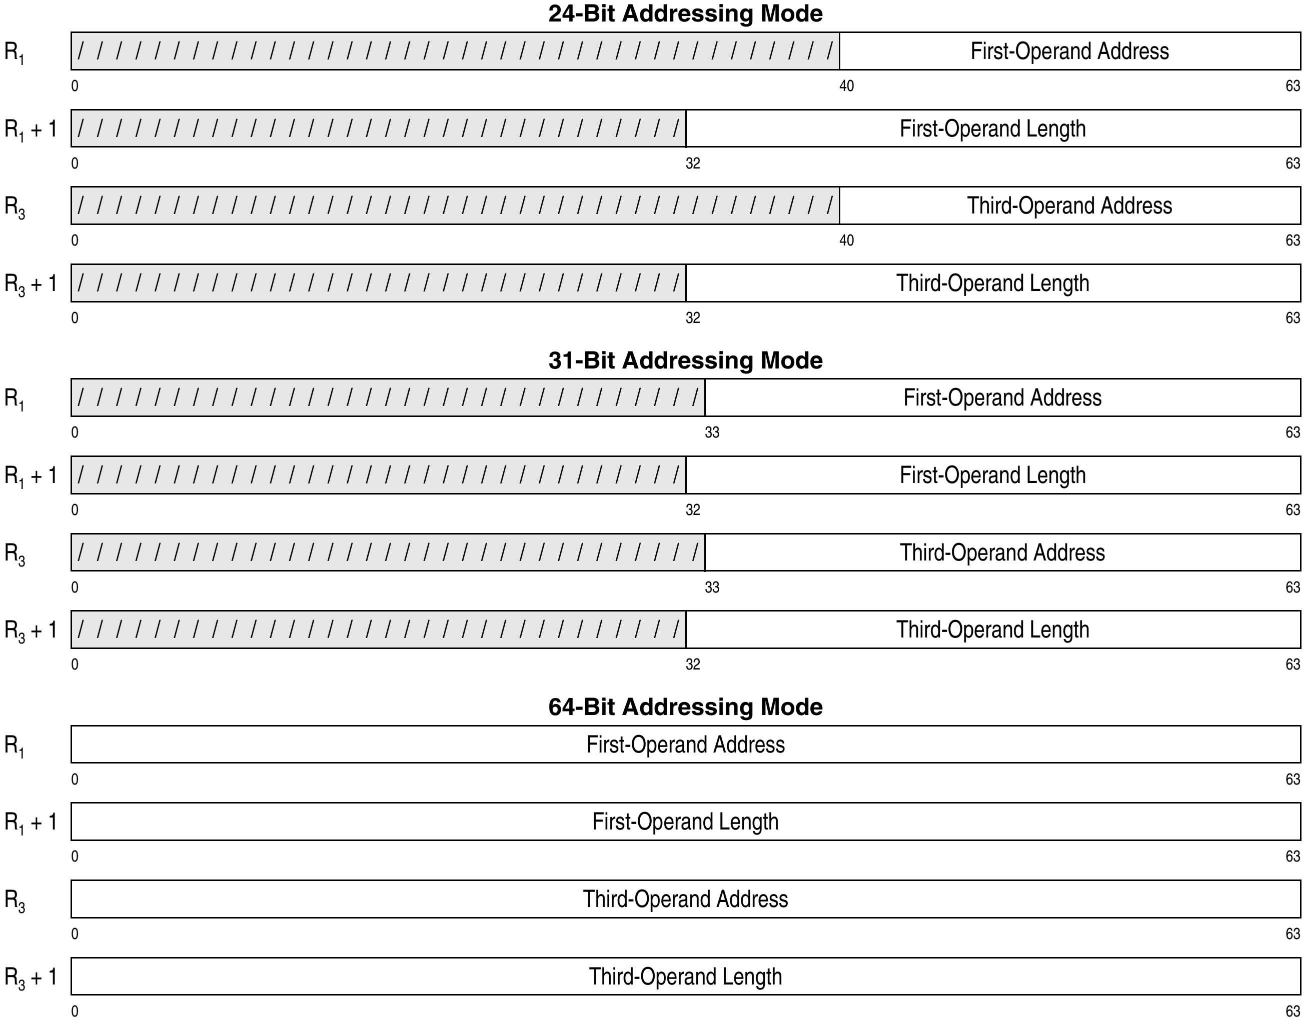


Figure 7-197. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG EXTENDED (Part 1 of 2)

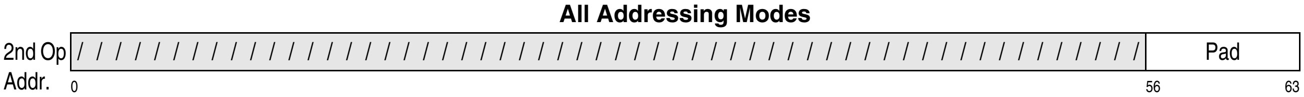

Figure 7-197. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG EXTENDED (Part 2 of 2)

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found, the end of the longer operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If both operands are of zero length, the operands are considered to be equal.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_3 at completion identify the first unequal byte in each operand. The lengths in bit positions 32-63, in the 24-bit or 31-bit addressing mode, or in bit positions 0-63, in the 64-bit addressing mode, of general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes that were equal, unless the inequality occurred with the padding byte, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_3 are incremented by the amounts by which the corresponding length fields were decremented. Condition code 1 is set if the first operand is low, or condition code 2 is set if the first operand is high.

If the two operands, including the padding byte, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values. Condition code 0 is set.

If the operation is completed because a CPU-determined number of bytes have been compared without finding an inequality or reaching the end of the longer operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes compared, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next bytes to be compared. If the operation is completed after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and the operand address is updated accordingly. Condition code 3 is set.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_3, and $R_3 + 1$, always remain unchanged.

The padding byte may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The maximum amount is approximately 4K bytes of either operand.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, even when one or both of the initial length values are zero.

Access exceptions for the portion of a storage operand to the right of the first unequal byte may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the byte being processed. Access exceptions are not indicated for locations more than 4K bytes beyond the first unequal byte.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 All bytes compared; operands equal, or both zero length
1 All bytes compared, first operand low
2 All bytes compared, first operand high
3 CPU-determined number of bytes compared without finding an inequality

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Specification
- Transaction constraint

Programming Notes:

1. COMPARE LOGICAL LONG EXTENDED is intended for use in place of COMPARE LOGICAL LONG when the operand lengths are specified as 32-bit or 64-bit binary integers. COMPARE LOGICAL LONG EXTENDED sets condition code 3 in cases in which COMPARE LOGICAL LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of bytes that were compared.

3. The function of not processing more than approximately 4K bytes of either operand is intended to permit software polling of a flag that may be set by a program on another CPU during long operations.

4. When the R_1 and R_3 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by the number of bytes compared, not by twice the number of bytes compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, the condition code is finally set to 0 after possible settings to 3. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed. If storage is not accessed, condition code 3 may or may not be set regardless of the operand length.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE LOGICAL LONG UNICODE

CLCLU $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'8F'

0 8 12 16 20 32 40 47

The first operand is compared with the third operand until unequal two-byte Unicode characters are compared, the end of the longer operand is reached, or a CPU-determined number of characters have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with two-byte padding characters. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost character of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The contents of general registers $R_1 + 1$ and $R_3 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the registers constitute the address.

The second-operand address is not used to address data; instead, the rightmost 16 bits of the second-operand address, bits 48-63, are the two-byte padding character. Bits 0-47 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-198.

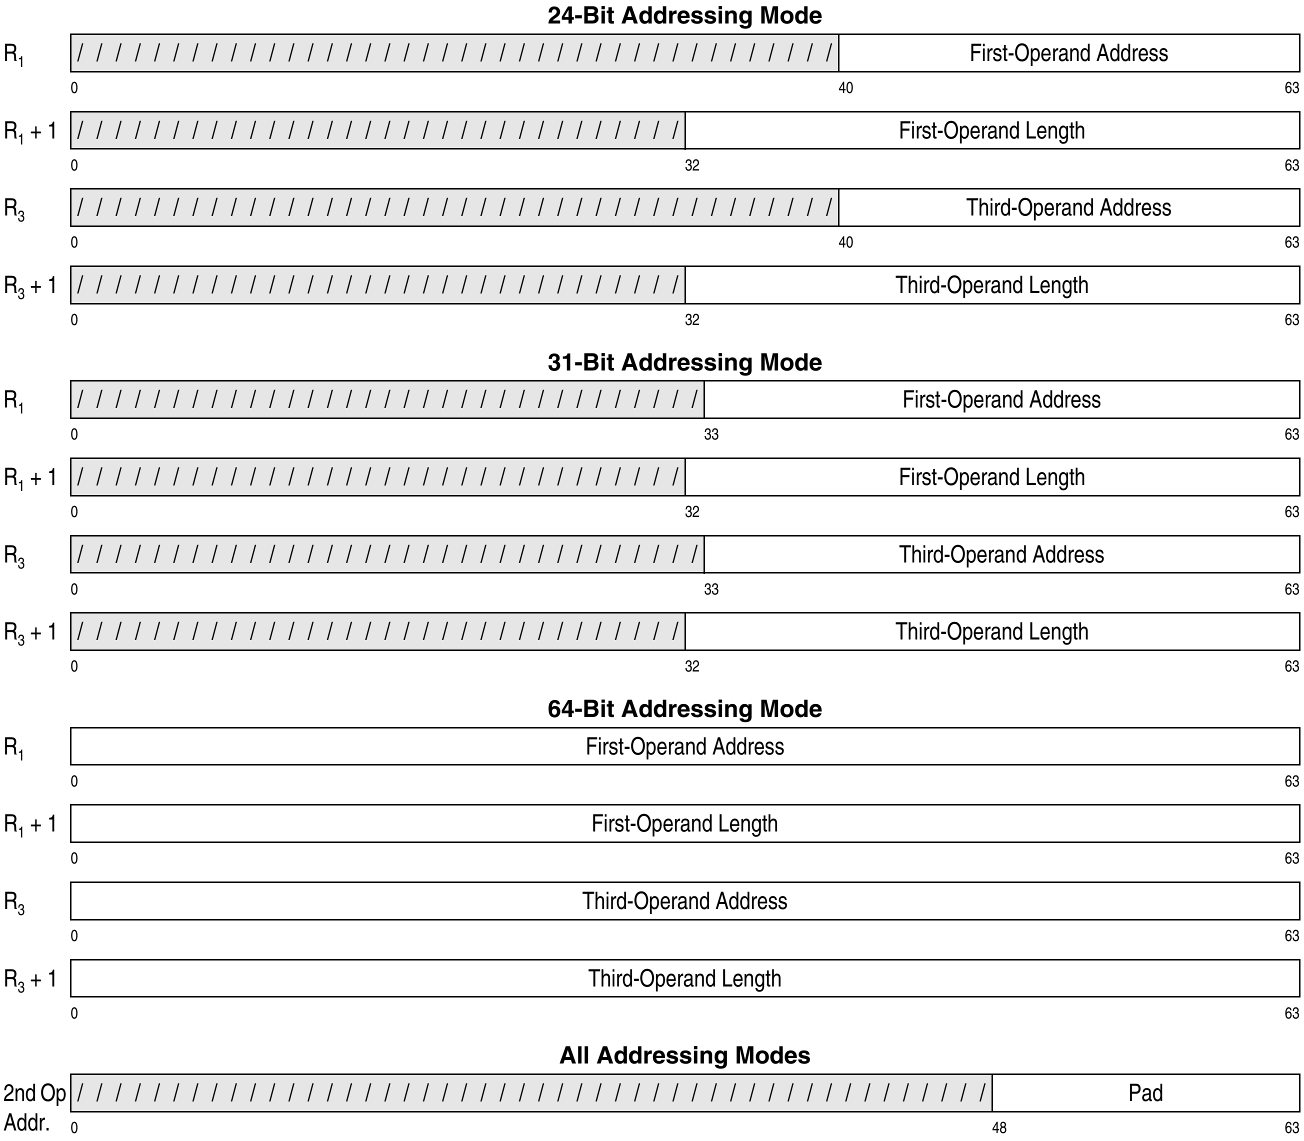

Figure 7-198. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG UNICODE

The comparison proceeds left to right, character by character, and ends as soon as an inequality is found, the end of the longer operand is reached, or a CPU-determined number of characters have been compared, whichever occurs first. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of two-byte padding characters.

If both operands are of zero length, the operands are considered to be equal.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_3 at completion identify the first unequal two-byte character in each operand. The lengths in bit positions 32-63, in the 24-bit or 31-bit addressing mode, or in bit positions 0-63, in the 64-bit addressing mode, of general registers $R_1 + 1$ and $R_3 + 1$ are decremented by 2 times the number of characters that were equal, unless the inequality occurred with the two-byte padding character, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_3 are incremented by the amounts by which the corresponding length fields were decremented. Condition code 1 is set if the first operand is low, or condition code 2 is set if the first operand is high.

If the two operands, including the two-byte padding character, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values. Condition code 0 is set.

If the operation is completed because a CPU-determined number of characters have been compared without finding an inequality or reaching the end of the longer operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by 2 times the number of characters compared, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next characters to be compared. If the operation is completed after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and the operand address is updated accordingly. Condition code 3 is set.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_3, and $R_3 + 1$, always remain unchanged.

The two-byte padding character may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, including the case when one or both of the initial length values are zero.

Access exceptions for the portion of a storage operand to the right of the first unequal character may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the character being processed. Access exceptions are not indicated for locations more than 4K bytes beyond the first unequal character.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field or length associated with that operand is odd.

Resulting Condition Code:

0 All characters compared; operands equal, or both zero length
1 First operand low
2 First operand high
3 CPU-determined number of characters compared without finding an inequality

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. COMPARE LOGICAL LONG UNICODE is intended for use in place of COMPARE LOGICAL LONG or COMPARE LOGICAL LONG EXTENDED when two-byte characters are to be compared. The characters may be Unicode characters or any other double-byte characters. COMPARE LOGICAL LONG UNICODE sets condition code 3 in cases in which COMPARE LOGICAL LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of characters that were compared.

3. When the R_1 and R_3 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by 2 times the number of characters compared, not by 4 times the number of characters compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, the condition code is finally set to 0 after possible settings to 3. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed. If storage is not accessed, condition code 3 may or may not be set regardless of the operand length.

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

5. The padding character may be represented in the displacement field of the instruction. The following example illustrates padding with a Unicode space character.

   CLCLU 6,8,X'020'

   When the B_2 field of the instruction designates general register 0, and the long-displacement facility is not installed, the padding character is limited to a character whose representation is less than or equal to FFF hex.

COMPARE LOGICAL STRING

CLST R_1,R_2 [RRE]

'B25D'	////////	R_1	R_2
0	16	24	28 31

The first operand is compared with the second operand until unequal bytes are compared, the end of either operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. The CPU-determined number is at least 256. The result is indicated in the condition code.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The first and second operands may be of the same or different lengths. The end of an operand is indicated by an ending character in the last byte position of the operand. The ending character to be used to determine the end of an operand is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right, byte by byte, and ends as soon as the ending character is encountered in either or both operands, unequal bytes which do not include an ending character are compared, or a CPU-determined number of bytes have been compared, whichever occurs first. The CPU-determined number is at least 256. When the ending character is encountered simultaneously in both operands, including when it is in the first byte position of the operands, the operands are of the same length and are considered to be equal, and condition code 0 is set. When the ending character is encountered in only one operand, that operand, which is the shorter operand, is considered to be low, and condition code 1 or 2 is set. Condition code 1 is set if the first operand is low, or condition code 2 is set if the second operand is low. Similarly, when unequal bytes which do not include an ending character are compared, condition code 1 is set if the lower byte is in the first operand, or condition code 2 is set if the lower byte is in the second operand. When a CPU-determined number of bytes have been compared, condition code 3 is set.

When condition code 1 or 2 is set, the address of the last byte processed in the first and second operands is placed in general registers R_1 and R_2, respectively. That is, when condition code 1 is set, the address of the ending character or first unequal byte in the first operand, whichever was encountered, is placed in general register R_1, and the address of the second-operand byte corresponding in position to the first-operand byte is placed in general register R_2. When condition code 2 is set, the address of the ending character or first unequal byte in the second operand, whichever was encountered, is placed in general register R_2, and the address of the first-operand byte corresponding in position to the second-operand byte is placed in general register R_1. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32 in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When condition code 0 is set, the contents of general registers R_1 and R_2 remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the first and second operands are recognized only for that portion of the operand which is necessarily examined in the operation.

Resulting Condition Code:

0 Entire operands equal; general registers R_1 and R_2 unchanged
1 First operand low; general registers R_1 and R_2 updated with addresses of last bytes processed
2 First operand high; general registers R_1 and R_2 updated with addresses of last bytes processed
3 CPU-determined number of bytes equal; general registers R_1 and R_2 updated with addresses of next bytes

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. Several examples of the use of the COMPARE LOGICAL STRING instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When condition code 0 is set, no indication is given of the position of either ending character.
3. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of bytes that were compared.
4. R_1 or R_2 may be zero, in which case general register 0 is treated as containing an address and also the ending character.
5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE UNTIL SUBSTRING EQUAL

CUSE R_1,R_2 [RRE]

'B257'	////////	R_1	R_2
0	16	24	28 31

The first operand is compared with the second operand until equal substrings (sequences of bytes) of a specified length are found, the end of the longer operand is reached, or a CPU-determined number of unequal bytes have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with padding bytes. The CPU-determined number is at least 256. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is specified by the contents of the R_1 and R_2 general registers, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the 32-bit signed binary integer in bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively. In the 64-bit addressing mode, the number of bytes is specified by the 64-bit signed binary integer in bit positions 0-63 of those registers. When an operand length is negative, it is treated as zero, and it remains unchanged upon completion of the instruction.

Bits 56-63 of general register 0 specify the unsigned substring length, a value of 0-255, in bytes. Bits 56-63 of general register 1 are the padding byte. Bits 0-55 of general registers 0 and 1 are ignored.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-199.

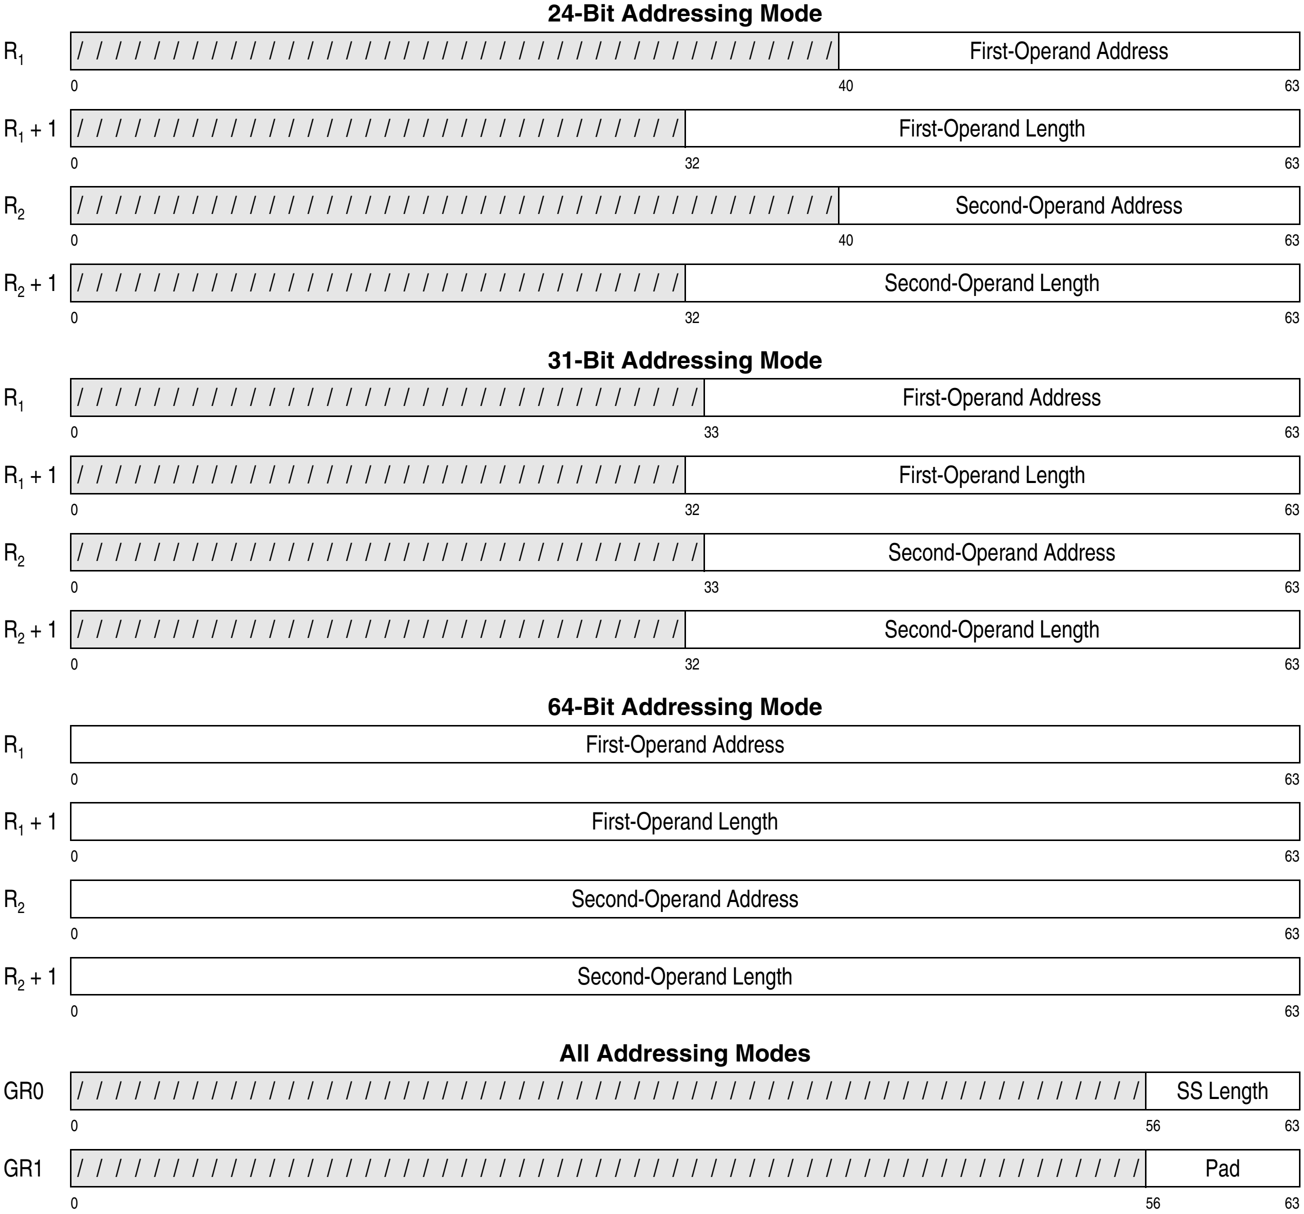

Figure 7-199. Register Contents for COMPARE UNTIL SUBSTRING EQUAL

The result is obtained as if the operands were processed from left to right. However, multiple accesses may be made to all or some of the bytes of each operand.

The comparison proceeds left to right, byte by byte, and ends as soon as (1) equal substrings of the specified length are found, (2) the end of the longer operand is reached without finding equal substrings of the specified length, or (3) the last bytes compared are unequal, and a CPU-determined number of bytes have been compared. The CPU-determined number is at least 256. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If the operation ends because equal substrings of the specified length were found, the condition code is set to 0. If the operation ends because the end of the longer operand was reached without finding equal substrings of the specified length, the condition code is set to 1 if equal bytes were the last bytes compared, or it is set to 2 if unequal bytes were the last bytes compared. If the operation ends because unequal bytes were compared when a CPU-determined number of bytes had been compared, the condition code is set to 3.

If the specified substring length is zero, it is considered that equal substrings of the specified length were found, and condition code 0 is set.

If both operands are of zero length but the specified substring length is not zero, it is considered that the end of the longer operand was reached when unequal bytes were the last bytes compared, and condition code 2 is set.

If equal bytes have been compared but then unequal bytes are compared, it is considered that all bytes so far compared are unequal.

At the completion of the operation, the operand-length fields in the $R_1 + 1$ and $R_2 + 1$ registers are decremented by the number of unequal bytes compared (including equal bytes before unequal bytes compared), and the addresses in the R_1 and R_2 registers are incremented by the same number. However, in the case when a byte of the longer operand is compared against the padding byte, the length field for the shorter operand is not decremented below zero, and the corresponding address is not incremented above the address of the first byte after the shorter operand. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the addresses in bit positions 32-63 of registers R_1 and R_2 are set to zeros, even if the substring length is zero or both operand lengths are initially zero.

Thus, when condition code 0 or 1 is set, the resulting addresses in the R_1 and R_2 registers designate the first bytes of equal substrings in the two operands, and the lengths in the $R_1 + 1$ and $R_2 + 1$ registers have been decremented by the number of bytes preceding the equal substrings, except when the equal substring in the shorter operand begins with the padding byte, in which case the length field for the shorter operand is zero, and the corresponding address field has been incremented by the operand length. When condition code 2 is set, each address field designates the first byte after the corresponding operand, and both length fields are zero. When condition code 3 is set, each address field designates the first byte after the last compared byte of the corresponding operand, and both length fields have been decremented by the number of bytes compared, except that a length field is not decremented below zero.

When the contents of the R_1 and R_2 fields are the same, the first and second operands may be compared, or the condition code may be set to 0 or 1 without comparing the operands.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

The substring length and padding byte may be fetched from general registers 0 and 1 multiple times during the execution of the instruction, and the registers designated by R_1 and R_2 may be updated multiple times. Therefore, if R_1 or R_2 is zero, the results are unpredictable.

When condition code 3 is set, the general registers used by the instruction have been set so that the remainder of the operands can be processed by simply branching back and reexecuting the instruction.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

The execution of the instruction is interruptible when the last bytes compared are unequal; it is not interruptible when the last bytes compared are equal. When an interruption occurs, other than one that follows termination, the contents of the registers designated by the R_1 and R_2 fields are updated the same as upon normal completion of the instruction, so that the instruction, when reexecuted, resumes at the point of interruption. The condition code is unpredictable.

Access exceptions for the portion of a storage operand to the right of the last byte processed may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Although the operand address and length fields remain unchanged when a zero substring length is specified, the recognition of access exceptions is not necessarily prevented.

Resulting Condition Code:

0 Equal substrings of specified length found
1 End of longer operand reached when last bytes compared are equal
2 End of longer operand reached when last bytes compared are unequal
3 Last bytes compared are unequal, and CPU-determined number of bytes compared

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. When the R_1 and R_2 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, and, in the absence of dynamic modification of the operand area by another CPU or by a channel program, condition code 0, 1, or 2 is set (as explained in the next note). However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed.

2. If the contents of the R_1 and R_2 fields are the same and the operand length is nonzero, and provided that another CPU or a channel program is not changing an operand, condition code 0 is set if the operand length is equal to or greater than the specified substring length, or condition code 1 is set if the operand length is less than the specified substring length. Whether or not R_1 equals R_2, if both operand lengths are zero, condition code 0 is set if the specified substring length is zero, or condition code 2 is set if the specified substring length is nonzero. In all of these cases, the addresses in the R_1 and R_2 registers and the lengths in the $R_1 + 1$ and $R_2 + 1$ registers remain unchanged.

3. Special precautions should be taken when COMPARE UNTIL SUBSTRING EQUAL is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

4. Other programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

6. The storage-operand references of COMPARE UNTIL SUBSTRING EQUAL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

COMPRESSION CALL

CMPSC R_1,R_2 [RRE]

'B263'	////////	R_1	R_2
0	16	24	28 31

This definition assumes knowledge of the introductory information and information about dictionary formats in Appendix D.

The second operand is compressed or expanded, depending on a specification in general register 0, and the results are placed at the first-operand location. The compressed-data operand consists of either index symbols corresponding to entries in a dictionary designated by an address in general register 1, or codewords which are converted to index symbols depending on the specification of entropy encoding. This dictionary is a compression dictionary during a compression operation or an expansion dictionary during an expansion operation.

During compression when format-1 sibling descriptors are specified in general register 0, an expansion dictionary immediately follows the compression dictionary. During compression when the symbol-translation option is specified in general register 0, the index symbols resulting from compression are translated to interchange symbols by means of a symbol-translation table designated by the address and an offset in general register 1, and it is the interchange symbols that are placed at the first-operand location. During compression when the order preservation option is specified in general register 0, a modified form of symbol translation occurs. During compression when the entropy-encoding option is specified in general register 0, the index symbols are translated into codewords via a modified version of symbol translation whose parameters are specified by the address and offset in general register 1. The number of bits in an index or interchange symbol in the compressed-data operand or in an index symbol used in entropy encoding is specified in general register 0. The operation proceeds until the end of either operand is reached or a CPU-determined amount of data has been processed, whichever occurs first. The results are indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte containing any bit of the first operand and second operand is designated by an address in general registers R_1 and R_2, respectively. The number of bytes containing any bits of the first operand and second operand is specified by bits 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, in the 24-bit or 31-bit addressing mode or by bits 0-63 of the registers in the 64-bit addressing mode. The contents of general registers $R_1 + 1$ and $R_2 + 1$ are treated as 32-bit unsigned binary integers in the 24-bit or 31-bit addressing mode or as 64-bit unsigned binary integers in the 64-bit addressing mode.

The location of the leftmost byte of the compression dictionary during compression, or of the expansion dictionary during expansion, is designated on a 4 K-byte boundary by an address in general register 1. Optionally, general register 1 also contains an offset to the first byte of an entropy descriptor or symbol translation table.

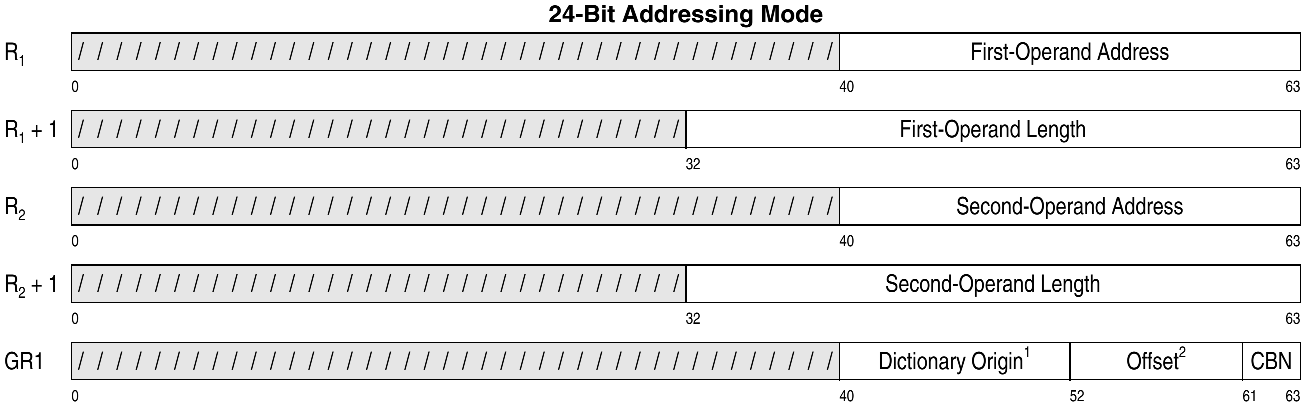

Figure 7-200. Register Contents for COMPRESSION CALL (Part 1 of 2)

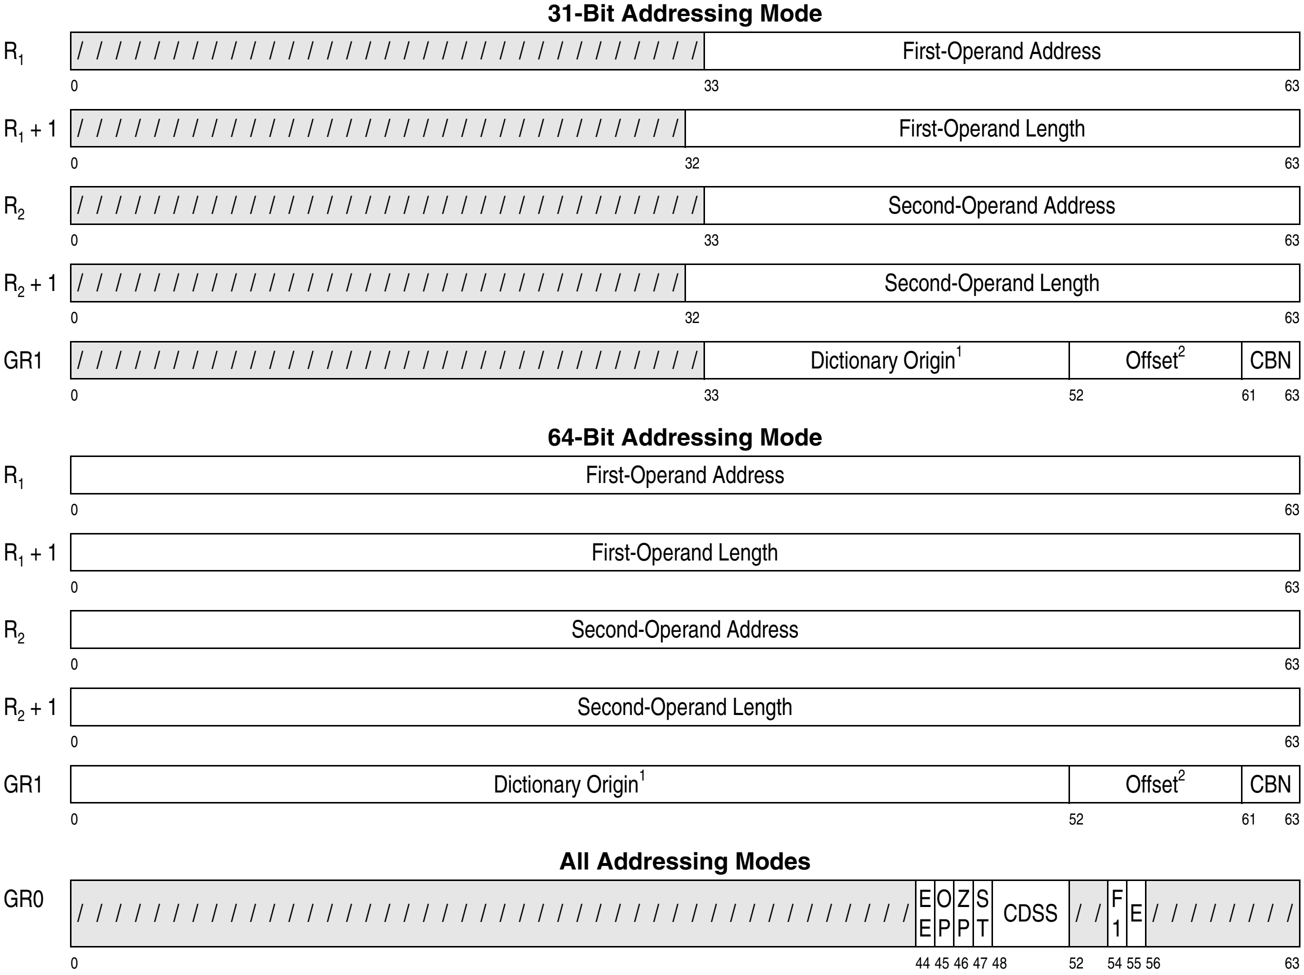

Explanation:

[1] Compression dictionary during compression, or expansion dictionary during expansion

[2] The Offset field is only meaningful during compression when any of the ST, EE, and OP bits are one. When the ST, EE, and OP bits are zero during compression, or the EE bit is zero during expansion, the Offset field is ignored.

CBN Compressed-data bit number

CDSS Compressed-data symbol size

CDSS (binary)	Symbol Size	Dictionary Size
0000	Causes a specification exception to be recognized	
0001	9 bits	512 entries, 4K bytes
0010	10 bits	1K entries, 8K bytes
0011	11 bits	2K entries, 16K bytes
0100	12 bits	4K entries, 32K bytes
0101	13 bits	8K entries, 64K bytes
0110-1111	Causes a specification exception to be recognized	

E Expansion operation

EE Entropy-encoding option (when the entropy-encoding compression facility is installed).

F1 Format-1 sibling descriptors (ignored during expansion)

Offset Offset to symbol translation table or entropy descriptor

OP Order-preservation option (ignored during expansion, or when the order-preserving-compression facility is not installed)

ST Symbol-translation option (ignored during expansion, implied one for entropy encoding)

ZP Zero padding control (when the CMPSC-enhancement facility is installed).

Figure 7-200. Register Contents for COMPRESSION CALL (Part 2 of 2)

The handling of the addresses in general registers R_1, R_2, and 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of registers R_1 and R_2 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of registers R_1 and R_2 constitute the address. In the 24-bit addressing mode, the contents of bit positions 40-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 0-39 and 52-63 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 0-32 and 52-63 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 52-63 are ignored.

Although the contents of bit positions 52-63 of general register 1 are ignored in the formation of a dictionary address, those contents are used as follows. The contents of bit positions 61-63 of the register are the compressed-data bit number (CBN). At the beginning of the operation, the CBN designates the leftmost bit within the leftmost byte of the compressed-data operand. The compressed-data operand is the first operand during compression, or it is the second operand during expansion. When the symbol-translation or order-preservation option is specified during compression and the entropy-encoding option is not specified, the contents of bit positions 52-60 of the register, with seven rightmost zeros appended, are the byte offset from the beginning of the compression dictionary to the leftmost byte of the symbol-translation table. When the entropy-encoding option is specified the contents of bit positions 52-60 of the register, with seven rightmost zeros appended, are the byte offset from the beginning of the compression dictionary to the leftmost byte of the entropy descriptor. When the entropy encoding option is specified during compression, the leftmost byte of the entropy encoding symbol translation table is located at the byte offset plus 32. Symbol translation and order-preservation cannot be specified during expansion, and the contents of bit positions 52-60 are ignored during expansion.

The contents of the registers just described and also of general register 0 are shown in Figure 7-200 on page 7-170.

Bit 55 (E) of general register 0 specifies the compression operation if zero or the expansion operation if one.

When the CMPSC-enhancement facility is installed, bit 46 of general register 0 is the zero-padding (ZP) control. When the ZP control is zero, zero padding of the first operand is not performed. When the ZP control is one, zero padding of the first operand may be performed, as described below. When the CMPSC-enhancement facility is not installed, bit 46 of general register 0 is ignored.

Bit 44 (EE) of general register 0 is the entropy-encoding-option bit; this bit is only meaningful when the entropy-encoding-compression facility is installed. Bit 45 (OP) of general register 0 is the order-preservation-option bit; this bit is only meaningful when the order-preserving-compression facility is installed. Bit 47 (ST) of general register 0 is the symbol-translation-option bit. When bit 44 (EE) is one, bit 45 (OP) must be zero; otherwise results are unpredictable.

During compression when bits 45 and 47 are both zero, the operation produces indexes, called index symbols, to compression-dictionary entries that represent character strings, and the operation then places the index symbols in the compressed-data operand. During compression when bit 45 is zero and bit 47 is one, the operation still produces index symbols but then translates the index symbols to other symbols, called interchange symbols, that it then places in the compressed-data operand. This symbol translation is done by using the symbol-translation table specified by the address and offset in general register 1. During compression when bit 45 is one, bit 47 is ignored, and a modified form of symbol translation is done by using the symbol-translation table. Bits 45 and 47 and the offset in general register 1 are ignored during expansion. During expansion, the compressed-data operand always contains index symbols that designate entries in the expansion dictionary.

When bit 44 of general register 0 is one during compression the operation produces indexes called index symbols which are translated to codewords which are then placed in the compressed-data operand. The translation is done by using the symbol-translation table specified by the address and offset + 32 bytes. During expansion the compressed-data operand always contains codewords that are converted to index symbols by the process shown in Figure 7-205, “Entropy Encoded Expansion” on page 7-186 which are then used to designate entries in the expansion dictionary.

When bit 44 of general register 0 is zero, bits 48-51 (CDSS) of the register specify the number of bits in the index symbols or interchange symbols in the compressed-data operand, as shown in the figure. Bits 48-51 must not have any of the values 0000 or 0110-1111 binary; otherwise, a specification exception is recognized. When bit 44 (EE) of general register 0 is one, bits 48-51 (CDSS) are ignored. When order preservation, entropy encoding, and symbol-translation are not specified, bits 48-51 also specify, as shown in the figure, the number of eight-byte entries in each of the compression and expansion dictionaries, and, thus, they specify the size in bytes of each of the dictionaries. When order preservation, entropy encoding or symbol translation is specified, the compression dictionary is considered to extend to the beginning of the symbol-translation table, that is, the size in bytes of the compression dictionary is the offset in bit positions 52-60 of general register 1, with seven rightmost zeros appended. The size in bytes of the symbol-translation table is considered to be one fourth that of the compression dictionary. However, the offset in general register 1 must be at least as large as the size of the compression dictionary would be if symbol translation were not specified and the CDSS were one less than it actually is, and, when the CDSS is 0001 binary, the offset must be at least 2K bytes; otherwise, the results are unpredictable. For example, if the CDSS is 0101, the offset must be at least 32 K-bytes. When entropy encoding is specified, the compression dictionary must be at least 2K bytes and at most 64 K-bytes; otherwise, the results are unpredictable.

Bit 54 (F1) of general register 0 specifies that the compression dictionary contains format-0 sibling descriptors if the bit is zero or format-1 sibling descriptors if the bit is one. Sibling descriptors are used during the compression operation. A format-0 sibling descriptor is eight bytes at an index position in the compression dictionary. A format-1 sibling descriptor is 16 bytes, with the first eight bytes at an index position in the compression dictionary and the second eight bytes at the same index position in the expansion dictionary. During compression when bit 54 is one, an expansion dictionary is considered to immediately follow the compression dictionary specified by the address in general register 1. Bit 54 is ignored during expansion. During compression when bit 54 is one, bits 44, 45 and 47 of general register 0 must be zeros; otherwise, the results are unpredictable.

Bits 47 and 54 of general register 0 must not both be ones; otherwise, the results are unpredictable.

The unused bit positions in general register 0 are reserved for possible future extensions and should contain zeros; otherwise, the program may not operate compatibly in the future.

In the access-register mode, the contents of access register R_1 are used for accessing the first operand, and the contents of access register R_2 are used for accessing the second operand, the dictionaries, the entropy descriptor, and the symbol-translation table.

When the entropy-encoding option is not specified and the first or second operand lengths are initially zero, the dictionary, first, and second operands are not accessed and condition code 0 or 1 is set.

The operation starts at the left end of both operands and proceeds to the right. The operation is ended when the end of either operand is reached or when a CPU-determined amount of data has been processed, whichever occurs first.

During a compression operation, the end of the first operand is considered to be reached when the number of unused bit positions remaining in the first-operand location is not sufficient to contain additional compressed data. When the entropy-encoding option is specified and the first operand length is non-zero, this check can only be performed after compression is attempted and the codeword size is determined.

During an expansion operation, the end of the first-operand location is considered to be reached when any of the following conditions are met:

1. The number of unused byte positions remaining in the first-operand location is not sufficient to contain all the characters that would result from expansion of the next index symbol or codeword.

2. Immediately when the number of unused byte positions is zero, that is, immediately when the expansion of an index symbol or codeword completely fills the first-operand location.

During an expansion operation, the end of the second-operand location is considered to be reached when the next index symbol or codeword does not reside entirely within the second-operand location or if the entropy-encoding option is specified and a codeword of all zeros is encountered. The second-operand location ends at the beginning of the byte designated by the sum of the address in general register R_2 and the length in general register $R_2 + 1$, regardless of the compressed-data bit number in bit positions 61-63 of general register 1.

If the operation is ended because the end of the second operand is reached, condition code 0 is set. If the operation is ended because the end of the first operand is reached, condition code 1 is set, except that condition code 0 is set provided that the end of the second operand is also reached. If the operation is ended because a CPU-determined amount of data has been processed, condition code 3 is set.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of complete bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. During compression, a complete byte is considered to be stored only if all of its bit positions contain bits of compressed data. During compression when the first bit of compressed data stored is not in bit position 0 of a byte, the bits in the byte to the left of the first bit of compressed data remain unchanged. During compression if the last byte stored does not completely contain compressed data, the bits in the byte to the right of the rightmost bit of compressed data in the byte either are unchanged or are set to zeros.

The length in general register $R_2 + 1$ is decremented by the number of complete bytes processed at the second-operand location, and the address in general register R_2 is incremented by the same amount. During expansion, a complete byte is considered to be processed only if all of its bits have been used to produce expanded data.

The leftmost bits which are not part of the address in general registers R_1 and R_2 may be set to zeros or may remain unchanged. However, in the 24-bit or 31-bit addressing mode, bits 0-31 of these registers and also of general registers $R_1 + 1$ and $R_2 + 1$ always remain unchanged.

When all of the following conditions are met, zero padding may be performed, as described below.

- The CMPSC-enhancement facility is installed.
- The zero-padding (ZP) control, bit 46 of general register 0, is one.
- Any of the following is true:
  - The end of the first operand is reached (CC1).
  - The end of the second operand is reached (CC0).
  - A CPU-determined amount of data has been processed (CC3).
  - A codeword consisting of all zero bits is found in the middle of the compressed operand (CC0).
- The last byte of compressed or expanded data does not coincide with the rightmost byte of a model-dependent integral storage boundary.
- The remaining length in general register $R_1 + 1$ is sufficient to store up to the model-dependent integral storage boundary.

It is model dependent whether zero padding is performed. When none of the conditions listed above are met, zero padding is not performed.

Zero padding consists of storing zeros to the right of the last compressed or expanded byte, up to a model-dependent integral storage boundary. The address in general register R_1 and the length in general register $R_1 + 1$ are not updated to account for the zero padding. PER storage-alteration events are recognized for stores that occur as a result of zero padding. The model-dependent integral storage boundary is no larger than 4,096.

When the R_1 and R_2 fields do not designate general register 0, the handling of general register 1 is as follows. The bit number of the bit following the last bit of compressed data processed is placed in bit positions 61-63 of general register 1, and bits 52-60 of the register and the leftmost bits which are not part of the address in the register may be set to zeros or may remain unchanged, except that when one or both of the original length values are so small that no compressed data can be processed, all bits in the register may remain unchanged. However, when bits 44, 45 or 47 of general register 0 are one, bits 52-60 of general register 1 always remain unchanged. Also, in the 24-bit or 31-bit addressing mode, bits 0-31 of the register always remain unchanged.

If (a) the operands overlap one another, (b) the first operand overlaps the dictionaries, entropy descriptor, or the symbol-translation table in storage in any way, or (c) either the R_1 or the R_2 field designates general register 0, the results are unpredictable.

The compression dictionary is a tree of entries in which a parent entry may have child entries. Each entry represents one or more characters called extension characters, and it also represents a character symbol consisting of the extension characters represented by the entry preceded by the extension characters represented by all of the entry's ancestors.

When order preservation is not specified, the compression process uses an unordered comparison algorithm: the children of a parent are not considered to be in any particular order, and the next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until either a match is found or all of the children have been processed. (However, see Appendix D, “Restriction on Identical Child and Sibling Characters” for a restriction on identical first extension characters of children of the same parent.) The result of the compression process is the index symbol that designates the last matched entry, which is the parent entry if no match was found on any child or there are no children.

The order-preservation option causes the compression process to use an ordered comparison algorithm: the children of a parent are considered to be ordered such that the string of one or more extension characters represented by any child is always earlier in the collating sequence than the string of one or more extension characters represented by the next child of the same parent, that is, the children are considered to be in collating-sequence order. The next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until any of the following is true: (1) a match is found on an entry without children, or a match is found on an entry with children but there is not another character in the string; (2) the next characters from the string have a collating-sequence value less than that of the extension characters represented by a child of the last matched parent; or (3) the next characters from the string have a collating-sequence value greater than that of the extension characters represented by the last child of the last matched parent. The result of the compression process in each of the three cases is as follows:

Case	Resulting Index Symbol
1	If the process ends because of a match on an entry without children or because of a match on an entry when there is not another character in the string, the result is the index symbol that designates the entry.
2	If the process ends because the next characters of the string have a value less than that of the characters represented by a child, the result is the index symbol that designates the child.
3	If the process ends because the next characters of the string have a value greater than that of the characters represented by the last child, the result is the index symbol that designates the last child.

Note that Case 2 includes the case when the next character of the string match the leftmost extension characters represented by a child but there are not as many next characters remaining in the string as there are additional extension characters represented in the child.

When symbol translation is specified, the symbol-translation table consists of two-byte entries, and an entry contains an interchange symbol in the rightmost bit positions of the entry. The length of the interchange symbol is specified by bits 48-51 of general register 0. The left-hand bits that are not part of the interchange symbol in a symbol-translation-table entry must be zeros; otherwise, the results are unpredictable.

To translate an index symbol to an interchange symbol, the index symbol is multiplied by 2 and then added to the address of the beginning of the symbol-translation table to locate an entry in the table, and then the interchange symbol is obtained from the entry.

When order preservation is specified, the index symbol produced by the compression process is used to locate a symbol-translation-table entry containing an interchange symbol just as when the symbol-translation option is specified. The resulting interchange symbol that is placed in the compressed-data operand depends on which of the above three cases the index symbol was produced. The resulting interchange symbol is as follows:

Case	Resulting Interchange Symbol
1	The interchange symbol in the entry.
2	The interchange symbol in the entry, minus one; that is, one is subtracted from the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.
3	The interchange symbol in the entry, plus one; that is, one is added to the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.

In the above, the result of subtracting one from an interchange symbol consisting of all zero bits is an interchange symbol consisting of all one bits, and the result of adding one to an interchange symbol consisting of all one bits is an interchange symbol consisting of all zero bits.

When entropy encoding is specified, the index symbol produced by the compression process is used to locate a two-byte symbol-translation-table entry containing a codeword. The size of the codeword is determined and that number of leftmost bits of the symbol-translation-table entry are placed in the compressed data operand. The size of the codeword can be determined by the process shown in Figure 7-206, “Entropy Encoded Compression” on page 7-187.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the contents of the registers designated by the R_1 and R_2 fields and of general register 1 are updated the same as upon normal completion of the instruction, so that the instruction, when reexecuted, resumes at the point of interruption. The condition code is unpredictable.

For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions may be recognized for all locations in the dictionaries and symbol-translation table if those areas are specified to be used and even if the locations would not be used during the operation. Access exceptions are not recognized for an operand, the dictionaries, or the symbol-translation table if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

If an access exception is due to be recognized for either of the operands or for a dictionary, entropy descriptor, or the symbol-translation table, the result is that either the exception is recognized or condition code 3 is set. If condition code 3 is set, the exception will be recognized when the instruction is executed again to continue processing the same operands, assuming that the exception condition still exists.

During compression, regardless of whether the exception is recognized or condition code 3 is set, a nullifying access-exception condition or a suppressing DAT-protection exception conditionis handled so that an index symbol is generated only if it is the one that would result if there were no access-exception condition.

During compression or expansion, regardless of whether the exception is recognized or condition code 3 is set, a nullifying or suppressing access-exception condition may result in data having been stored at the first-operand location at or to the right of the location designated by the final address in general register R_1, which result is not true nullification or suppression. The amount of data stored depends on the reason for the access-exception condition. If the condition is due to a reference to a dictionary or the symbol-translation table, up to 4K bytes of data may have been stored at or to the right of the location designated by the final address. If the condition is due to a reference to the first or second operand, part of one index or interchange symbol, during compression, or part of one character symbol, during expansion, may have been stored at or to the right of the location designated by the final address. In all cases, the storing will be repeated when the instruction is executed again to continue processing the same operands.

If the end of the first operand is reached and an access exception is due to be recognized for the second operand, it is unpredictable whether condition code 1 is set or the access exception is recognized.

During expansion when the expansion dictionary is not logically correct, unusual storing may occur as described in Appendix D, “Expansion Process”. The results of an access exception in this case may not be true nullification or suppression.

Special Conditions

A specification exception is recognized for any of the following conditions:

1. Either the R_1 or R_2 fields contain an odd-numbered register.
2. Bits 48-51 of general register 0 contain any value not in the range of 0001-0101 binary and bit 44 of general register 0 is zero.

During compression of each character symbol, either the characters in the symbol or the dictionary character entries (not sibling descriptors) representing characters of the symbol are counted, and a general-operand data exception is recognized if this count becomes too large. The count can reach at least 260 without the exception being recognized.

During compression, the number of child characters or sibling characters processed during the processing of each parent entry are counted, and a general-operand data exception is recognized if this count becomes too large. The count can reach at least 260 without the exception being recognized. That is, a parent must not have more than 260 children; otherwise, a general-operand data exception may be recognized. Extension characters are not counted toward the maximum number of child and sibling characters until a child becomes a parent. When the examine child bit is zero, and a match is encountered, further matches are stopped and the child does not become a parent.

During expansion of each character symbol, either the characters in the symbol or the dictionary entries representing characters of the symbol are counted, and a general-operand data exception is recognized if this count becomes too large. If the characters in the symbol are counted, the count can reach at least 260 without the exception being recognized. If the dictionary entries representing characters of the symbol are counted, the count can reach at least 127 without the exception being recognized.

Certain error conditions in the dictionaries cause a general-operand data exception to be recognized and the operation to be either suppressed or terminated. Some of these error conditions are described in the sections “Expansion Process”, “Results of Dictionary Errors”, “Compression Dictionary”, and “Expansion Dictionary” in Appendix D.

When entropy encoding is specified, the entropy descriptor must satisfy the following properties otherwise a general-operand data exception is recognized.

1. The sum of the sixteen entries must add up to the number of dictionary entries plus one.
2. There is no arithmetic underflow or overflow when performing bounds calculations see Figure 7-204, “Entropy Descriptor Validation” on page 7-186.

During compression, when entropy encoding is specified, a symbol-translation-table entry with a zero value or an entry not padded on the right with zeros will cause a general-operand data exception to be recognized.

Resulting Condition Code:

0 End of second operand reached
1 End of first operand reached and end of second operand not reached
2 --
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, operand 2, dictionaries, and symbol-translation table; store, operand 1)
- Data with DXC 0, general operand
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the operation. The program need not determine the amount of data processed.
2. During compression when a nullifying access exception is due to be recognized, an index symbol is generated only if it is the one that would result if there were no access-exception condition. The result of this is that compression of the same expanded data by means of one or more executions of the instruction and by using the same dictionary always results in the same compressed data. That is, (1) the best possible matches in the dictionary are always found for the characters in the second operand, or else the execution is ended by either setting CC3 or rec-

ognizing the exception, and (2) the results of compression are repeatable (although possibly by means of a different number of executions of the instruction) and predictable.

For example, if the next characters of the string being compressed are ABC, and dictionary entry A has a child B, which has a child C, the normal operation is to compress ABC as a single index symbol, but if the C of the string is in the first byte of an invalid page (a page-translation exception is due to be recognized), no index symbol is generated. More specifically, an index symbol corresponding to the character symbol AB is not generated because this is not the index symbol that would be generated if the access-exception condition did not exist.

In the above, “best possible match” refers only to the characters in the second operand. In the example above, if the next two characters of the second operand (the string) are AB, and these are the last two characters of the second operand, the best possible match is on AB, even though there could be a match on ABC if the second operand included one more byte containing C.

Expansion is normally always repeatable. An index symbol is always expanded to exactly the character symbol it represents unless an exception that causes termination is recognized.

3. During expansion, if at least one unused byte position remains in the first operand location, COMPRESSION CALL may completely process the next index symbol in the second operand before it determines that the first-operand location does not have sufficient unused byte positions to contain the expanded data that would result from the next index symbol. If that next index symbol causes encountering of bad dictionary entries, the result can be either a data exception or condition code 1.

   COMPRESSION CALL immediately sets condition code 1 when processing of an index symbol exactly fills the first-operand location, except that it sets condition code 0 if the end of the second-operand location also has been reached. Immediately setting condition code 1 has the advantage that data can be compressed using one dictionary and then followed immediately, possibly on a bit boundary, by a different type of data compressed using another dictionary. The compressed data can be successfully expanded if, during the expansion of the data compressed using the first dictionary, the length of the first-operand location is specified to be exactly the length of the expanded data that will be produced. Condition code 1 will then be set when the first-operand location is full, at which time the specification of the dictionary can be changed in order to expand the remainder of the compressed data using the second dictionary. If the definition allowed condition code 1 not to be set, it might be attempted to expand the next index symbol, which resulted from use of the second dictionary, by means of the first dictionary, and this might cause recognition of a general-operand data exception. For example, the next index symbol, which properly designates a character entry in the second dictionary, might designate the second half of a format-1 sibling descriptor in the first dictionary, and that second half might begin with a character, such as 0 (F0 hex), that would appear to be an invalid partial symbol length in a character entry.

4. A nullifying access-exception condition due to a reference to a dictionary or the symbol-translation table may result in the storing of data at or to the right of the location designated by the final address in general register R_1. This storing and the processing needed to produce the data stored will be repeated when COMPRESSION CALL is executed again to continue processing the same operands. The repeated processing will reduce the performance of the instruction execution, and it should be avoided by ensuring that the environment in which the program is executed is one in which page-translation-exception conditions for the dictionaries and symbol-translation table are infrequent.

5. Following is an example of how the compressed-data bit number (CBN) is used and set. In this example:

   - The operation is an expansion operation.
   - The CDSS in general register 0 is 0010 binary. Therefore, there are 1K entries in the expansion dictionary, and the length of an index symbol is 10 bits.
   - The second operand (compressed-data operand) begins at location 6000 hex and has a length of five bytes. The initial CBN is

7. Therefore, there are three index symbols to be expanded, and the final CBN will be 5.

- The compressed data beginning at location 6000 hex is 0081FF9FF8 hex. Therefore, the three index symbols are 103, 3FC, and 3FF hex.

- The first operand (expanded-data operand) begins at location 5000 hex and has a length of 64 bytes. The three index symbols are expanded to a total of 14 bytes of expanded data.

The following figure shows the initial and final contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, the contents of locations 6000-6004 hex in binary, and the way a cursor corresponding to the CBN is advanced during the expansion operation.

Register	Initial Contents in Hex	Final Contents in Hex
R_1	5000	500E
R_1+1	40	32
R_2	6000	6004
R_2+1	5	1

Contents of Locations 6000-6004 Hex in Binary

```
00000000 10000001 11111111 10011111 11111000
       ↑            ↑          ↑           ↑
    Initial                              Final
      CBN                                 CBN
      (7)                                 (5)
```

6. The reason for allowing a parent to have no more than 260 children is as follows. The parent can contain five identical child characters. Then, 255 different sibling characters are possible — all of these must be different from the child characters and each other, or else they may be wasted (never matched against), depending on the implementation. Thus, every possible child is permitted.

7. Symbol translation is for use by VTAM. VTAM will begin by doing compression by means of software and an adaptive dictionary. When the adaptive dictionary has matured such that the degree of compression becomes sufficiently good (crosses some threshold), VTAM will “freeze” (stop adapting) its dictionary, inform the other end of the session to freeze also, transform its adaptive dictionary to the dictionary form used by COMPRESSION CALL, and then use COMPRESSION CALL to continue on with the compression. The other end of the session can continue to use its frozen adaptive dictionary.

   Following is clarification about the STT offset. Assume VTAM uses a 4K-entry adaptive dictionary, which is the largest size VTAM uses. All of the entries in this dictionary correspond to character symbols because there are no sibling descriptors in the VTAM dictionary. The VTAM dictionary cannot map one-to-one to a COMPRESSION CALL dictionary because the latter requires that some of the entries be sibling descriptors. Therefore, VTAM must have an 8K-entry dictionary for use in the basic compression operation. Only the first hundred or so entries in the second 4K of the 8K need to be used, and these entries compensate for (take the place of) the entries in the first 4K that must be sibling descriptors. The STT can and should, to save space, begin immediately after those hundred or so entries in the second 4K. In this example, the index symbols will be 13 bits but will be transformed to 12-bit interchange symbols.

8. A program may place the dictionaries in pages that are managed by means of chaining fields at their beginnings. In this case, either the parts of a dictionary have to be moved to be compacted into contiguous locations or there have to be holes in the dictionaries. The definition of COMPRESSION CALL contains nothing explicitly to support holes. However, assuming there is at least one character that never appears in the expanded data, that character can be used as a child character in a parent entry or as a sibling character in a sibling descriptor to specify a child or children that will never be referenced, thus creating a hole.

9. The references to the operands, dictionaries, and symbol-translation table for COMPRESSION CALL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

10. Setting the ZP control to one may provide improved performance on models in which the CMPSC-enhancement facility is installed.

11. Zero padding is not necessarily performed in every case where it is permissible.

12. Figure 7-201 on page 7-181 and Figure 7-203 on page 7-185 show possible forms (not the only possible forms) of the compression process

(without order preservation), the order preservation compression process and expansion processes. The figures do not show testing for or the results of dictionary errors.

13. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

14. When the entropy-encoding option is specified the minimum dictionary size is 128-bytes or 16 entries. The dictionary must also be a multiple of 16 entries.

COMPUTE INTERMEDIATE MESSAGE DIGEST

KIMD R_1,R_2 [RRE]

'B93E'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R_1 field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-207 shows the assigned function codes for COMPUTE INTERMEDIATE MESSAGE DIGEST. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

The assigned function codes are enumerated in Figure 7-207. All other function codes are unassigned.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KIMD-Query *	16	—
1	KIMD-SHA-1 *	20	64
2	KIMD-SHA-256 *	32	64
3	KIMD-SHA-512 *	64	128
32	KIMD-SHA3-224	200	144
33	KIMD-SHA3-256	200	136
34	KIMD-SHA3-384	200	104
35	KIMD-SHA3-512	200	72
36	KIMD-SHAKE-128	200	168
37	KIMD-SHAKE-256	200	136
65	KIMD-GHASH	32	16

Explanation:

— Not applicable

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

Figure 7-207. Function Codes for COMPUTE INTERMEDIATE MESSAGE DIGEST

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and $R_2 + 1$ are ignored for the query function.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the chaining value. For COMPUTE LAST MESSAGE DIGEST, the operation also uses a message bit length in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. For all functions except KIMD-query, the number of bytes in general register $R_2 + 1$ must be a multiple of the data block size for the function; otherwise, a specification exception is recognized.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

Figure 7-208 shows the contents of the general registers just described.

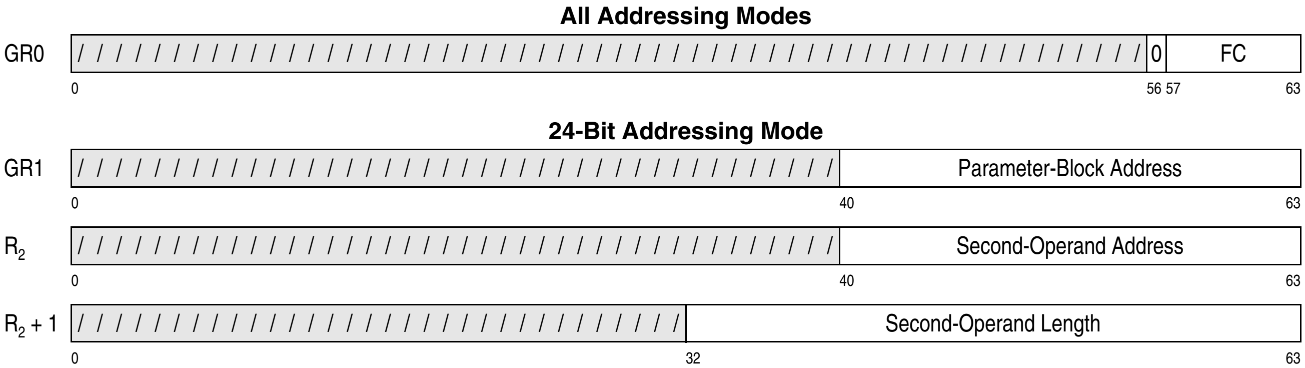

Figure 7-208. General Register Assignment for KIMD and KLMD (Part 1 of 2)

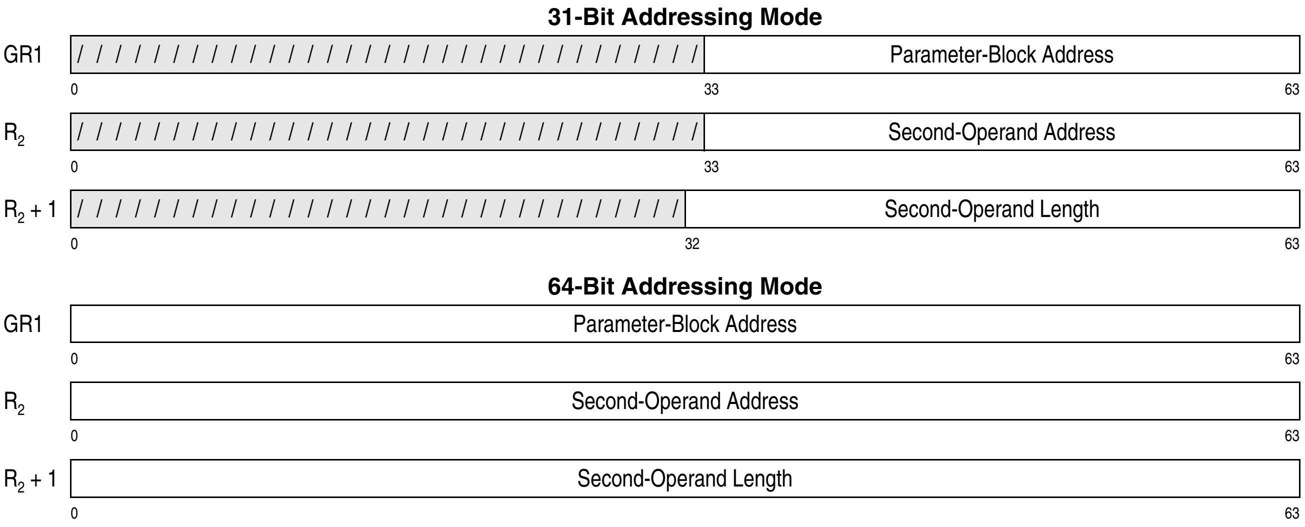

Figure 7-208. General Register Assignment for KIMD and KLMD (Part 2 of 2)

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. The operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

Normal completion occurs when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed.

When the operation ends due to normal completion, condition code 0 is set, the second-operand address in general register R_2 is updated, and the second-operand length in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in $R_2 + 1$ is nonzero.

When the second-operand length is initially zero, the second operand is not accessed, the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed, and condition code 0 is set. The parameter block is not accessed.

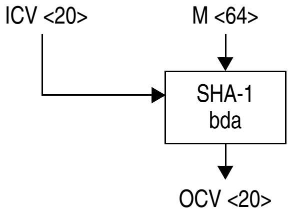
A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored. A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block. When PER events are detected for more than one location, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST functions. Further description of the secure hash algorithm may be found in Reference [15.] on page xxx. Further description of the GCM (Galois/counter mode) multiplication over GF(2^{128}) may be found in Reference [17.] on page xxx. Further description of the SHA-3 and SHAKE hash algorithms and the KECCAK family of sponge functions may be found in Reference [21.] on page xxx.



Symbol	Explanation
<n>	Length of item in bytes
bda	Block digest algorithm
ICV	Initial chaining value
M	Message block
OCV	Output chaining value

KIMD-Query (KIMD Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

	0	63
0	Status Word	
8		

Figure 7-213. Parameter Block for KIMD-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KIMD-Query function completes; condition code 3 is not applicable to this function.

KIMD-SHA-1 (KIMD Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

0	H0
4	H1
8	H2
12	H3
16	H4

0 31

Figure 7-214. Parameter Block for KIMD-SHA-1

A 20-byte intermediate message digest is generated for the 64-byte message blocks in operand 2 using the SHA-1 block digest algorithm with the 20-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-215.

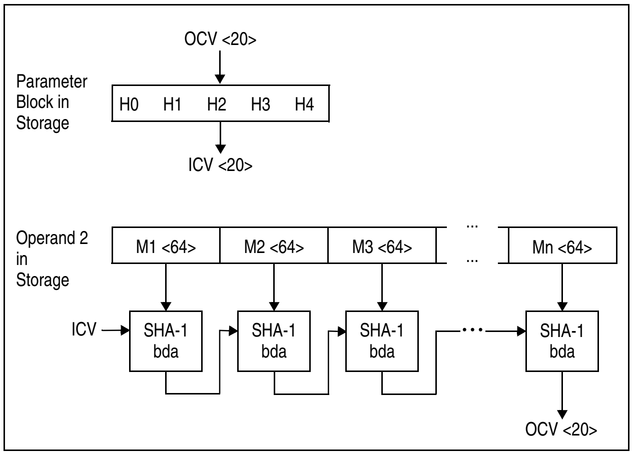

Figure 7-215. KIMD-SHA-1

KIMD-SHA-256 (KIMD Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

0	H0
4	H1
8	H2
12	H3
16	H4
20	H5
24	H6
28	H7

0 31

Figure 7-216. Parameter Block for KIMD-SHA-256

A 32-byte intermediate message digest is generated for the 64-byte message blocks in operand 2 using the SHA-256 block digest algorithm with the 32-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-217.

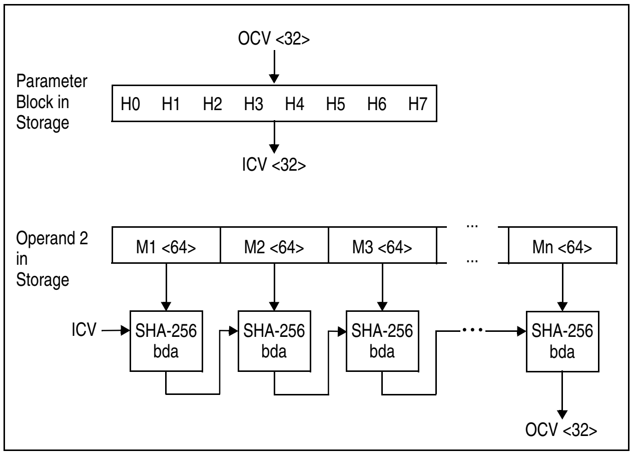

Figure 7-217. KIMD-SHA-256

KIMD-SHA-512 (KIMD Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

0	H0
8	H1
16	H2
24	H3
32	H4
40	H5
48	H6
56	H7
	0 63

Figure 7-218. Parameter Block for KIMD-SHA-512

A 64-byte intermediate message digest is generated for the 128-byte message blocks in operand 2 using the SHA-512 block digest algorithm with the 64-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-219.

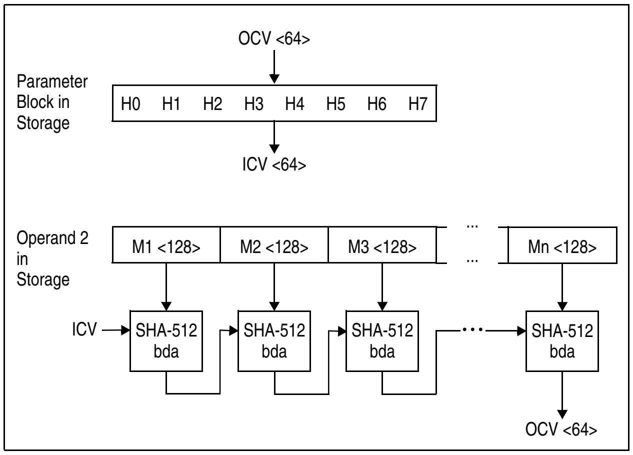

Figure 7-219. KIMD-SHA-512

KIMD-SHA3-224 (KIMD Function Code 32)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

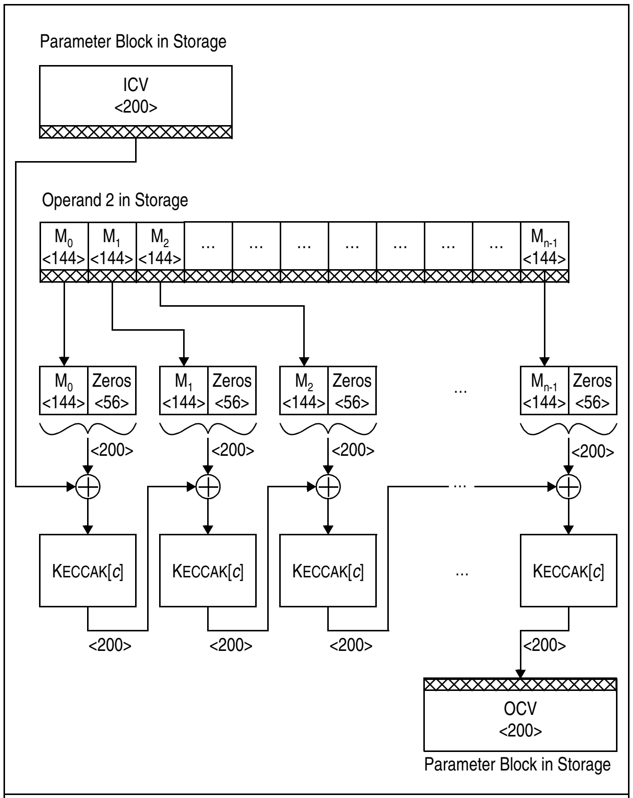
0 ⋮ 192	ICV
	0 63

Figure 7-220. Parameter Block for KIMD-SHA3-224

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

A 200-byte intermediate message digest is generated for the 144-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-221.



Explanation:

▨ The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.

<#> Size of an item in bytes

ICV Input chaining value (in the parameter block)

M 144-byte block of the second-operand message

n Number of blocks in the second-operand (that is, the second operand length divided by the block size of 144)

OCV Output chaining value (in the parameter block)

Figure 7-221. KIMD-SHA3-224 Processing

KIMD-SHA3-256 (KIMD Function Code 33)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

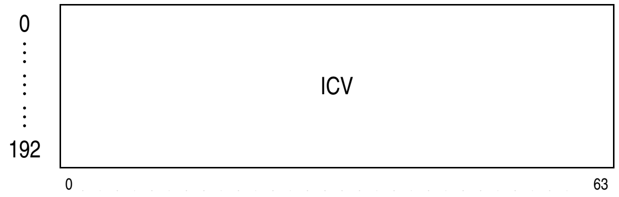


Figure 7-222. Parameter Block for KIMD-SHA3-256

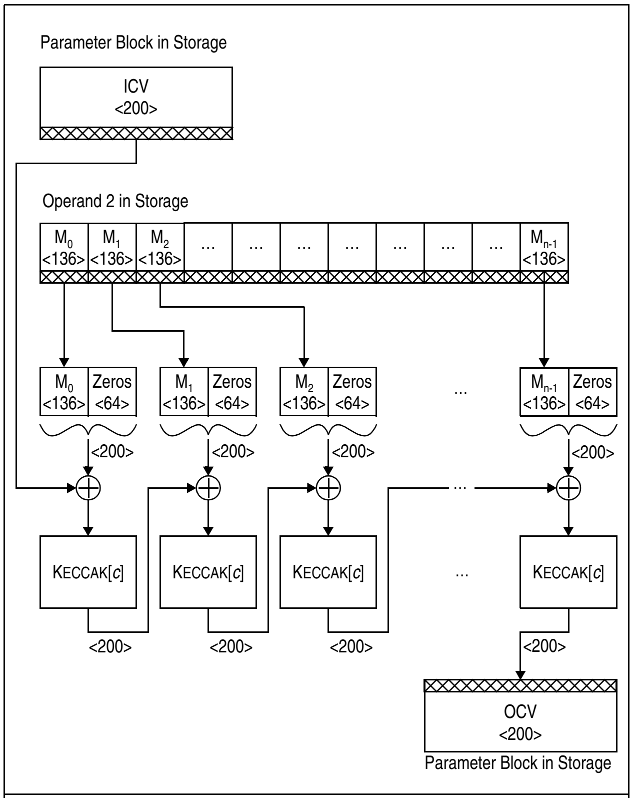
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

A 200-byte intermediate message digest is generated for the 136-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-223.



Explanation:

Figure 7-223. KIMD-SHA3-256 Processing

KIMD-SHA3-384 (KIMD Function Code 34)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the function has the following format:

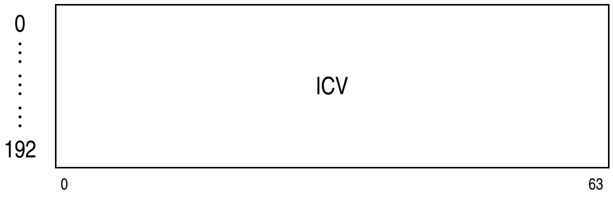

Figure 7-224. Parameter Block for KIMD-SHA3-384

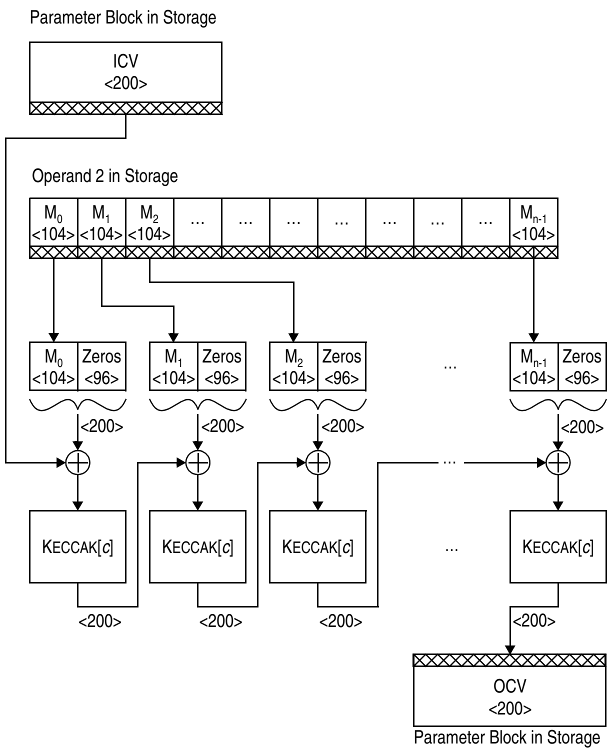
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[c] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

A 200-byte intermediate message digest is generated for the 104-byte message blocks in operand 2 using the KECCAK[c] algorithm with the 200-byte initial chaining value in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-225.



Explanation:

▨ The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[c] state array.

n	Number of blocks in the second-operand (that is, the second operand length divided by the block size of 168)
OCV	Output chaining value (in the parameter block)

Figure 7-229. KIMD-SHAKE-128 Processing

KIMD-SHAKE-256 (KIMD Function Code 37)

The operands, addresses, parameter-block format, and operation of the KIMD-SHAKE-256 function are identical to those of the KIMD-SHA3-256 function.

Note: A separate function code for KIMD-SHAKE-256 is defined to retain symmetry with the KLMD functions (where the operation of KLMD-SHAKE-256 differs from that of KLMD-SHA3-256).

KIMD-GHASH (Function Code 65)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-208 on page 7-188.

The parameter block used for the KIMD-GHASH function has the following format:

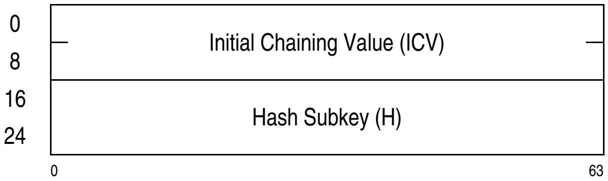

Figure 7-230. Parameter Block for KIMD-GHASH

The initial-chaining value is in byte offsets 0-15 of the parameter block, and the hash subkey is in byte offsets 16-31 of the parameter block.

The GHASH for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the hash subkey and the 128-bit chaining value.

The first message block is exclusive-ORed with the initial chaining value (ICV) in the parameter block. The result of the exclusive-OR operation and the hash subkey (H) are multiplied using a Galois/counter-mode (GCM) multiplication operation over a Galois field (GF(2^{128})) to produce the chaining value for the next message block. The process is repeated until all message blocks have been processed, or until a CPU-determined number of message blocks have been processed.

The GHASH, called the output chaining value (OCV), is stored into the Initial-chaining-value field of the parameter block. The operation is shown in Figure 7-231 on page 7-197.

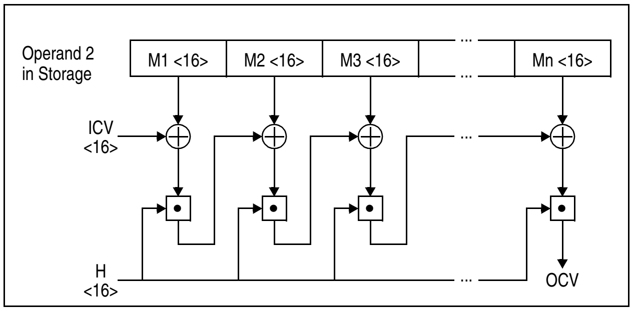

Figure 7-231. KIMD-GHASH

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
3. The R_2 field designates an odd-numbered register or general register 0.
4. The second-operand length is not a multiple of the data block size of the designated function (see Figure 7-207 on page 7-187 for COMPUTE INTERMEDIATE MESSAGE DIGEST functions).

Resulting Condition Code:

0 Normal completion
1 --
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2 and message bit length; fetch and store, chaining value)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Condition code 0 due to second-operand length originally zero.
11.	Access exceptions for an access to the parameter block or second operand.
12.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).
13.	Condition code 3 due to partial completion (second-operand length still nonzero).

Figure 7-232. Priority of Execution: KIMD

Figure 7-232. Priority of Execution: KIMD

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. Bit 56 of general register 0 is reserved for future extension and should be set to zero.

3. When condition code 3 is set, the second operand address and length in general registers R_2 and $R_2 + 1$, respectively, and the chaining-value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation.

   For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

4. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

5. The instructions COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST are designed to be used by a security service application programming interface (API). These APIs provide the program with means to compute the digest of messages of almost unlimited size, including those too large to fit in storage all at once. This is accomplished by permitting the program to pass the message to the API in parts. The following programming notes are described in terms of these APIs.

6. Before processing the first part of a message, the program must set the initial values for the chaining-value field. For SHA-1, the initial hexadecimal chaining values are listed as follows:

   H0 = 6745 2301
   H1 = EFCD AB89
   H2 = 98BA DCFE
   H3 = 1032 5476
   H4 = C3D2 E1F0

   For SHA-256, the initial hexadecimal chaining values are listed as follows:

   H0 = 6A09 E667
   H1 = BB67 AE85
   H2 = 3C6E F372
   H3 = A54F F53A
   H4 = 510E 527F
   H5 = 9B05 688C
   H6 = 1F83 D9AB
   H7 = 5BE0 CD19

   For SHA-512, the initial hexadecimal chaining value are listed as follows:

   H0 = 6A09 E667 F3BC C908
   H1 = BB67 AE85 84CA A73B
   H2 = 3C6E F372 FE94 F82B
   H3 = A54F F53A 5F1D 36F1
   H4 = 510E 527F ADE6 82D1
   H5 = 9B05 688C 2B3E 6C1F
   H6 = 1F83 D9AB FB41 BD6B
   H7 = 5BE0 CD19 137E 2179

   For the SHA3 and SHAKE functions, the initial chaining value must be set to all zeros.

7. When computing a message digest, the program may not initially be aware of the total message-bit length; for example, for a message being read from an I/O device, the message-bit length may not be known until the final block is read. When computing a message digest for a message whose length is not known, or for a message where it is known that the last message block is not included in the calculation, COMPUTE INTERMEDIATE MESSAGE DIGEST may be used. When computing a message digest for a message that includes the last block, COMPUTE LAST MESSAGE DIGEST must be used.

8. The SHA-224 algorithm is the same as the SHA-256 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-224 message digest using the SHA-256 functions with the following two actions:

   a. The following initial hexadecimal chaining values for SHA-224 are used:

      H0 = C105 9ED8
      H1 = 367C D507
      H2 = 3070 DD17
      H3 = F70E 5939
      H4 = FFC0 0B31
      H5 = 6858 1511
      H6 = 64F9 8FA7
      H7 = BEFA 4FA4

   b. The 224-bit message digest is obtained by truncating the final message digest to its leftmost 224 bits.

9. The SHA-384 algorithm is the same as the SHA-512 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-384 message digest using the SHA-512 functions with the following two actions:

   a. The following initial hexadecimal chaining values for SHA-384 are used:

      H0 = CBBB 9D5D C105 9ED8
      H1 = 629A 292A 367C D507
      H2 = 9159 015A 3070 DD17
      H3 = 152F ECD8 F70E 5939
      H4 = 6733 2667 FFC0 0B31
      H5 = 8EB4 4A87 6858 1511
      H6 = DB0C 2E0D 64F9 8FA7
      H7 = 47B5 481D BEFA 4FA4

   b. The 384-bit message digest is obtained by truncating the final message digest to its leftmost 384 bits.

10. For the SHA3 and SHAKE functions (for both KIMD and KLMD), the KECCAK[*c*] algorithm uses a 1,600-bit state array in the parameter block. The state array comprises 25 *lanes* having 64 bits each. The bits of the state array are numbered from 0 to from 1,599, and the bits of each lane are numbered from 0 to 63.

    In the parameter block, the bytes of the state array appear in ascending order from left-to-right; but within each byte, the bits appear in descending order from left to right. That is, byte 0 of the parameter block contains (from left to right) bits 7, 6, 5, 4, 3, 2, 1, and 0 of the state array; byte 1 contains bits 15, 14, 13, 12, 11, 10, 9 and 8 of the state array; and so forth. When represented in memory, the bit positions of any individual lane of the state array correspond to powers of two, as shown below.

Byte	0								1									6								7							
Lane Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	...	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56

The bit ordering of the parameter block described above also applies to the message bytes of the second operand. For the KLMD-SHAKE functions, the results stored in the first operand are similar to that of the parameter block in that the left-to-right ordering of bits within each byte is 7, 6, 5, 4, 3, 2, 1, and 0.

11. For the GHASH function, the hash subkey, H, is the result of encrypting a 128-bit zero using the AES encryption algorithm with a 128-bit, 192-bit, or 256-bit cryptographic key.

COMPUTE LAST MESSAGE DIGEST

KLMD R_1,R_2 [RRE]

'B93F'	////////	R_1	R_2

0 16 24 28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are reserved, and for all functions except KLMD-SHAKE-128 and KLMD-SHAKE-256, the R_1 field is reserved. Reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-233 show the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. For the KLMD-SHAKE functions, bit 55 of general register 0 is the padding state; bit 55 of the register is ignored for all other functions. All other bits of general register 0 are ignored.

The assigned function codes are enumerated in Figure 7-233. All other function codes are unassigned.

Code	Function	Parm. Block Size (bytes)	Data Block Size[1] (bytes)
0	KLMD-Query *	16	—
1	KLMD-SHA-1 *	28	64
2	KLMD-SHA-256 *	40	64
3	KLMD-SHA-512 *	80	128
32	KLMD-SHA3-224	200	144
33	KLMD-SHA3-256	200	136
34	KLMD-SHA3-384	200	104
35	KLMD-SHA3-512	200	72
36	KLMD-SHAKE-128	200	168
37	KLMD-SHAKE-256	200	136

Explanation:

— Not applicable

[1] For all data blocks except the last block. The size of the last data block ranges from 0 to one less than the value shown.

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

Figure 7-233. Function Codes for COMPUTE LAST MESSAGE DIGEST

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, $R_1 + 1$, R_2 and $R_2 + 1$ are ignored for the query function.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the chaining value. For the SHA-1, SHA-256, and SHA-512 functions, the operation also uses a message bit length in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first.

For the KLMD-SHAKE functions, when the end of the second operand is reached, an extended-output-function (XOF) digest is stored at the first operand location. The operation then proceeds until either the end of the first-operand location is reached or a CPU-determined number of bytes have been stored, whichever occurs first.

The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

For the two KLMD-SHAKE functions, the following applies:

- Bit 55 of general register 0 is the padding state (PS). A value of zero indicates that padding of the second operand has not yet been performed. A value of one indicates that padding of the second operand has been performed.

  A specification exception is recognized, and the operation is suppressed when the padding state is one and the second-operand length in general register $R_2 + 1$ is nonzero at the beginning of the instruction.

  When the remaining second-operand length is zero, the CPU inspects the padding state to determine whether padding of the second operand is to be performed. The padding state is set to one by the CPU when padding of the second operand has been performed.

- The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0 and other than general register R_2; otherwise a specification exception is recognized.

- The location of the leftmost byte of the first operand is specified by the contents of general register R_1. The number of bytes in the first-operand location is specified in general register $R_1 + 1$.

- As a part of the operation, the address in general register R_1 is incremented by the number of bytes stored into the first operand, and the length in general register $R_1 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

- The addressing-mode characteristics for general registers R_1 and $R_1 + 1$ are identical to those for general registers R_2 and $R_2 + 1$, respectively, as described above.

For functions other than the two KLMD-SHAKE functions, bit 55 of general register 0 and the R_1 field of the instruction are ignored. In this case, a first operand is not present, and general registers R_1 and $R_1 + 1$ are not modified.

Figure 7-234 shows the contents of the general registers just described.

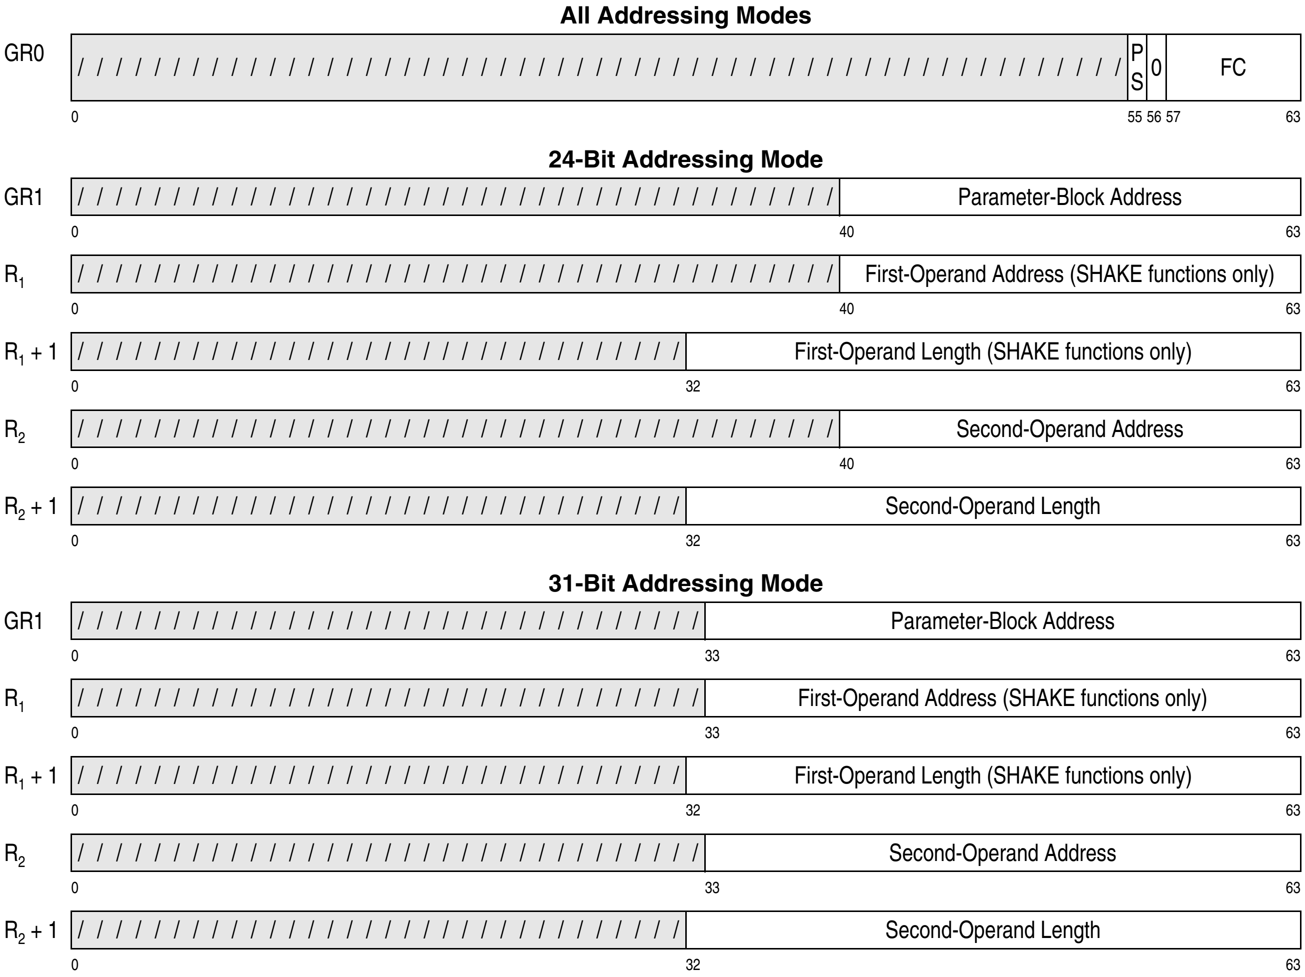

Figure 7-234. General Register Assignment for KLMD (Part 1 of 2)

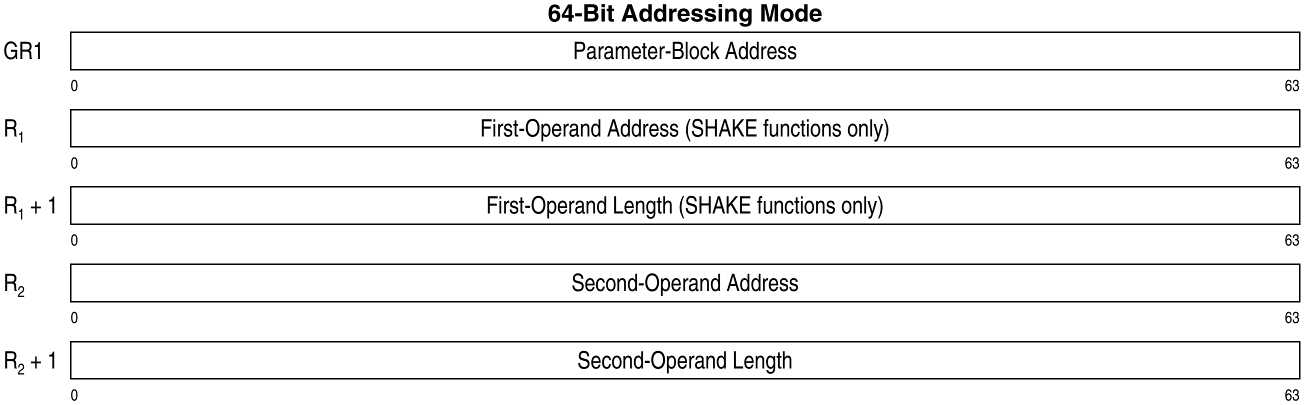

Figure 7-234. General Register Assignment for KLMD (Part 2 of 2)

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively. For the KLMD-SHAKE functions, access register R_1 specifies the address space containing the first operand.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. For all functions except the KLMD-SHAKE functions, the operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the chaining-value field overlaps any portion of the first or second operand, the result in the chaining-value field is unpredictable.

For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, after all bytes in the second operand as specified in general register $R_2 + 1$ have been processed, the padding operation is performed, a final hashing operation is performed on the padded block, and then normal completion occurs. For the KLMD-SHA3 and KLMD-SHAKE functions, after all full blocks of the second operand have been processed, the padding operation is performed on either the remaining partial block or on a null block, a final hashing operation is performed on the padded block; normal completion then occurs for the KLMD-SHA3 functions.

For the KLMD-SHAKE functions, when padding has been performed, the padding state is set to one in general register 0, and an extended-output-function (XOF) message digest is stored into the first-operand location. XOF message-digest generation is ended when all of the first operand has been stored (called normal completion) or when a CPU-determined number of blocks that is less than the length of the first operand have been stored (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set, the second-operand address in general register R_2 is updated, and the second-operand length in general register $R_2 + 1$ is zero; for the KLMD-SHAKE functions, the first-operand address in general register R_1 is updated, and the first-operand length in general register $R_1 + 1$ is zero.

When the operation ends due to partial completion, condition code 3 is set. For all functions except the KLMD-SHAKE functions, the resulting value in general register $R_2 + 1$ is nonzero. For the KLMD-SHAKE functions, if the second operand has not been completely processed, the resulting value in general register $R_2 + 1$ is nonzero, and if the first operand has not been completely processed, the resulting value in general register R_1 is nonzero.

When the second-operand length is initially zero, the second operand is not accessed, the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed, and condition code 0 is set. Except for the KLMD-SHAKE functions when the padding-state (PS) control is one, the empty block padding operation is performed and the result is stored into the parameter block.

For the KLMD-SHAKE functions, when the first-operand length is initially zero, the first operand is not accessed, and the first-operand address and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. When the first-operand length is initially zero and the PS control is one, it is model dependent whether the parameter block is updated.

A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block and first-operand location that is stored. A PER zero-address-detection event is recognized, when applicable, for the first-operand location, for the second-operand location and for the parameter block. When PER events are detected for more than one location, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Access exceptions may be reported for a larger portion of the first operand (when applicable) and second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the first or second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The subsequent description of COMPUTE LAST MESSAGE DIGEST uses the same symbols as those used in COMPUTE INTERMEDIATE MESSAGE DIGEST, plus the following additional symbols. Further description of the secure hash algorithm may be found in Reference [15.] on page xxx. Further description of the SHA-3 and SHAKE hash algorithms and the Keccak family of sponge functions may be found in Reference [21.] on page xxx.

Symbol	Explanation for KLMD Function Figures
L	Byte length of operand 2 in storage.
p <n>	n padding bytes; leftmost byte is 80 hex; all other bytes are 00 hex.
z <n>	n padding bytes of zero.
mbl	an 8-byte or 16-byte value specifying the bit length of the total message.
q <64>	a padding block, consisting of 56 bytes of zero followed by an 8-byte mbl.
q <128>	a padding block, consisting of 112 bytes of zero followed by a 16-byte mbl.
sp<n>	n padding bytes used by SHA-3 functions. Bit positions 7, 6, and 5 of the leftmost byte of the pad contain binary 0, 1, and 1, respectively, and bit position 0 of the rightmost byte of the pad contains a binary one. All other bits are zeros. Padding for SHA-3 functions is performed even if the second-operand length is zero.
xp<n>	n padding bytes used by SHAKE functions. Bit positions 3 through 7 of the leftmost byte of the pad all contain binary ones, and bit position 0 of the rightmost pad byte contains a binary one. All other bits are zeros. Padding for SHAKE functions is performed when the padding state (PS, bit 55 of general register 0) is zero and the remaining second-operand length is less than the data-block size.

KLMD-Query (KLMD Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

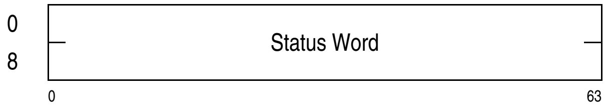

Figure 7-235. Parameter Block for KLMD-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE LAST MESSAGE DIGEST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KLMD-Query function completes; condition code 3 is not applicable to this function.

KLMD-SHA-1 (KLMD Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

0	H0
4	H1
8	H2
12	H3
16	H4
20 24	Message Bit Length (mbl)
	0 31

Figure 7-236. Parameter Block for KLMD-SHA-1

The message digest for the message (M) in operand 2 is generated using the SHA-1 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the length of the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-1 block digest algorithm with the 20-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-237 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-238 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-239 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-240 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

Figure 7-239. KLMD-SHA-1 Partial-Block Case 1 (1 ≤ L ≤ 55)

Figure 7-240. KLMD-SHA-1 Partial-Block Case 2 (56 ≤ L ≤ 63)

KLMD-SHA-256 (KLMD Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

The message digest for the message (M) in operand 2 is generated using the SHA-256 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-256 block digest algorithm with the 32-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-242 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-243 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-244 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-245 is performed. The message digest, also called the out-

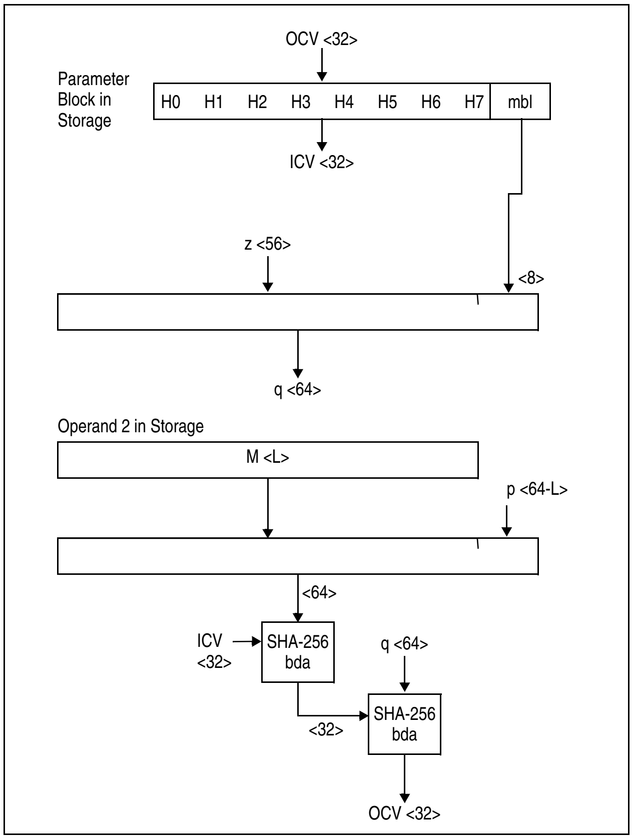

Figure 7-245. KLMD-SHA-256 Partial-Block Case 2 (56 ≤ L ≤ 63)

KLMD-SHA-512 (KLMD Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

	0 … 63
0	H0
8	H1
16	H2
24	H3
32	H4
40	H5
48	H6
56	H7
64	Message Bit Length (mbl)
72	

Figure 7-246. Parameter Block for KLMD-SHA-512

The message digest for the message (M) in operand 2 is generated using the SHA-512 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 128 bytes, an intermediate message digest is generated for each 128-byte message block using the SHA-512 block digest algorithm with the 64-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-247 and repeats until the remaining message is less than 128 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-248 is performed. If the length of the message or the remaining message is between one byte and 111 bytes inclusive, then the operation in Figure 7-249 is performed; if the length is between 112 bytes and 127 bytes inclusive, then the operation in Figure 7-250 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

KLMD-SHA3-224 (KLMD Function Code 32)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

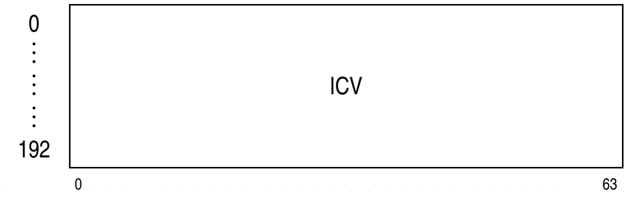

Figure 7-251. Parameter Block for KLMD-SHA3-224

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register R_2 + 1 is greater than or equal to 144 bytes, then the operation is identical to that described in the section “KIMD-SHA3-224 (KIMD Function Code 32)” on page 7-192. This operation proceeds until the length of the second operand is less than 144 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 144-byte message block as described for the symbol “sp<n>” on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 224-bit (28-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The message digest is generated regardless of whether the second-operand length is zero. The entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block. The generated message digest is contained in bytes 0-27 of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-252.

KLMD-SHA3-256 (KLMD Function Code 33)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

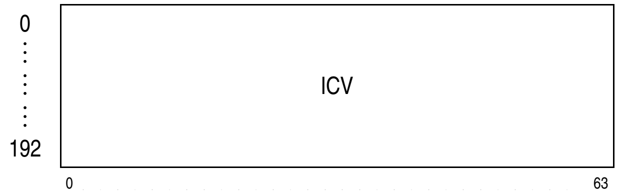

Figure 7-253. Parameter Block for KLMD-SHA3-256

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register R_2 + 1 is greater than or equal to 136 bytes, then the operation is identical to that described in the section “KIMD-SHA3-256 (KIMD Function Code 33)” on page 7-193. This operation proceeds until the length of the second operand is less than 136 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 136-byte message block as described for the symbol “sp<n>” on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 256-bit (32-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The message digest is generated regardless of whether the second-operand length is zero. The entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block. The generated message digest is contained in bytes 0-31 of the parameter block. See programming note 10 on page page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-254.

KLMD-SHA3-384 (KLMD Function Code 34)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

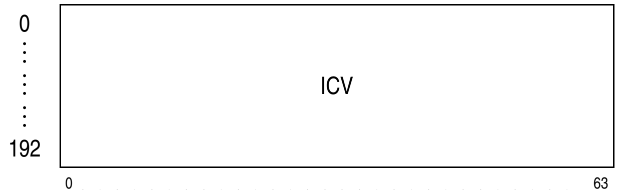

Figure 7-255. Parameter Block for KLMD-SHA3-384

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register $R_2 + 1$ is greater than or equal to 104 bytes, then the operation is identical to that described in the section “KIMD-SHA3-384 (KIMD Function Code 34)” on page 7-194. This operation proceeds until the length of the second operand is less than 104 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 104-byte message block as described for the symbol “sp<n>” on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 384-bit (48-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The message digest is generated regardless of whether the second-operand length is zero. The entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block. The generated message digest is contained in bytes 0-47 of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-256.

KLMD-SHA3-512 (KLMD Function Code 35)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

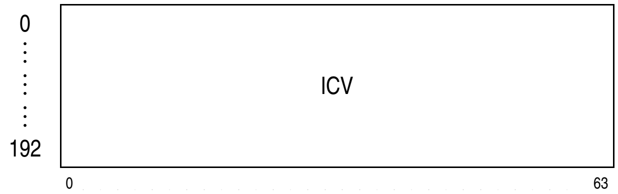

Figure 7-257. Parameter Block for KLMD-SHA3-512

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register $R_2 + 1$ is greater than or equal to 72 bytes, then the operation is identical to that described in the section "KIMD-SHA3-512 (KIMD Function Code 35)" on page 7-195. This operation proceeds until the length of the second operand is less than 72 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 72-byte message block as described for the symbol "sp<n>" on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 512-bit (64-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block. The message digest is generated regardless of whether the second-operand length is zero. The entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block. The generated message digest is contained in bytes 0-63 of the parameter block. See programming note 10 on page 7-199 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-258.

Figure 7-258. KLMD-SHA3-512 Processing (L < 72)

KLMD-SHAKE-128 (KLMD Function Code 36)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

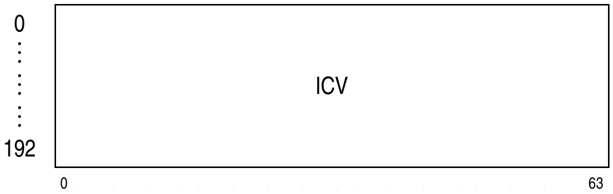

Figure 7-259. Parameter Block for KLMD-SHAKE-128

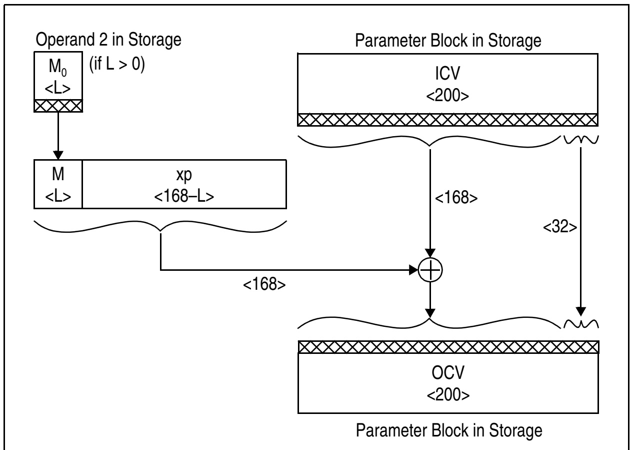
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register R_2 + 1 is greater than or equal to 168 bytes, the operation is identical to that described in the section “KIMD-SHAKE-128 (KIMD Function Code 36)” on page 7-196, except that when the remaining second-operand length is zero, processing is as described below.

When the padding state, bit 55 of general register 0 is zero (indicating that padding has not yet been performed), the following occurs:

- Any remaining bytes of the second operand are padded on the right to form a 168-byte message block as described for the symbol “xp<n>” on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.
- The padding state is set to one, indicating that padding has been performed.
- The second-operand address in general register R_2 is incremented by the number of message bytes processed, and the second-operand length in general register R_2+1 is set to zero.
- The 168-byte padded message, is exclusive ORed with the contents of the leftmost 168 bytes of the state array (from the ICV in the parameter block or from the OCV resulting from the previous block’s processing) to form an output chaining value that is used in the extended-output-function (XOF) processing. The rightmost 32 bytes of the state array are unchanged.

The padding operation is shown in Figure 7-260.



Explanation:

▨	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block)
L	Length of the second operand (< 168 bytes)
M	Message block (when L > 0)
OCV	Output chaining value (used in XOF processing, below)
xp	SHAKE padding algorithm

Figure 7-260. KLMD-SHAKE-128 Padding (L < 168)

Depending on the number of second-operand blocks processed when padding is completed, either (a) the output chaining value is stored into the parameter block, and the instruction completes by setting condition code 3 (partial completion), or (b) the operation continues with extended-output-function (XOF) processing, as described below.

When the padding state is one (indicating that padding has been performed for the message, either by the current or a previous execution of the instruction), extended-output-function (XOF) processing is performed as follows.

1. If the first-operand length in general register $R_1 + 1$ is zero, then the output chaining value is stored into the parameter block, and the instruction completes with condition code 0. If the first-operand length is zero at the beginning of the instruction, then it is model dependent whether the ICV is fetched from the parameter block and stored back unmodified as the OCV.

2. The KECCAK[*c*] function is invoked using the previous output-chaining value (OCV) as input, and replacing the output-chaining value.

3. General register R_1 contains the current address of the first operand, and general register $R_1 + 1$ contains the remaining length of the first operand. The number of bytes to be stored, *n*, is either the remaining first-operand length or 168, whichever is smaller.

   The first *n* bytes of the output-chaining value are stored at the first-operand location. See programming note 10 on page 7-199 regarding the numbering of the bits in the first operand as compared with the numbering of the bits in the state array.

   The first-operand address in general register R_1 is incremented by *n*, and the first-operand length general register $R_1 + 1$ is decremented by *n*.

Steps 1-3 of this process are repeated until the first-operand length becomes zero (in which case, the instruction completes with condition code 0) or until a CPU-determined number of bytes have been stored (in which case, the instruction completes with condition code 3). The output-chaining value is stored into bytes 0-199 of the parameter block regardless of whether condition code 0 or 3 is set. Figure 7-261 illustrates the XOF processing described above.

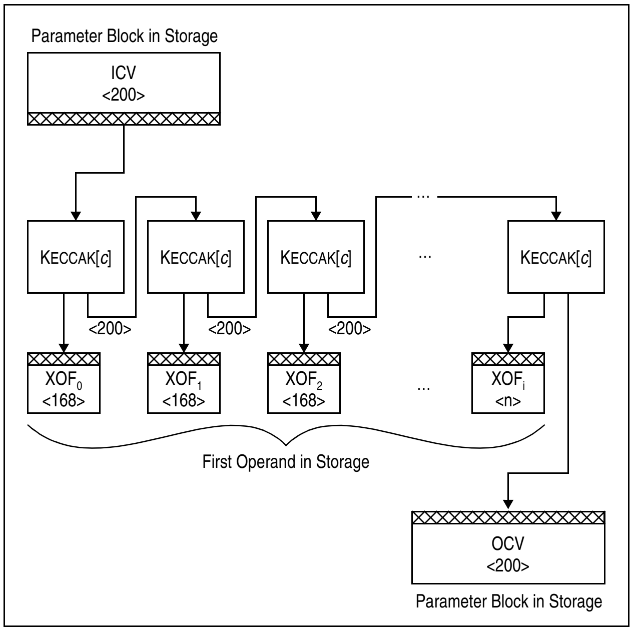


Figure 7-261. KLMD-SHAKE-128 Extended-Output-Function (XOF) Processing

Explanation:

<#> Size of an item in bytes

ICV Input chaining value (either from the parameter block or from the output of the padding operation).

OCV Output chaining value; (the final OCV appears in the parameter block)

n The residual length of the final block of the first operand (less than or equal to 168 bytes)

XOF_i<n> Block i of the extended-output-function results in the first operand.

Figure 7-261. KLMD-SHAKE-128 Extended-Output-Function (XOF) Processing (Continued)

KLMD-SHAKE-256 (KLMD Function Code 37)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-234 on page 7-202.

The parameter block used for the function has the following format:

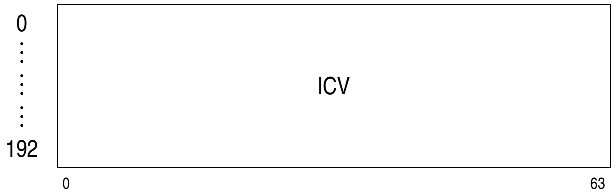

Figure 7-262. Parameter Block for KLMD-SHAKE-256

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxx.

When the length of the second operand in general register R_2 + 1 is greater than or equal to 136 bytes, the operation is identical to that described in the section "KIMD-SHAKE-256 (KIMD Function Code 37)" on page 7-197, except that when the remaining second-operand length is zero, processing is as described below. This operation proceeds until the length of the second operand is less than 136 bytes, at which point the operation continues as described below.

When the padding state, bit 55 of general register 0 is zero (indicating that padding has not yet been performed), the following occurs:

- Any remaining bytes of the second operand are padded on the right to form a 136-byte message block as described for the symbol "xp<n>" on page 7-204. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

- The padding state is set to one, indicating that padding has been performed.

- The second-operand address in general register R_2 is incremented by the number of message bytes processed, and the second-operand length in general register R_2+1 is set to zero.

- The 136-byte padded message, is exclusive ORed with the contents of the leftmost 136 bytes of the state array (from the ICV in the parameter block or from the OCV resulting from the previous block's processing) to form an output chaining value that is used in the extended-output-function (XOF) processing. The rightmost 64 bytes of the state array are unchanged.

The padding operationis shown in Figure 7-263.

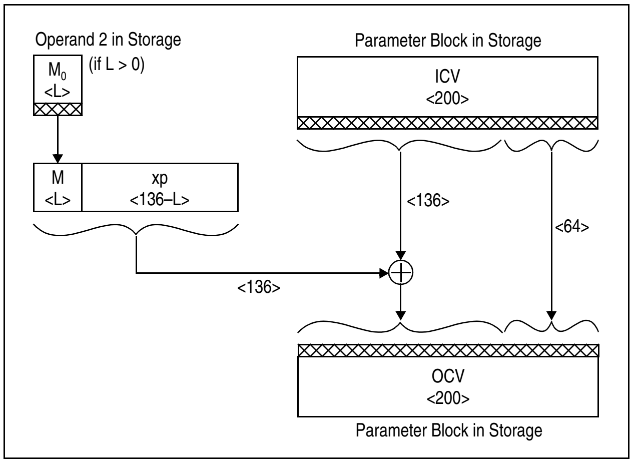

Figure 7-263. KLMD-SHAKE-256 Padding (L < 136)

Explanation:

▨ The bit positions of each byte of the parameter block and the XOF block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕ Bitwise exclusive-OR operation
<#> Size of an item in bytes
ICV Input chaining value (in the parameter block)
L Length of the second operand (< 136 bytes)
M Message block (when L > 0)
OCV Output chaining value (used in XOF processing, below)
xp SHAKE padding algorithm

Figure 7-263. KLMD-SHAKE-256 Padding (L < 136)

Depending on the number of second-operand blocks processed when padding is completed, either (a) the output chaining value is stored into the parameter block, and the instruction completes by setting condition code 3 (partial completion), or (b) the operation continues with extended-output-function (XOF) processing, as described below.

When the padding state is one (indicating that padding has been performed for the message, either by the current or a previous execution of the instruction), extended-output-function (XOF) processing is performed as follows.

1. If the first-operand length in general register $R_1 + 1$ is zero, then the output chaining value is stored into the parameter block, and the instruction completes with condition code 0. If the first-operand length is zero at the beginning of the instruction, then it is model dependent whether the ICV is fetched from the parameter block and stored back unmodified as the OCV.

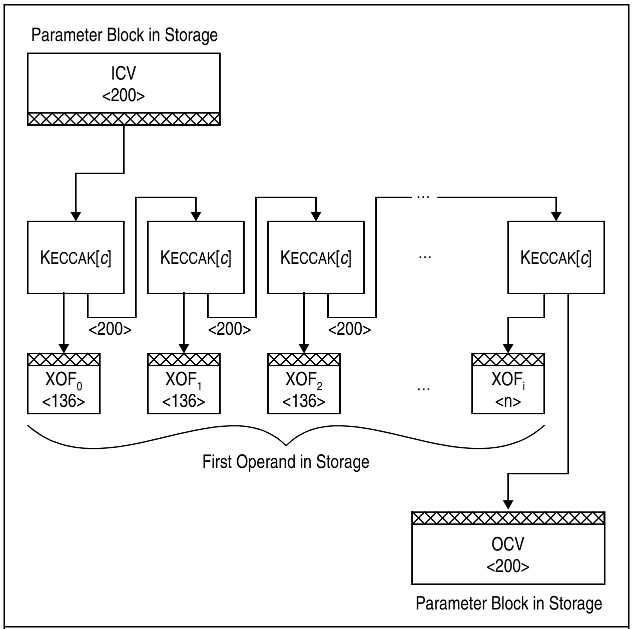
2. The KECCAK[*c*] function is invoked using the previous output-chaining value (OCV) as input, and replacing the output-chaining value.

3. General register R_1 contains the current address of the first operand, and general register $R_1 + 1$ contains the remaining length of the first operand. The number of bytes to be stored, *n*, is either the remaining first-operand length or 136, whichever is smaller.

   The first *n* bytes of the output-chaining value are stored at the first-operand location. See programming note 10 on page 7-199 regarding the numbering of the bits in the first operand as compared with the numbering of the bits in the state array.

   The first-operand address in general register R_1 is incremented by *n*, and the first-operand length general register $R_1 + 1$ is decremented by *n*.

Steps 1-3 of this process are repeated until the first-operand length becomes zero (in which case, the instruction completes with condition code 0) or until a CPU-determined number of bytes have been stored (in which case, the instruction completes with condition code 3). The output-chaining value is stored into bytes 0-199 of the parameter block regardless of whether condition code 0 or 3 is set. Figure 7-264 illustrates the XOF processing described above.



Explanation:

▨ The bit positions of each byte of the parameter block and the XOF block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
<#> Size of an item in bytes
ICV Input chaining value (either from the parameter block or from the output of the padding operation).
OCV Output chaining value; (the final OCV appears in the parameter block)
n The residual length of the final block of the first operand (less than or equal to 136 bytes)
XOF_i<n> Block i of the extended-output-function results in the first operand.

Figure 7-264. KLMD-SHAKE-256 Extended-Output-Function (XOF) Processing

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

- Bit 56 of general register 0 is not zero.
- Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
- The R_2 field designates an odd-numbered register or general register 0.
- For the KLMD-SHAKE functions, either of the following is true:
  - The R_1 field designates an odd-numbered register, general register 0, or register R_2.
  - The second-operand length is nonzero, and the padding state is one.

Resulting Condition Code:

0	Normal completion
1	--
2	--
3	Partial completion

Program Exceptions:

- Access (fetch, operand 2 and message bit length; fetch and store, chaining value; store, operand 1)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.a	Specification exception due to invalid function code, or invalid register number.
8.b	Specification exception due to nonzero second-operand length when the padding state is one (SHAKE functions only).

Figure 7-265. Priority of Execution: KLMD

9.	Condition code 0 due to second-operand length originally zero.
10.	Access exceptions for an access to the parameter block or second operand.
11.	Access exceptions for an access to the first operand (SHAKE functions only).
12.	Condition code 0 due to normal completion (for functions other than SHAKE, second-operand length originally nonzero, but stepped to zero; for SHAKE functions, second-operand length zero and first-operand length stepped to zero).
13.	Condition code 3 due to partial completion (for functions other than SHAKE, second-operand length still nonzero; for SHAKE functions, either first- or second-operand length still nonzero).

Figure 7-265. Priority of Execution: KLMD (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. Programming notes 2-10 for COMPUTE INTERMEDIATE MESSAGE DIGEST are also applicable to COMPUTE LAST MESSAGE DIGEST.

3. For the KLMD-SHAKE functions, when condition code 3 is set during the XOF processing, the first operand address and length in general registers R_1 and $R_1 + 1$, respectively, are updated such that the program can simply branch back to the instruction to continue the operation.

   For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

4. For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, if the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the chaining value in this case is such that additional oper-

ands can be processed as if they were part of the same chain.

5. For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, when processing the last message part, the program must compute the length of the original message in bits and place this length value in the message-bit-length field of the parameter block, and use the COMPUTE LAST MESSAGE DIGEST instruction.

6. The COMPUTE LAST MESSAGE DIGEST instruction does not require the second operand to be a multiple of the data block size. It first processes complete blocks, and may set condition code 3 before processing all blocks. After processing all complete blocks, it then performs the padding operation including the remaining portion of the second operand. This may require one or two iterations of the designated block digest algorithm.

7. The COMPUTE LAST MESSAGE DIGEST instruction provides the SHA padding for messages that are a multiple of eight bits in length. If a SHA function is to be applied to a bit string which is not a multiple of eight bits, the program must perform the SHA padding and use the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction.

8. The following applies to the message-bit length (MBL) in the parameter block of KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512.

   a. The MBL is completely independent of the second-operand length in general register $R_2 + 1$.

   b. Regardless of whether the instruction ends with condition code 0 or 3, the MBL is not decremented by the number of bytes processed.

   c. In normal usage, the MBL is expected to be eight times the total size of the message in bytes. If the program supplies a MBL that is not a multiple of eight, the results will be algorithmically correct, but may not be usable in any practical application.

   d. The secure-hash algorithm described in Reference [21.] on page xxx allows for message-bit length that are not multiples of eight. COMPUTE LAST MESSGE DIGEST requires the message-bit length to be a multiple of eight.

9. For the KLMD-SHAKE functions, the following applies:

   a. The padding-state, bit 55 of general register 0, should be set to zero prior to the first execution of KLMD for a message, and the padding state should not be altered by the program for any subsequent executions of KLMD for the same message until normal completion occurs.

   b. If padding of the final (short or null) block of the second operand is performed when the first-operand length is zero, then the padded block is exclusive ORed with the contents of the state array, the result is stored as the output-chaining value in the parameter block, and the instruction completes with condition code 0. The Keccak[c] function is not invoked in this case.

10. The KLMD SHA-3 and SHAKE functions perform padding according to the adopted NIST SHA-3 specification (see Reference [21.] on page xxx). Earlier draft versions of the SHA-3 specification used different padding bit sequences. Software that was designed according to earlier draft SHA-3 specifications can still benefit from the KIMD SHA-3 and SHAKE functions if the software performs the padding of the last message block.

COMPUTE MESSAGE AUTHENTICATION CODE

KMAC R_1,R_2 [RRE]

'B91E'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R_1 field are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-266 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for COMPUTE MESSAGE AUTHENTICATION CODE are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMAC-Query *	16	—
1	KMAC-DEA *	16	8
2	KMAC-TDEA-128 *	24	8
3	KMAC-TDEA-192 *	32	8
9	KMAC-Encrypted-DEA	40	8
10	KMAC-Encrypted-TDEA-128	48	8
11	KMAC-Encrypted-TDEA-192	56	8
18	KMAC-AES-128	32	16
19	KMAC-AES-192	40	16
20	KMAC-AES-256	48	16
26	KMAC-Encrypted-AES-128	64	16
27	KMAC-Encrypted-AES-192	72	16
28	KMAC-Encrypted-AES-256	80	16

Explanation:

— Not applicable

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

Figure 7-266. Function Codes for COMPUTE MESSAGE AUTHENTICATION CODE

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and $R_2 + 1$ are ignored.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the initial chaining value. The operation also uses a cryptographic key in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored and, the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

Figure 7-267 shows the contents of the general registers just described.

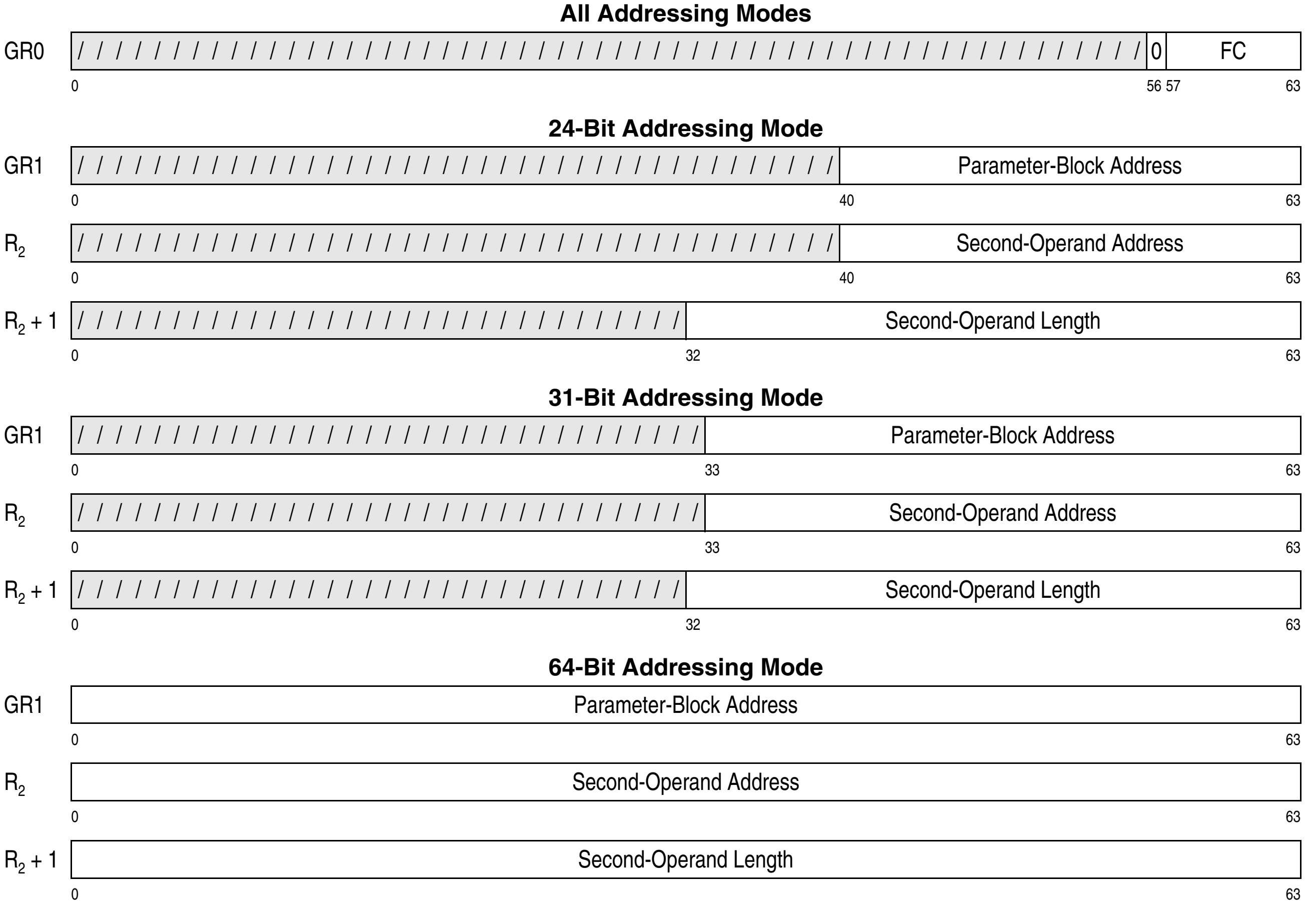


Figure 7-267. General Register Assignment for KMAC

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. The operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the initial-chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

Normal completion occurs when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in $R_2 + 1$ is nonzero.

When the second-operand length is initially zero, the second operand and the parameter block are not accessed, general registers R_2 and $R_2 + 1$ are not changed, and condition code 0 is set.

A PER storage-alteration event may be recognized for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the second-operand location and for the parameter block. When PER events are detected for one or more locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operand may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the second operand when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE MESSAGE AUTHENTICATION CODE functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key. Further description of the data-encryption algorithm may be found in Reference [13.] on page xxx. Further description of the AES standard may be found in Reference [14.] on page xxx.

KMAC-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the function has the following format:

0 8	Status Word
	0 63

Figure 7-273. Parameter Block for KMAC-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the KMAC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMAC-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMAC-DEA (Function Code 1)

KMAC-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-DEA function has the following format:

0	Chaining Value (CV)
8	Cryptographic Key (K)
	0 63

Figure 7-274. Parameter Block for KMAC-DEA

For the KMAC-DEA function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMAC-Encrypted-DEA function has the following format:

0	Initial Chaining Value (ICV)
8	Encrypted Cryptographic Key (WK_d(K))
16 24 32	DEA Wrapping-Key Verification Pattern (WK_dVP)
	0 63

Figure 7-275. Parameter Block for KMAC-Encrypted-DEA

For the KMAC-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-431, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the DEA algorithm with the 64-bit cryptographic key and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-chaining-value field of the parameter block. The operation is shown in Figure 7-276.

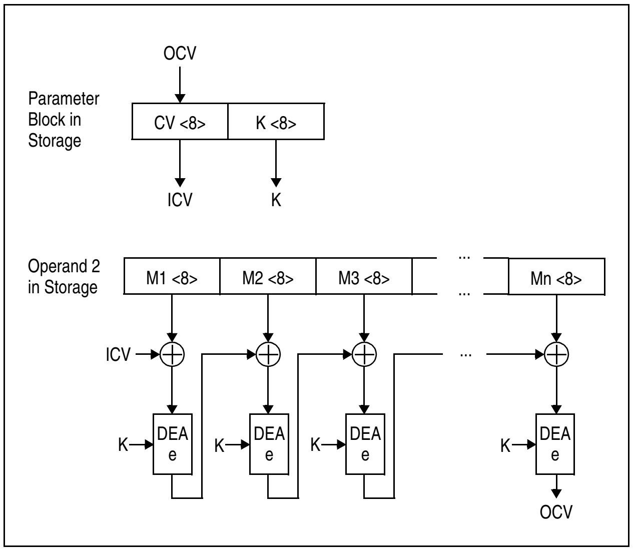

Figure 7-276. MAC Computation Using 64-bit DEA Key

KMAC-TDEA-128 (Function Code 2)

KMAC-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-TDEA-128 function has the following format:

0	Initial Chaining Value (CV)
8	Cryptographic Key 1 (K1)
16	Cryptographic Key 2 (K2)
	0 63

Figure 7-277. Parameter Block for KMAC-TDEA-128

For the KMAC-TDEA-128 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMAC-Encrypted-TDEA-128 function has the following format:

0	Initial Chaining Value (ICV)
8 16	Encrypted Cryptographic Key (WK_d(K))
24 32 40	DEA Wrapping-Key Verification Pattern (WK_dVP)
	0 63

Figure 7-278. Parameter Block for KMAC-Encrypted-TDEA-128

For the KMAC-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-431, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the TDEA algorithm with the two 64-bit cryptographic keys and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-279.

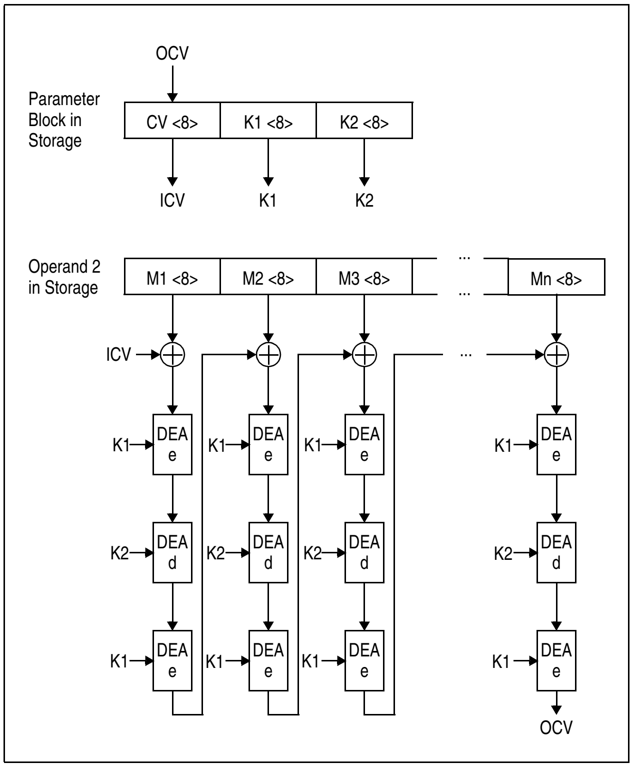

Figure 7-279. MAC Computation Using 128-bit TDEA Key

KMAC-TDEA-192 (Function Code 3)

KMAC-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-TDEA-192 function has the following format:

	0 … 63
0	Initial Chaining Value (CV)
8	Cryptographic Key 1 (K1)
16	Cryptographic Key 2 (K2)
24	Cryptographic Key 3 (K3)

Figure 7-280. Parameter Block for KMAC-TDEA-192

For the KMAC-TDEA-192 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.

The parameter block used for the KMAC-Encrypted-TDEA-192 function has the following format:

	0 … 63
0	Initial Chaining Value (ICV)
8	Encrypted Cryptographic Key (WK$_d$(K))
16	
24	
32	DEA Wrapping-Key Verification Pattern (WK$_d$VP)

Figure 7-281. Parameter Block for KMAC-Encrypted-TDEA-192

For the KMAC-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-431, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the TDEA algorithm with the three 64-bit cryptographic keys and the 64-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-282.

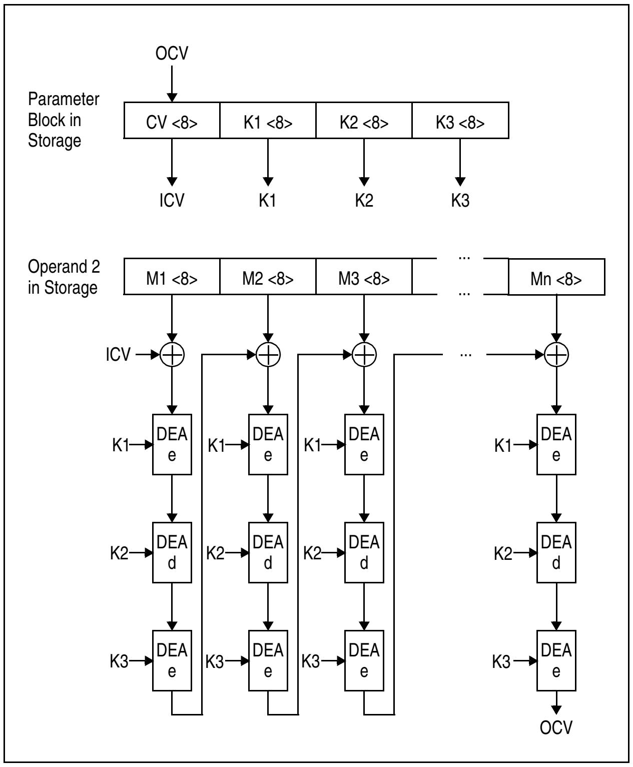

Figure 7-282. MAC Computation Using 192-bit TDEA Key

KMAC-AES-128 (Function Code 18)

KMAC-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-AES-128 function has the following format:

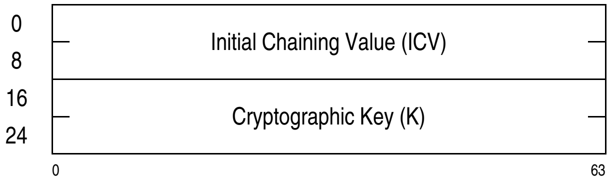

Figure 7-283. Parameter Block for KMAC-AES-128

For the KMAC-AES-128 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-128 function has the following format:

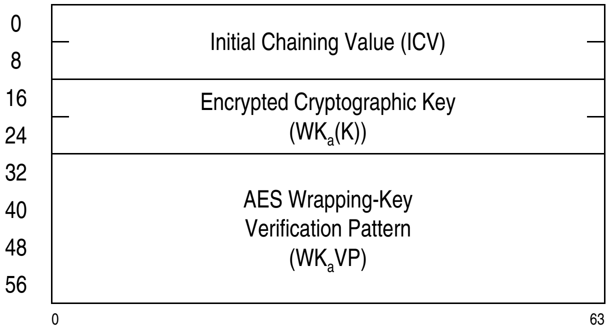

Figure 7-284. Parameter Block for KMAC-Encrypted-AES-128

For the KMAC-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the AES algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-285.

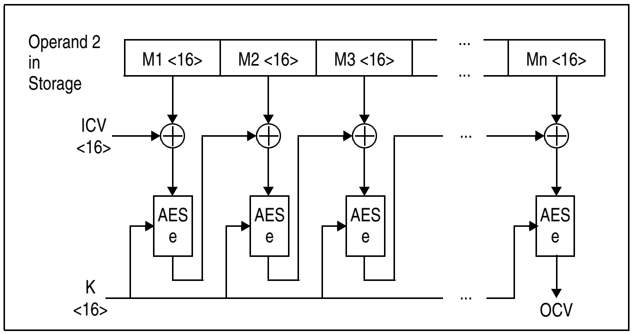

Figure 7-285. KMAC-AES-128

KMAC-AES-192 (Function Code 19)

KMAC-Encrypted-AES-192 (Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-AES-192 function has the following format:

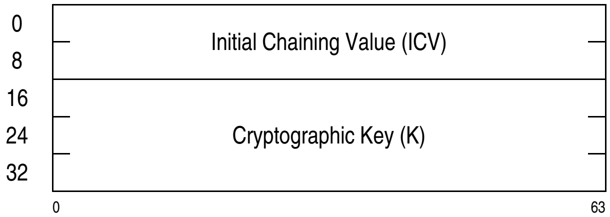

Figure 7-286. Parameter Block for KMAC-AES-192

For the KMAC-AES-192 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-39 of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-192 function has the following format:

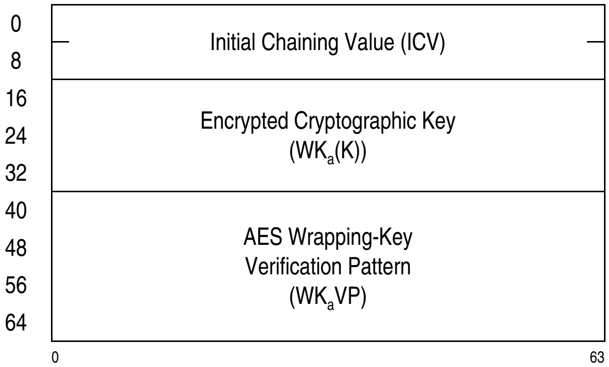

Figure 7-287. Parameter Block for KMAC-Encrypted-AES-192

For the KMAC-Encrypted-AES-192 function, the contents of byte offsets 40-71 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-39 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, ..., Mn) in operand 2 is computed using the AES algorithm with the 192-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-288.

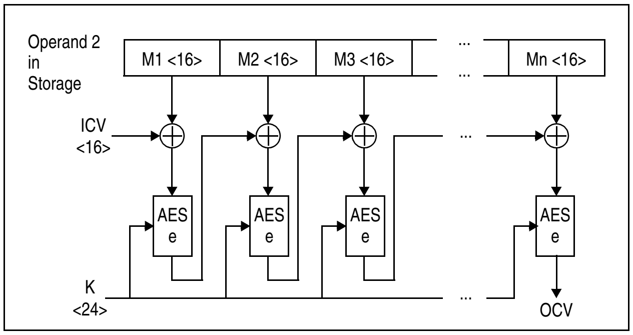

Figure 7-288. KMAC-AES-192

KMAC-AES-256 (Function Code 20)

KMAC-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-267 on page 7-220.

The parameter block used for the KMAC-AES-256 function has the following format:

0	Initial Chaining Value (ICV)
8	
16	Cryptographic Key (K)
24	
32	
40	
	0 … 63

Figure 7-289. Parameter Block for KMAC-AES-256

For the KMAC-AES-256 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-256 function has the following format:

0	Initial Chaining Value (ICV)
8	
16	Encrypted Cryptographic Key (WK$_a$(K))
24	
32	
40	
48	AES Wrapping-Key Verification Pattern (WK$_a$VP)
56	
64	
72	
	0 … 63

Figure 7-290. Parameter Block for KMAC-Encrypted-AES-256

For the KMAC-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the AES algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-291.

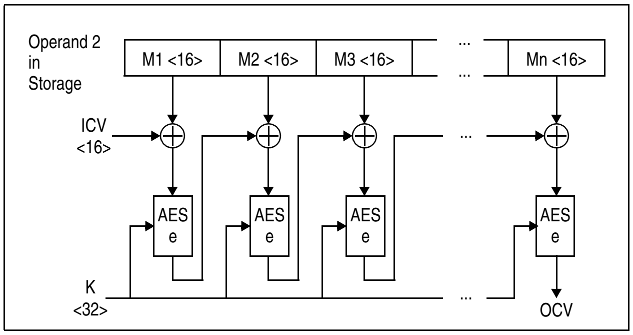

Figure 7-291. KMAC-AES-256

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
3. The R_2 field designates an odd-numbered register or general register 0.
4. The second-operand length is not a multiple of the data block size of the designated function (see Figure 7-266 on page 7-219 to determine the data block size for COMPUTE MESSAGE AUTHENTICATION CODE functions).

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; fetch and store, chaining value)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second instruction halfword.

7.B Operation exception.

7.C Transaction constraint

8. Specification exception due to invalid function code or invalid register number.

9. Specification exception due to invalid operand length.

10. Condition code 0 due to second-operand length originally zero.

11.A.1 Access exceptions for an access to the parameter block.

11.A.2. Condition code 1 due to verification-pattern mismatch.

11.B Access exceptions for an access to the parameter block or second operand.

12. Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

13. Condition code 3 due to partial completion (second-operand length still nonzero).

Figure 7-292. Priority of Execution: KMAC

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. When condition code 3 is set, the second operand address and length in general registers R_2 and $R_2 + 1$, respectively, and the initial-chaining-value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation. For unusual situations, the CPU protects against endless reoccurrence for the no-progress case.

Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

3. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the initial chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

4. Before processing the first part of a message, the program must set the initial values for the initial-chaining-value field. To comply with ANSI X9.9, ANSI X9.19, or Reference [17.] on page xxx, the initial chaining value shall be set to all binary zeros.

CONVERT TO BINARY

CVB $R_1,D_2(X_2,B_2)$ [RX-a]

'4F'	R_1	X_2	B_2	D_2	
0	8	12	16	20	31

CVBY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'06'	
0	8	12	16	20	32	40	47

CVBG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'0E'	
0	8	12	16	20	32	40	47

The second operand is changed from decimal to binary, and the result is placed at the first-operand location.

For CONVERT TO BINARY (CVB, CVBY), the second operand occupies eight bytes in storage, and, for CONVERT TO BINARY (CVBG), the second operand occupies sixteen bytes in storage. The second operand has the format of signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” It is checked for valid sign and digit codes, and a general-operand data exception is recognized when an invalid code is detected.

For CONVERT TO BINARY (CVB, CVBY), the result of the conversion is a 32-bit signed binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of the register remain unchanged. The maximum positive number that can be converted and still be contained in 32 bit positions is 2,147,483,647; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -2,147,483,648.

For any decimal number outside this range, the operation is completed by placing the 32 rightmost bits of the binary result in the register, and a fixed-point-divide exception is recognized.

For CONVERT TO BINARY (CVBG), the result of the conversion is a 64-bit signed binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 9,223,372,036,854,775,807; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -9,223,372,036,854,775,808. For any decimal number outside this range, a fixed-point-divide exception is recognized, and the operation is suppressed.

The displacement for CVB is treated as a 12-bit unsigned binary integer. The displacement for CVBY and CVBG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 0, general operand
- Fixed-point divide
- Operation (CVBY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Notes:

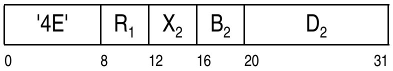
1. An example of the use of the CONVERT TO BINARY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When the second operand is negative, the result is in two’s-complement notation.

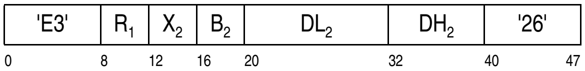
3. The storage-operand references for CONVERT TO BINARY may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

CONVERT TO DECIMAL

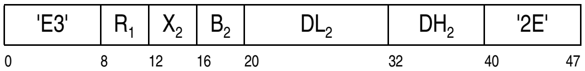
CVD $R_1,D_2(X_2,B_2)$ [RX-a]



CVDY $R_1,D_2(X_2,B_2)$ [RXY-a]



CVDG $R_1,D_2(X_2,B_2)$ [RXY-a]



The first operand is changed from binary to decimal, and the result is stored at the second-operand location.

For CONVERT TO DECIMAL (CVD, CVDY), the first operand is treated as a 32-bit signed binary integer, and the result occupies eight bytes in storage. For CONVERT TO DECIMAL (CVDG), the first operand is treated as a 64-bit signed binary integer, and the result occupies sixteen bytes in storage.

The result is in the format for signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” The rightmost four bits of the result represent the sign. A positive sign is encoded as 1100; a negative sign is encoded as 1101.

The displacement for CVD is treated as a 12-bit unsigned binary integer. The displacement for CVDY and CVDG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

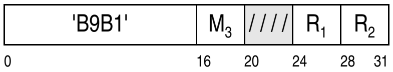
- Access (store, operand 2)
- Operation (CVDY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Notes:

1. An example of the use of the CONVERT TO DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For CVD and CVDY, the number to be converted is a 32-bit signed binary integer obtained from a general register. Since 15 decimal digits are available for the result, and the decimal equivalent of 31 bits requires at most 10 decimal digits, an overflow cannot occur. Similarly, for CVDG, 31 decimal digits are available, the decimal equivalent of 63 bits is at most 19 digits, and an overflow cannot occur.
3. The storage-operand references for CONVERT TO DECIMAL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

CONVERT UTF-16 TO UTF-32

CU24 $R_1,R_2[,M_3]$ [RRF-c]



The two-byte UTF-16 (Unicode) characters of the second operand are converted to UTF-32 characters and placed at the first-operand location. The UTF-32 characters are four bytes. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid Unicode character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-293.

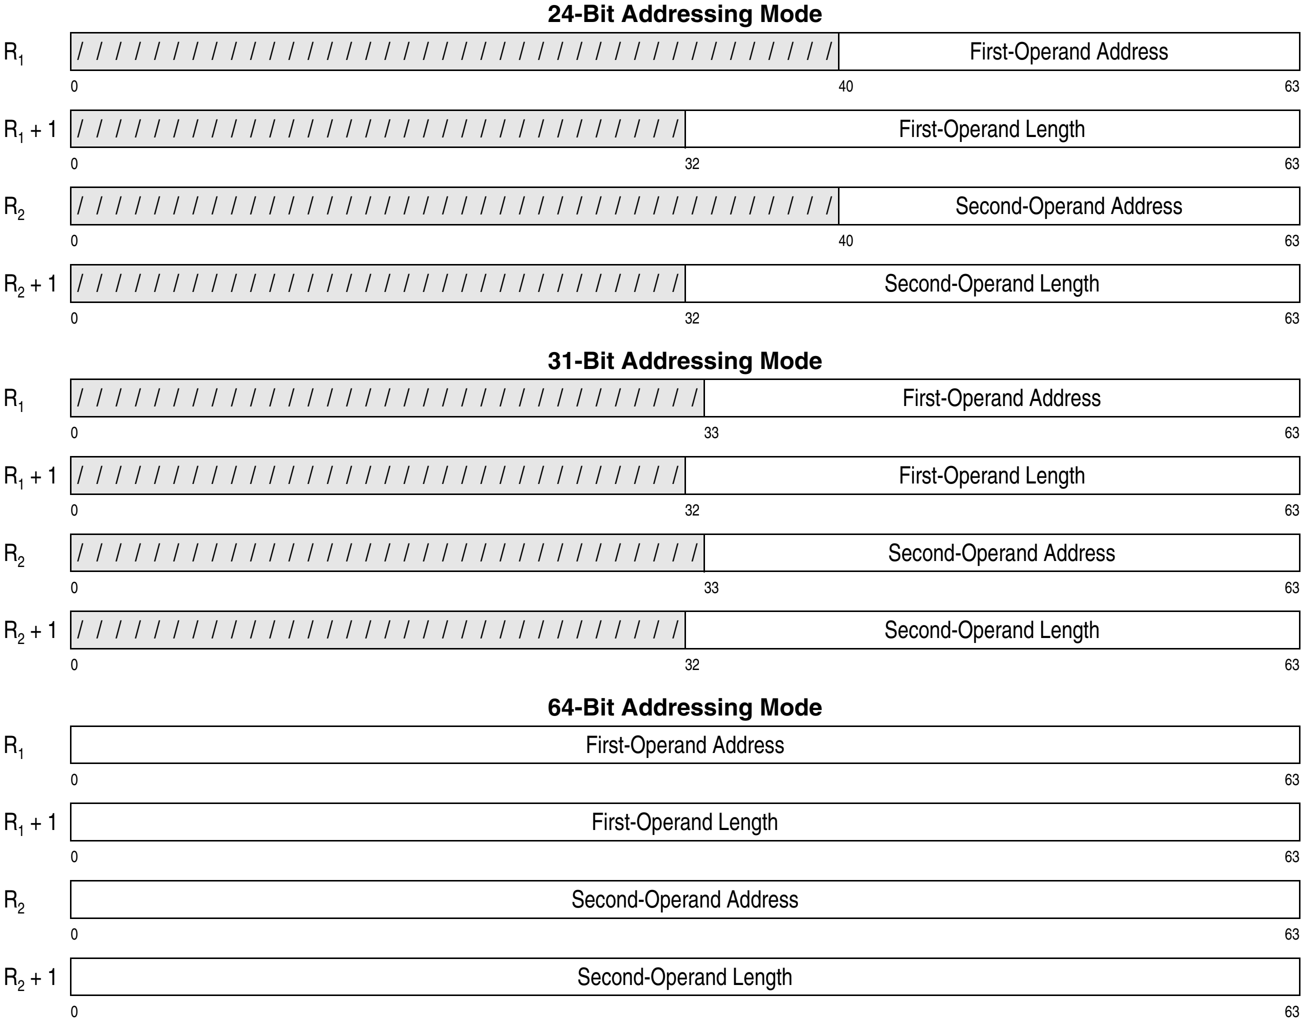


Figure 7-293. Register Contents for CONVERT UTF-16 TO UTF-32

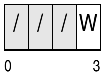
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

CONVERT UTF-16 TO UTF-32

When the ETF3-enhancement facility is not installed, the M_3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The characters resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or on some models when the W bit of the M_3 field is one, an invalid Unicode character is detected.

To show the method of converting a UTF-16 character to a UTF-32 character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

A low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) that is not immediately preceded by a high surrogate (that is, a Unicode character in the range of D800 to DBFF hex) is called an isolated low surrogate.

Any Unicode character in the range 0000 to D7FF or E000 to FFFF hex is converted to a four-byte UTF-32 character as follows:

Unicode Character	a b c d e f g h	i j k l m n o p		
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p

On some models, an isolated low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) is also converted to a four-byte UTF-32 character as shown above, regardless of whether the ETF3-enhancement facility is installed and regardless of the W bit of the M_3 field. On other models, when the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the next Unicode character is an isolated low surrogate, condition code 2 is set.

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-32 character as follows:

Unicode Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t
where uvwxy = abcd + 1				

When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 field is zero, the first six bits of an expected Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, the following applies:

- When a Unicode high surrogate immediately precedes an invalid low surrogate, general register R_2 contains the address of the Unicode high surrogate.
- When an isolated Unicode low surrogate is detected, general register R_2 contains the address of the isolated low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid Unicode low surrogate
3 CPU-determined number of characters converted

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.
2. The storage-operand references of CONVERT UTF-16 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)
3. The CONVERT UTF-16 TO UTF-32 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
5. Determining that isolated Unicode low surrogates are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-16 TO UTF-8
CONVERT UNICODE TO UTF-8

CU21	$R_1,R_2[,M_3]$	[RRF-c]
CUUTF	$R_1,R_2[,M_3]$	[RRF-c]

'B2A6'	M_3	////	R_1	R_2
0	16	20	24	28 31

The two-byte Unicode characters of the second operand are converted to UTF-8 characters and placed at the first-operand location. The UTF-8 characters are one, two, three, or four bytes, depending on the Unicode characters that are converted. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid Unicode character is encountered in the second operand, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-294.

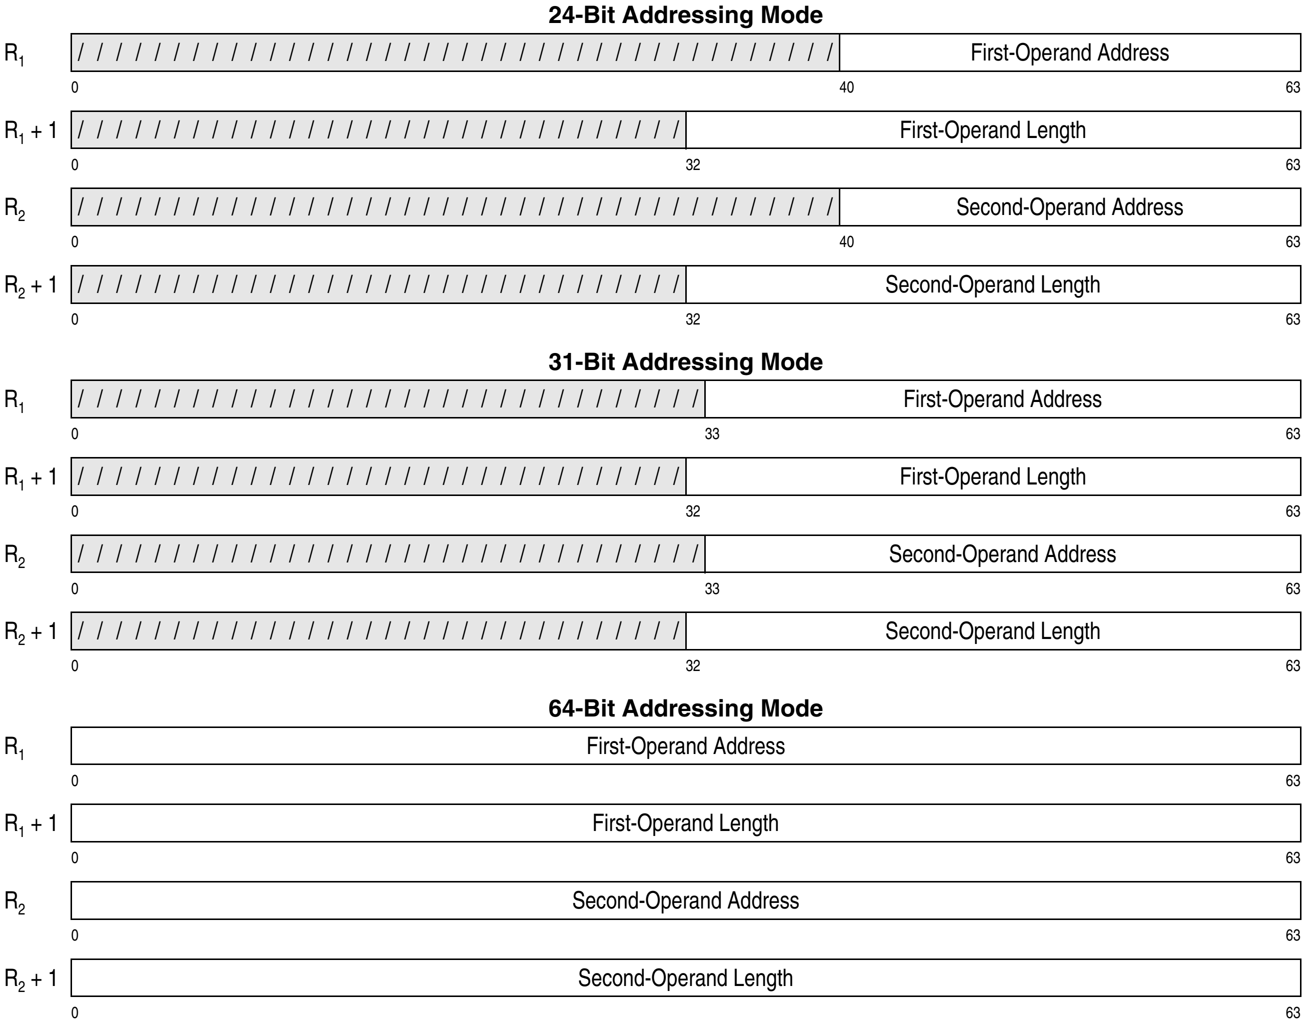


Figure 7-294. Register Contents for CONVERT UTF-16 TO UTF-8

When the ETF3-enhancement facility is installed, the M_3 field has the following format:

/	/	/	W
0			3

The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored. When the ETF3-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid Unicode character is encountered in the second operand.

To show the method of converting a Unicode character to a UTF-8 character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

A low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) that is not immediately preceded by a high surrogate (that is, a Unicode character in the range of D800 to DBFF hex) is called an isolated low surrogate.

Any Unicode character in the range 0000 to 007F hex is converted to a one-byte UTF-8 character as follows:

Unicode Character	0 0 0 0 0 0 0 0	0 j k l m n o p
UTF-8 Character	0 j k l m n o p	

Any Unicode character in the range 0080 to 07FF hex is converted to a two-byte UTF-8 character as follows:

Unicode Character	0 0 0 0 0 f g h	i j k l m n o p
UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p

Any Unicode character in the range 0800 to D7FF or E000 to FFFF hex is converted to a three-byte UTF-8 character as follows:

Unicode Character	a b c d e f g h	i j k l m n o p	
UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p

On some models, an isolated low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) is also converted to a three-byte UTF-8 character as shown above, regardless of whether the ETF3-enhancement facility is installed and regardless of the W bit of the M_3 field. On other models, when the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the next Unicode character is an isolated low surrogate, condition code 2 is set.

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-8 character as follows:

Unicode Characters	110110ab	cdefghij	110111kl	mnopqrst
UTF-8 Character	11110uvw	10xyefgh	10ijklmn	10opqrst
where uvwxy = abcd + 1				

When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 field is zero, the first six bits of an expected Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R_2 + 1 are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register R_1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_1 + 1, R_2, and R_2 + 1, always remain unchanged.

When condition code 2 is set, the following applies:

- When a Unicode high surrogate immediately precedes an invalid low surrogate, general register R_2 contains the address of the Unicode high surrogate.
- When an isolated Unicode low surrogate is detected, general register R_2 contains the address of the isolated low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid Unicode low surrogate
3 CPU-determined number of characters converted

Program Exceptions:

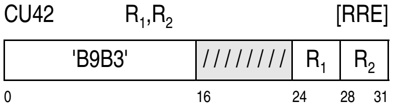
- Access (fetch, operand 2; store, operand 1)

- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.
2. The storage-operand references of CONVERT UNICODE TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)
3. The CONVERT UTF-16 TO UTF-8 (CONVERT UNICODE TO UTF-8) instruction supports UTF-16 characters only in the big-endian encoding.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
5. Determining that isolated Unicode low surrogates are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-32 TO UTF-16



The four-byte UTF-32 characters of the second operand are converted to two-byte UTF-16 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-32 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-295.

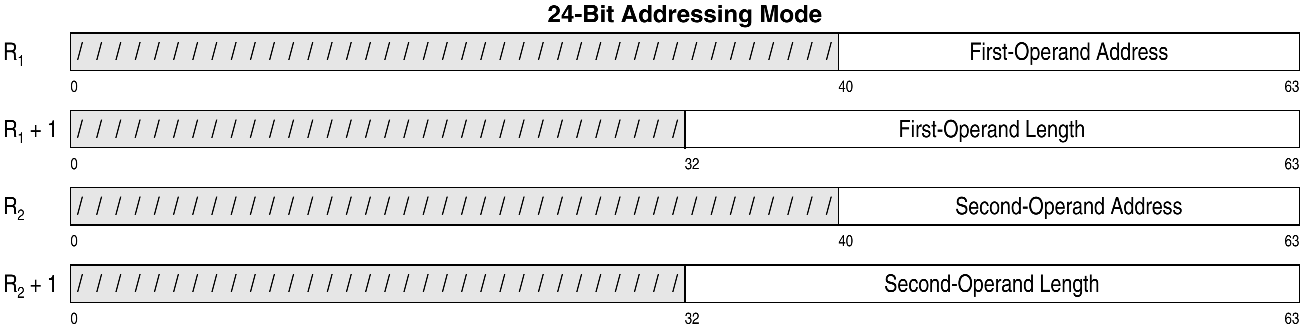


Figure 7-295. Register Contents for CONVERT UTF-32 TO UTF-16 (Part 1 of 2)

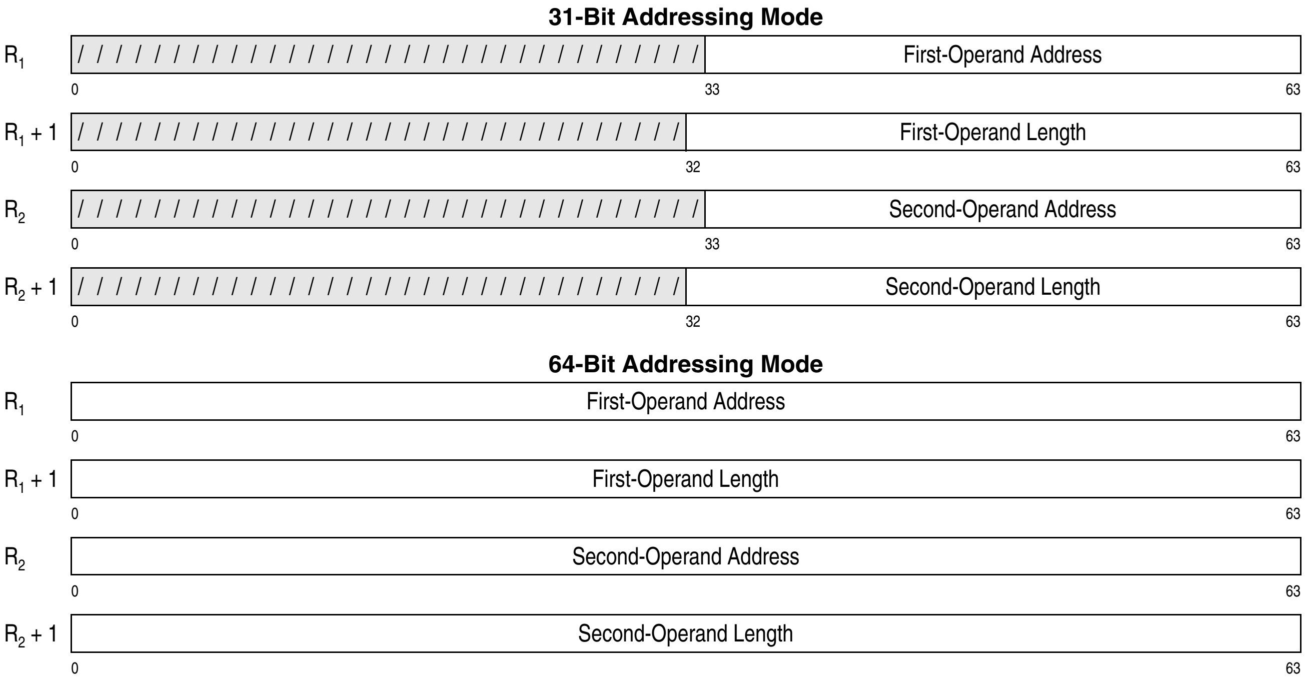

Figure 7-295. Register Contents for CONVERT UTF-32 TO UTF-16 (Part 2 of 2)

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-32 character is encountered in the second operand.

To show the method of converting a UTF-32 character to a UTF-16 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Identifying Bit Letters	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UTF-32 Character Bit Numbers	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Identifying Bit Letters	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Identifying Bit Letters	0	0	0	0	0	0	0	0	0	0	0	u	v	w	x	y

UTF-32 Character Bit Numbers	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Identifying Bit Letters	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t

The bits of a UTF-16 character in the range 0000 to D7FF or DC00 to FFFF hex are identified by letters as follows:

UTF-16 Character Bit Numbers	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Identifying Bit Letters	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p

In the case of a UTF-16 surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

UTF-16 High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

UTF-16 Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

When the contents of the UTF-32 characters are in the range 00000000 to 0000D7FF or 0000E000 to 0000FFFF hex, the character is converted to a two-byte UTF-16 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p
UTF-16 Character	a b c d e f g h	i j k l m n o p		

On some models, when the contents of the UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is also converted to a two-byte UTF-16 character as described above.

When the contents of a UTF-32 character are in the range 00010000 to 0010FFFF hex, the character is converted to two two-byte UTF-16 characters (a surrogate pair) as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t
UTF-16 Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
where zabcd = uvwxy - 1				

The high order bit (z) produced by the subtract operation is necessarily zero and is ignored.

The second-operand location is considered exhausted when it does not contain at least four remaining bytes. The first-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes in the case when a UTF-32 character in the range 00010000 to 0010FFFF hex is converted.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set. On some models, when the contents of the next UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-32 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-32 character
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-32 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

3. The CONVERT UTF-32 TO UTF-16 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

5. Determining that UTF-32 characters in the range of 0000DC00 to 0000DFFF are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-32 TO UTF-8

CU41 R_1,R_2 [RRE]

'B9B2'	////////	R_1	R_2
0	16	24	28 31

The four-byte UTF-32 characters of the second operand are converted to UTF-8 characters and placed at the first-operand location. The UTF-8 characters are one, two, three, or four bytes, depending on the Unicode characters that are converted. The operation proceeds until the end of the first or second operand is reached or a CPU-determined number of characters have been converted, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-296.

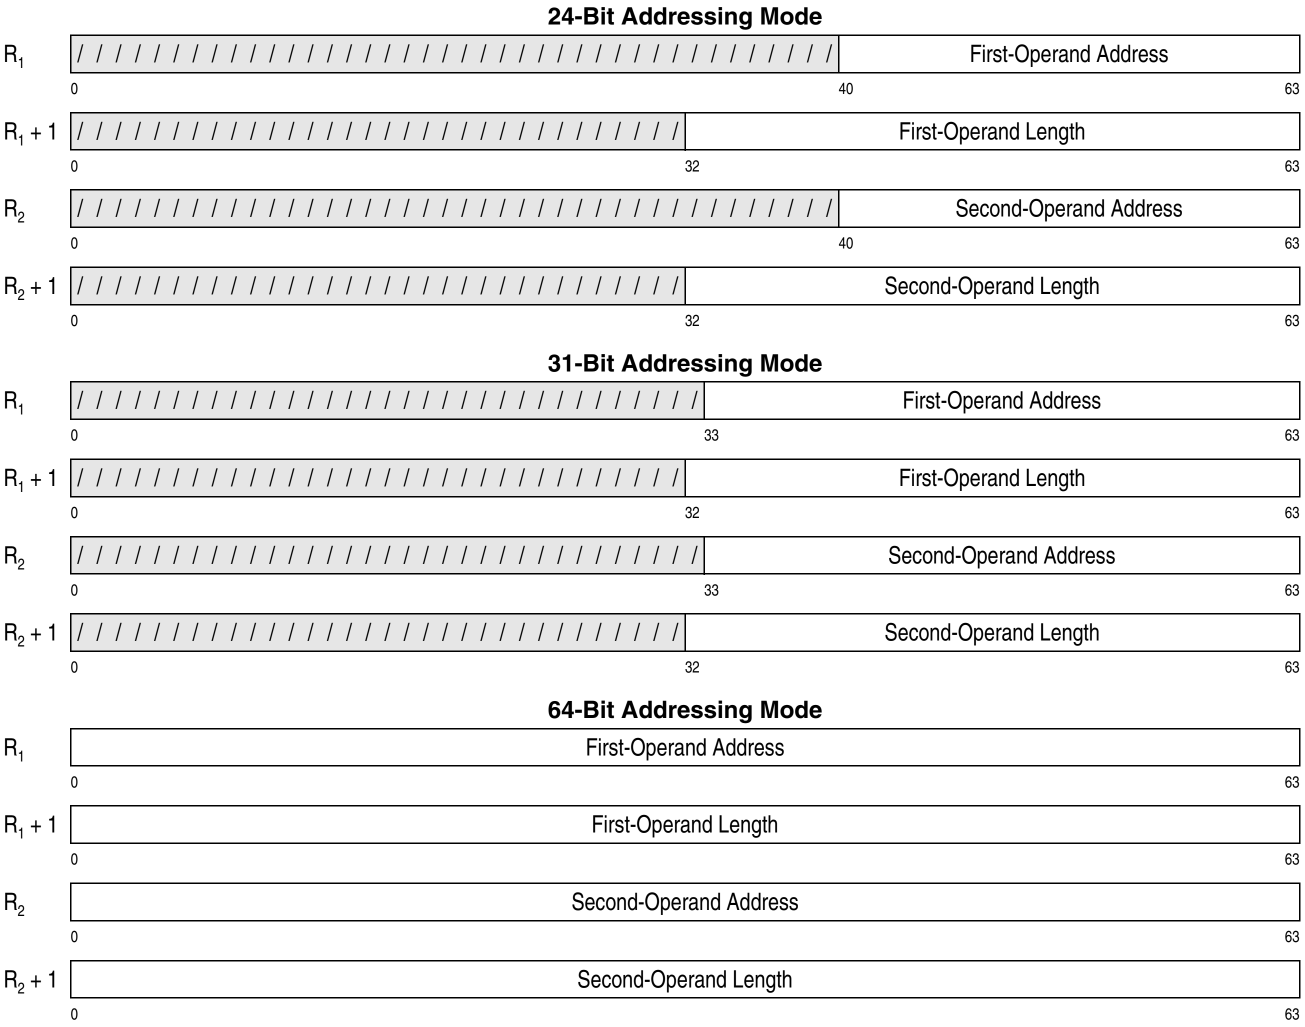

Figure 7-296. Register Contents for CONVERT UTF-32 TO UTF-8

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or on some models, until an invalid Unicode character is detected.

To show the method of converting a UTF-32 character to a UTF-8 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Identifying Bit Letters	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UTF-32 Character Bit Numbers	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Identifying Bit Letters	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex (UTF-16 surrogate pair) are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 u v w x y

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	e f g h i j k l	m n o p q r s t

Any UTF-32 character in the range 00000000 to 0000007F hex is converted to a one-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 j k l m n o p
UTF-8 Character	0 j k l m n o p			

Any UTF-32 character in the range 00000080 to 000007FF hex is converted to a two-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 f g h	i j k l m n o p
UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p		

Any UTF-32 character in the range 00000800 to 0000D7FF or 0000E000 to 0000FFFF hex is converted to a three-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p
UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p	

On some models, any UTF-32 character the range of 0000DC00 to 0000DFFF hex is converted to a three-byte UTF-8 character as described above.

Any UTF-32 character in the range 00010000 to 0010FFFF hex is converted to a four-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t
UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t

The second-operand location is considered exhausted when it does not contain at least four remaining bytes. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set. On some models, when the contents of the next UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-32 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-32 character.
3 CPU-determined number of characters converted

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-32 TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

3. The CONVERT UTF-32 TO UTF-8 instruction supports UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

5. Determining that UTF-32 characters in the range of 0000DC00 to 0000DFFF are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-8 TO UTF-16
CONVERT UTF-8 TO UNICODE

CU12	$R_1,R_2[,M_3]$	[RRF-c]
CUTFU	$R_1,R_2[,M_3]$	[RRF-c]

'B2A7'	M_3	////	R_1	R_2
0	16	20	24	28 31

The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to two-byte Unicode characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-297.

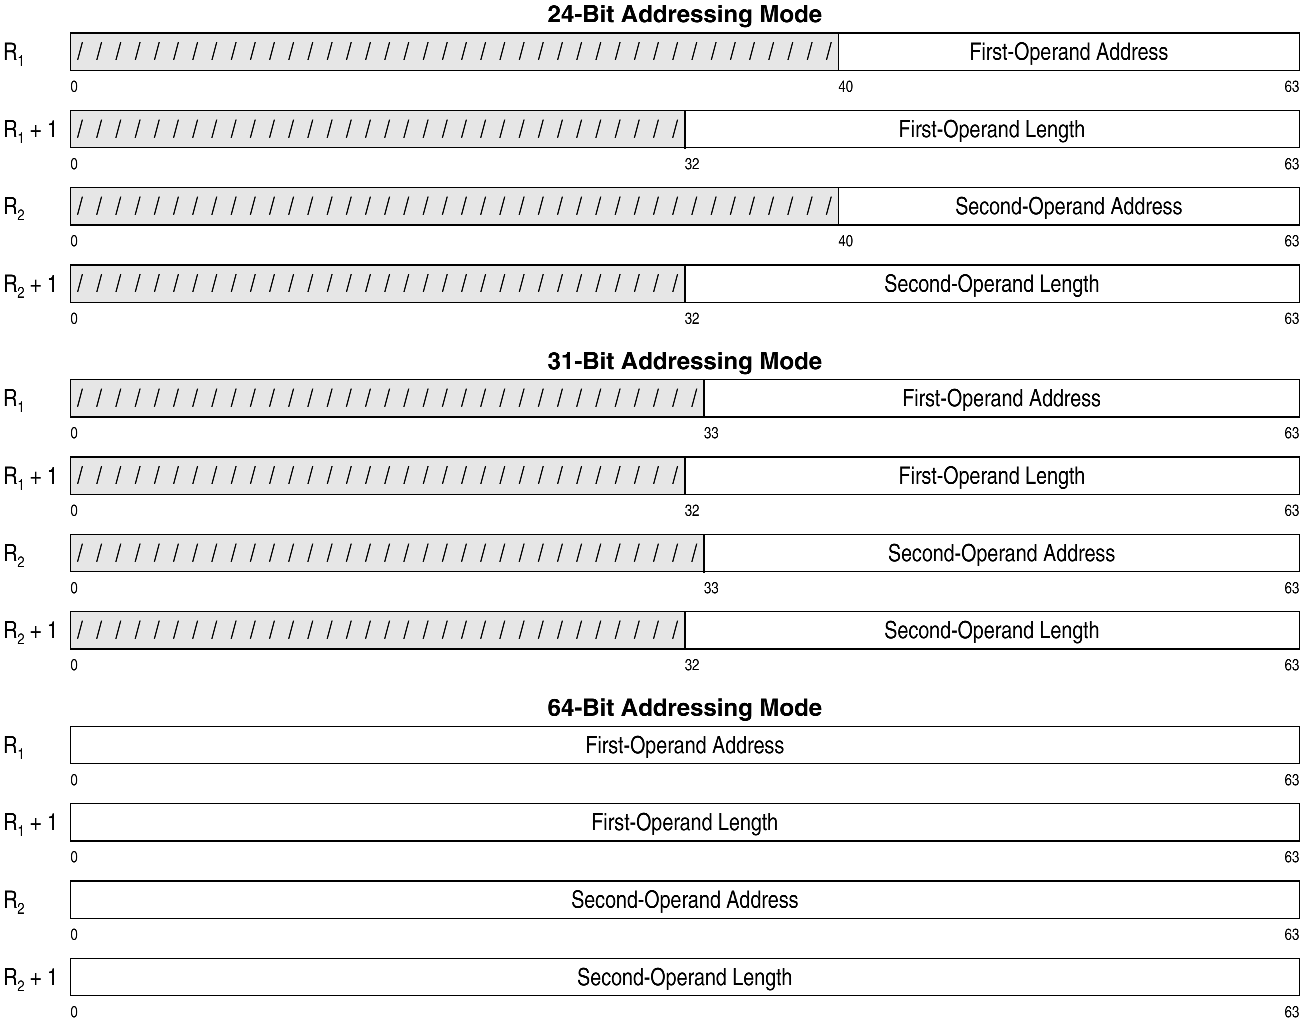

Figure 7-297. Register Contents for CONVERT UTF-8 TO UTF-16

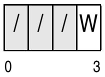
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored. When the ETF3-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a Unicode character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

Conversion of a UTF-8 character to a Unicode character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	0 j k l m n o p	
Unicode Character	0 0 0 0 0 0 0 0	0 j k l m n o p

2. When the contents of the first byte of the UTF-8 character are in the range 80 to BF hex, the character is invalid. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range C0 to C1 hex, the character is also invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of C2 to DF hex; the character is a two-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p
Unicode Character	0 0 0 0 0 f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p
Unicode Character	a b c d e f g h	i j k l m n o p	

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.

Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to two two-byte Unicode characters (a surrogate pair) as follows:

UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t
Unicode Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
where zabcd = uvwxy - 1				

   When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored, and the high order bit (z) produced by the subtract operation should be zero but is ignored.

   When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

   - When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
   - When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
   - When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

   Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.
7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R_2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes in the case when a four byte UTF-8 character is to be converted.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register R_2 + 1 are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register R_1 + 1 are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_1 + 1, R_2, and R_2 + 1, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-8 character
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

3. The storage-operand references of CONVERT UTF-8 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

4. The CONVERT UTF-8 TO UTF-16 (CONVERT UTF-8 TO UNICODE) instruction supports UTF-16 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CONVERT UTF-8 TO UTF-32

CU14 $R_1,R_2[,M_3]$ [RRF-c]

'B9B0'	M_3	////	R_1	R_2
0	16	20	24	28 31

The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to four-byte UTF-32 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions

0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-298.

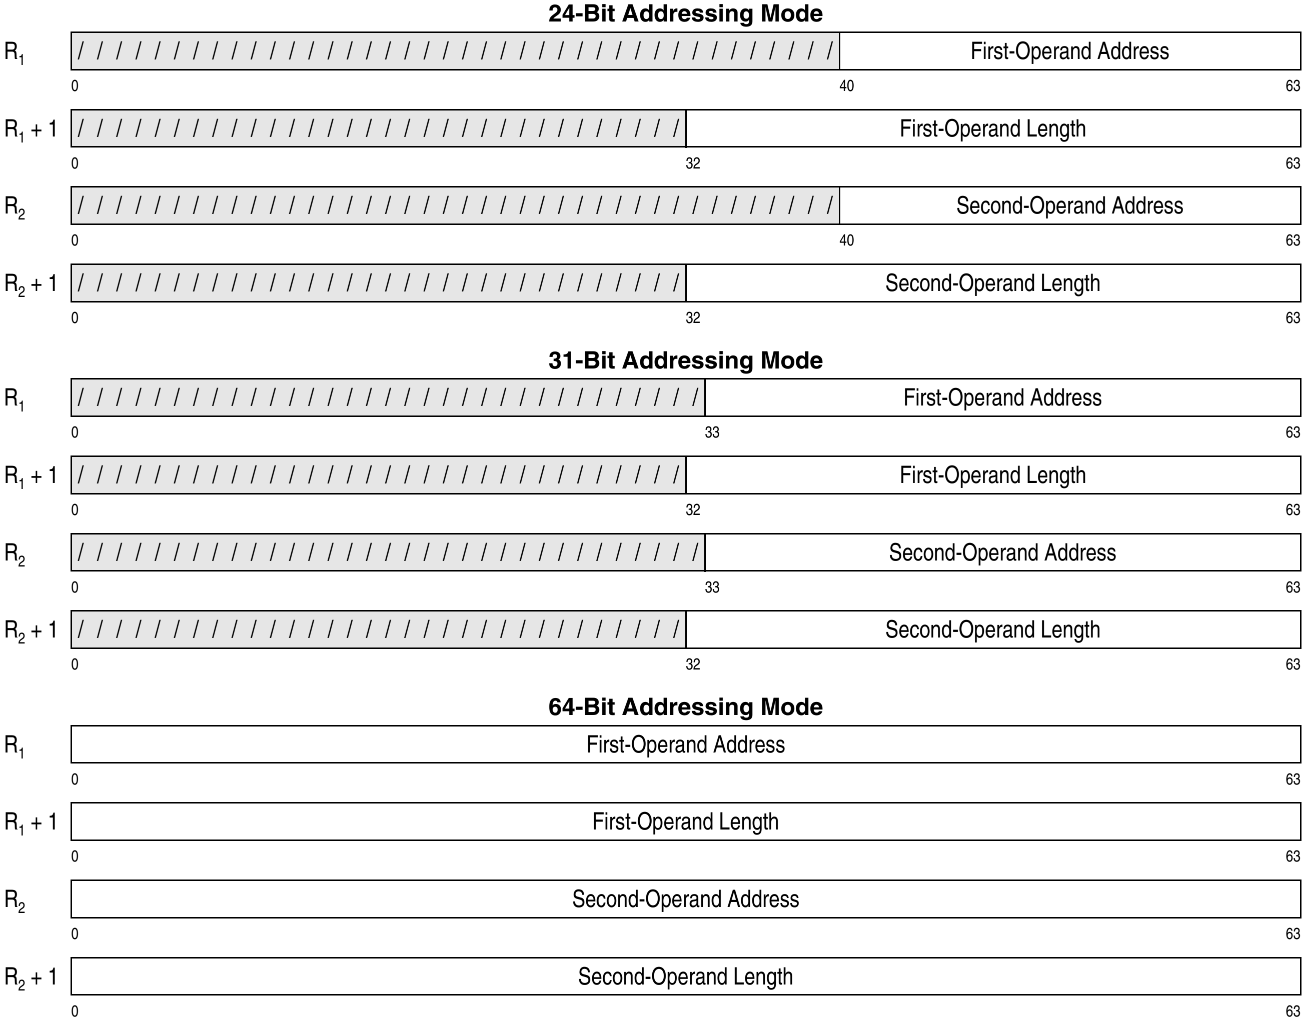


Figure 7-298. Register Contents for CONVERT UTF-8 TO UTF32

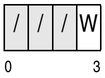
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a UTF-32 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

The bits of a UTF-32 character in the range 00010000 0010FFFF hex (UTF-16 surrogate pair) are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 u v w x y

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	e f g h i j k l	m n o p q r s t

Conversion of a UTF-8 character to a UTF-32 character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	0 j k l m n o p			
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 j k l m n o p

2. When the contents of the first byte of the UTF-8 character are in the range 80 to BF hex, the character is invalid. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range C0 to C1 hex, the character is also invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of C2 to DF hex; the character is a two-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p		
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p	
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.

Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to a four-byte UTF-32 character (a surrogate pair) as follows:

UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t

   When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored.

   When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

   - When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
   - When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
   - When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

   Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.

7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R_2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-8 character
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

3. The storage-operand references of CONVERT UTF-8 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

4. The CONVERT UTF-8 TO UTF-32 instruction supports UTF-32 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

COPY ACCESS

CPYA R_1,R_2 [RRE]

'B24D'	////////	R_1	R_2
0	16	24	28 31

The contents of access register R_2 are placed in access register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

DIVIDE

Register-and-register format:

DR R_1,R_2 [RR]

'1D'	R_1	R_2
0	8	12 15

Register-and-storage format:

D $R_1,D_2(X_2,B_2)$ [RX-a]

'5D'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

The 64-bit first operand (the dividend) is divided by the 32-bit second operand (the divisor), and the 32-bit remainder and quotient are placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend is treated as a 64-bit signed binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R_1, and the rightmost 32 bits are in bit positions 32-63 of general register $R_1 + 1$.

The divisor, remainder, and quotient are treated as 32-bit signed binary integers. For DIVIDE (DR), the divisor is in bit positions 32-63 of general register R_2. The remainder is placed in bit positions 32-63 of general register R_1, and the quotient is placed in bit positions 32-63 of general register $R_1 + 1$. Bits 0-31 of the registers remain unchanged.

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 32-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of D only)
- Fixed-point divide
- Specification
- Transaction constraint

DIVIDE LOGICAL

Register-and-register formats:

DLR R_1,R_2 [RRE]

'B997'	////////	R_1	R_2
0	16	24	28 31

DLGR R_1,R_2 [RRE]

'B987'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

DL $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'97'
0	8	12	16	20	32	40 47

DLG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'87'
0	8	12	16	20	32	40 47

The 64-bit or 128-bit first operand (the dividend) is divided by the 32-bit or 64-bit second operand (the divisor), and the 32-bit or 64-bit remainder and quotient are placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For DIVIDE LOGICAL (DLR, DL), the dividend is treated as a 64-bit unsigned binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R_1, and the rightmost 32 bits are in bit positions 32-63 of general register $R_1 + 1$.

The divisor, remainder, and quotient are treated as 32-bit unsigned binary integers. For DIVIDE LOGICAL (DLR), the divisor is in bit positions 32-63 of general register R_2. The remainder is placed in bit positions 32-63 of general register R_1, and the quotient is placed in bit positions 32-63 of general register $R_1 + 1$. Bits 0-31 of the registers remain unchanged.

For DIVIDE LOGICAL (DLGR, DLG), the dividend is treated as a 128-bit unsigned binary integer. The leftmost 64 bits of the dividend are in general register R_1, and the rightmost 64 bits are in general register $R_1 + 1$. The divisor, remainder, and quotient are treated as 64-bit unsigned binary integers. The remainder is placed in general register R_1, and the quotient is placed in general register $R_1 + 1$.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed as a 32-bit unsigned binary integer for DIVIDE LOGICAL (DLR, DL), or a 64-bit unsigned binary integer for DIVIDE LOGICAL (DLGR, DLG), a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of DL or DLG only)
- Fixed-point divide
- Specification
- Transaction constraint

DIVIDE SINGLE

Register-and-register formats:

DSGR R_1,R_2 [RRE]

'B90D'	////////	R_1	R_2
0	16	24	28 31

DSGFR R_1,R_2 [RRE]

'B91D'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

DSG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'0D'
0	8	12	16	20	32	40 47

DSGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'1D'
0	8	12	16	20	32	40 47

The 64-bit contents of general register $R_1 + 1$ (the dividend) are divided by the 64-bit or 32-bit second operand (the divisor), the 64-bit remainder is placed in general register R_1, and the 64-bit quotient is placed in general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend, quotient, and remainder are treated as 64-bit signed binary integers. For DIVIDE SINGLE (DSGR, DSG), the divisor is treated as a 64-bit signed binary integer. For DIVIDE SINGLE (DSGFR, DSGF), the divisor is treated as a 32-bit signed binary integer. For DSGFR, the divisor is in bit positions 32-63 of general register R_2.

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 64-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of DSG and DSGF only)
- Fixed-point divide
- Specification
- Transaction constraint

EXCLUSIVE OR

0	8	16	20 31

XIY $D_1(B_1),I_2$ [SIY]

'EB'	I_2	B_1	DL_1	DH_1	'57'
0	8	16	20	32	40 47

Storage-and-storage format:

XC $D_1(L,B_1),D_2(B_2)$ [SS-a]

'D7'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

For X, XC, XG, XGR, XI, XIY, XR, and XY, the EXCLUSIVE OR of the first and second operands is placed at the first-operand location. For XGRK and XRK, the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

For EXCLUSIVE OR (XC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For EXCLUSIVE OR (XI, XIY), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility 2 is installed, the update of the first operand appears to be an interlocked-update reference as observed by other CPUs and channel programs, and a specific-operand-serialization operation is performed.

For EXCLUSIVE OR (X, XR, XRK, and XY), the operands are 32 bits, and for EXCLUSIVE OR (XG, XGR, and XGRK), they are 64 bits.

The displacements for X, XI, and both operands of XC are treated as 12-bit unsigned binary integers. The displacement for XY, XIY, and XG is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch, operand 2, X, XY, XG, and XC; fetch and store, operand 1, XI, XIY, and XC)
- Operation (XY and XIY, if the long-displacement facility is not installed; XGRK and XRK, if the distinct-operands facility is not installed)
- Transaction constraint (XC)

Programming Notes:

1. An example of the use of the EXCLUSIVE OR instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. EXCLUSIVE OR may be used to invert a bit, an operation particularly useful in testing and setting programmed binary switches.

3. A field EXCLUSIVE-ORed with itself becomes all zeros.

4. For EXCLUSIVE OR (XR or XGR), the sequence A EXCLUSIVE-OR B, B EXCLUSIVE-OR A, A EXCLUSIVE-OR B results in the exchange of the contents of A and B without the use of an additional general register.

5. Accesses to the first operand of EXCLUSIVE OR (XC) – and, when the interlocked-access facility 2 is not installed, accesses to the first operand of EXCLUSIVE OR (XI, XIY) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” on page A-45.

   When the interlocked-access facility 2 is installed, EXCLUSIVE OR (XI, XIY) can be safely used to update a location in storage, even if the possibility exists that another CPU or a channel program may also be updating the location.

EXCLUSIVE OR IMMEDIATE

XIHF R_1,I_2 [RIL-a]

'C0'	R_1	'6'	I_2
0	8	12	16 47

XILF R_1,I_2 [RIL-a]

'C0'	R_1	'7'	I_2
0	8	12	16 47

The second operand is EXCLUSIVE ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are EXCLUSIVE ORed with the second operand and then replaced are as follows:

Instruction	Bits Exclusive ORed and Replaced
XIHF	0-31
XILF	32-63

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

The condition code is set based on the result of the 32-bit EXCLUSIVE OR operation.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

Program Exceptions:

- Operation, if the extended-immediate facility is not installed)

Programming Note: The setting of the condition code is based only on the bits that are exclusive ORed and replaced.

EXECUTE

EX $R_1,D_2(X_2,B_2)$ [RX-a]

'44'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

EXECUTE RELATIVE LONG

EXRL R_1,RI_2 [RIL-b]

'C6'	R_1	'0'	RI_2
0	8	12	16 47

The single instruction at the second-operand address is modified by the contents of general register R_1, and the resulting instruction, called the target instruction, is executed.

When the R_1 field is not zero, bits 8-15 of the instruction designated by the second-operand address are ORed with bits 56-63 of general register R_1. The ORing does not change either the contents of general register R_1 or the instruction in storage, and it is effective only for the interpretation of the instruction to be executed. When the R_1 field is zero, no ORing takes place.

The target instruction may be two, four, or six bytes in length. The execution and exception handling of the target instruction are exactly as if the target instruction were obtained in normal sequential operation, except for the instruction address and the instruction-length code.

The instruction address in the current PSW is increased by the length of the execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG). This updated address and the instruction-length code of the execute-type instruction are used, for example, as part of the link information when the target instruction is BRANCH AND LINK. When the target instruction is a successful branching instruction, the instruction address in the current PSW is replaced by the branch address specified by the target instruction.

When the target instruction is any of the following instructions, an execute exception is recognized.

- Another execute-type instruction
- TRANSACTION ABORT
- TRANSACTION BEGIN

- TRANSACTION END

The effective address of EXECUTE must be even; otherwise, a specification exception is recognized.

When the target instruction is two or three halfwords in length but can be executed without fetching its second or third halfword, it is unpredictable whether access exceptions are recognized for the unused halfwords. Access exceptions are not recognized for the second-operand address when the address is odd.

The second-operand address of an execute-type instruction is an instruction address rather than a logical address; thus, the target instruction is fetched from the primary address space when in the primary-space, secondary-space, or access-register mode.

For EXECUTE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the target instruction in storage.

Condition Code: The code may be set by the target instruction.

Program Exceptions:

- Access (fetch, target instruction)
- Execute
- Operation (EXRL, when the execute-extensions facility is not installed)
- Specification (EX)
- Transaction constraint

Programming Notes:

1. An example of the use of the EXECUTE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The ORing of eight bits from the general register with the designated instruction permits the indirect specification of the length, index, mask, immediate-data, register, or extended-op-code field.

3. The fetching of the target instruction is considered to be an instruction fetch for purposes of program-event recording and for purposes of reporting access exceptions.

4. An access or specification exception may be caused by execute-type instructions or by the target instruction, except that EXECUTE RELATIVE LONG cannot cause a specification exception due to a misaligned target operand.

5. When an interruptible instruction is made the target of an execute-type instruction, the program normally should not designate any register updated by the interruptible instruction as the R_1, X_2, or B_2 register for EXECUTE or R_1 register for EXECUTE RELATIVE LONG. Otherwise, on resumption of execution after an interruption, or if the instruction is refetched without an interruption, the updated values of these registers will be used in the execution of the execute-type instruction. Similarly, the program should normally not let the destination field in storage of an interruptible instruction include the location of an execute-type instruction, since the new contents of the location may be interpreted when resuming execution.

6. Exception conditions that occur during the execution of EXECUTE or EXECUTE RELATIVE LONG are recognized before exception conditions for the target instruction.

EXTRACT ACCESS

EAR R_1,R_2 [RRE]

'B24F'	////////	R_1	R_2
0	16	24	28 31

The contents of access register R_2 are placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions: None.

EXTRACT CPU ATTRIBUTE

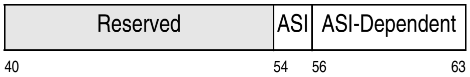
ECAG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'4C'
0	8	12	16	20	32	40 47

Information regarding the specified attribute of the CPU or storage subsystem is placed into the first-operand location. The first operand is 64 bits.

The second-operand address is not used to address data; rather, the rightmost 24 bits of the address are treated as a code specifying which attribute is returned in general register R_1.

The rightmost 24 bits of the second-operand address are defined as follows:



Attribute-Set Indication (ASI): Bit positions 54-55 of the second-operand address contain a 2-bit unsigned binary integer indicating the set of attributes from which an attribute to be extracted is selected. The attribute-set indications are:

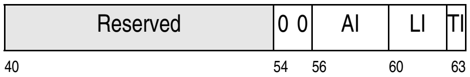
0 Cache attributes

1 CPU attributes

All other attribute-set-indication values are reserved.

Cache-Attribute-Set Operation

The rightmost 24 bits of the second-operand address are defined as follows:



The attribute, level, and type indications for the cache-attribute set are as follows:

Attribute Indication (AI): Bit positions 56-59 of the second-operand address contain a 4-bit unsigned binary integer indicating the cache attribute to be extracted, as follows:

0 Extract topology summary

1 Extract line size of the cache, in bytes

2 Extract total size of the cache, in bytes

3 Extract set-associativity level of the cache

4-15 Reserved

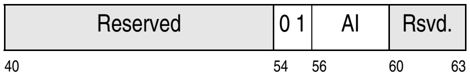
Level Indication (LI): Bit positions 60-62 of the second-operand address contain a 3-bit unsigned binary integer indicating the level of the cache for which the cache attribute is to be extracted, with 0 indicating the first-level cache, 1 indicating the second-level cache and so forth. If a cache level is not implemented on a model, its corresponding level indication is reserved.

Type Indication (TI): Bit 63 of the second-operand address indicates the type of cache for which the cache attribute is to be extracted, with 0 indicating the data cache and 1 indicating the instruction cache. When a cache level has a unified data and instruction cache, the same result is returned regardless of the type indication.

When the attribute indication is zero, the level indication (LI) and type indication (TI) are ignored.

CPU-Attribute-Set Operation

The rightmost 24 bits of the second-operand address are defined as follows:



The attribute indication for the CPU-attribute set are as follows:

Attribute Indication (AI): Bit positions 56-59 of the second-operand address contain a 4-bit unsigned binary integer indicating the CPU attribute to be extracted, as follows:

0 Extract CPU speed

1-15 Reserved

Reserved: Bit positions 60-63 of the second-operand address are reserved and ignored.

Common Operation

Bits 0-39 of the second-operand address are ignored. Bits 40-53 of the second-operand address are reserved and should contain zeros.

Bits 0-63 of general register R_1 are set to ones if any of the following apply:

- A reserved bit position in the second-operand address contains one and is otherwise not specifically designated as ignored.
- A reserved ASI, AI, or, when applicable, LI value is specified and is otherwise not specifically designated as ignored.

- The specified ASI and AI values and, when applicable, the LI value are all valid, but the model does not provide the data.

The contents of general register R_3 are ignored, however the R_3 field should specify register 0; otherwise, the program may not operate compatibly in the future.

Cache-Attribute Results (ASI = 0)

When the cache attribute indication is zero, a summary of each level of cache is returned in general register R_1. Each summary field is eight bits, where bits 0-7 of the register contain the summary for the first-level cache, bits 8-15 contain the summary for the second-level cache, and so forth. The contents of an eight-bit summary field are as follows:

Bits Meaning

0-3 Reserved, stored as zeros

4-5 Cache scope, as follows:

- 00 Cache does not exist at this level
- 01 Cache is private to the CPU
- 10 Cache may be shared by multiple CPUs
- 11 Reserved

6-7 When bit positions 4-5 contain a nonzero value, bit positions 6-7 contain the cache type, as follows:

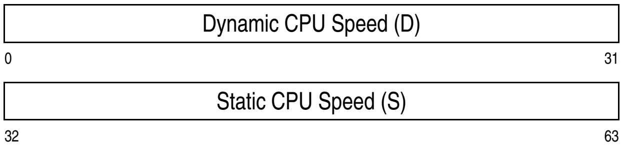
- 00 Separate instruction and data caches exist at this level
- 01 Only an instruction cache exists at this level
- 10 Only a data cache exists at this level
- 11 A unified instruction and data cache exists at this level

When bit positions 4-5 contain zeros, bit positions 6-7 also contain zeros.

When the cache attribute indication is one, two, or three, the attribute value is returned in general register R_1, as a 64-bit unsigned integer.

CPU-Attribute Results (ASI = 1)

When the CPU attribute indication is zero, the CPU speeds are returned in general register R_1, specified in the following format:



The fields are defined as follows:

Bits Meaning

0-31 Bit positions 0-31 (D) contain a 32-bit unsigned binary integer whose value represents the dynamic CPU speed, encoded as the approximate number of CPU cycles per microsecond.

32-63 Bit positions 32-63 (S) contain a 32-bit unsigned binary integer whose value represents the static CPU speed, encoded as the approximate number of CPU cycles per microsecond.

The dynamic CPU speed may or may not be the same as the static CPU speed. The static CPU speed reflects a CPU running at its nominal capacity and corresponds to the particular model. The dynamic CPU speed reflects a CPU running at a changed capacity caused by, for example, a manual control set to a power-save position.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

1. Knowledge of the cache line size is useful when determining the placement of PREFETCH DATA and PREFETCH DATA RELATIVE LONG instructions.

2. The value placed in the first-operand location is model dependent and may differ significantly from one model to another. For example, the size of the data cache on one model may be smaller or larger than the size of the data cache on another model. To ensure compatible operation across multiple models, the program should not rely on any particular value being returned in the first-operand location.

3. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, bit positions 4-5 of each 8-bit field returned in general register R_1 contain a cache-scope indication. When the cache-scope indication is 10 binary, the cache may be shared by more than one CPU

in the configuration. The System Library publication for the model may provide further explanation of cache topology.

4. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, the summary indications are returned in contiguous 8-bit fields in general register R_1. Thus if the program scans the resulting summary-indication fields from left to right and encounters an 8-bit field containing all zeros, no further meaningful fields exist.

5. Cache information returned reflects the depth specified by the level indication and the cache information accessible from the issuing CPU. The total sizes and associativity do not include other, parallel cache structures accessible from other CPUs of the configuration.

6. The static CPU speed (S) may be less than, equal to, or greater than the dynamic CPU speed (D), as follows:

   - When the CPU is operating at nominal capacity, the D and S values are equal.
   - The sections “Capacity-Change Reason (CCR)” on page 10-146 and “Capacity-Adjustment Indication (CAI)” on page 10-147 describe various reasons why a CPU may not be operating at nominal capacity, in which case, D may be less than S.
   - Under certain circumstances, D may be greater than S.

7. Depending on the model, the dynamic CPU speed (D) values may be different from one CPU to another. Similarly, the static CPU speed values may be different from one CPU to another.

8. In most cases, the dynamic CPU speed returned for CPU-attribute-indicator zero is the same as would be returned by the QUERY SAMPLING INFORMATION (QSI) instruction of the CPU-measurement facility. The value returned is also subject to most of the same factors that affect the value returned by QSI.

EXTRACT CPU TIME

ECTG $D_1(B_1),D_2(B_2),R_3$ [SSF]

'C8'	R_3	'1'	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The value of the current CPU timer is subtracted from the first operand, and the difference is placed in general register 0. The second operand is placed unchanged in general register 1. The eight bytes at the third operand location replace the contents of general register R_3.

The first and second operands and the results in general registers 0, 1, and R_3 are treated as 64-bit unsigned binary integers.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_3 constitute the address of the third operand, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address. In the access-register mode, the contents of access register R_3 are used for accessing the third operand.

All operands are fetched before any general register is modified. If the R_3 field designates general register 0, it is unpredictable whether the result placed in the register is the first operand minus the CPU timer or the third operand. If the R_3 field designates general register 1, it is unpredictable whether the result placed in the register is the second operand or the third operand.

The contents of the registers just described are shown in Figure 7-299.

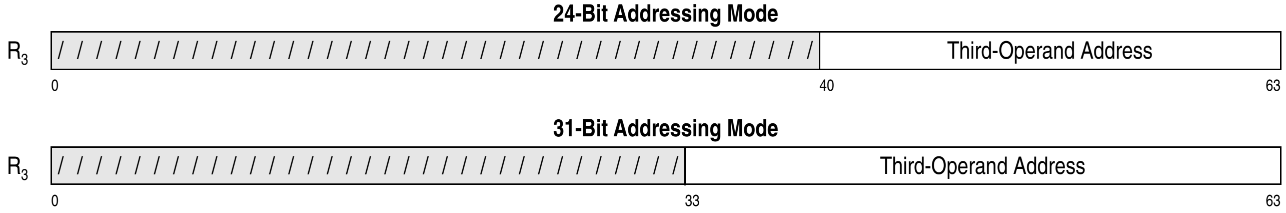


Figure 7-299. General Register Assignment for EXTRACT CPU TIME (Part 1 of 2)

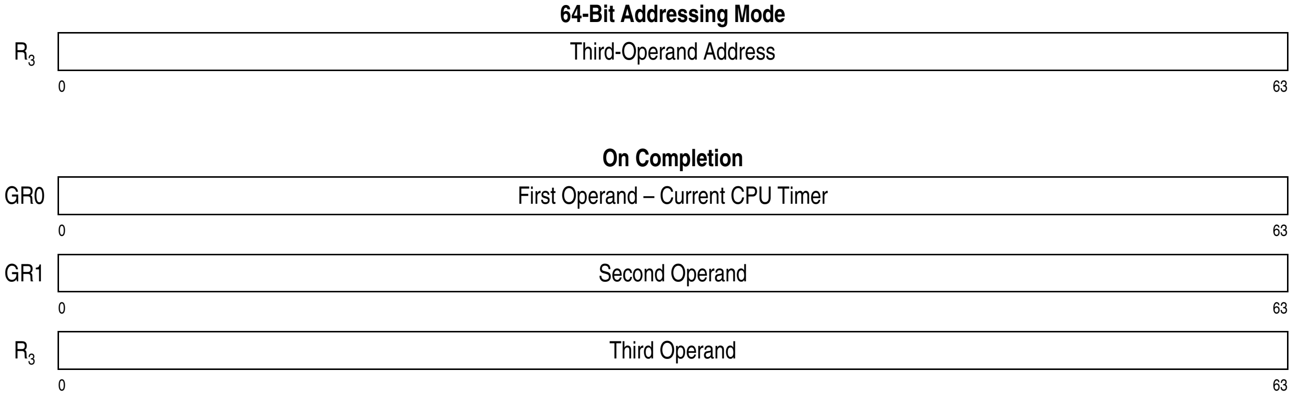

Figure 7-299. General Register Assignment for EXTRACT CPU TIME (Part 2 of 2)

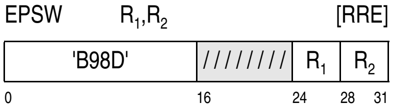
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operands 1, 2, and 3)
- Operation (the extract-CPU-time facility is not installed)
- Transaction constraint

EXTRACT PSW



Bits 0-11 and 13-31 of the current PSW are placed in bit positions 32-43 and 45-63 of the first operand, and bits 0-31 of the operand remain unchanged. When the configuration is in the z/Architecture architectural mode, bit 44 of the first operand is set to zero, and when the configuration is in the ESA/390-compatibility mode, bit 44 of the first operand is set to one.

Subsequently, bits 32-63 of the current PSW are placed in bit positions 32-63 of the second operand, and bits 0-31 of the operand remain unchanged. The action associated with the second operand is not performed if the R_2 field is zero.

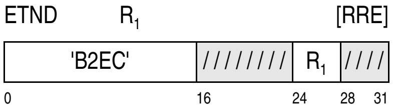
Bits 0-63 of the 128-bit PSW are illustrated in Figure 4-2 on page 4-5.

Condition Code: The code remains unchanged.

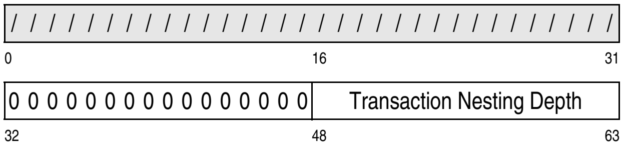
Program Exceptions:

- Transaction constraint

EXTRACT TRANSACTION NESTING DEPTH



The current transaction nesting depth is placed in bits 48-63 of general register R_1. Bits 0-31 of the register remain unchanged, and bits 32-47 of the register are set to zero, as illustrated below.



A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (transactional-execution facility not installed)
- Special operation
- Transaction constraint

Programming Note: A transaction nesting depth of zero indicates that the CPU is not in the transactional-execution mode.

FIND LEFTMOST ONE

FLOGR R_1,R_2 [RRE]

'B983'	////////	R_1	R_2
0	16	24	28 31

Bits 0-63 of general register R_2 are scanned left to right for the leftmost one bit. A 64-bit binary integer designating the bit position of the leftmost one bit, or 64 if there is no one bit, is placed in general register R_1. When a one bit is found in the second operand, the original contents of general register R_2, with the leftmost one bit set to zero, are placed in general register R_1 + 1. When a one bit is not found, the contents of general register R_1 + 1 are set to zeros.

The condition code indicates whether or not a one bit was found in the second operand.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 No one bit found
1 --
2 One bit found
3 --

Program Exceptions:

- Operation (if the extended-immediate facility is not installed)
- Specification

Programming Notes:

1. An example of the use of the FIND LEFTMOST ONE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When the R_1 and R_2 fields designate the same register, the original contents of general register R_2 are replaced by the resulting bit-position value, or 64 if no one bit was found.

3. When the R_2 field designates general register R_1 + 1, the leftmost one bit (if any) of general register R_2 is set to zero; if no one bit is found, the entire register is set to zero.

4. When the R_2 field designates neither the even nor the odd registers designated by the R_1 field, then general register R_2 is not modified.

INSERT CHARACTER

IC $R_1,D_2(X_2,B_2)$ [RX-a]

'43'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

ICY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'73'
0	8	12	16	20	32	40 47

The byte at the second-operand location is inserted into bit positions 56-63 of general register R_1. The remaining bits in the register remain unchanged.

The displacement for IC is treated as a 12-bit unsigned binary integer. The displacement for ICY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (ICY, if the long-displacement facility is not installed)

INSERT CHARACTERS UNDER MASK

ICM $R_1,M_3,D_2(B_2)$ [RS-b]

'BF'	R_1	M_3	B_2	D_2
0	8	12	16	20 31

ICMY $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'81'
0	8	12	16	20	32	40 47

ICMH $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'80'
0	8	12	16	20	32	40 47

Bytes from contiguous locations beginning at the second-operand address are inserted into general register R_1 under control of a mask.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R_1. For INSERT CHARACTERS UNDER MASK (ICM, ICMY), the four bytes to which the mask bits correspond are in the low-order half, bit positions 32-63 of general register R_1. For INSERT CHARACTERS UNDER MASK (ICMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The byte positions corresponding to ones in the mask are filled, left to right, with bytes from successive storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The bytes in the general register corresponding to zeros in the mask remain unchanged. For ICM and ICMY, bits 0-31 of the register remain unchanged, and, for ICMH, bits 32-63 remain unchanged.

The resulting condition code is based on the mask and on the value of the bits inserted. When the mask is zero or when all inserted bits are zeros, the condition code is set to 0. When the inserted bits are not all zeros, the code is set according to the leftmost bit of the storage operand: if this bit is one, the code is set to 1; if this bit is zero, the code is set to 2.

When the mask is not zero, exceptions associated with storage-operand access are recognized only for the number of bytes specified by the mask. When the mask is zero, access exceptions are recognized for one byte at the second-operand address.

The displacement for ICM is treated as a 12-bit unsigned binary integer. The displacement for ICMY and ICMH is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 All inserted bits zeros, or mask bits all zeros
1 Leftmost inserted bit one
2 Leftmost inserted bit zero, and not all inserted bits zeros
3 --

Program Exceptions:

- Access (fetch, operand 2)
- Operation (ICMY, if the long-displacement facility is not installed)

Programming Notes:

1. Examples of the use of the INSERT CHARACTERS UNDER MASK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The condition code for INSERT CHARACTERS UNDER MASK (ICM, ICMY only) is defined such that, when the mask is 1111, the instruction causes the same condition code to be set as for LOAD AND TEST (LTR only) Thus, the instruction may be used as a storage-to-register load-and-test operation.
3. INSERT CHARACTERS UNDER MASK (ICM, ICMY) with a mask of 1111 or 0001 performs a function similar to that of a LOAD (L) or INSERT CHARACTER (IC) instruction, respectively, with the exception of the condition-code setting. However, the performance of INSERT CHARACTERS UNDER MASK may be slower.

INSERT IMMEDIATE

IIHF R_1,I_2 [RIL-a]

'C0'	R_1	'8'	I_2	
0	8	12	16	47

IIHH R_1,I_2 [RI-a]

'A5'	R_1	'0'	I_2	
0	8	12	16	31

IIHL R_1,I_2 [RI-a]

'A5'	R_1	'1'	I_2	
0	8	12	16	31

IILF R_1,I_2 [RIL-a]

'C0'	R_1	'9'	I_2	
0	8	12	16	47

IILH R_1,I_2 [RI-a]

'A5'	R_1	'2'	I_2	
0	8	12	16	31

IILL R_1,I_2 [RI-a]

'A5'	R_1	'3'	I_2	
0	8	12	16	31

The second operand is placed in bit positions of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

Instruction	Bit Positions Loaded
IIHF	0-31
IIHH	0-15
IIHL	16-31
IILF	32-63
IILH	32-47
IILL	48-63

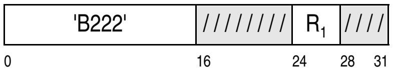
Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (IIHF and IILF, if the extended-immediate facility is not installed)

INSERT PROGRAM MASK

IPM R_1 [RRE]



The condition code and program mask from the current PSW are inserted into bit positions 34 and 35 and 36-39, respectively, of general register R_1. Bits 32 and 33 of the register are set to zeros; bits 0-31 and 40-63 are left unchanged.

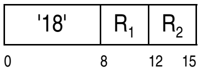
Condition Code: The code remains unchanged.

Program Exceptions: None.

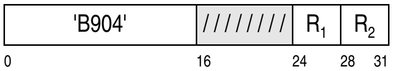
LOAD

Register-and-register formats:

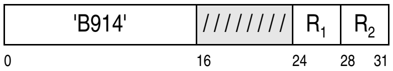
LR R_1,R_2 [RR]



LGR R_1,R_2 [RRE]

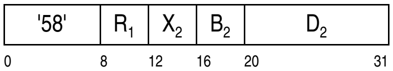


LGFR R_1,R_2 [RRE]

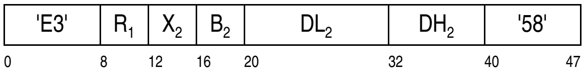


Register-and-storage formats:

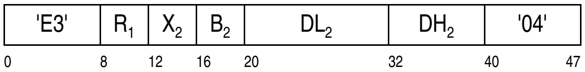
L $R_1,D_2(X_2,B_2)$ [RX-a]



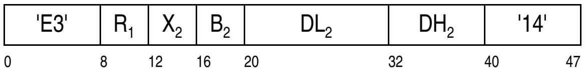
LY $R_1,D_2(X_2,B_2)$ [RXY-a]



LG $R_1,D_2(X_2,B_2)$ [RXY-a]

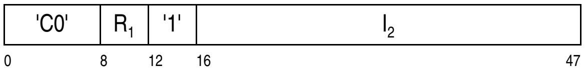


LGF $R_1,D_2(X_2,B_2)$ [RXY-a]



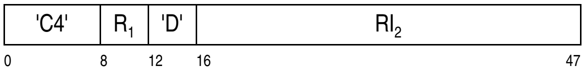
LOAD IMMEDIATE

LGFI R_1,I_2 [RIL-a]

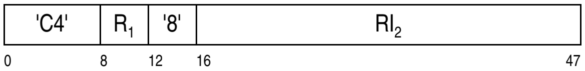


LOAD RELATIVE LONG

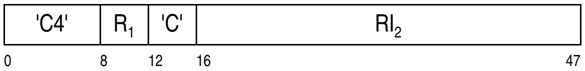
LRL R_1,RI_2 [RIL-b]



LGRL R_1,RI_2 [RIL-b]



LGFRL R_1,RI_2 [RIL-b]



The second operand is placed unchanged at the first-operand location, except that, for LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGFRL), it is sign extended.

For LOAD (LR, L, LY) and LOAD RELATIVE LONG (LRL), the operands are 32 bits, and, for LOAD (LGR, LG), and LOAD RELATIVE LONG (LGRL), the operands are 64 bits. For LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGFRL), the second operand is treated as a 32-bit signed binary integer, and the first operand is treated as a 64-bit signed binary integer.

The displacement for L is treated as a 12-bit unsigned binary integer. The displacement for LY, LG, and LGF is treated as a 20-bit signed binary integer.

For LOAD IMMEDIATE, the contents of the I_2 field form the second operand directly.

For LOAD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD RELATIVE LONG (LRL, LGFRL), the second operand must be aligned on a word boundary, and for LOAD RELATIVE LONG (LGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of L, LY, LG, LGF, LRL, LGRL, and LGFRL only)
- Operation (LY, if the long-displacement facility is not installed; LGFI, if the extended-immediate facility is not installed; LRL, LGRL, LGFRL, if the general-instructions-extension facility is not installed)
- Specification (LRL, LGFRL, LGRL only)

Programming Notes:

1. An example of the use of the LOAD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For LOAD RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.
3. When LOAD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD ACCESS MULTIPLE

LAM $R_1,R_3,D_2(B_2)$ [RS-a]

'9A'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

LAMY $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'9A'
0	8	12	16	20	32	40 47

The set of access registers starting with access register R_1 and ending with access register R_3 is loaded from the locations designated by the second-operand address.

The storage area from which the contents of the access registers are obtained starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The access registers are loaded in ascending order of their register numbers, starting with access register R_1 and continuing up to and including access register R_3, with access register 0 following access register 15.

The displacement for LAM is treated as a 12-bit unsigned binary integer. The displacement for LAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)

- Operation (LAMY, if the long-displacement facility is not installed)
- Specification
- Transaction constraint

LOAD ADDRESS

LA $R_1,D_2(X_2,B_2)$ [RX-a]

'41'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

LAY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'71'
0	8	12	16	20	32	40 47

The address specified by the X_2, B_2, and D_2 fields is placed in general register R_1. The address computation follows the rules for address arithmetic.

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The displacement for LA is treated as a 12-bit unsigned binary integer. The displacement for LAY is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (LAY if the long-displacement facility is not installed)

Programming Notes:

1. An example of the use of the LOAD ADDRESS instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. LOAD ADDRESS may be used to increment the rightmost bits of a general register, other than register 0, by the contents of the D_2 field of the instruction. LOAD ADDRESS (LAY) may also be used to decrement the rightmost bits of a register, other than register 0. The register to be incremented should be designated by R_1 and by either X_2 (with B_2 set to zero) or B_2 (with X_2 set to zero). The instruction increments 24 bits in the 24-bit addressing mode, 31 bits in the 31-bit addressing mode, and 64 bits in the 64-bit addressing mode.

LOAD ADDRESS EXTENDED

LAE $R_1,D_2(X_2,B_2)$ [RX-a]

'51'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

LAEY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'75'
0	8	12	16	20	32	40 47

The address specified by the X_2, B_2, and D_2 fields is placed in general register R_1. Access register R_1 is loaded with a value that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW. If the address-space-control bits are 01 binary, the value placed in the access register also depends on whether the B_2 field is zero or nonzero.

The address computation follows the rules for address arithmetic. In the 24-bit addressing mode, the address is placed in bit positions 40-63 of general register R_1, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The value placed in access register R_1 is as shown in the following table:

PSW Bits 16 and 17	Value Placed in Access Register R_1
00	00000000 hex (zeros in bit positions 0-31)
10	00000001 hex (zeros in bit positions 0-30 and one in bit position 31)
01	If B_2 field is zero: 00000000 hex (zeros in bit positions 0-31) If B_2 field is nonzero: Contents of access register B_2

PSW Bits 16 and 17	Value Placed in Access Register R_1
11	00000002 hex (zeros in bit positions 0-29 and 31, and one in bit position 30)

However, when PSW bits 16 and 17 are 01 binary and the B_2 field is nonzero, bit positions 0-6 of access register B_2 must contain all zeros; otherwise, the results in general register R_1 and access register R_1 are unpredictable.

The displacement for LAE is treated as a 12-bit unsigned binary integer. The displacement for LAEY is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (LAEY; if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

1. When DAT is on, the different values of the address-space-control bits correspond to translation modes as follows:

PSW Bits 16 and 17	Translation Mode
00	Primary-space mode
10	Secondary-space mode
01	Access-register mode
11	Home-space mode

2. In the access-register mode, the value 00000000 hex in an access register designates the primary address space, and the value 00000001 hex designates the secondary address space. The value 00000002 hex designates the home address space if the control program assigns entry 2 of the dispatchable-unit access list as designating the home address space and places a zero access-list-entry sequence number (ALESN) in that entry.

LOAD ADDRESS RELATIVE LONG

LARL R_1,RI_2 [RIL-b]

'C0'	R_1	'0'	RI_2
0	8	12	16 47

The address specified by the RI_2 field is placed in general register R_1. The address computation follows the rules for the branch address of BRANCH RELATIVE ON CONDITION LONG and BRANCH RELATIVE AND SAVE LONG.

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the computed address.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions: None.

Programming Notes:

1. Only even addresses (halfword addresses) can be generated. If an odd address is desired, LOAD ADDRESS can be used to add one to an address formed by LOAD ADDRESS RELATIVE LONG.

2. When LOAD ADDRESS RELATIVE LONG is the target of an execute-type instruction, the address produced is relative to the location of the LOAD ADDRESS RELATIVE LONG instruction, not of the execute-type instruction. This is consistent with the operation of the relative-branch instructions.

LOAD AND ADD

LAA $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'F8'
0	8	12	16	20	32	40 47

LAAG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'E8'
0	8	12	16	20	32	40 47

The second operand is added to the third operand, and the sum is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the addition) are placed unchanged at the first-operand location.

For LAA, the operands are treated as being 32-bit signed binary integers. For LAAG, the operands are treated as being 64-bit signed binary integers.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAA must be designated on a word boundary. The second operand of LAAG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch and store, operand 2)
- Fixed-point overflow
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Except for the case where the R_1 and R_3 fields designate the same register, general register R_3 is unchanged.

2. The operation of LOAD AND ADD, LOAD AND ADD LOGICAL, LOAD AND AND, LOAD AND EXCLUSIVE OR, and LOAD AND OR may be expressed as follows.

```
temp ← operand_2;
operand_2 ← temp OP operand_3;
operand_1 ← temp;
```

   OP represents the arithmetic or logical operation being performed by the instruction.

LOAD AND ADD LOGICAL

LAAL $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'FA'
0	8	12	16	20	32	40 47

LAALG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'EA'
0	8	12	16	20	32	40 47

The second operand is added to the third operand, and the sum is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the addition) are placed unchanged at the first-operand location.

For LAAL, the operands are treated as being 32-bit unsigned binary integers. For LAALG, the operands are treated as being 64-bit unsigned binary integers.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAAL must be designated on a word boundary. The second operand of LAALG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero; no carry
1 Result not zero; no carry
2 Result zero; carry
3 Result not zero; carry

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND AND

LAN $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'F4'
0	8	12	16	20	32	40 47

LANG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'E4'
0	8	12	16	20	32	40 47

The AND of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the AND operation) are placed unchanged at the first-operand location.

For LAN, the operands are 32 bits. For LANG, the operands are 64 bits.

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operands contain ones; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAN must be designated on a word boundary. The second operand of LANG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND EXCLUSIVE OR

LAX $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'F7'
0	8	12	16	20	32	40 47

LAXG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'E7'
0	8	12	16	20	32	40 47

The EXCLUSIVE OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the EXCLUSIVE OR operation) are placed unchanged at the first-operand location.

For LAX, the operands are 32 bits. For LAXG, the operands are 64 bits.

The connective exclusive OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAX must be designated on a word boundary. The second operand of LAXG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND OR

LAO $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'F6'
0	8	12	16	20	32	40 47

LAOG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'E6'
0	8	12	16	20	32	40 47

The OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the OR operation) are placed unchanged at the first-operand location.

For LAO, the operands are 32 bits. For LAOG, the operands are 64 bits.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAO must be designated on a word boundary. The second operand of LAOG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND TEST

Register-and-register formats:

LTR R_1,R_2 [RR]

'12'	R_1	R_2
0	8	12 15

LTGR R_1,R_2 [RRE]

'B902'	////////	R_1	R_2
0	16	24	28 31

LTGFR R_1,R_2 [RRE]

'B912'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LT $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'12'
0	8	12	16	20	32	40 47

LTG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'02'
0	8	12	16	20	32	40 47

LTGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'32'
0	8	12	16	20	32	40 47

The second operand is placed unchanged at the first-operand location, except that, for LTGF and LTGFR, it is sign extended. The sign and magnitude of the second operand, treated as a signed binary integer, are indicated in the condition code.

For LT and LTR, the operands are 32 bits, and, for LTG and LTGR, the operands are 64 bits. For LTGF and LTGFR, the second operand is 32 bits, and the first operand is treated as a 64-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of LT, LTG, and LTGF only)
- Operation (LT and LTG, if the extended-immediate facility is not installed; LTGF, if the general-instructions-extension facility is not installed)

Programming Note: For LOAD AND TEST (LTR and LTGR) when the R_1 and R_2 fields designate the same register, the operation is equivalent to a test without data movement.

LOAD AND TRAP

LAT $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'9F'
0	8	12	16	20	32	40 47

LGAT $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'85'
0	8	12	16	20	32	40 47

The second operand is placed unchanged at the first operand location. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

For LAT, the second operand is treated as a 32-bit signed integer and placed in bit positions 32-63 of general register R_1, and bit positions 0-31 remain unchanged.

For LGAT, the second operand is treated as a 64-bit signed integer and placed in bit positions 0-63 of general register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD AND TRAP include checking for pointers containing zero (null pointer).

LOAD AND ZERO RIGHTMOST BYTE

LZRF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'3B'
0	8	12	16	20	32	40 47

LZRG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'2A'
0	8	12	16	20	32	40 47

The second operand, with the rightmost byte set to zero, is placed at the first-operand location. For LZRF, the first and second operands are 32 bits, and for LZRG, the first and second operands are 64 bits.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the load-and-zero-rightmost-byte facility is not installed)

LOAD BYTE

Register-and-register formats:

LBR R_1,R_2 [RRE]

'B926'	////////	R_1	R_2
0	16	24	28 31

LGBR R_1,R_2 [RRE]

'B906'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LB $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'76'
0	8	12	16	20	32	40 47

LGB $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'77'
0	8	12	16	20	32	40 47

The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer. For LOAD BYTE (LB and LGB), the second operand is a byte in storage. For LOAD BYTE (LBR and LGBR), the second operand is in bits 56-63 of general register R_2.

For LOAD BYTE (LB and LBR), the first operand is treated as a 32-bit signed binary integer. For LOAD BYTE (LGB and LGBR), the first operand is treated as a 64-bit signed binary integer.

The displacement for LB and LGB is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LB and LGB)
- Operation (LB and LGB, if the long-displacement facility is not installed; LBR and LGBR, if the extended-immediate facility is not installed)

LOAD BYTE HIGH

LBH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C0'
0	8	12	16	20	32	40 47

The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer.

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R_1; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD COMPLEMENT

LCR R_1,R_2 [RR]

'13'	R_1	R_2
0	8	12 15

LCGR R_1,R_2 [RRE]

'B903'	////////	R_1	R_2
0	16	24	28 31

LCGFR R_1,R_2 [RRE]

'B913'	////////	R_1	R_2
0	16	24	28 31

The two's complement of the second operand is placed at the first-operand location. For LOAD COMPLEMENT (LCR), the second operand and result are treated as 32-bit signed binary integers. For LOAD COMPLEMENT (LCGR), they are treated as 64-bit signed binary integers. For LOAD COMPLEMENT (LCGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow (LCR and LCGR only)

Programming Note: The operation complements all numbers. Zero remains unchanged. For LCR or LCGR, the maximum negative 32-bit number or 64-bit number, respectively, remains unchanged, and an overflow condition occurs when the number is complemented. LCGFR complements the maximum negative 32-bit number without recognizing overflow.

LOAD COUNT TO BLOCK BOUNDARY

LCBB $R_1,D_2(X_2,B_2),M_3$ [RXE]

'E7'	R_1	X_2	B_2	D_2	M_3	////	'27'
0	8	12	16	20	32	36	40 47

A 32-bit unsigned binary integer containing the number of bytes possible to load from the second operand location without crossing a specified block boundary, with a maximum of sixteen is placed in the first operand. If the number of bytes is greater than sixteen, sixteen is placed in the first operand.

The displacement is treated as a 12-bit unsigned integer.

The second operand address is not used to address data.

The M_3 field specifies a code that is used to signal the CPU as to the block boundary size to compute the number of possible bytes loaded. If a reserved value is specified then a specification exception is recognized.

Code	**Boundary**
0	64 Byte
1	128 Byte
2	256 Byte
3	512 Byte
4	1 K-byte
5	2 K-Byte
6	4 K-Byte
7-15	Reserved

Resulting Condition Code:

0 Operand one is sixteen
1 --
2 --
3 Operand one is less than sixteen

Program Exceptions:

- Operation (if the vector facility for z/Architecture is not installed)
- Specification

Programming Note: It is expected that LOAD COUNT TO BLOCK BOUNDARY will be used in conjunction with VECTOR LOAD TO BLOCK BOUNDARY to determine the number of bytes that were loaded.

LOAD GUARDED

LGG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'4C'
0	8	12	16	20	32	40 47

LOAD LOGICAL AND SHIFT GUARDED

LLGFSG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'48'
0	8	12	16	20	32	40 47

Note: See the section “Guarded-Storage Facility” on page 4-65 for details on the terminology used below.

A 64-bit intermediate result is formed as follows:

- For LOAD GUARDED: The second operand is a doubleword in storage. A specification exception is recognized and the operation is suppressed if the second-operand address is not on a doubleword boundary.

  In the 24-bit addressing mode, the intermediate result is formed from the concatenation of 40 binary zeros with bits 40-63 of the second operand. In the 31-bit addressing mode, the intermediate result is formed from the concatenation of 33 binary zeros with bits 33-63 of the second operand. In the 64-bit addressing mode, the intermediate result is formed from the entire second operand.

- For LOAD LOGICAL AND SHIFT GUARDED: The second operand is a word in storage. A specification exception is recognized and the operation is suppressed if the second-operand address is not on a word boundary.

  When the guarded-storage facility is enabled (by means of bit 59 of control register 2), the intermediate result is formed using the guarded-load-shift value (GLS, in bits 53-55 of the guarded-storage-designation register). When the guarded-storage facility is not enabled, the GLS value is assumed to be zero.

  In the 24-bit addressing mode, the intermediate result is formed from the concatenation of 40 binary zeros, bits (8+GLS) through 31 of the second operand, and GLS binary zeros. In the 31-bit addressing mode, the intermediate result is formed from the concatenation of 33 binary zeros, bits (1+GLS) through 31 of the second operand, and GLS binary zeros. In the 64-bit addressing mode, the intermediate result is formed from the concatenation of (32-GLS) binary zeros, the entire 32-bit second operand, and GLS binary zeros.

When the guarded-storage facility is enabled, the intermediate result is used as described in “Guarded-Storage-Event Detection” on page 4-70. If a guarded-storage event is recognized, then general register R_1 is not modified, and the instruction is completed as described in “Guarded-Storage-Event Processing” on page 4-71.

When either the guarded-storage facility is not enabled, or the facility is enabled but a guarded-storage event is not recognized, then the 64-bit intermediate result is placed into general register R_1, and the instruction is completed.

The displacement is treated as a 20-bit signed binary integer.

The guarded-storage-event parameter list (GSEPL) is only accessed when a guarded-storage event is recognized. Store-type accesses apply to the entire GSEPL.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, second operand; when a guarded-storage-event is recognized, fetch and store, GSEPL fields)
- Operation (guarded-storage facility not installed)

- Specification

1.-7. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

8. Access exceptions for the second operand in storage.

9. Completion with no guarded-storage-event recognized.

10. Side-effect access exceptions for the guarded-storage-event parameter list.

11. Completion with a guarded-storage-event recognized.

Figure 7-300. Priority of Execution: LGG and LLGFSG

Programming Notes:

1. LOAD LOGICAL AND SHIFT GUARDED may be useful in loading what are sometimes referred to as *compressed pointers* in which some number of rightmost bits of the pointer address are absent in storage and assumed to be zeros.

2. When the guarded-storage facility is installed in a configuration, the LOAD GUARDED and LOAD LOGICAL AND SHIFT GUARDED instructions can be executed regardless of the contents of the guarded-storage-facility-enablement control (GSFE, bit 59 of control register 2). However, guarded-storage events are only recognized as a result of executing LGG or LLGFSG when (a) the GSFE control is one, and (b) the GSSM is nonzero. The GSSM cannot be loaded without the GSFE control being one.

3. A guarded-storage event is never recognized when all 64 bits of the guarded-storage selection mask (GSSM) are zero. The program can ensure that guarded-storage events are not recognized by either (a) not loading the guarded-storage controls, in which case the GSSM will contain its reset state of zeros, or (b) loading zeros into the GSSM.

LOAD GUARDED STORAGE CONTROLS

LGSC $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'4D'
0	8	12	16	20	32	40 47

The contents of the guarded-storage control block (GSCB) at the second-operand address are loaded into the three guarded-storage registers. The format of the guarded-storage control block is shown in Figure 4-19 on page 4-67. The R_1 field of the instruction is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.

Access exceptions are recognized for all 32 bytes of the GSCB.

The section “Guarded-Storage-Designation (GSD) Register” on page 4-66 describes the valid values of the GSD register. If either the GLS or GSC fields of the GSD register being loaded contain invalid values, or if reserved bit positions of the register do not contain zeros the results are unpredictable. If the second operand contains either (a) invalid GLS or GSC values, or (b) nonzero values in the reserved bit positions, then it is model dependent whether the CPU replaces the invalid or nonzero values with corrected values. Furthermore, it is unpredictable whether such corrected values are subsequently stored by STORE GUARDED STORAGE CONTROLS.

Special Conditions

A special-operation exception is recognized and the operation is suppressed when the guarded-storage-facility-enablement control, bit 59 of control register 2, is zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, second operand)
- Operation (if the guarded-storage facility is not installed)
- Special operation
- Transaction constraint

Programming Notes:

1. If the GSC field of the GSD register contains an invalid value, guarded-storage events may not occur or erroneous guarded-storage events may be detected.

2. If the GLS field of the GSD register contains an invalid value, the intermediate result used by LLGFSG may be formed from an unpredictable

range of bits in the second operand, shifted by an unpredictable number of bits.

LOAD HALFWORD

Register-and-register formats:

LHR R_1,R_2 [RRE]

'B927'	////////	R_1	R_2
0	16	24	28 31

LGHR R_1,R_2 [RRE]

'B907'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LH R_1,D_2(X_2,B_2) [RX-a]

'48'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

LHY R_1,D_2(X_2,B_2) [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'78'
0	8	12	16	20	32	40 47

LGH R_1,D_2(X_2,B_2) [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'15'
0	8	12	16	20	32	40 47

LOAD HALFWORD IMMEDIATE

LHI R_1,I_2 [RI-a]

'A7'	R_1	'8'	I_2
0	8	12	16 31

LGHI R_1,I_2 [RI-a]

'A7'	R_1	'9'	I_2
0	8	12	16 31

LOAD HALFWORD RELATIVE LONG

LHRL R_1,RI_2 [RIL-b]

'C4'	R_1	'5'	RI_2
0	8	12	16 47

LGHRL R_1,RI_2 [RIL-b]

'C4'	R_1	'4'	RI_2
0	8	12	16 47

The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. For LOAD HALFWORD (LH, LHY, and LGH) and LOAD HALFWORD RELATIVE LONG, the second operand is in storage. For LOAD HALFWORD (LHI and LGHI), the second operand is the immediate field of the instruction. For LOAD HALFWORD (LHR and LGHR), the second operand is in bits 48-63 of general register R_2.

For LOAD HALFWORD (LH, LHR, and LHY), LOAD HALFWORD IMMEDIATE (LHI), and LOAD HALFWORD RELATIVE LONG (LHRL), the first operand is treated as a 32-bit signed binary integer. For LOAD HALFWORD (LGH and LGHR), LOAD HALFWORD IMMEDIATE (LGHI), and LOAD HALFWORD RELATIVE LONG (LGHRL), the first operand is treated as a 64-bit signed binary integer.

The displacement for LH is treated as a 12-bit unsigned binary integer. The displacement for LHY and LGH is treated as a 20-bit signed binary integer.

For LOAD HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LH, LHY, LGH, LHRL and LGHRL)
- Operation (LHY, if the long-displacement facility is not installed; LHR and LGHR, if the extended-immediate facility is not installed; LHRL and LGHRL, if the general-instructions-extension facility is not installed)

Programming Notes:

1. An example of the use of the LOAD HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For LOAD HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.

3. When LOAD HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD HALFWORD HIGH

LHH R$_1$,D$_2$(X$_2$,B$_2$) [RXY-a]

'E3'	R$_1$	X$_2$	B$_2$	DL$_2$	DH$_2$	'C4'
0	8	12	16	20	32	40 47

The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as an 16-bit signed binary integer.

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R$_1$; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD HALFWORD IMMEDIATE ON CONDITION

LOCHI R$_1$,I$_2$,M$_3$ [RIE-g]

'EC'	R$_1$	M$_3$	I$_2$	////////	'42'
0	8	12	16	32	40 47

LOCGHI R$_1$,I$_2$,M$_3$ [RIE-g]

'EC'	R$_1$	M$_3$	I$_2$	////////	'46'
0	8	12	16	32	40 47

LOAD HALFWORD HIGH IMMEDIATE ON CONDITION

LOCHHI R$_1$,I$_2$,M$_3$ [RIE-g]

'EC'	R$_1$	M$_3$	I$_2$	////////	'4E'
0	8	12	16	32	40 47

The second operand is sign extended and placed at the first-operand location if the condition code has one of the values specified by M$_3$; otherwise, the first operand remains unchanged.

For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCHI), the first operand is treated as a 32-bit signed binary integer in bits 32-63 of general register R$_1$, and bits 0-31 of the register are unchanged. For LOAD HALFWORD HIGH IMMEDIATE ON CONDITION, the first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R$_1$, and bits 32-63 of the register are unchanged. For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCGHI), the first operand is treated as a 64-bit signed binary integer in bits 0-63 of general register R$_1$.

The second operand is the two byte I$_2$ field of the instruction and is treated as a 16-bit signed binary integer.

The M$_3$ field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Instruction Bit Number of Mask	12	13	14	15
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the load/store-on-condition facility 2 is not installed)

Programming Notes: See programming note 4 on page 7-284 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

LOAD HIGH

LFH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'CA'	
0	8	12	16	20	32	40	47

The second operand is placed unchanged at the first-operand location. The second operand is 32 bits, and the first operand is in bits 0-31 of general register R_1; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD HIGH AND TRAP

LFHAT $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C8'	
0	8	12	16	20	32	40	47

The second operand is treated as a 32-bit signed integer and placed unchanged in bit positions 0-31 of general register R_1, and bit positions 32-63 remain unchanged. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD HIGH AND TRAP include checking for pointers containing zero (null pointer).

LOAD LOGICAL

Register-and-register format:

LLGFR R_1,R_2 [RRE]

'B916'	////////	R_1	R_2	
0	16	24	28	31

Register-and-storage format:

LLGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'16'	
0	8	12	16	20	32	40	47

LOAD LOGICAL RELATIVE LONG

LLGFRL R_1,RI_2 [RIL-b]

'C4'	R_1	'E'	RI_2	
0	8	12	16	47

The four-byte second operand is placed in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31 of general register R_1.

For LOAD LOGICAL (LLGFR), the second operand is in bit positions 32-63 of general register R_2.

For LOAD LOGICAL RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD LOGICAL RELATIVE LONG, the second operand must be aligned on a word boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLGF and LLGFRL only)
- Operation (LLGFRL, if the general-instructions-extension facility is not installed)
- Specification (LLGFRL only)

LOAD LOGICAL AND TRAP

LLGFAT $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'9D'
0	8	12	16	20	32	40 47

The four-byte second operand is placed unchanged in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD LOGICAL AND TRAP include checking for pointers containing zero (null pointer).

LOAD LOGICAL AND ZERO RIGHTMOST BYTE

LLZRGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'3A'
0	8	12	16	20	32	40 47

The four-byte second operand, with the rightmost byte set to zero, is placed in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31 of the register.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the load-and-zero-rightmost-byte facility is not installed)

LOAD LOGICAL CHARACTER

Register-and-register formats:

LLCR R_1,R_2 [RRE]

'B994'	////////	R_1	R_2
0	16	24	28 31

LLGCR R_1,R_2 [RRE]

'B984'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LLC $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'94'
0	8	12	16	20	32	40 47

LLGC $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'90'
0	8	12	16	20	32	40 47

The one-byte second operand is placed in bit positions 56-63 of general register R_1. For LOAD LOGICAL CHARACTER (LLGC, LLGCR), zeros are placed in bit positions 0-55 of general register R_1. For LOAD LOGICAL CHARACTER (LLC, LLCR), zeros are placed in bit positions 32-55 of general register R_1; bit positions 0-31 of general register R_1 are unchanged.

For LOAD LOGICAL CHARACTER (LLC, LLGC), the second operand is in storage. For LOAD LOGICAL CHARACTER (LLCR, LLGCR), the second operand is in bits 56-63 of general register R_2.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLC and LLGC)
- Operation (LLC, LLCR, and LLGCR, if the extended-immediate facility is not installed)

LOAD LOGICAL CHARACTER HIGH

LLCH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C2'
0	8	12	16	20	32	40 47

The one-byte second operand is placed in bit positions 24-31 of general register $R_{1,}$ and zeros are placed in bit positions 0-23 of general register R_1; bit positions 32-63 of general register R_1 are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD LOGICAL HALFWORD

Register-and-register formats:

LLHR R_1,R_2 [RRE]

'B995'	////////	R_1	R_2
0	16	24	28 31

LLGHR R_1,R_2 [RRE]

'B985'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LLH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'95'
0	8	12	16	20	32	40 47

LLGH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'91'
0	8	12	16	20	32	40 47

LOAD LOGICAL HALFWORD RELATIVE LONG

LLHRL R_1,RI_2 [RIL-b]

'C4'	R_1	'2'	RI_2
0	8	12	16 47

LLGHRL R_1,RI_2 [RIL-b]

'C4'	R_1	'6'	RI_2
0	8	12	16 47

The two-byte second operand is placed in bit positions 48-63 of general register R_1. For LOAD LOGICAL HALFWORD (LLGH, LLGHR) and LOAD LOGICAL HALFWORD RELATIVE LONG (LLGHRL), zeros are placed in bit positions 0-47 of general register R_1. For LOAD LOGICAL HALFWORD (LLH, LLHR) and LOAD LOGICAL HALFWORD RELATIVE LONG (LLHRL), zeros are placed in bit positions 32-47 of general register R_1; bit positions bits 0-31 of general register R_1 are unchanged.

For LOAD LOGICAL HALFWORD (LLGH, LLH) and LOAD LOGICAL HALFWORD RELATIVE LONG, the second operand is in storage. For LOAD LOGICAL HALFWORD (LLGHR, LLHR), the second operand is in bits 48-63 of general register R_2.

For LOAD LOGICAL HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLGH, LLH, LLHRL, and LLGHRL)
- Operation (LLGHR, LLH, and LLHR, if the extended-immediate facility is not installed; LLHRL and LLGHRL, if the general-instructions-extension facility is not installed)

Programming Notes:

1. For LOAD LOGICAL HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand's size.
2. When LOAD LOGICAL HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD LOGICAL HALFWORD HIGH

LLHH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C6'
0	8	12	16	20	32	40 47

The two-byte second operand is placed in bit positions 16-31 of general register $R_{1,}$ and zeros are placed in bit positions 0-15 of general register R_1; bit positions 32-63 of general register R_1 are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD LOGICAL IMMEDIATE

LLIHF R_1,I_2 [RIL-a]

'C0'	R_1	'E'	I_2
0	8	12	16 47

LLIHH R_1,I_2 [RI-a]

'A5'	R_1	'C'	I_2
0	8	12	16 31

LLIHL R_1,I_2 [RI-a]

'A5'	R_1	'D'	I_2
0	8	12	16 31

LLILF R_1,I_2 [RIL-a]

'C0'	R_1	'F'	I_2
0	8	12	16 47

LLILH R_1,I_2 [RI-a]

'A5'	R_1	'E'	I_2
0	8	12	16 31

LLILL R_1,I_2 [RI-a]

'A5'	R_1	'F'	I_2
0	8	12	16 31

The second operand is placed in bit positions of the first operand. The remainder of the first operand is set to zeros.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

Instruction	Bit Positions Loaded
LLIHF	0-31
LLIHH	0-15
LLIHL	16-31
LLILF	32-63
LLILH	32-47
LLILL	48-63

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (LLIHF and LLILF, if the extended-immediate facility is not installed)

LOAD LOGICAL THIRTY ONE BITS

Register-and-register format:

LLGTR R_1,R_2 [RRE]

'B917'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage format:

LLGT R_1,D_2(X_2,B_2) [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'17'
0	8	12	16	20	32	40 47

For LLGTR, bits 33-63 of general register R_2, with 33 zeros appended on the left, are placed in general register R_1. For LLGT, bits 1-31 of the four bytes at the second-operand location, with 33 zeros appended on the left, are placed in general register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLGT only)

LOAD LOGICAL THIRTY ONE BITS AND TRAP

LLGTAT R_1,D_2(X_2,B_2) [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'9C'
0	8	12	16	20	32	40 47

Bits 1-31 of the four bytes at the second operand location are placed unchanged in bit positions 33-63 of general register R_1, and zeros are placed in bit positions 0-32. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD LOGICAL THIRTY ONE BITS AND TRAP include checking for pointers containing zero (null pointer).

LOAD MULTIPLE

LM R_1,R_3,D_2(B_2) [RS-a]

'98'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

LMY R_1,R_3,D_2(B_2) [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'98'
0	8	12	16	20	32	40 47

LMG R_1,R_3,D_2(B_2) [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'04'
0	8	12	16	20	32	40 47

Bit positions of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD MULTIPLE (LM, LMY), bit positions 32-63 of the general registers are loaded from successive four-byte fields beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD MULTIPLE (LMG), bit positions 0-63 of the general registers are loaded from successive eight-byte fields beginning at the second-operand address.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

The displacement for LM is treated as a 12-bit unsigned binary integer. The displacement for LMY and LMG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (LMY, if the long-displacement facility is not installed)

Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes, for LM or

LMY or eight bytes, for LMG, are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

LOAD MULTIPLE DISJOINT

LMD $R_1,R_3,D_2(B_2),D_4(B_4)$ [SS-e]

'EF'	R_1	R_3	B_2	D_2	B_4	D_4
0	8	12	16	20	32	36 47

Bit positions 0-31 of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed. Bit positions 32-63 of the same registers are similarly loaded from storage beginning at the location designated by the fourth-operand address.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operands 2 and 4)
- Transaction constraint

Programming Notes:

1. All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only eight bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

2. The second-operand and fourth-operand addresses are computed before the contents of any register are changed.

3. The combination of a LOAD MULTIPLE instruction and a LOAD MULTIPLE HIGH instruction provides equal or better performance than a LOAD MULTIPLE DISJOINT instruction for the same register range. LOAD MULTIPLE DISJOINT is for use when the second or fourth operand must be addressed by means of one of the registers loaded.

LOAD MULTIPLE HIGH

LMH $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'96'
0	8	12	16	20	32	40 47

The high-order halves, bit positions 0-31, of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, bit positions 0-31 are loaded from successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers remain unchanged.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)

Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

LOAD NEGATIVE

LNR R_1,R_2 [RR]

'11'	R_1	R_2
0	8	12 15

LNGR R_1,R_2 [RRE]

'B901'	////////	R_1	R_2
0	16	24	28 31

LNGFR R_1,R_2 [RRE]

'B911'	////////	R_1	R_2
0	16	24	28 31

The two's complement of the absolute value of the second operand is placed at the first-operand location. For LOAD NEGATIVE (LNR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD NEGATIVE (LNGR), they are treated as 64-bit signed binary integers. For LOAD NEGATIVE (LNGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 --
3 --

Program Exceptions: None.

Programming Note: The operation complements positive numbers; negative numbers remain unchanged. The number zero remains unchanged.

LOAD ON CONDITION

Register-and-register formats:

LOCR R_1,R_2,M_3 [RRF-c]

'B9F2'	M_3	////	R_1	R_2
0	16	20	24	28 31

LOCGR R_1,R_2,M_3 [RRF-c]

'B9E2'	M_3	////	R_1	R_2
0	16	20	24	28 31

Register-and-storage formats:

LOC R_1,D_2(B_2),M_3 [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'F2'
0	8	12	16	20	32	40 47

LOCG R_1,D_2(B_2),M_3 [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'E2'
0	8	12	16	20	32	40 47

LOAD HIGH ON CONDITION

LOCFHR R_1,R_2,M_3 [RRF-c]

'B9E0'	M_3	////	R_1	R_2
0	16	20	24	28 31

LOCFH R_1,D_2(B_2),M_3 [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'E0'
0	8	12	16	20	32	40 47

The second operand is placed unchanged at the first-operand location if the condition code has one of the values specified by M_3; otherwise, the first operand remains unchanged.

For LOC, LOCFH, LOCFHR, and LOCR, the first and second operands are 32 bits, and for LOCG and LOCGR, the first and second operands are 64 bits.

For LOC and LOCR, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are unchanged. For LOCFH and LOCFHR, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are unchanged.

For LOCR, the second operand is in bits 32-63 of general register R_2, and bits 0-31 of the register are ignored. For LOCFHR, the second operand is in bits 0-31 of general register R_2, and bits 32-63 of the register are ignored.

The M_3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

The displacement for LOC, LOCFH, and LOCG is treated as a 20-bit signed binary integer.

For LOC, LOCFH, and LOCG, when the condition specified by the M_3 field is not met (that is, the load operation is not performed), it is model dependent whether an access exception or a PER zero-address detection event is recognized for the second operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LOC, LOCFH, and LOCG)
- Operation (LOC, LOCG, LOCGR, LOCR, if the load/store-on-condition facility 1 is not installed; LOCFH, LOCFHR, if the load/store-on-condition facility 2 is not installed)

Programming Notes:

1. When the M_3 field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M_3 field contains all ones and no exception condition exists, the load operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional load, respectively.

2. For LOC, LOCFH, and LOCG, when the condition specified by the M_3 field is not met, it is model dependent whether the second operand is brought into the cache.

3. LOAD ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a LOAD instruction, except that LOAD ON CONDITION does not provide an index register. For example, the following two instruction sequences are equivalent.

```
LOCG   15,256(7),8          BC    7,SKIP
                            LG    15,256(0,7)
                       SKIP DS    0H
```

   On models that implement predictive branching, the combination of the BRANCH ON CONDITION and LOAD instructions may perform somewhat better than the LOAD ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the LOAD ON CONDITION instruction may provide significant performance improvement.

4. The High-Level Assembler (HLASM) provides the following extended-mnemonic suffixes for the load/store-on-condition facilities' instructions in place of the M_3 field.

Suffix	Meaning	Effective M_3 Value
E	Equal	B'1000'
L	Low	B'0100'
H	High	B'0010'
NE	Not equal	B'0111'
NL	Not low	B'1011'
NH	Not high	B'1101'

   Later versions of HLASM provide the following extended-mnemonic suffixes for the load/store-on-condition facilities' instructions in place of the M_3 field.

Suffix	Meaning	Effective M_3 Value
Z	Zero	B'1000'
M	Minus or mixed	B'0100'
P	Plus	B'0010'
O	Overflow or ones	B'0001'
NZ	Not zero	B'0111'
NM	Not minus or not mixed	B'1011'
NP	Not plus	B'1101'
NO	Not overflow or not ones	B'1110'

   When the extended mnemonic is coded, the M_3 field must be omitted.

LOAD PAIR DISJOINT

LPD $R_3,D_1(B_1),D_2(B_2)$ [SSF]

'C8'	R_3	'4'	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

LPDG $R_3,D_1(B_1),D_2(B_2)$ [SSF]

'C8'	R_3	'5'	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

General register R_3 designates the even numbered register of an even/odd register pair.

The first operand is placed unchanged into the even-numbered register of the third operand, and the second operand is placed unchanged into odd-numbered register of the third operand. The condition code indicates whether the first and second operands appear to be fetched by means of block-concurrent interlocked fetch.

For LPD, the first and second operands are words in storage, and the third operand is in bits 32-63 of general registers R_3 and $R_3 + 1$; bits 0-31 of the registers are unchanged. For LPDG, the first and second operands are doublewords in storage, and the third operand is in bits 0-63 of general registers R_3 and $R_3 + 1$.

When, as observed by other CPUs, the first and second operands appear to be fetched by means of block-concurrent interlocked fetch, condition code 0 is set. When the first and second operands do not appear to be fetched by means of block-concurrent interlocked update, condition code 3 is set. The third operand is loaded regardless of the condition code.

The displacement of the first and second operands is treated as a 12-bit unsigned binary integer.

The first and second operands of LPD must be designated on a word boundary. The first and second operands of LPDG must be designated on a doubleword boundary. General register R_3 must designate the even numbered register. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Register pair loaded by means of interlocked fetch
1 --
2 --
3 Register pair not loaded by means of interlocked fetch

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The setting of the condition code is dependent upon storage accesses by other CPUs in the configuration.

2. When the resulting condition code is 3, the program may branch back to re-execute the LOAD PAIR DISJOINT instruction. However, after repeated unsuccessful attempts to attain an interlocked fetch, the program should use an alternate means of serializing access to the storage operands. It is recommended that the program re-execute the LOAD PAIR DISJOINT no more than 10 times before branching to the alternate path.

3. The program should be able to accommodate a situation where condition code 0 is never set.

LOAD PAIR FROM QUADWORD

LPQ $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'8F'
0	8	12	16	20	32	40 47

The quadword second operand is loaded into the first-operand location. The second operand appears to be fetched with quadword concurrency as observed by other CPUs. The left doubleword of the quadword is loaded into general register R_1, and the right doubleword is loaded into general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Specification
- Transaction constraint

Programming Notes:

1. The LOAD MULTIPLE (LM or LMG) instruction does not necessarily provide quadword-concurrent access.

2. The performance of LOAD PAIR FROM QUADWORD on some models may be significantly slower than that of LOAD MULTIPLE (LMG). Unless quadword consistency is required, LMG should be used instead of LPQ.

LOAD POSITIVE

LPR R_1,R_2 [RR]

'10'	R_1	R_2
0	8	12 15

LPGR R_1,R_2 [RRE]

'B900'	////////	R_1	R_2
0	16	24	28 31

LPGFR R_1,R_2 [RRE]

'B910'	////////	R_1	R_2
0	16	24	28 31

The absolute value of the second operand is placed at the first-operand location. For LOAD POSITIVE (LPR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD POSITIVE (LPGR), they are treated as 64-bit signed binary integers. For LOAD POSITIVE (LPGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 --
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow (LPR and LPGR only)

Programming Note: The operation complements negative numbers; positive numbers and zero remain unchanged. For LPR or LPGR, an overflow condition occurs when the maximum negative 32-bit number or 64-bit number, respectively, is complemented; the number remains unchanged. LPGFR complements the maximum negative 32-bit number without recognizing overflow.

LOAD REVERSED

Register-and-register formats:

LRVR R_1,R_2 [RRE]

'B91F'	////////	R_1	R_2
0	16	24	28 31

LRVGR R_1,R_2 [RRE]

'B90F'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

LRVH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'1F'
0	8	12	16 20		32	40 47

LRV $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'1E'
0	8	12	16 20		32	40 47

LRVG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'0F'
0	8	12	16 20		32	40 47

The second operand is placed at the first-operand location with the left-to-right sequence of the bytes reversed.

For LOAD REVERSED (LRVH), the second operand is two bytes, the result is placed in bit positions 48-63 of general register R_1, and bits 0-47 of the register remain unchanged.

For LOAD REVERSED (LRVR, LRV), the second operand is four bytes, the result is placed in bit positions 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. For LOAD REVERSED (LRVR), the second operand is in bit positions 32-63 of general register R_2.

For LOAD REVERSED (LRVGR, LRVG), the second operand is eight bytes.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LRVH, LRV, LRVG only)

Programming Notes:

1. The instruction can be used to convert two, four, or eight bytes from a “little-endian” format to a “big-endian” format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

2. LOAD REVERSED (LRVR) can be used with a two-byte value already in a register as shown in the following example. In the example, the two bytes of interest are in bit positions 48-63 of the R1 register.

   ```
   LRVR   R1,R1
   SRA    R1,16
   ```

   The LOAD REVERSED instruction places the two bytes of interest in bit positions 32-47 of the register, with the order of the bytes reversed. The SHIFT RIGHT SINGLE (SRA) instruction shifts the two bytes to bit positions 48-63 of the register and extends them on their left, in bit positions 32-47, with their sign bit. The instruction SHIFT RIGHT SINGLE LOGICAL (SRL) should be used, instead, if the two bytes of interest are unsigned.

MONITOR CALL

MC $D_1(B_1),I_2$ [SI]

'AF'	I_2	B_1	D_1
0	8	16	20 31

Subject to the control of the monitor class and the monitor masks, a monitor event may be recognized. When the enhanced-monitor facility is not installed, a monitor event results in a monitor-event program interruption. When the enhanced-monitor facility is installed, a monitor event results in either a monitor-event program interruption or a monitor-event counting operation.

Bit positions 12-15 of the instruction (bit positions 4-7 of the I_2 field) contain a 4-bit unsigned binary number specifying the monitor class. The monitor-mask bits are in bit positions 48-63 of control register 8, which correspond to monitor classes 0-15, respectively.

When the monitor-mask bit corresponding to the specified monitor class is one, a monitor event occurs. When the monitor-mask bit corresponding to the specified monitor class is zero, no monitor-event occurs, and the instruction is executed as a no-operation.

When the enhanced-monitor facility is installed, the enhanced-monitor-mask bits are in bit positions 16-31 of control register 8, which correspond to monitor classes 0-15 respectively. When a monitor event occurs and either (a) the enhanced-monitor facility is not installed, or (b) the facility is installed but the enhanced-monitor-mask bit corresponding to the monitor class is zero, then a monitor-event program interruption occurs, as described below. When a monitor event occurs and the enhanced-monitor-mask bit corresponding to the monitor class is one, a monitor-event counting operation is performed.

The first-operand address is not used to address data; instead, the address specified by the B_1 and D_1 fields forms the monitor code. Address computation follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

Monitor-Event Program Interruption

When a monitor-event program interruption occurs:

- The monitor code formed by the first-operand address is placed in the doubleword at real location 176.

- The contents of the I_2 field are stored at real location 149, with zeros stored at real location 148.

- Bit 9 of the program-interruption code is set to one.

Monitor-Event Counting Operation

The monitor-event counting operation is described in “Monitor-Event Counting” on page 5-109.

Special Conditions

Bit positions 8-11 of the instruction must contain zeros; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Monitor event
- Specification
- Transaction constraint

Programming Notes:

1. The monitor-event program interruption provides the capability for passing control to a monitoring program when selected points are reached in the monitored program. This is accomplished by implanting MONITOR CALL instructions at the desired points in the monitored program. This function may be useful in performing various measurement functions; specifically, tracing information can be generated indicating which programs were executed, counting information can be generated indicating how often particular programs were used, and timing information can be generated indicating the amount of time a particular program required for execution.

2. The monitor masks provide a means of disallowing all monitor events or allowing monitor events for all or selected classes.

3. When used to generate a monitor-event program interruption, the monitor code provides a means of associating descriptive information, in addition to the class number, with each MONITOR CALL.

   Without the use of a base register, up to 4,096 distinct monitor codes can be associated with a monitor event. With the base register designated by a nonzero value in the B_1 field, each monitoring interruption can be identified by a 24-bit, 31-bit, or 64-bit code, depending on the addressing mode.

4. A monitor-event counting operation can never occur in the ESA/390-compatibility mode.

MOVE

Storage-and-storage format:

MVC $D_1(L,B_1),D_2(B_2)$ [SS-a]

'D2'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

Storage-and-immediate formats:

'E54C'	B_1	D_1	I_2
0	16	20	32 47

MVGHI $D_1(B_1),I_2$ [SIL]

'E548'	B_1	D_1	I_2
0	16	20	32 47

MVI $D_1(B_1),I_2$ [SI]

'92'	I_2	B_1	D_1
0	8	16	20 31

MVIY $D_1(B_1),I_2$ [SIY]

'EB'	I_2	B_1	DL_1	DH_1	'52'
0	8	16	20	32	40 47

The second operand is placed at the first-operand location.

For MOVE (MVC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand byte.

For MOVE (MVI, MVIY), the first operand is one byte in length, and only one byte is stored.

For MOVE (MVGHI, MVHHI, and MVHI), the second operand is treated as a 16-bit signed integer, sign-extended as necessary, and placed in the first-operand location. The first operand is two, four, or eight bytes for MVHHI, MVHI, and MVGHI, respectively.

The displacements for MVGHI, MVHHI, MVHI, MVI and both operands of MVC are treated as 12-bit unsigned binary integers. The displacement for MVIY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MVC; store, operand 1, MVC, MVGHI, MVHHI, MVHI, MVI, and MVIY)
- Operation (MVIY, if the long-displacement facility is not installed; MVGHI, MVHHI, and MVHI, if the general-instructions-extension facility is not installed)
- Transaction constraint (MVC)

Programming Notes:

1. Examples of the use of the MOVE instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For MOVE (MVC), it is possible to propagate one byte through an entire field by having the first operand start one byte to the right of the second operand.

MOVE INVERSE

MVCIN $D_1(L,B_1),D_2(B_2)$ [SS-a]

'E8'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The second operand is placed at the first-operand location with the left-to-right sequence of the bytes inverted.

The first-operand address designates the leftmost byte of the first operand. The second-operand address designates the rightmost byte of the second operand. Both operands have the same length.

The result is obtained as if the second operand were processed from right to left and the first operand from left to right. The second operand may wrap around from location 0 to location 2^{24} - 1 in the 24-bit addressing mode, to location 2^{31} - 1 in the 31-bit addressing mode, or to location 2^{64} - 1 in the 64-bit addressing mode. The first operand may wrap around from location 2^{24} - 1 to location 0 in the 24-bit addressing mode, from location 2^{31} - 1 to location 0 in the 31-bit addressing mode, or from location 2^{64} - 1 to location 0 in the 64-bit addressing mode.

When the operands overlap by more than one byte, the contents of the overlapped portion of the result field are unpredictable.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE INVERSE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The contents of each byte moved remain unchanged.
3. MOVE INVERSE is the only SS-format instruction for which the second-operand address designates the rightmost, instead of the leftmost, byte of the second operand.
4. The storage-operand references for MOVE INVERSE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125)

MOVE LONG

MVCL R_1,R_2 [RR]

'0E'	R_1	R_2
0	8	12 15

The second operand is placed at the first-operand location, provided overlapping of operand locations would not affect the final contents of the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. The number of bytes in the first-operand and second-operand locations is specified by unsigned binary integers in bit positions 40-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively. Bit positions 32-39 of general register $R_2 + 1$ contain the padding byte. The contents of bit positions 0-39 of general register $R_1 + 1$ and of bit positions 0-31 of general register $R_2 + 1$ are ignored.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-301.

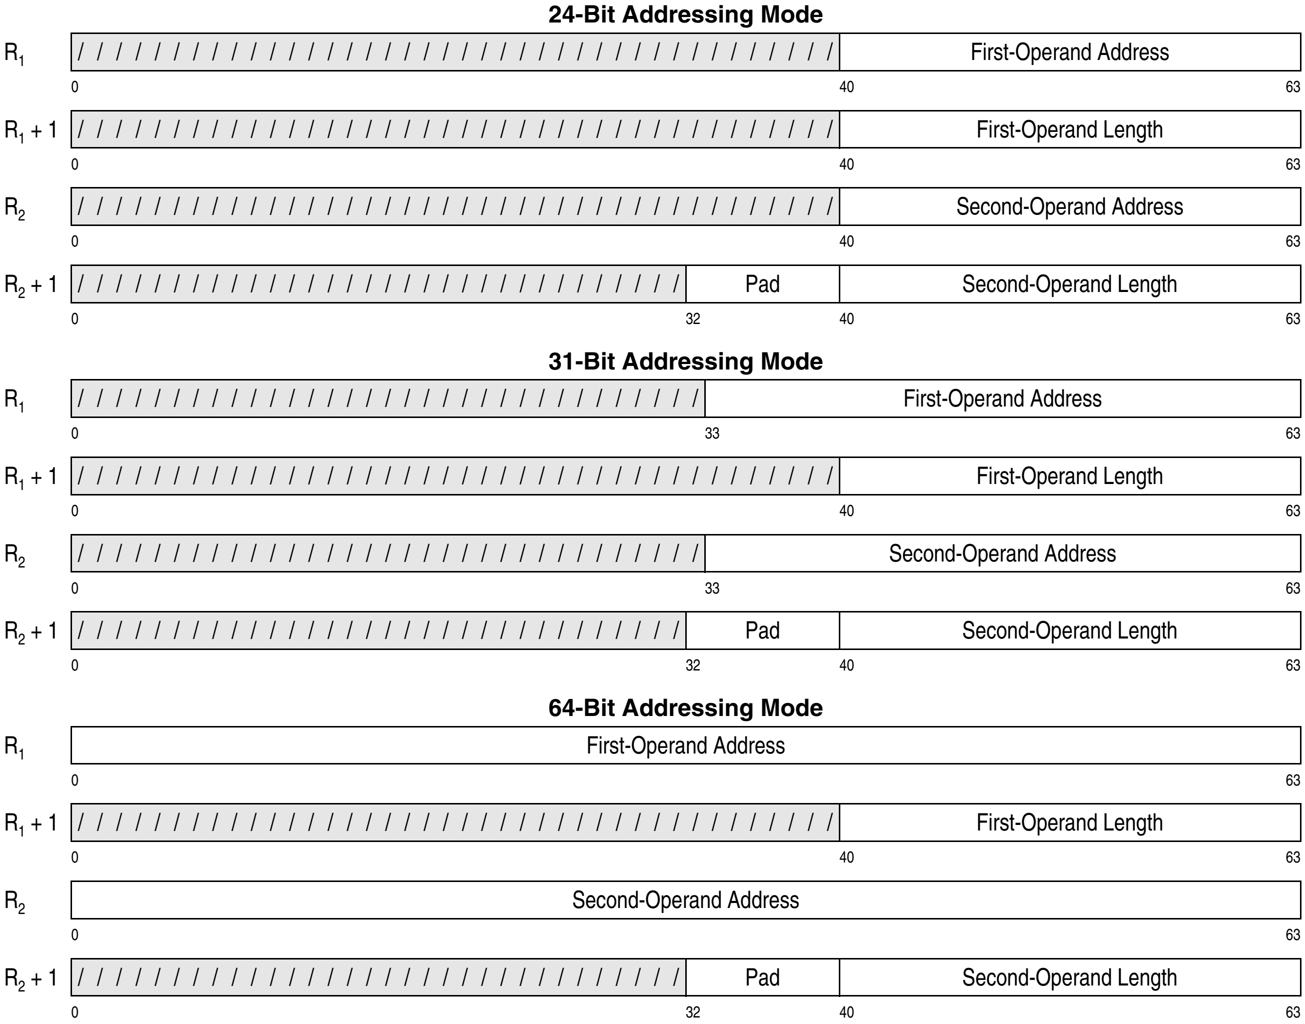

Figure 7-301. Register Contents for MOVE LONG

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by bits 40-63 of general register $R_1 + 1$ have been moved into the first-operand location. If the second operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

As part of the execution of the instruction, the values of the two length fields are compared for the setting of the condition code, and a check is made for destructive overlap of the operands. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it, assuming the inspection for overlap is performed by the use of logical operand addresses. When the operands overlap destructively, no movement takes place, and condition code 3 is set.

Operands do not overlap destructively, and movement is performed, if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) to location 0, operand bytes in locations up to and including 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 2^{24} - 1 to location 0; in the 31-bit addressing mode, wraparound is from location 2^{31} - 1 to location 0; in the 64-bit addressing mode, wraparound is from location 2^{64} - 1 to location 0.

In the access-register mode, the contents of access register R_1 and access register R_2 are compared. If the R_1 or R_2 field is zero, 32 zeros are used rather than the contents of access register 0. If all 32 bits of the compared values are equal, then the destructive overlap test is made. If all 32 bits of the compared values are not equal, destructive overlap is declared not to exist. If, for this case, the operands actually overlap in real storage, it is unpredictable whether the result reflects the overlap condition.

When the length specified by bits 40-63 of general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the lengths in general registers $R_1 + 1$ and $R_2 + 1$ are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_2 are incremented by the same number, so that the instruction, when reexecuted, resumes at the point of interruption. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, and the contents of bit positions 0-31 remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged; and the condition code is unpredictable. If the operation is interrupted during padding, the length field in general register $R_2 + 1$ is 0, the address in general register R_2 is incremented by the original length in general register $R_2 + 1$, and general registers R_1 and $R_1 + 1$ reflect the extent of the padding operation.

When the first-operand location includes the location of the instruction or of an execute-type instruction, the instruction may be refetched from storage and reinterpreted even in the absence of an interruption during execution. The exact point in the execution at which such a refetch occurs is unpredictable.

Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register $R_2 + 1$ is decremented by the number of bytes moved out of the second-operand location, and the address in general register R_2 is incremented by the same amount. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, even when one or both of the original length values are zeros or when condition code 3 is set. The contents of bit positions 0-31 of the registers remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

When condition code 3 is set, no exceptions associated with operand access are recognized. When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the second operand is longer than the first operand, access exceptions are not recognized for the part of the second-operand field that is in excess of the first-operand field. For operands longer than 2K bytes, access exceptions are not recognized for locations more than 2K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

Resulting Condition Code:

0 Operand lengths equal; no destructive overlap
1 First-operand length low; no destructive overlap
2 First-operand length high; no destructive overlap
3 No movement performed because of destructive overlap

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE LONG instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE LONG may be used for clearing storage by setting the padding byte to zero and the second-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-125.

3. When the first-operand length is zero, the operation consists in setting the condition code and, in the 24-bit or 31-bit addressing mode, of setting the leftmost bits in bit positions 32-63 of general registers R_1 and R_2 to zero.

4. When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. Condition code 0 is set.

5. The following is a detailed description of those cases in which movement takes place, that is, where destructive overlap does not exist.

   In the access-register mode, the contents of the access registers used are called the effective space designations. When the effective space designations are not equal, destructive overlap is declared not to exist and movement occurs. When the effective space designations are the same or when not in the access-register mode, then the following cases apply.

   Depending on whether the second operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$, depending on the addressing mode) to location 0, movement takes place in the following cases:

   a. When the second operand does not wrap around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, *or* if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

   b. When the second operand wraps around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, *and* if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

The rightmost second-operand byte is determined by using the smaller of the first-operand and second-operand lengths.

When the second-operand length is one or zero, destructive overlap cannot exist.

6. Special precautions should be taken if MOVE LONG is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

7. Since the execution of MOVE LONG is interruptible, the instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not let the first operand of MOVE LONG include the location of the instruction or of an execute-type instruction because the new contents of the location may be interpreted for a resumption after an interruption, or the instruction may be refetched without an interruption.

8. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” in Chapter 5, “Program Execution.”

9. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

MOVE LONG EXTENDED

MVCLE R_1,R_3,D_2(B_2) [RS-a]

'A8'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

All or part of the third operand is placed at the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The second-operand address is not used to address data; instead, the rightmost eight bits of the second-operand address, bits 56-63, are the padding byte. Bits 0-55 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-302.

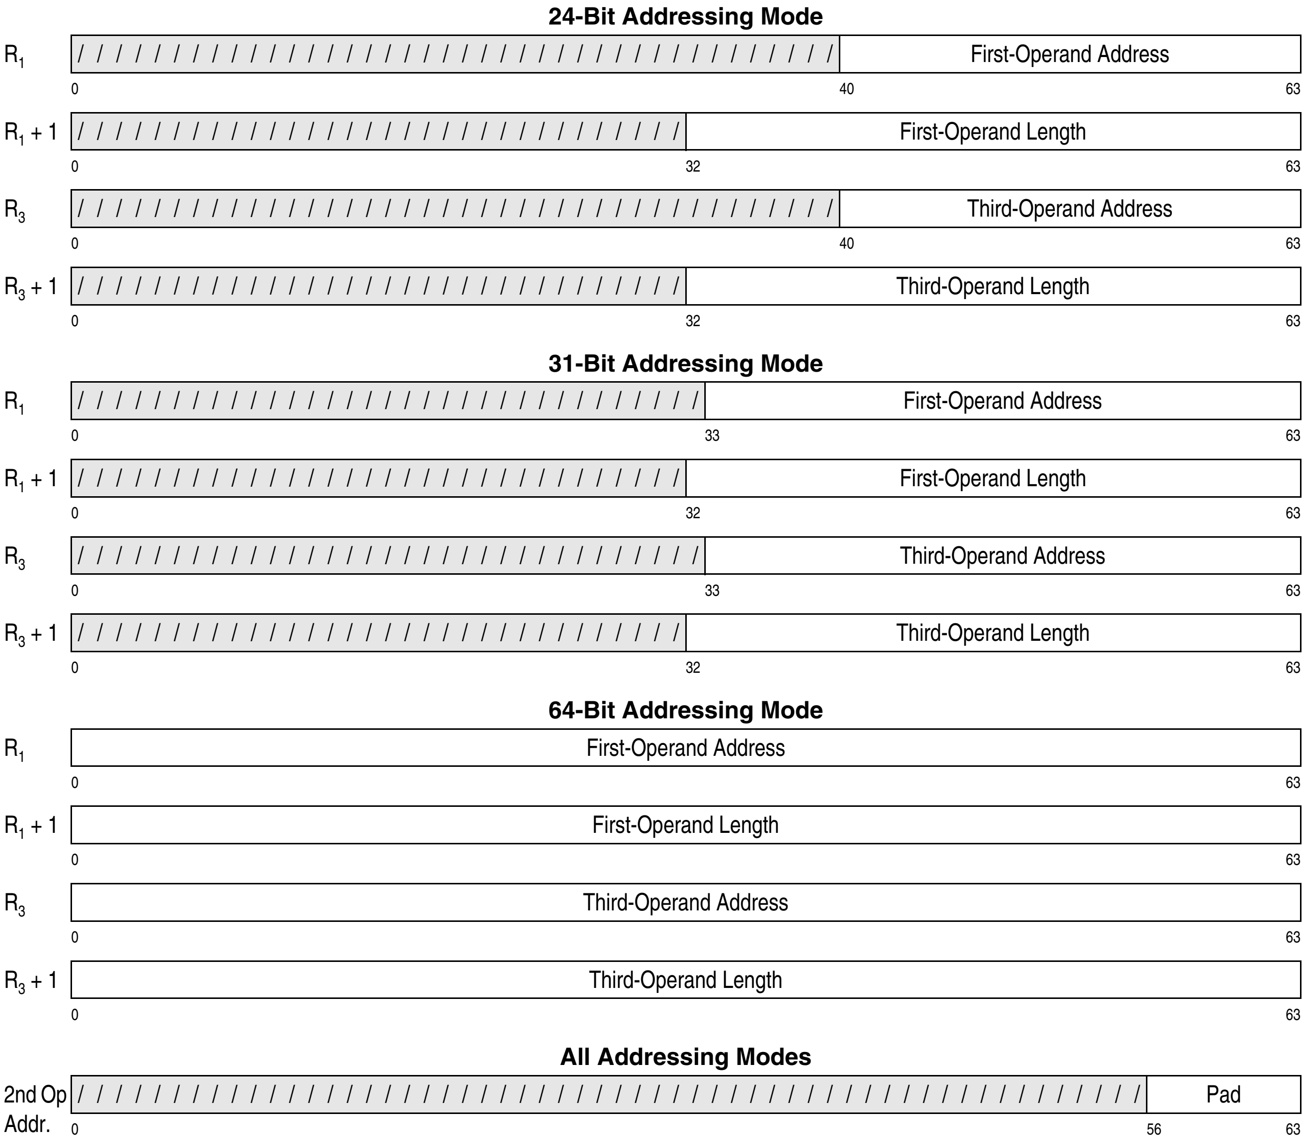

Figure 7-302. Register Contents and Second-Operand Address for MOVE LONG EXTENDED

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified in general register R_1 + 1 have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first. If the third operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-operand length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) to location 0, operand bytes in locations up to and including 2^{24} - 1 (or 2^{31} - 1 or 2^{64} - 1) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 2^{24} - 1 to location 0; in the 31-bit addressing mode, wraparound is from location 2^{31} - 1 to location 0; and, in the 64-bit addressing mode, wraparound is from location 2^{64} - 1 to location 0.

When the length specified in general register R_1 + 1 is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG EXTENDED may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register R_1 + 1 is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register R_3 + 1 is decremented by the number of bytes moved out of the third-operand location, and the address in general register R_3 is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers R_1 + 1 and R_3 + 1 are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register R_3 + 1 is zero, the address in general register R_3 is incremented by the original length in general register R_3 + 1, and general registers R_1 and R_1 + 1 reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_1 + 1, R_3, and R_3 + 1, always remain unchanged.

The padding byte may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, R_1 + 1, R_3, or R_3 + 1 and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The maximum amount is approximately 4K bytes of either operand.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, even when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

Resulting Condition Code:

0 All bytes moved, operand lengths equal
1 All bytes moved, first-operand length low
2 All bytes moved, first-operand length high
3 CPU-determined number of bytes moved without reaching end of first operand

Program Exceptions:

- Access (fetch, operand 3; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE LONG EXTENDED is intended for use in place of MOVE LONG when the operand lengths are specified as 32-bit or 64-bit binary integers and a test for destructive overlap is not required. MOVE LONG EXTENDED sets condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. The function of not processing more than approximately 4K bytes of either operand is intended to permit software polling of a flag that may be set by a program on another CPU during long operations.

4. MOVE LONG EXTENDED may be used for clearing storage by setting the padding byte to zero and the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-125.

5. When the contents of the R_1 and R_3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

6. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

MOVE LONG UNICODE

MVCLU $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'8E'
0	8	12	16	20	32	40 47

All or part of the third operand is placed at the first-operand location. The remaining rightmost positions, if any, of the first-operand location are filled with one or more padding bytes, alternating between the even padding byte and the odd padding byte. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

On some models, the contents of general registers $R_1 + 1$ and $R_3 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the registers constitute the address.

The second-operand address is not used to address data; instead, the rightmost 16 bits of the second-operand address, bits 48-63, are the two padding bytes; bits 48-55 are the even padding byte, and bits 56-63 are the odd padding byte. Bits 0-47 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-303.

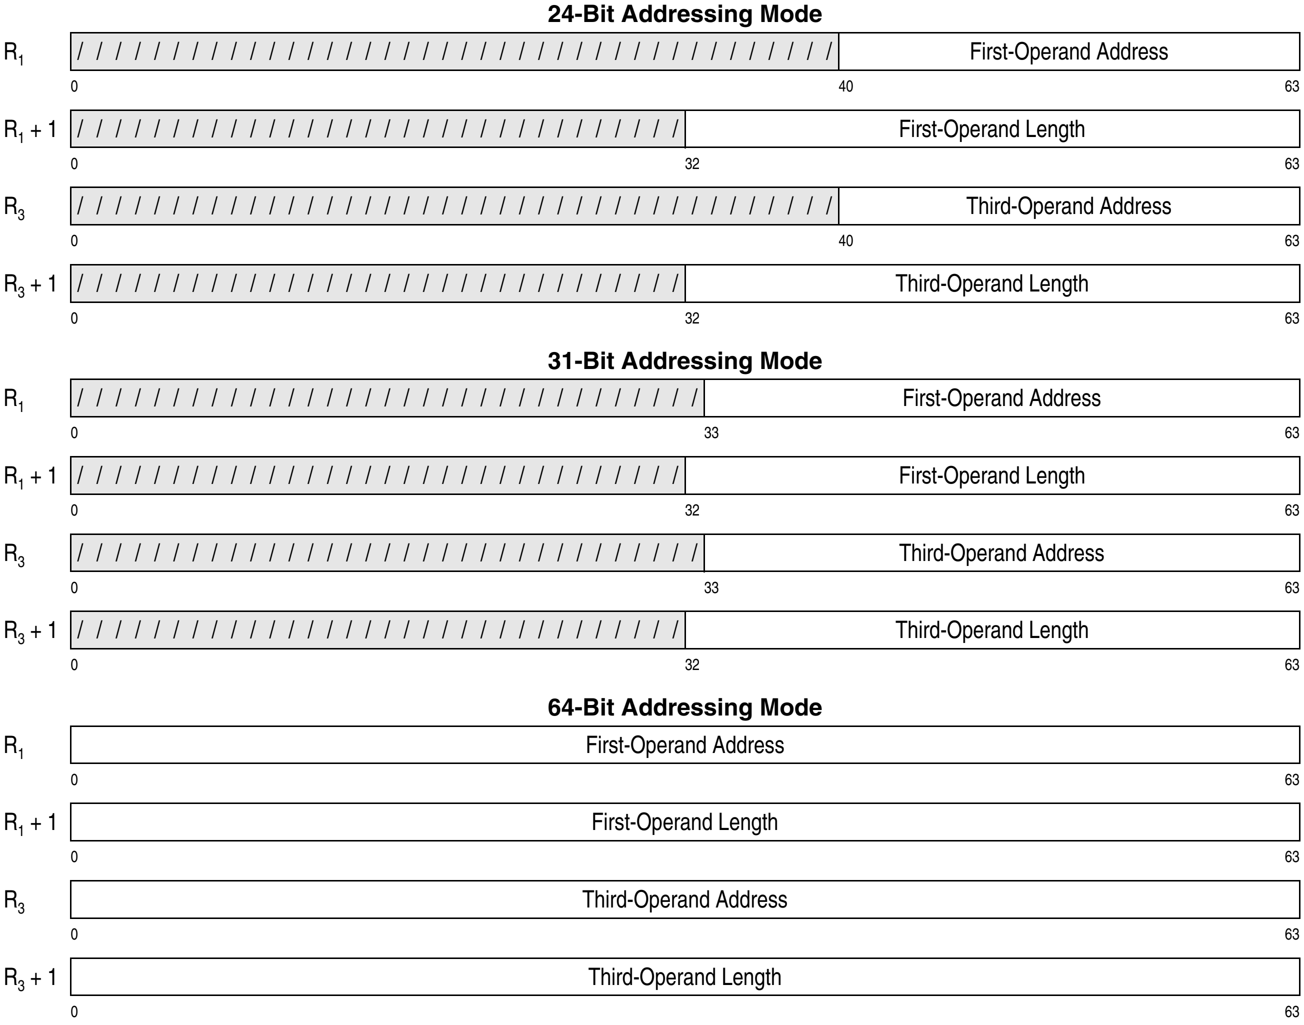

Figure 7-303. Register Contents and Second-Operand Address for MOVE LONG UNICODE (Part 1 of 2)

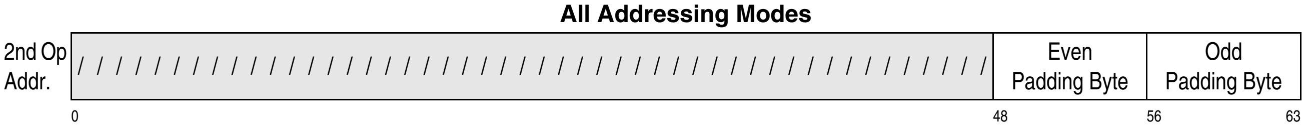

Figure 7-303. Register Contents and Second-Operand Address for MOVE LONG UNICODE (Part 2 of 2)

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by the contents of general register $R_1 + 1$ have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first.

If the third operand is shorter than the first operand, the remaining rightmost positions of the first-operand location are filled with alternating padding bytes. When the number of bytes remaining in the first-operand location is an even number, the even padding byte is placed first; when the number of bytes remaining in the first-operand location is odd, the odd padding byte is placed first.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-operand length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

When the length specified in general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

For the nonpadding part of the operation, accesses to the operands for MOVE LONG UNICODE may be multiple-access references. These accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by channel programs. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by he channel subsystem, that portion of the first operand which is filled with the padding bytes is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding bytes may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register $R_3 + 1$ is decremented by the number of bytes moved out of the third-operand location, and the address in general register R_3 is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register $R_3 + 1$ is zero, the address in general register R_3 is incremented by the number of bytes moved from operand 3, and general registers R_1 and $R_1 + 1$ reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

The padding bytes may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, including the case when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set. On models that recognize a specification exception if the length associated with an operand is odd, access exceptions and PER storage-alteration events are not recognized and no change bits are set if the length is odd.

Resulting Condition Code:

0	All bytes moved, operand lengths equal
1	All bytes moved, first-operand length low
2	All bytes moved, first-operand length high
3	CPU-determined number of bytes moved without reaching end of first operand

Program Exceptions:

- Access (fetch, operand 3; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE LONG UNICODE is intended for use in place of MOVE LONG or MOVE LONG EXTENDED when padding with double-byte characters. The character may be a Unicode character or any other double-byte character. MOVE LONG UNICODE may set condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. MOVE LONG UNICODE may be used for filling storage with padding bytes by placing the padding bytes in the second-operand address and setting the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-125.

4. When the contents of the R_1 and R_3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by two times the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

6. The padding bytes may be represented in the displacement field of the instruction. The following example illustrates padding with a Unicode space character.

   ```
   MVCLU   6,8,X'0020'
   ```

   When the B_2 field of the instruction designates general register 0, and the long-displacement facility is not installed, the padding bytes are limited to a character whose representation is less than or equal to 0FFF hex.

7. MOVE LONG UNICODE is intended to be used to move and pad pairs of bytes. Although some models allow the first- and third-operand length registers to designate an odd length, without recognizing a specification exception, the program should always be coded to provide an even length. This ensures that the program will operate compatibly in configurations that recognize a specification exception for an odd length value.

MOVE NUMERICS

MVN $D_1(L,B_1),D_2(B_2)$ [SS-a]

'D1'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The rightmost four bits of each byte in the second operand are placed in the rightmost bit positions of the corresponding bytes in the first operand. The leftmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE NUMERICS instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE NUMERICS moves the numeric portion of a decimal-data field that is in the zoned format. The zoned-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes.

3. Accesses to the first operand of MOVE NUMERICS consist in fetching the leftmost four bits of each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

MOVE RIGHT TO LEFT

MVCRL $D_1(B_1),D_2(B_2)$ [SSE]

'E50A'	B_1	D_1	B_2	D_2
0	16	20	32	36 47

The second operand is placed at the first-operand location by moving bytes in a right-to-left sequence, beginning with the rightmost byte of each operand.

Both operand addresses designate the leftmost byte of their respective operands. The displacements for both operands are treated as 12-bit unsigned binary integers.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 32-55 of general register 0 should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-31 of general register 0 are ignored. The contents of general register 0 are shown below:

/ /	
0 8 16 24	31

/ /	L
32 40 48	56 63

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The result is obtained as if both operands are processed from right to left. However, as observed by other CPUs and channel programs, the sequence of accesses to the operands is undefined. Either operand may wrap around from location 2^{24} - 1 to 0 in the 24-bit addressing mode, from location 2^{31} - 1 to 0 in the 31-bit addressing mode, or from location 2^{64} - 1 to 0 in the 64-bit addressing mode.

Destructive overlap occurs and results are unpredictable when the byte location designated by the second-operand address (the leftmost byte of the source) overlaps with any byte location of the first operand, other than the byte location designated by the first-operand address (the leftmost byte of the target).

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)
- Transaction Constraint

Programming Notes:

1. MOVE RIGHT TO LEFT can be used to open a hole in an array, for subsequent insertion of an element, by moving the original element and all higher elements to the right. The MVC instruction, which moves left to right, can not be used in this case since it would destructively overwrite array elements.

2. For most other instructions with more than one storage operand, destructive overlap occurs when the leftmost byte of the destination operand lies within the source operand and the two operands do not perfectly overlap. However, for MOVE RIGHT TO LEFT, destructive overlap occurs when the rightmost byte of the destination operand lies within the source operand and does not perfectly overlap the source operand. Therefore, the scenario described in programming note 1 is not destructive overlap for MVCRL but would be if MVC were used. If there is no overlap of any type between the operands, MVC and MVCRL perform similarly, as observed by this CPU, except that the manner the length is specified is different.

3. Since results are unpredictable if destructive overlap exists on MOVE RIGHT TO LEFT, this instruction can not be used to replicate data from higher addresses to lower addresses. However, MVC which has precisely defined left to right behavior with destructive overlap, can be used for the purpose of replicating data from lower addresses to higher addresses.

MOVE STRING

MVST R_1,R_2 [RRE]

'B255'	////////	R_1	R_2
0	16	24	28 31

All or part of the second operand is placed in the first-operand location. The operation proceeds until the end of the second operand is reached or a CPU-determined number of bytes have been moved, whichever occurs first. The CPU-determined number is at least one. The result is indicated in the condition code.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The end of the second operand is indicated by an ending character in the last byte position of the operand. The ending character to be used to determine the end of the second operand is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the second-operand ending character has been moved or a CPU-determined number of second-operand bytes have been moved, whichever occurs first. The CPU-determined number is at least one. When the ending character is in the first byte position of the second operand, only the ending character is moved. When the ending character has been moved, condition code 1 is set. When a CPU-determined number of second-operand bytes not including an ending character have been moved, condition code 3 is set. Destructive overlap is not recognized. If the second operand is used as a source after it has been used as a destination, the results are unpredictable.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the first and second operands are recognized only for that portion of the operand that is necessarily used in the operation.

The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction, except that destructive overlap is not recognized.

Resulting Condition Code:

0 --
1 Entire second operand moved; general register R_1 updated with address of ending character in first operand; general register R_2 unchanged
2 --
3 CPU-determined number of bytes moved; general registers R_1 and R_2 updated with addresses of next bytes

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE STRING instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the data movement. The program need not determine the number of bytes that were moved.

3. R_1 or R_2 may be zero, in which case general register 0 is treated as containing an address and also the ending character.

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

5. If the second operand is used as a source after it has been used as a destination, an ending character in the second operand may not be recognized.

MOVE WITH OFFSET

MVO $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'F1'	L_1	L_2	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The second operand is placed to the left of and adjacent to the rightmost four bits of the first operand.

The rightmost four bits of the first operand are attached as the rightmost bits to the second operand, the second-operand bits are offset by four bit positions, and the result is placed at the first-operand location.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time, as if each result byte were stored immediately after fetching the necessary operand bytes, and as if the left digit of each second-operand byte were to remain available for the next result byte and need not be refetched.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE WITH OFFSET instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. MOVE WITH OFFSET may be used to shift packed decimal data by an odd number of digit positions. The packed-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes. In many cases, however, SHIFT AND ROUND DECIMAL may be more convenient to use.
3. Access to the rightmost byte of the first operand of MOVE WITH OFFSET consists in fetching the rightmost four bits and subsequently storing the updated value of this byte. These fetch and store accesses to the rightmost byte of the first operand do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”
4. The storage-operand references for MOVE WITH OFFSET may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

MOVE ZONES

MVZ $D_1(L,B_1),D_2(B_2)$ [SS-a]

'D3'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The leftmost four bits of each byte in the second operand are placed in the leftmost four bit positions of the corresponding bytes in the first operand. The rightmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte is fetched.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE ZONES instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. MOVE ZONES moves the zoned portion of a decimal field in the zoned format. The zoned format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes.
3. Accesses to the first operand of MOVE ZONES consist in fetching the rightmost four bits of each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the

other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for the OR (OI) instruction in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

MULTIPLY

Register-and-register format:

MR R_1,R_2 [RR]

'1C'	R_1	R_2
0	8	12 15

MGRK R_1,R_2,R_3 [RRF-a]

'B9EC'	R_3	////	R_1	R_2
0	16	20	24	28 31

Register-and-storage formats:

M $R_1,D_2(X_2,B_2)$ [RX-a]

'5C'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

MFY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'5C'
0	8	12	16	20	32	40 47

MG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'84'
0	8	12	16	20	32	40 47

For M, MFY, and MR, the 32-bit first operand (the multiplicand) is multiplied by the 32-bit second-operand (the multiplier), and the 64-bit product is placed at the first-operand location. For MG, the 64-bit first operand (the multiplicand) is multiplied by the 64-bit second-operand (the multiplier), and the 128-bit product is placed at the first-operand location. For MGRK, the 64-bit third operand (the multiplicand) is multiplied by the 64-bit second-operand (the multiplier), and the 128-bit product is placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The following applies to M, MFY, and MR:

- Both the multiplicand and multiplier are treated as 32-bit signed binary integers.
- The multiplicand is in bit positions 32-63 of general register R_1 + 1.
- For MULTIPLY (MR), the multiplier is in bit positions 32-63 of general register R_2. The contents of general register R_1 and of bit positions 0-31 of general register R_1 + 1 and, for MR, of general register R_2 are ignored.

  For M and MY, the multiplier is at the second-operand location in storage.
- The product is a 64-bit signed binary integer. Bits 0-31 of the product replace bits 32-63 of general register R_1. Bits 32-63 of the product replace bits 32-63 of general register R_1 + 1. Bits 0-31 of general registers R_1 and R_1 + 1 remain unchanged.

The following applies to MG and MGRK:

- Both the multiplicand and multiplier are treated as 64-bit signed binary integers.
- For MG, the multiplicand is in bit positions 0-63 of general register R_1 + 1, and the contents of general register R_1 are ignored. For MGRK, the multiplicand is in bit positions 0-63 of general register R_3, and the contents of general registers R_1 and R_1 + 1 are ignored.
- For MG, the multiplier is at the second-operand location in storage. For MGRK, the multiplier is in bit positions 0-63 of general register R_2.
- For both MG and MGRK, the product is a 128-bit signed binary integer. Bits 0-63 of the product replace bits 0-63 of general register R_1. Bits 64-127 of the product replace bits 0-63 of general register R_1 + 1.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive. An overflow cannot occur.

The displacement for M is treated as a 12-bit unsigned binary integer. The displacement for MFY and MG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of M, MFY, and MG only)
- Operation (MFY, if the general-instructions-extension facility is not installed; MG, MGRK, if the miscellaneous-instruction-extensions facility 2 is not installed)
- Specification

Programming Notes:

1. An example of the use of the MULTIPLY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For M, MFY, and MR, the significant part of the product usually occupies 62 bit positions or fewer. Only when two maximum 32-bit negative numbers are multiplied are 63 significant product bits formed.

   Similarly, for MG and MGRK, the significant part of the product usually occupies 126 bit positions or fewer. Only when two maximum 64-bit negative numbers are multiplied are 127 significant product bits formed.

3. Care should be taken not to confuse the mnemonic for MULTIPLY UNNORMALIZED (MY) with the mnemonic for MULTIPLY (MFY).

MULTIPLY HALFWORD

MH $R_1,D_2(X_2,B_2)$ [RX-a]

'4C'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

MHY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'7C'
0	8	12	16	20	32	40 47

MGH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'3C'
0	8	12	16	20	32	40 47

MULTIPLY HALFWORD IMMEDIATE

MHI R_1,I_2 [RI-a]

'A7'	R_1	'C'	I_2
0	8	12	16 31

MGHI R_1,I_2 [RI-a]

'A7'	R_1	'D'	I_2
0	8	12	16 31

The 32-bit or 64-bit first operand (the multiplicand) is multiplied by the 16-bit second operand (the multiplier), and the rightmost 32 or 64 bits of the product are placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer.

For MULTIPLY HALFWORD (MH, MHY) and MULTIPLY HALFWORD IMMEDIATE (MHI), the multiplicand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1, and it is replaced by the rightmost 32 bits of the signed-binary-integer product. The bits to the left of the 32 rightmost bits of the product are not tested for significance; no overflow indication is given. Bits 0-31 of general register R_1 are ignored and remain unchanged.

For MULTIPLY HALFWORD (MGH) and MULTIPLY HALFWORD IMMEDIATE (MGHI), the multiplicand is treated as a 64-bit signed binary integer in bit positions 0-63 of general register R_1, and it is replaced by the rightmost 64 bits of the signed-binary-integer product. The bits to the left of the 64 rightmost bits of the product are not tested for significance; no overflow indication is given.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MH is treated as a 12-bit unsigned binary integer. The displacement for MHY and MGH is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MH, MHY, and MGH only)

- Operation (MHY; if the general-instructions-extension facility is not installed; MGH, if the miscellaneous-instruction-extensions facility 2 is not installed)

Programming Notes:

1. An example of the use of the MULTIPLY HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For MH, MHY, and MHI, the significant part of the product usually occupies 46 bit positions or fewer. Only when two maximum negative numbers are multiplied are 47 significant product bits formed. Since the rightmost 32 bits of the product are placed unchanged at the first-operand location, ignoring all bits to the left, the sign bit of the result may differ from the true sign of the product in the case of overflow. For a negative product, the 32 bits placed in register R_1 are the rightmost part of the product in two's-complement notation.

   Similarly, for MGH and MGHI, the significant part of the product usually occupies 78 bit positions or fewer, but may occupy 79 bits when two maximum negative numbers are multiplied. Since the rightmost 64 bits of the product are placed unchanged at the first-operand location, the sign of the result may differ from the true sign of the 80-bit product in the case of overflow.

MULTIPLY LOGICAL

Register-and-register formats:

MLR R_1,R_2 [RRE]

'B996'	////////	R_1	R_2
0	16	24	28 31

MLGR R_1,R_2 [RRE]

'B986'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

ML $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'96'
0	8	12	16	20	32	40 47

MLG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'86'
0	8	12	16	20	32	40 47

The 32-bit or 64-bit first operand (the multiplicand) is multiplied by the 32-bit or 64-bit second operand (the multiplier), and the 64-bit or 128-bit product is placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For MULTIPLY LOGICAL (MLR, ML), both the multiplicand and the multiplier are treated as 32-bit unsigned binary integers. The multiplicand is in bit positions 32-63 of general register $R_1 + 1$. For MULTIPLY LOGICAL (MLR), the multiplier is in bit positions 32-63 of general register R_2. The contents of general register R_1 and of bit positions 0-31 of general register $R_1 + 1$ and, for MLR, of general register R_2 are ignored. The product is a 64-bit unsigned binary integer. Bits 0-31 of the product replace bits 32-63 of general register R_1, and bits 32-63 of the product replace bits 32-63 of general register $R_1 + 1$. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged. An overflow cannot occur.

For MULTIPLY LOGICAL (MLGR, MLG), the multiplicand and the multiplier are treated as 64-bit unsigned binary integers. The multiplicand is in general register $R_1 + 1$. The contents of general register R_1 are ignored. The product is a 128-bit unsigned binary integer. Bits 0-63 of the product replace the contents of general register R_1, and bits 64-127 of the product replace the contents of general register $R_1 + 1$. An overflow cannot occur.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of ML and MLG only)
- Specification

MULTIPLY SINGLE

Register-and-register formats:

MSR R_1,R_2 [RRE]

MULTIPLY SINGLE IMMEDIATE

MSFI R_1,I_2 [RIL-a]

'C2'	R_1	'1'	I_2
0	8	12	16 47

MSGFI R_1,I_2 [RIL-a]

'C2'	R_1	'0'	I_2
0	8	12	16 47

The multiplicand is multiplied by the second operand (multiplier), and the rightmost 32 or 64 bits of the product are placed at the first-operand location. Depending on the instruction format, the multiplicand is in either general register R_1 or R_3.

The following applies to MULTIPLY (MS, MSC, MSR, MSRKC, MSY) and to MULTIPLY SINGLE IMMEDIATE (MSFI) – that is, to those operations which produce a 32-bit result:

- The multiplicand is a 32-bit signed binary integer. For MS, MSC, MSFI, MSR, and MSY, the multiplicand is in bit positions 32-63 of general register R_1. For MSRKC, the multiplicand is in bit positions 32-63 of general register R_3.
- The multiplier is a 32-bit signed binary integer. For MSR and MSRKC, the multiplier is in bit positions 32-63 of general register R_2. For MSFI, the multiplier is in the I_2 field of the instruction. For MS, MSC, and MSY, the multiplier is at the second-operand location in storage.
- The rightmost 32 bits of the signed-binary-integer product replace bits 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. For MS, MSFI, MSR, and MSY, the bits to the left of the 32 rightmost bits of the product are not tested for significance.

  For MSC and MSRKC, an overflow condition exists when the leftmost 33 bits of an intermediate 64-bit product are neither all zeros nor all ones. Condition code 3 is set. If the fixed-point-overflow mask in the PSW is one, a program interruption for fixed-point overflow occurs.

The following applies to MULTIPLY SINGLE (MSG, MSGC, MSGF, MSGFR, MSGR, MSGRKC) and to MULTIPLY SINGLE IMMEDIATE (MSGFI) – that is, to those operations which produce a 64-bit result:

- The multiplicand is a 64-bit signed binary integer. For MSG, MSGC, MSGF, MSGFI, MSGR, and MSGFR, the multiplicand is in bit positions 0-63 of general register R_1. For MSGRKC, the multiplicand is in bit positions 0-63 of general register R_3.
- For MSGR and MSGRKC, the multiplier is a 64-bit signed binary integer in bit positions 0-63 of general register R_2. For MSGFR, the multiplier is a 32-bit signed-binary integer in bit positions 32-63 of general register R_2. For MSGFI, the multiplier is a 32-bit signed-binary integer in the I_2 field of the instruction. For MSG and MSGC, the multiplier is a 64-bit signed binary integer at the second-operand location in storage. For MSGF, the multiplier is a 32-bit signed binary integer at the second-operand location in storage.
- The rightmost 64 bits of the signed-binary-integer product replace bits 0-63 of general register R_1. For MSG, MSGF, MSGFR, MSGR, MSGFI, the bits to the left of the 64 rightmost bits of the product are not tested for significance.

  For MSGC and MSGRKC, an overflow condition exists when the leftmost 65 bits of an intermediate 128-bit product are neither all zeros or all ones. Condition code 3 is set. If the fixed-point-overflow mask in the PSW is one, a program interruption for fixed-point overflow occurs.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MS is treated as a 12-bit unsigned binary integer. The displacement for MSC, MSG, MSGF, and MSY is treated as a 20-bit signed binary integer.

Resulting Condition Code: For MSC, MSGC, MSGRKC, and MSRKC, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

For all other operations, the condition code remains unchanged, and no overflow indication is provided.

Program Exceptions:

- Access (fetch, operand 2 of MS, MSC, MSG, MSGC, MSGF, MSY only)
- Fixed-point overflow (MSC, MSGC, MSGRKC, MSRKC only)
- Operation (MSY, if the long-displacement facility is not installed; MSFI, MSGFI, if the general-instructions-extension facility is not installed; MSC, MSGC, MSGRKC, MSRKC, if the miscellaneous-instruction-extensions facility 2 is not installed.))

NAND

NNRK R_1,R_2,R_3 [RRF-a]

'B974'	R_3	////	R_1	R_2
0	16	20	24	28 31

NNGRK R_1,R_2,R_3 [RRF-a]

'B964'	R_3	////	R_1	R_2
0	16	20	24	28 31

The one's complement of the AND of the second and third operands is placed at the first-operand location.

The connective NAND is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in both source operands contain ones; otherwise, the result bit is set to one.

For NNRK, the operands are 32 bits, and for NNGRK, they are 64 bits.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

NEXT INSTRUCTION ACCESS INTENT

NIAI I_1,I_2 [IE]

'B2FA'	////////	I_1	I_2
0	16	24	28 31

Note: In this instruction definition, the term primary-access operand means the lowest numbered storage operand of an instruction. Similarly, the term secondary-access operand means the next-lowest numbered storage operand of the instruction. These terms do not have the same meaning as the terms first operand and second operand, even though there may be some correlation. For example, for the MOVE instruction the first operand is the primary-access operand and the second operand is the secondary-access operand. However, for the LOAD MULTIPLE DISJOINT instruction, the second operand is the primary-access operand and the fourth operand is the secondary-access operand.

Subject to the controls in the I_1 and I_2 fields, the CPU is signaled the future access intent for either or both the primary-access and secondary-access operands of the next-sequential instruction. The I_1 field contains a code to signal the CPU the access intent for the primary-access operand of the next-sequential instruction. The I_2 field contains a code to signal the CPU the access intent for the secondary-access operand of the next-sequential instruction. When the next-sequential instruction has only a single storage operand, the I_2 field is ignored.

The I_1 and the I_2 fields have the following format:

AI
0 3

Access Intent (AI): Bits 0-3 of the I_1 and I_2 fields contain an unsigned integer that is used as a code to signal the CPU the access intent for the corresponding operand of the next-sequential instruction as follows:

Code	Meaning
0	The corresponding operand of the next-sequential instruction may or may not be accessed as an instruction operand by subsequent instructions.
1	The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand store access, and may also be accessed for operand fetch access.
2	The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand fetch access.
3	The corresponding operand of the next-sequential instruction will not be accessed as an instruction operand by subsequent instructions.
4-15	Reserved.

Reserved access-intent codes should not be specified; otherwise, the program may not operate compatibly in the future.

Depending on the model, the CPU may not recognize all of the access intents for an operand. For access intents that are not recognized by the CPU, the instruction acts as a no-operation. If the instruction has more than two storage operands, no access intent is specified for the additional operands.

Depending on the model, the CPU may not recognize access intents for a particular instruction. For such cases, the instruction acts as a no-operation.

The NEXT INSTRUCTION ACCESS INTENT instruction only affects subsequent instruction's operand accesses; it does not affect subsequent instruction fetches.

No references to storage are made.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the execution-hint facility is not installed)

Programming Notes:

1. NEXT INSTRUCTION ACCESS INTENT signals the CPU of the future access intent for the storage operands of the next-sequential instruction, but it does not guarantee that the CPU will necessarily retain or use this information.

2. Specifying an incorrect access intent or an access intent for a non-existent operand may lead to performance degradation.

3. Caches are managed on a cache-line-size granularity. Therefore, when a corresponding storage operand specifies any portion of a cache line, the access intent is signaled for the entire cache line. The cache line size can be determined by executing the EXTRACT CPU ATTRIBUTE instruction.

4. When a corresponding storage operand specifies crossing one or more cache-line boundaries, it is model dependent whether the access intent is signaled for one or multiple cache lines.

   It is anticipated a program may use access-intent values of one, two, or three, with corresponding storage operands that may cross one or more cache-line boundaries.

5. Specifying an access-intent value of three does not signal the CPU to actively release the cache line from the cache for the specified operand. Instead, it signals the CPU that it should not actively try to retain that line in the cache.

6. Specifying an access-intent value of zero to a single operand instruction is not encouraged and not necessary. However, in the case where an instruction has two operands and access intent is known for one operand, but not the other, the access intent value of zero can be used for the operand of unknown intent.

7. If an interruption occurs after the execution of NEXT INSTRUCTION ACCESS INTENT and before the execution of the next-sequential instruction, NEXT INSTRUCTION ACCESS INTENT acts as a no-operation and the specified access intent is ignored.

8. If the next sequential instruction after NEXT INSTRUCTION ACCESS INTENT is a PREFETCH DATA (RELATIVE LONG) instruction, it is unpredictable what the CPU will do with data prefetching.

9. When the next-sequential instruction after NEXT INSTRUCTION ACCESS INTENT is an execute-type instruction (EX or EXRL), the following applies:

   - Access-intent codes are not associated with the execute-type instruction. The second operand of an execute-type instruction corresponds to an instruction fetch.
   - Depending on the model, access-intent codes may be associated with the target instruction of the execute-type instruction.

NONTRANSACTIONAL STORE

NTSTG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'25'
0	8	12	16	20	32	40 47

The 64-bit first operand is nontransactionally placed unchanged at the second-operand location.

The displacement is treated as a 20-bit signed binary integer.

The second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized and the operation is suppressed.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, second operand)
- Operation (transactional-execution facility not installed)
- Specification
- Transaction constraint

Programming Notes:

1. NONTRANSACTIONAL STORE provides a means by which a program executing in the nonconstrained transactional-execution mode can perform stores that will be retained, even if the transaction aborts. This may facilitate debugging of the transaction if it is aborted.

2. When the CPU is not in the transactional-execution mode, the operation of NONTRANSACTIONAL STORE is identical to that of STORE (STG), except that the second operand of NONTRANSACTIONAL STORE is required to be on a doubleword boundary (regardless of transactional-execution mode) whereas the second operand of STG has no alignment requirements.

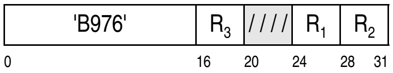
3. Depending on the model, the performance of NONTRANSACTIONAL STORE may be slower than that of STORE (STG).

4. If a CPU makes transactional and non-transactional stores to the same storage location within a transaction, and the transaction then aborts, the content of all storage locations altered by either the transactional or nontransactional store are unpredictable.

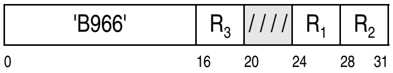
5. On some models, attempting to execute a non-transactional store and a transactional store in a transaction when both designate any locations within the same cache line results in the transaction being aborted with abort code 16 (cache other condition) and condition code 3 set. This occurs even if the nontransactional store does not overlap the transactional store. The cache line size may be determined by the EXTRACT CPU ATTRIBUTES (ECAG) instruction.

NOR

NORK R_1,R_2,R_3 [RRF-a]



NOGRK R_1,R_2,R_3 [RRF-a]



The one's complement of the OR of the second and third operands is placed at the first-operand location.

The connective NOR is applied to the operands bit-by-bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both source operands contain zero; otherwise, the result bit is set to zero.

For NORK, the operands are 32 bits, and for NOGRK, they are 64 bits.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

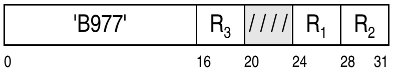
Programming Note: NOR can be used to provide the functionality of a bit-wise NOT operation by specifying the same general register for R_2 and R_3. The high-level assembler (HLASM) provides the extended-mnemonic forms shown below.

Extended Mnemonics:

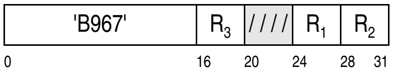
Extended Mnemonic		**Base Mnemonic**	
NOTR	R_1,R_2	NORK	R_1,R_2,R_2
NOTGR	R_1,R_2	NOGRK	R_1,R_2,R_2

NOT EXCLUSIVE OR

NXRK R_1,R_2,R_3 [RRF-a]



NXGRK R_1,R_2,R_3 [RRF-a]



The one's complement of the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR and complementation is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the bits in the corresponding bit positions in the two source operands are unlike; otherwise, the result bit is set to one.

For NXRK, the operands are 32 bits, and for NXGRK, they are 64 bits

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

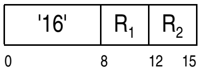
Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

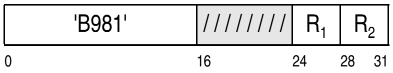
OR

Register-and-register formats:

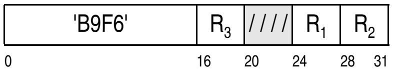
OR R$_1$,R$_2$ [RR]



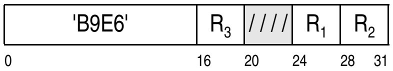
OGR R$_1$,R$_2$ [RRE]



ORK R$_1$,R$_2$,R$_3$ [RRF-a]

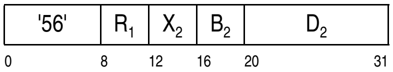


OGRK R$_1$,R$_2$,R$_3$ [RRF-a]

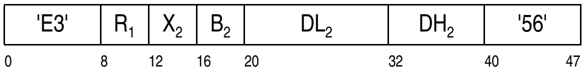


Register-and-storage formats:

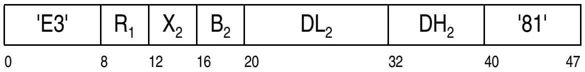
O R$_1$,D$_2$(X$_2$,B$_2$) [RX-a]



OY R$_1$,D$_2$(X$_2$,B$_2$) [RXY-a]

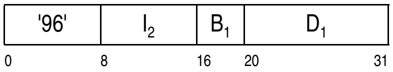


OG R$_1$,D$_2$(X$_2$,B$_2$) [RXY-a]

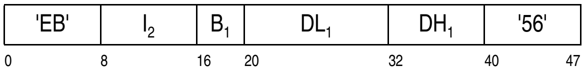


Storage-and-immediate formats:

OI D$_1$(B$_1$),I$_2$ [SI]

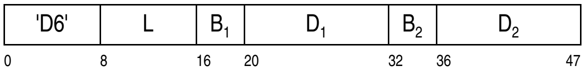


OIY D$_1$(B$_1$),I$_2$ [SIY]



Storage-and-storage format:

OC D$_1$(L,B$_1$),D$_2$(B$_2$) [SS-a]



For O, OC, OG, OGR, OI, OIY, OR, and OY, the OR of the first and second operands is placed at the first-operand location. For OGRK and ORK, the OR of the second and third operands is placed at the first-operand location.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

For OR (OC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For OR (OI, OIY), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility 2 is installed, the update of the first operand appears to be an interlocked-update reference as observed by other CPUs and channel programs, and a specific-operand-serialization operation is performed.

For OR (O, OR, ORK, and OY), the operands are 32 bits, and for OR (OG, OGR, and OGRK), they are 64 bits.

The displacements for O, OI, and both operands of OC are treated as 12-bit unsigned binary integers. The displacement for OY, OIY, and OG is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch, operand 2, O, OY, OG, and OC; fetch and store, operand 1, OI, OIY, and OC)

- Operation (OY and OIY, if the long-displacement facility is not installed; OGRK and ORK, if the distinct-operands facility is not installed)
- Transaction constraint (OC)

Programming Notes:

1. Examples of the use of the OR instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. OR may be used to set a bit to one.

3. Accesses to the first operand of OR (OC) – and, when the interlocked-access facility 2 is not installed, accesses to the first operand of OR (OI, OIY) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown in “Multiprogramming and Multiprocessing Examples” on page A-45.

   When the interlocked-access facility 2 is installed, OR (OI, OIY) can be safely used to update a location in storage, even if the possibility exists that another CPU or a channel program may also be updating the location.

OR IMMEDIATE

OIHF R_1,I_2 [RIL-a]

'C0'	R_1	'C'	I_2
0	8	12	16 — 47

OIHH R_1,I_2 [RI-a]

'A5'	R_1	'8'	I_2
0	8	12	16 — 31

OIHL R_1,I_2 [RI-a]

'A5'	R_1	'9'	I_2
0	8	12	16 — 31

OILF R_1,I_2 [RIL-a]

'C0'	R_1	'D'	I_2
0	8	12	16 — 47

OILH R_1,I_2 [RI-a]

'A5'	R_1	'A'	I_2
0	8	12	16 — 31

OILL R_1,I_2 [RI-a]

'A5'	R_1	'B'	I_2
0	8	12	16 — 31

The second operand is ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are ORed with the second operand and then replaced are as follows:

Instruction	**Bits ORed and Replaced**
OIHF	0-31
OIHH	0-15
OIHL	16-31
OILF	32-63
OILH	32-47
OILL	48-63

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

Program Exceptions:

- Operation (OIHF and OILF, if the extended-immediate facility is not installed)

Programming Note: The setting of the condition code is based only on the bits that are ORed and replaced.

OR WITH COMPLEMENT

OCRK R_1,R_2,R_3 [RRF-a]

'B975'	R_3	////	R_1	R_2
0	16	20	24	28 31

OCGRK R_1,R_2,R_3 [RRF-a]

'B965'	R_3	////	R_1	R_2
0	16	20	24	28 31

The second operand is ORed with the bit-wise complement of the third operand and the result is placed in the first-operand location.

The connective OR is applied to the second operand and bit-wise complemented third operand, bit by bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in the second and third operands contain zero and one, respectively; otherwise, the result bit is set to one.

For OCRK, the operands are 32 bits, and for OCGRK, they are 64 bits.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

PACK

PACK $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'F2'	L_1	L_2	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The format of the second operand is changed from zoned to signed-packed-decimal, and the result is placed at the first-operand location. The zoned and signed-packed-decimal formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the zoned format. The numeric bits of each byte are treated as a digit. The zone bits are ignored, except the zone bits in the rightmost byte, which are treated as a sign.

The sign and digits are moved unchanged to the first operand and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the necessary operand bytes. Two second-operand bytes are needed for each result byte, except for the rightmost byte of the result field, which requires only the rightmost second-operand byte.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the PACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. PACK may be used to interchange the two hexadecimal digits in one byte by specifying a zero in the L_1 and L_2 fields and the same address for both operands.

3. To remove the zone bits of all bytes of a field, including the rightmost byte, both operands should be extended on the right with a dummy byte, which subsequently should be ignored in the result field.

4. The storage-operand references for PACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

PACK ASCII

PKA $D_1(B_1),D_2(L_2,B_2)$ [SS-f]

'E9'	L_2	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The format of the second operand is changed from ASCII to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second-operand bytes are treated as containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost four bit positions of a byte are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

The length of the first operand is 16 bytes.

The length of the second operand is designated by the contents of the L_2 field. The second-operand length must not exceed 32 bytes (L_2 must be less than or equal to 31); otherwise, a specification exception is recognized.

When the length of the second operand is 32 bytes, the leftmost byte is ignored.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Although PACK ASCII is primarily intended to change the format of ASCII decimal digits, its use is not restricted to ASCII since the leftmost four bits of each byte are ignored.

2. The following example illustrates the use of the instruction to pack ASCII digits:

```
ASDIGITS  DS    0CL31
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'31'
PKDIGITS  DS    PL16
           :
          PKA   PKDIGITS,ASDIGITS(31)
```

3. The instruction can also be used to pack EBCDIC digits, which is especially useful when the length of the second operand is greater than the 16-byte second-operand limit of PACK.

```
EBDIGITS  DS    0CL31
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1'
PKDIGITS  DS    PL16
           :
          PKA   PKDIGITS,EBDIGITS(31)
```

4. The storage-operand references for PACK ASCII may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

PACK UNICODE

PKU $D_1(B_1),D_2(L_2,B_2)$ [SS-f]

'E1'	L_2	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The format of the second operand is changed from Unicode to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The two-byte second-operand characters are treated as Unicode Basic Latin characters containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost 12 bit positions of a character are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

The length of the first operand is 16 bytes.

The byte length of the second operand is designated by the contents of the L_2 field. The second-operand length must not exceed 32 characters or 64 bytes, and the byte length must be even (L_2 must be less than or equal to 63 and must be odd); otherwise, a specification exception is recognized.

When the length of the second operand is 32 characters (64 bytes), the leftmost character is ignored.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The following example illustrates the use of PACK UNICODE to pack European numbers:

```
UNDIGITS  DS   0CL62
          DC   X'00310032003300340035'
          DC   X'00360037003800390030'
          DC   X'00310032003300340035'
          DC   X'00360037003800390030'
          DC   X'00310032003300340035'
          DC   X'00360037003800390030'
          DC   X'0031'
PKDIGITS  DS   PL16
           ⋮
          PKU  PKDIGITS,UNDIGITS(62)
```

2. Because the leftmost 12 bits of each character are ignored, those Unicode decimal digits where the digit zero has four rightmost zero bits can also be packed by the instruction. For example, for Thai digits:

```
UNDIGITS  DS   0CL62
          DC   X'0E510E520E530E540E55'
          DC   X'0E560E570E580E590E50'
          DC   X'0E510E520E530E540E55'
          DC   X'0E560E570E580E590E50'
          DC   X'0E510E520E530E540E55'
          DC   X'0E560E570E580E590E50'
          DC   X'0E51'
PKDIGITS  DS   PL16
           ⋮
          PKU  PKDIGITS,UNDIGITS(62)
```

3. The storage-operand references for PACK UNICODE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

PERFORM CRYPTOGRAPHIC COMPUTATION

PCC [RRE]

'B92C'	////////////////
0	16 31

A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-304 on page 7-317 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

If the message-security-assist extension 9 is installed, elliptic curve scalar multiply is supported in PCC-Scalar-Multiply function codes 64, 65, 66, 72, 73, 80, and 81.

The function codes for PERFORM CRYPTOGRAPHIC COMPUTATION are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	PCC-Query	16	—
1	PCC-Compute-Last-Block-CMAC-Using-DEA	32	8
2	PCC-Compute-Last-Block-CMAC-Using-TDEA-128	40	8
3	PCC-Compute-Last-Block-CMAC-Using-TDEA-192	48	8
9	PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA	56	8
10	PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128	64	8

Figure 7-304. Function Codes for PERFORM CRYPTOGRAPHIC COMPUTATION (Part 1 of 2)

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)

Figure 7-304. Function Codes for PERFORM CRYPTOGRAPHIC COMPUTATION (Part 2 of 2)

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.

Figure 7-305 shows the contents of general registers 0 and 1.

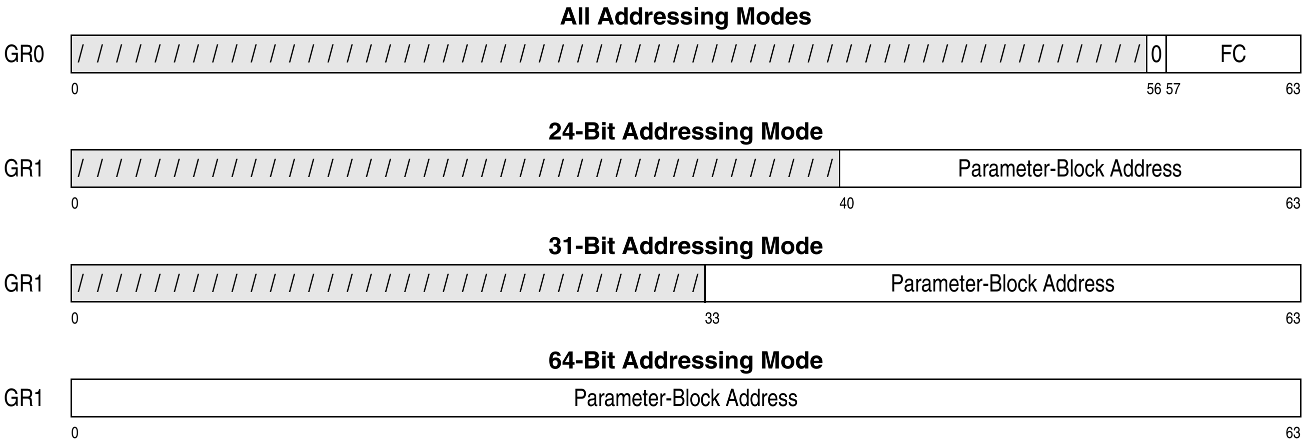

Figure 7-305. General Register Assignment for PCC

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by this CPU, other CPUs, and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the PERFORM CRYPTOGRAPHIC COMPUTATION functions. Further description of the AES standard may be found in Reference [14.] on page xxx. The XTS multiplication operation is the same as the GCM (Galois/counter mode) multiplication operation. Further description of the GCM multiplication over GF(2^{128}) may be found in Reference [17.] on page xxx.

PCC-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the function has the following format:

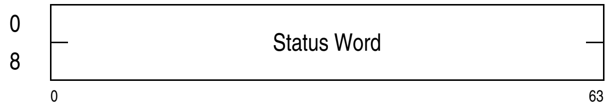

Figure 7-313. Parameter Block for PCC-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PCC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PCC-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

PCC-Compute-Last-Block-CMAC-Using-DEA (Function Code 1)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-DEA function has the following format:

0	ML	Reserved
8	Message	
16	Initial Chaining Value (ICV)	
24	Cryptographic Key (K)	
	0	63

Figure 7-314. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-DEA

For the PCC-Compute-Last-Block-CMAC-Using-DEA function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-31 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA function has the following format:

0	ML	Reserved
8	Message	
16	Initial Chaining Value (ICV)	
24	Encrypted Cryptographic Key ($WK_d(K)$)	
32 40 48	DEA Wrapping-Key Verification Pattern (WK_dVP)	
	0	63

Figure 7-315. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 64-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 64-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB $(L) = 0$, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB $(K_X) = 0$, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{64})

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 64-bit key and the DEA encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-316. Subkey Generation Algorithm

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-DEA function.

PCC-Compute-Last-Block-CMAC-Using-TDEA-128 (Function Code 2)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function has the following format:

0	ML	Reserved
8	Message	
16	Initial Chaining Value (ICV)	
24 32	Cryptographic Key (K)	
	0	63

Figure 7-317. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-TDEA-128

For the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-39 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function has the following format:

0	ML	Reserved
8	Message	
16	Initial Chaining Value (ICV)	
24 32	Encrypted Cryptographic Key $(WK_d(K))$	
40 48 56	DEA Wrapping-Key Verification Pattern (WK_dVP)	
	0	63

Figure 7-318. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function, the contents of byte offsets 40-63 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-39 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{64})

Figure 7-319. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 128-bit key and the TDEA-128 encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-319. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function.

PCC-Compute-Last-Block-CMAC-Using-TDEA-192 (Function Code 3)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function has the following format:

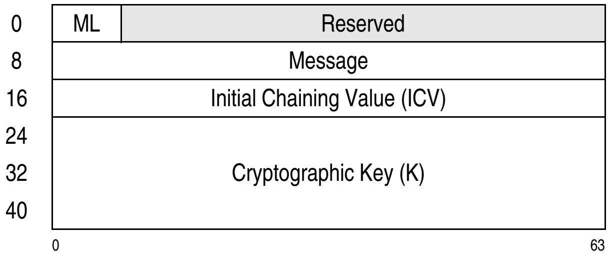

Figure 7-320. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-TDEA-192

For the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-47 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 function has the following format:

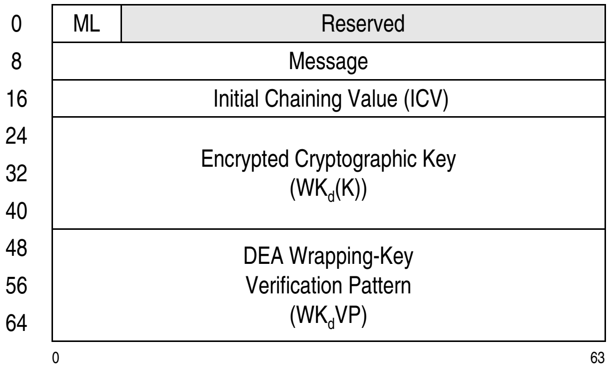

Figure 7-321. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 function, the contents of byte offsets 48-71 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-47 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB $(L) = 0$, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB $(K_X) = 0$, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{64})

Figure 7-322. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 192-bit key and the TDEA-192 encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-322. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function.

PCC-Compute-Last-Block-CMAC-Using-AES-128 (Function Code 18)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-128 function has the following format:

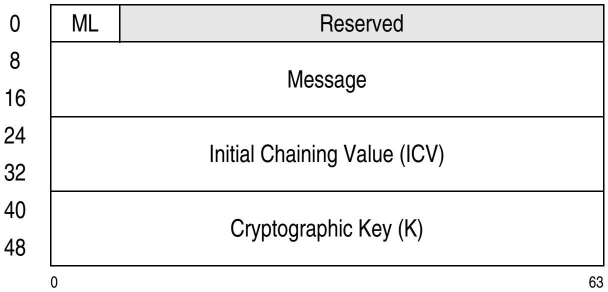

Figure 7-323. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-128

For the PCC-Compute-Last-Block-CMAC-Using-AES-128 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-55 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 function has the following format:

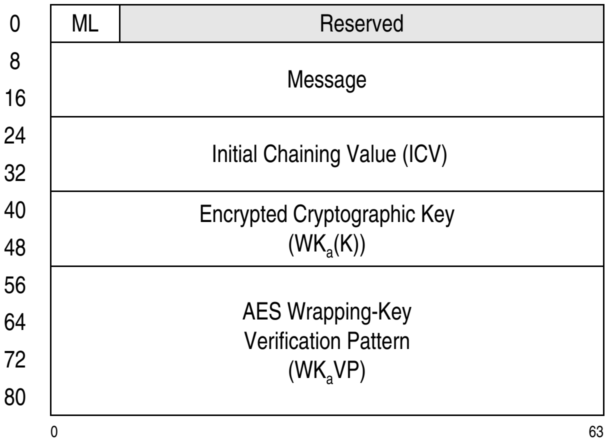

Figure 7-324. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 function, the contents of byte offsets 56-87 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-55 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_x, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{128})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{128})

Figure 7-325. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 128-bit key and the AES-128 encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{128}	A 128-bit value of 135.

Figure 7-325. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-128 function.

PCC-Compute-Last-Block-CMAC-Using-AES-192 (Function Code 19)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 (Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-192 function has the following format:

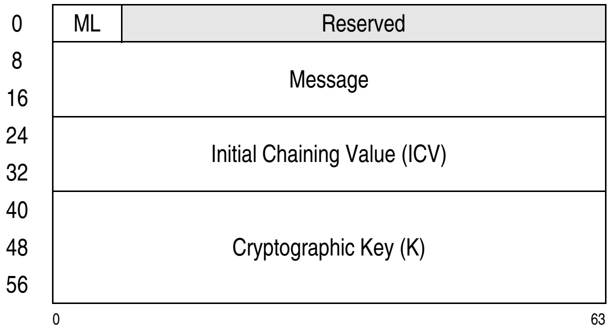

Figure 7-326. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-192

For the PCC-Compute-Last-Block-CMAC-Using-AES-192 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-63 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 function has the following format:

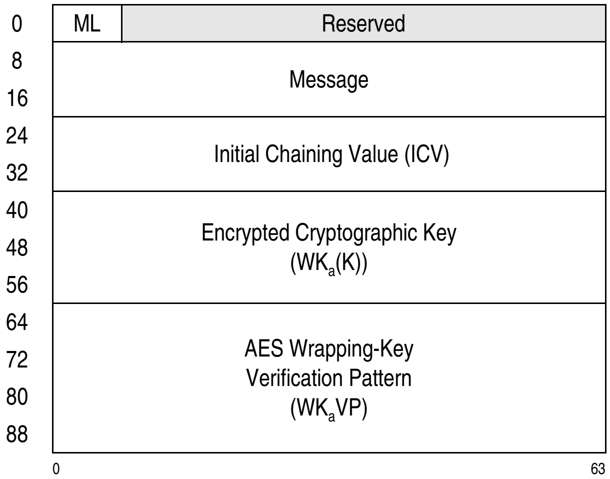

Figure 7-327. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 function, the contents of byte offsets 64-95 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-63 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_x, is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB $(L) = 0$, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{128})
3. If MSB $(K_X) = 0$, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{128})

Figure 7-328. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$ Encryption of the value zero using a 192-bit key and the AES-192 encryption algorithm.
MSB(A) Most significant (leftmost) bit of A
B<<1 The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR Bit-wise exclusive OR.
R_{128} A 128-bit value of 135.

Figure 7-328. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-192 function.

PCC-Compute-Last-Block-CMAC-Using-AES-256 (Function Code 20)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256(Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-256 function has the following format:

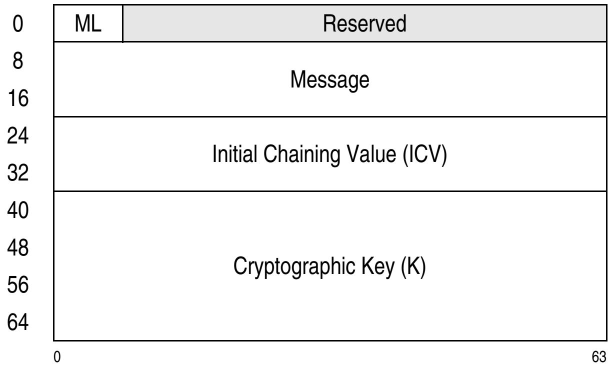

Figure 7-329. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-256

For the PCC-Compute-Last-Block-CMAC-Using-AES-256 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-71 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function has the following format:

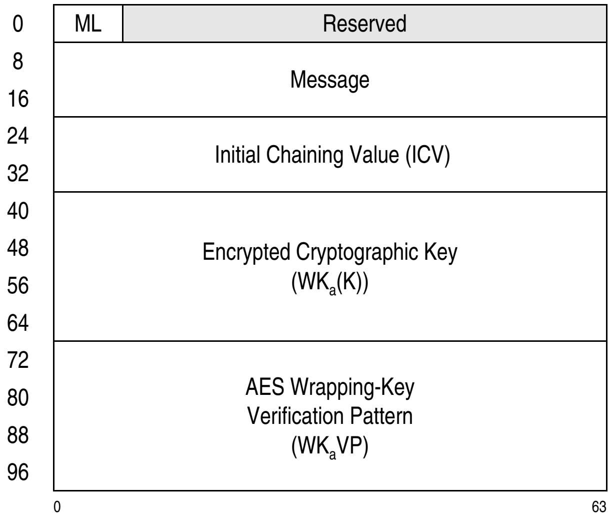

Figure 7-330. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function, the contents of byte offsets 72-103 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-71 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_x, is derived using the 256-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 256-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$;
   Else, $K_X = (L << 1)$ XOR (R_{128})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$;
   Else $K_Y = (K_X << 1)$ XOR (R_{128})

B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{128}	A 128-bit value of 135.

Figure 7-331. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, K, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, K, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-256 function.

PCC-Compute-XTS-Parameter-Using-AES-128 (Function Code 50)

PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 (Function Code 58)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-128 function has the following format:

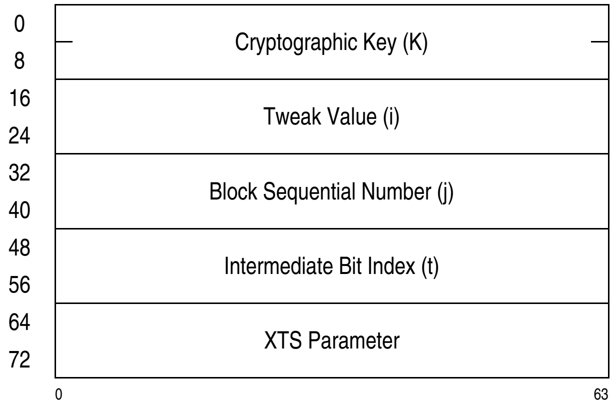

Figure 7-332. Parameter Block for PCC-Compute-XTS-Parameter-Using-AES-128

For the PCC-Compute-XTS-Parameter-Using-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block; the 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 16-31 and 32-47, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 48-79 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 64-79 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 48-63 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 48-63 are zero, then it is the initial execution of the computation, and the contents of byte offsets 64-79 of the parameter block are ignored; if the contents of byte offsets 48-63 are in the range between 1 and 127, inclusively, then byte offsets 64-79 contain the partial XTS parameter computed by a previous iteration; if byte offsets 48-63 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function has the following format:

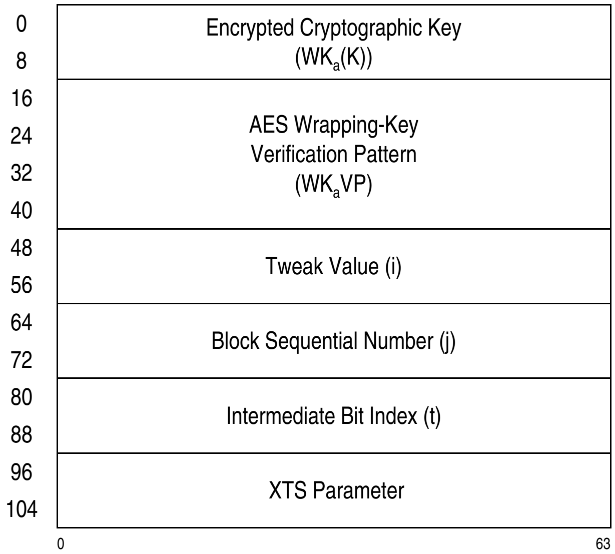

Figure 7-333. Parameter Block for PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128

For the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.) The 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 48-63 and 64-79, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 80-111 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 96-111 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 80-95 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 80-95 are zero, then it is the initial execution of the computation, and the contents of byte offsets 96-111 of the parameter block are ignored; if the contents of byte offsets 80-95 are in the range between 1 and 127, inclusively, then byte offsets 96-111 contain the partial XTS parameter computed by a previous iteration;

if byte offsets 80-95 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over GF(2^{128}). The 128-bit tweak value (i) is encrypted using the 128-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-334.

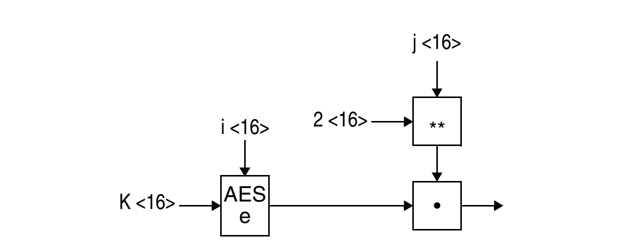

Figure 7-334. Compute XTS Parameter Using AES 128

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with an one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over GF(2^{128}).

For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the right most bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 64-79 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 96-111 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-128 function.

PCC-Compute-XTS-Parameter-Using-AES-256 (Function Code 52)

PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 (Function Code 60)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-305 on page 7-318.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-256 function has the following format:

	0 ... 63
0	Cryptographic Key (K)
8	
16	
24	
32	Tweak Value (i)

Figure 7-336. Parameter Block for PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256

For the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-431 for details.) The 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 64-79 and 80-95, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 96-127 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 112-127 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 96-111 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 96-111 are zero, then it is the initial execution of the computation, and the contents of byte offsets 112-127 of the parameter block are ignored; if the contents of byte offsets 96-111 are in the range between 1 and 127, inclusively, then byte offsets 112-127 contain the partial XTS parameter computed by a previous iteration; if byte offsets 96-111 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over $GF(2^{128})$. The 128-bit tweak value (i) is encrypted using the 256-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-337.

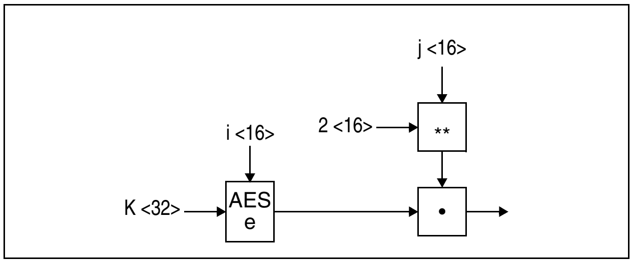

Figure 7-337. Compute XTS Parameter Using AES 256

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with an one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over $GF(2^{128})$.

For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the right most bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

PCC-Scalar-Multiply (Function Codes 64, 65, 66, 72, and 73)

Note: The description of the PCC-Scalar-Multiply instruction assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxx. This section illustrates the operation for five PCC-Scalar-Multiply functions:

- PCC-Scalar-Multiply-P256 (function code 64)
- PCC-Scalar-Multiply-P384 (function code 65)
- PCC-Scalar-Multiply-P521 (function code 66)
- PCC-Scalar-Multiply-Ed25519 (function code 72)
- PCC-Scalar-Multiply-Ed448 (function code 73)

The three functions with P256, P384, and P521 use NIST curves from Reference [24.] on page xxx. Also see Reference [27.] on page xxx section 5.4 p.17-18 for algorithm details and see D.1.2.3-5 in Reference [24.] on page xxx p.100 for the curve parameter values including the prime modulus, the order, the coefficient, the base point x coordinate, and the base point y coordinate used by these functions.

Two functions, PCC-Scalar-Multiply Ed25519 and Ed448 use twisted Edwards Curves using the EdDSA algorithm, see Reference [25.] on page xxx for algorithm details and curve parameter values, section 5.1 and 5.2 detail curve parameters for Ed25519 and Ed448 respectively.

The PCC-Scalar-Multiply function implements a scalar multiply of point on an elliptic curve as shown by the following:

- (Xr, Yr) <= d * (Xs, Ys)

where the input point is represented by the coordinates, Xs and Ys, is multiplied by a scalar, d, and results in the point represented by the coordinates Xr and Yr. The scalar multiply of a point can be accomplished by a series of point additions and point doublings along the elliptic curve. The bits of d are scanned from most significant to least significant. For every bit equal to one in the scalar, d, a point addition occurs and after each bit scanned a point doubling occurs and terminates on the scanning of the least significant bit and its possible point addition.

d equal to zero is a special case of point multiplication and results in infinity which can’t be represented with the two (Affine) coordinates Xr and Yr and instead is represented by setting condition code two and leaving the result unchanged.

The parameter block for PCC-Scalar-Multiply-P256 and Ed25519 functions is shown in Figure 7-338, below.

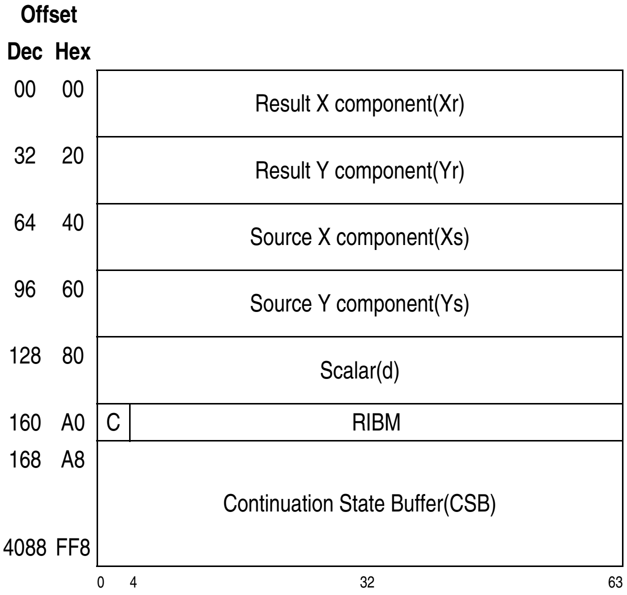

Figure 7-338. Parameter Block for PCC-Scalar-Multiply-P256 and Ed25519, Function

The parameter block for PCC-Scalar-Multiply-P384 function is shown in Figure 7-339, below.

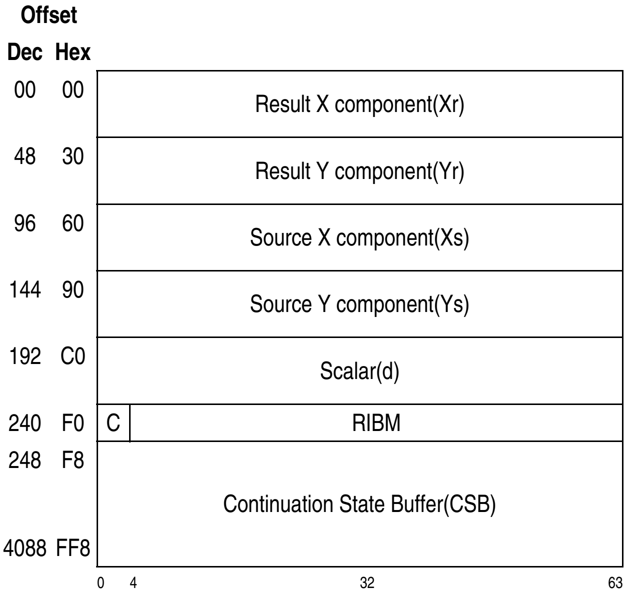

Figure 7-339. Parameter Block for PCC-Scalar-Multiply-P384 Function

The parameter block for PCC-Scalar-Multiply-P521 function is shown in Figure 7-340, below. The left most 14 bytes of the source operands are ignored, and for the result operands are not updated.

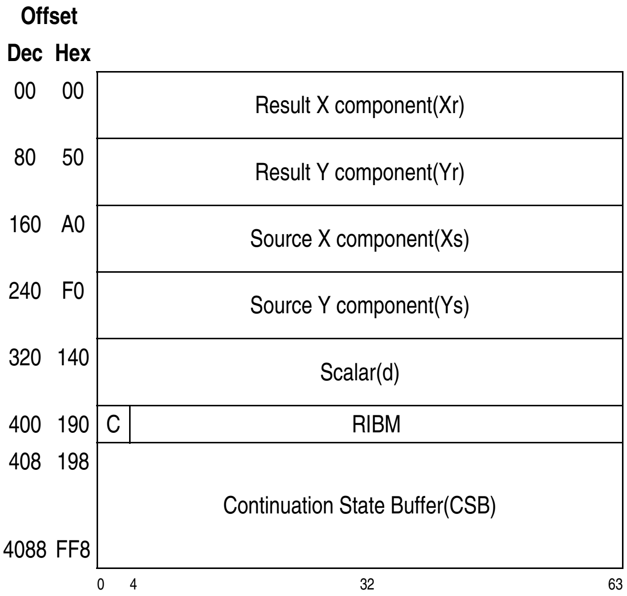

Figure 7-340. Parameter Block for PCC-Scalar-Multiply-P521 Function

The parameter block for PCC-Scalar-Multiply-Ed448 function is shown in Figure 7-341, below. The left most 8 bytes of each source operand is ignored and of each result operand is not updated.

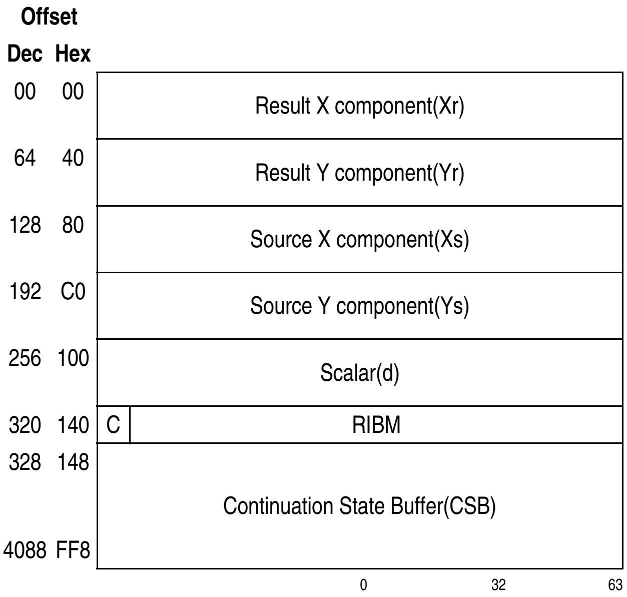

Figure 7-341. Parameter Block for PCC-Scalar-Multiply-Ed448 Function

Note that all fields are considered to be multiple bytes in width including Ed25519 and P521. The operands are right aligned within these bytes. And the most significant bits should be zero filled including 1 bit for Ed25519 format and 7 bits for P521 format. If these bits in the source operands are nonzero then the condition code is set to 1. The fields of the parameter block for all PCC-Scalar-Multiply function are as follows:

Result X component (Xr): This is the X component of the point on elliptic curve resulting from the multiply of scalar times the source point on curve. It is an integer greater than or equal to zero and less than the prime of the function and right aligned in this field. For P256, P384, and P521, are in Weierstrass form and for Ed25519 and Ed448 this coordinate is on an Edwards curve. Part of the result of PCC-Scalar-Multiply is stored to this field in the parameter block.

Result Y component (Yr): This is the Y component of the point on elliptic curve resulting from the multiply of scalar times the source point on curve. For P256, P384, and P521 this coordinate is on a Weierstrass curve and for Ed25519 and Ed448 this coordinate is on an Edwards curve. It is an integer greater than or equal to zero and less than the prime of the function and is right aligned in this field. Part of the result of PCC-Scalar-Multiply is stored to this field in the parameter block.

Source X component (Xs): This is the X component of the point on elliptic curve which is the source of the scalar multiply. For P256, P384, and P521, are in Weierstrass form and for Ed25519 and Ed448 this coordinate is on an Edwards curve. Xs is right aligned in this field and bytes to the left are ignored. Xs is an integer greater than or equal to zero and less than the prime of the function. For P256, P384, P521, Ed25519, and Ed448, if Xs is greater than or equal to the prime, the condition code is set to 1, or if the point is not on the curve.

Source Y component (Ys): This is the Y component of the point on elliptic curve which is the source of the scalar multiply. For P256, P384, and P521 this coordinate is in Weierstrass form, and for Ed25519 and Ed448 this coordinate is on an Edwards curve.Ys is right aligned in this field and bytes to the left are ignored and can be random values. Ys is an integer less than the prime of the function. If it is greater than or equal to the prime, the condition code is set to 1, or if the point is not on the curve.

Scalar (d): This is the source scalar to PCC-Scalar-Multiply function. d which is right aligned and bytes to the left are ignored. d is an unsigned integer. For P256, P384, and P521 the scalar has to be less than the order of the curve otherwise the condition code is set to 1. For Ed25519 the most significant bit of the most significant byte must be zero, for P521 the most significant 7 bits of the most significant byte must be zero otherwise the condition code is set to 1. For Ed448 the scalar can have any value. If d equals zero then the condition code is set to 2 to represent infinity.

Reserved for IBM use (RIBM), informational Code (C) and Continuation State Buffer (CSB): The C and RIBM must be initialized to zero prior to the first invocation of the instruction. The RIBM contains status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The CSB should not be altered by the programmer after partial completion and before subsequent invocation, otherwise intermediate results may be discarded causing long execution times. The CSB after a restart is cleared by the CPU of any intermediate state. The informational code, C, is reserved for future use.

Store-type access exceptions may be recognized for any location in the parameter block, even though only the Xr, Yr, RIBM, and CSB are stored by the instruction.

For P256, P384, P521, Ed25519, and Ed448 if Xs and Ys are zero or greater than or equal to the prime modulus, or not on the specified curve, or if P256, P384, or P521 and d is greater than or equal to the order of the curve, the condition code is set to 1 and the result is not updated. If d is equal to zero, the result is infinity which can not be represented with two coordinates, so the condition code is set to 2 and the result is not updated. Condition code 3 is set if the operation ends in partial completion and the parameter block may be updated. If none of these cases, Xr and Yr are updated and the condition code is set to 0.

PCC-Scalar-Multiply-Montgomery Form (Function Codes 80 and 81)

Note: The description of the PCC-Scalar Multiply for Montgomery Form function assumes that the reader is familiar with the Elliptic Curve Diffie-Hellman key exchange described in Reference [40.] on page xxxi.

This section illustrates the operation for two PCC-Scalar-Multiply functions using the Montgomery form of the curves:

- PCC-Scalar-Multiply-X25519 (function code 80)
- PCC-Scalar-Multiply-X448 (function code 81)

The two functions, PCC-Scalar-Multiply-X25519 and PCC-Scalar-Multiply-X448 use the ECDH algorithm and use curves defined in RFC-7748. Reference [40.] on page xxxi gives algorithm details and curve parameter values, section 4.1 and 4.2 gives curve parameters for X25519 and X448 respectively, which are used by these function codes. In Reference [40.] on page xxxi point coordinates are given on a Montgomery curve as (U, V) and on a twisted Edwards curve as (X, Y). For the PCC-Scalar-Multiply-X25519 and X448 functions the source and result coordinates are defined to be on the Montgomery form of the curve which uses the U and V coordinate naming in RFC-7748. The scalar multiplication function as defined in RFC-7748 has as input the scalar, d, and the U coordinate of a point, and the V coordinate is implied. The result is the U coordinate of the point produced. PCC-Scalar-Multiply-X25519 and X448 support this definition and the source and result V components do not appear in the parameter block. Also the source U component is assumed to be less than prime of the field.

The PCC-Scalar-Multiply function implements a scalar multiply of a point on an elliptic curve as shown by the following:

- (Ur, Vr) <= d * (Us, Vs)

where the input point represented by the coordinates, Us and Vs, is multiplied by a scalar, d, and results in the point represented by the coordinates Ur and Vr, where Vs and Vr are implied. The scalar multiply of a point can be accomplished by a series of point additions and point doublings along the elliptic curve. RFC-7748 gives a faster algorithm than using point additions and point doublings for special values of d. The scalar d must be of the form 2^254 + 8*k where k is between 0 and 2^251 -1 inclusive for X25519, and of the form 2^447 + 4*k where k is between 0 and 2^445 - 1 inclusive for X448. PCC-Scalar-Multiply-X25519 and X448 are unpredictable if the scalar d is not in this form or the U coordinate not less than the prime.

The parameter block for PCC-Scalar-Multiply-X25519 function is shown in Figure 7-342, below.

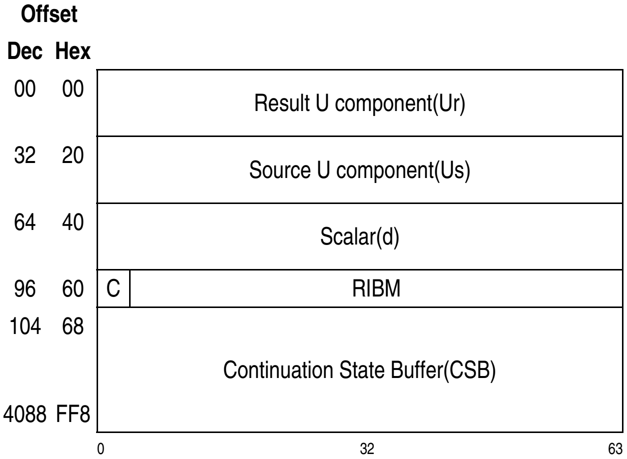

Figure 7-342. Parameter Block for PCC-Scalar-Multiply-X25519 Function

For X448 bytes 0 through 7 of the input operands are ignored. For both X25519 and X448 if Us is zero or greater than the prime modulus the condition code is set to 1, and the result is not updated; otherwise, Ur is updated and the condition code is set to 0.

The parameter block for PCC-Scalar-Multiply-X448 function is shown in Figure 7-343, below.

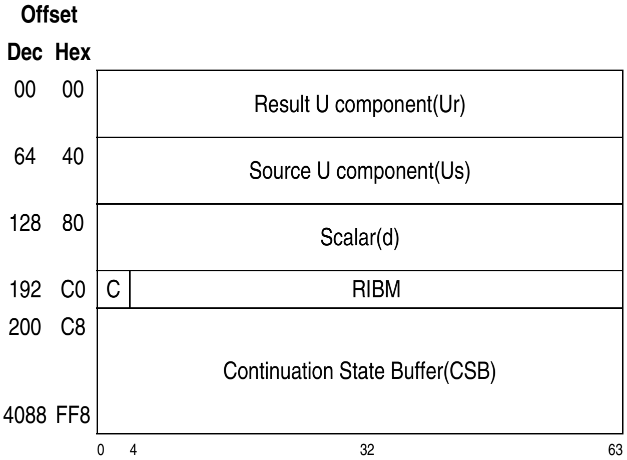

Figure 7-343. Parameter Block for PCC-Scalar-Multiply-X448 Function

Note that all the fields are considered to be multiple bytes in width including X25519 format. The most significant bit in X25519 is considered significant and should be zero otherwise the condition code is set to 1. The fields of the parameter block for all PCC-Scalar-Multiply functions are as follows:

Result U component (Ur): This is the U component of the point on the Montgomery form of the elliptic curve resulting from the multiply of scalar times the source point on curve. It is an integer greater than or equal to zero and less than the prime of the functions and right aligned in this field. The result of PCC-Scalar-Multiply is stored to this field in the parameter block. For X448 bytes 0 through 7 are not updated.

Source U component (Us): This is the U component of the point on the Montgomery form of the elliptic curve which is the source of the scalar multiply. Us is right aligned in this field and bytes to the left are ignored. Us is an integer less than the prime of the functions. If Us is greater than or equal to the prime, the condition code is set to 1. Note for X448 bytes 0 through 7 are ignored, though the most significant bit of X25519 format is significant and should be zero otherwise the condition code is set to 1.

Scalar (d): This is the source scalar to PCC-Scalar-Multiply function. d which is an unsigned integer and is right aligned and bytes to the left are ignored and can be random values. Note for X448 bytes 0 through 7 are ignored. Results are unpredictable if d is not of the form 2^254 + 8*k where k is between 0 and 2^251 -1 inclusive for X25519, and of the form 2^447 + 4*k where k is between 0 and 2^445 - 1 inclusive for X448. d should not be equal to zero.

Reserved for IBM use (RIBM), informational Code (C), and Continuation State Buffer (CSB): The C and RIBM must be initialized to zero prior to the first invocation of the instruction. The RIBM contains status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the programmer after partial completion and before subsequent invocation, otherwise the CPU may clear the CSB of intermediate status and results and end in partial completion which will allow a clean re-execution of the instruction. This results in longer execution. The CSB after a restart is cleared by the CPU of any intermediate state. The informational code (C) is reserved for future use on this instruction.

If Us is greater than or equal to the prime, condition code one is set and the result remains unchanged. Condition code 3 is set if the operation results in partial completion and the parameter block may be updated. If none of the above conditions, the result is updated and condition code zero is set. If d is not in the proper form the results are unpredictable.

Store-type access exceptions may be recognized for any location in the parameter block.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch or source operand out of range
2 Invalid bit index or message length, or for Scalar Multiply result is infinity for d equal to zero
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or bit 56 of general register 0 is not zero.
9.	Condition code 0 due to message length originally zero.
10.	Access exceptions for an access to the parameter block.

Figure 7-344. Priority of Execution: PCC

11.A Condition code 1 due to verification-pattern mismatch or source point Us, Xs, Ys coordinates out of range or (Xs,Ys) not on the curve. For scalar-multiply P256, P384, or P521 and scalar (d) greater than or equal to the order of the curve, condition code 1 is set. For scalar-multiply Ed25519 if bit 0 of d is 1 then condition code 1 is set.

11.B Condition code 2 due to invalid bit index or message length.

12. Condition code 2 due to scalar (d) equal to zero for scalar-multiply functions (infinity case).

13. Condition code 0 due to normal completion (message length originally nonzero, but stepped to zero).

14. Condition code 3 due to partial completion (message length still nonzero).

Figure 7-344. Priority of Execution: PCC (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. For the initial execution of a PCC Compute-XTS-Parameter function, the contents of the intermediate-bit-index (t) field in the parameter block shall be set to zeros.

Engineering Notes:

PERFORM LOCKED OPERATION

PLO $R_1,D_2(B_2),R_3,D_4(B_4)$ [SS-e]

'EE'	R_1	R_3	B_2	D_2	B_4	D_4
0	8	12	16	20	32	36 47

After the lock specified in general register 1 has been obtained, the operation specified by the function code in general register 0 is performed, and then the lock is released. However, as observed by other CPUs: (1) storage operands, including fields in a parameter list that may be used, may be fetched, and may be tested for store-type access exceptions if a store at a tested location is possible, before the lock is obtained, and (2) operands may be stored in the parameter list after the lock has been released. If an operand not in the parameter list is fetched before the lock is obtained, it is fetched again after the lock has been obtained.

The function code can specify any of six operations: compare and load, compare and swap, double compare and swap, compare and swap and store, compare and swap and double store, or compare and swap and triple store.

A test bit in general register 0 specifies, when one, that a lock is not to be obtained and none of the six operations is to be performed but, instead, the validity of the function code is to be tested. This will be useful if additional function codes for additional operations are assigned in the future. This definition is written as if the test bit is zero except when stated otherwise.

If compare and load is specified, the first-operand comparison value and the second operand are compared. If they are equal, the fourth operand is placed in the third-operand location. If the comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

If compare and swap is specified, the first-operand comparison value and the second operand are compared. If they are equal, the first-operand replacement value is stored at the second-operand location. If the comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

If double compare and swap is specified, the first-operand comparison value and the second operand are compared. If they are equal, the third-operand comparison value and the fourth operand are compared. If both comparisons indicate equality, the first-operand and third-operand replacement values are stored at the second-operand location and fourth-operand location, respectively. If the first comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value. If the first comparison indicates equality but the second does not, the fourth operand is placed in the third-operand-comparison-value location as a new third-operand comparison value.

If compare and swap and store, double store, or triple store is specified, the first-operand comparison value and the second operand are compared. If they are equal, the first-operand replacement value is stored at the second-operand location, and the third operand is stored at the fourth-operand location. Then, if the operation is the double-store or triple-store operation, the fifth operand is stored at the sixth-operand location, and, if it is the triple-store operation, the seventh operand is stored at the eighth-operand location. If the first-operand comparison indicates inequality, the second operand is placed in the first-operand-comparison-value location as a new first-operand comparison value.

After any of the six operations, the result of the comparison or comparisons is indicated in the condition code.

The function code (FC) is in bit positions 56-63 of general register 0. The function code specifies not only the operation to be performed but also the length of the operands and whether the first-operand comparison and replacement values and the third operand or third-operand comparison and replacement values, which are referred to collectively simply as the first and third operands, are in general registers or a parameter list. The pattern of the function codes is as follows:

- A function code that is a multiple of 4 (including 0) specifies a 32-bit length with the first and third operands in bit positions 32-63 of general registers.
- A function code that is one more than a multiple of 4 specifies a 64-bit length with the first and third operands in a parameter list.
- A function code that is 2 more than a multiple of 4 specifies a 64-bit length with the first and third operands in bit positions 0-63 of general registers.
- A function code that is 3 more than a multiple of 4 specifies a 128-bit length with the first and third operands in a parameter list.

Figure 7-345 on page 7-338 shows the function codes, operation names, and operand lengths, and also symbols that may be used to refer to the operations in discussions. For example, PLO.DCS may be used to mean PERFORM LOCKED OPERATION with function code 8. In the symbols, the letter “G” indicates a 64-bit operand length, the letter “R” indicates that some or all 64-bit operands are in general registers, and the letter “X” indicates a 128-bit operand length.

Function Code	Operation	Operand Length (Bits)	Function Symbol
0	Compare and load	32	CL
1	Same as 0	64	CLG
2	Same as 0	64	CLGR
3	Same as 0	128	CLX
4	Compare and swap	32	CS
5	Same as 4	64	CSG
6	Same as 4	64	CSGR
7	Same as 4	128	CSX
8	Double compare and swap	32	DCS
9	Same as 8	64	DCSG
10	Same as 8	64	DCSGR
11	Same as 8	128	DCSX
12	Compare and swap and store	32	CSST
13	Same as 12	64	CSSTG
14	Same as 12	64	CSSTGR
15	Same as 12	128	CSSTX
16	Compare and swap and double store	32	CSDST
17	Same as 16	64	CSDSTG
18	Same as 16	64	CSDSTGR
19	Same as 16	128	CSDSTX
20	Compare and swap and triple store	32	CSTST
21	Same as 20	64	CSTSTG
22	Same as 20	64	CSTSTGR
23	Same as 20	128	CSTSTX

Figure 7-345. PERFORM LOCKED OPERATION Function Codes and Operations

In the z/Architecture architectural mode, the CPU can perform all of the operations specified by the function codes listed in Figure 7-345. Function codes specifying operations that the CPU can perform are called valid. Function codes that have not been assigned to operations or that specify operations that the CPU cannot perform because the operations are not implemented (installed) are called invalid. In the ESA/390-compatibility mode, it is unpredictable whether the CPU can perform operations that are unique to the z/Architecture architectural mode (that is, function codes 2, 3, 6, 7, 10, 11, 14, 15, 18, 19, 22 and 23).

Bit 55 of general register 0 is the test bit (T). When bit 55 is zero, the function code in general register 0 must be valid; otherwise, a specification exception is recognized. When bit 55 is one, the condition code is set to 0 if the function code is valid or to 3 if the function code is invalid, and no other operation is performed. When the test operation is performed in the ESA/390-compatibility mode, function codes 2, 3, 6, 7, 10, 11, 14, 15, 18, 19, 22 and 23 result in condition code 3 being set.

Bits 32-54 of general register 0 must be all zeros; otherwise, a specification exception is recognized. When bit 55 of the register is one, this is the only exception that can be recognized. Bits 0-31 of general register 0 are ignored.

The lock to be used is represented by a program lock token (PLT) whose logical address is specified in general register 1. In the 24-bit addressing mode, the PLT address is bits 40-63 of general register 1, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, the PLT address is bits 33-63 of the register, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, the PLT address is bits 0-63 of the register.

The contents of general registers 0 and 1 described above are shown in Figure 7-346.

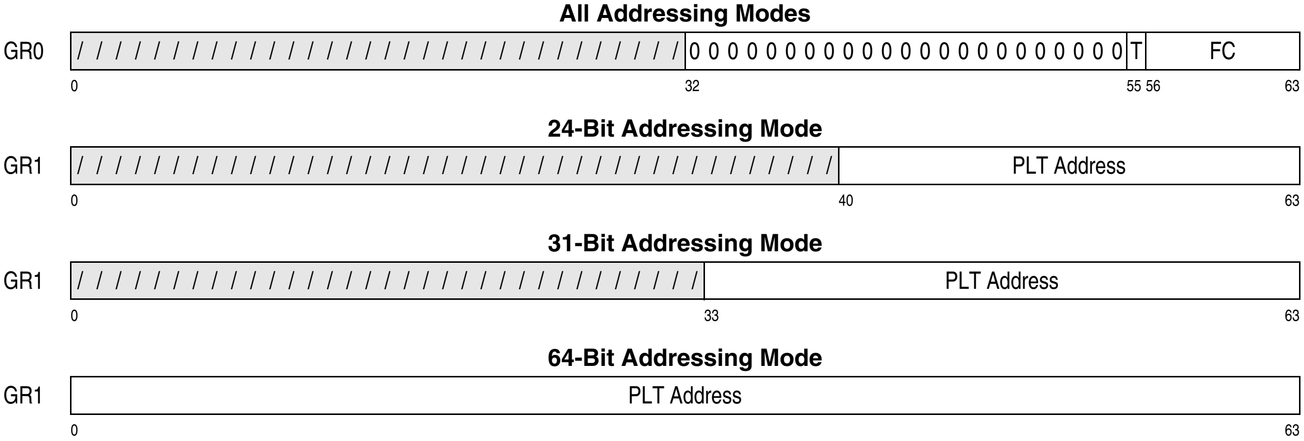

Figure 7-346. General Register Assignment for PLO

For the even-numbered function codes, including 0, the first-operand comparison value is in general register R_1. For the even-numbered function codes beginning with 4, the first-operand replacement value is in general register $R_1 + 1$, and R_1 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized. For function codes 0 and 2, R_1 can be even or odd.

For function codes 0, 2, 12, and 14, the third operand is in general register R_3, and R_3 can be even or odd.

For function codes 8 and 10, the third-operand comparison value is in general register R_3, the third-operand replacement value is in general register $R_3 + 1$, and R_3 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For all function codes, the B_2 and D_2 fields of the instruction specify the second-operand address.

For function codes 0, 2, 8, 10, 12, and 14, the B_4 and D_4 fields of the instruction specify the fourth-operand address.

For function codes 1, 3, 5, 7, 9, 11, 13, 15, and 16-23, the B_4 and D_4 fields of the instruction specify the address of a parameter list that is used by the instruction, and this address is not called the fourth-operand address. The parameter list contains odd-numbered operands, including comparison and replacement values, and addresses of even-numbered operands other than the second operand. In the access-register mode, the parameter list also contains access-list-entry tokens (ALETs) associated with the even-numbered-operand addresses.

In the access-register mode, for function codes that cause use of a parameter list containing an ALET, R_3 must not be zero; otherwise, a specification exception is recognized.

The rules about R_1 and R_3, and the use of the address specified by B_4 and D_4, are summarized in Figure 7-347 on page 7-340.

Function Codes	Operation	R_1	R_3	$D_4(B_4)$
0 and 2	Compare and load	EO	EO	Op4a
1 and 3	Compare and load	-	NZ	PLa
4 and 6	Compare and swap	E	-	-
5 and 7	Compare and swap	-	-	PLa
8 and 10	Double compare and swap	E	E	Op4a
9 and 11	Double compare and swap	-	NZ	PLa
12 and 14	Compare and swap and store	E	EO	Op4a
13 and 15	Compare and swap and store	-	NZ	PLa
16 and 18	Compare and swap and double store	E	NZ	PLa
17 and 19	Compare and swap and double store	-	NZ	PLa
20 and 22	Compare and swap and triple store	E	NZ	PLa
21 and 23	Compare and swap and triple store	-	NZ	PLa

Explanation:

-	Ignored.
E	Must be even.
EO	Can be even or odd.
NZ	Must be nonzero in the access-register mode. Ignored otherwise.
Op4a	D4(B4) is operand-4 address.
PLa	D4(B4) is parameter-list address.

Figure 7-347. Register Rules and $D_4(B_4)$ Usage for PERFORM LOCKED OPERATION

Figure 7-348 on page 7-341 shows the locations of the operands (including operand comparison and replacement values), operand addresses, and parameter-list address used by the instruction.

Operand addresses in a parameter list, if used, are in doublewords in the list. In the 24-bit addressing mode, an operand address is bits 40-63 of a doubleword, and bits 0-39 of the doubleword are ignored. In the 31-bit addressing mode, an operand address is bits 33-63 of a doubleword, and bits 0-32 of the doubleword are ignored. In the 64-bit addressing mode, an operand address is bits 0-63 of a doubleword.

In the access-register mode, access register 1 specifies the address space containing the program lock token (PLT), access register B_2 specifies the address space containing the second operand, and access register B_4 specifies the address space containing a fourth operand or a parameter list as shown in Figure 7-348 on page 7-341. Also, for an operand whose address is in the parameter list, an access-list-entry token (ALET) is in the list along with the address and is used in the access-register mode to specify the address space containing the operand.

In the access-register mode, if an access exception or PER storage-alteration event is recognized for an operand whose address is in the parameter list, the associated ALET in the parameter list is loaded into access register R_3 when the exception or event is recognized. Then, during the resulting program interruption, if a value is due to be stored as the exception access identification at real location 160 or the PER access identification at real location 161, R_3 is stored. If the instruction execution is completed without the recognition of an exception or event, the contents of access register R_3 are unpredictable. When not in the access-register mode, or when a parameter list containing an ALET is not used, the contents of access register R_3 remain unchanged.

Storage operand 2, and, when present, storage operands 4, 6, and 8 must be designated on an integral boundary, which is a word boundary for function codes that are a multiple of 4, a doubleword boundary for function codes that are one or 2 more than a multiple of 4, or a quadword boundary for function codes that are 3 more than a multiple of 4. A parameter list, if used, must be designated on a doubleword boundary. Otherwise, a specification exception is recognized. The program-lock-token (PLT) address in general register 1 does not have a boundary-alignment requirement.

All unused fields in a parameter list should contain all zeros; otherwise, the program may not operate compatibly in the future.

A serialization function is performed immediately after the lock is obtained and again immediately before it is released. However, values fetched from

Function					Op3			Op5	Op7	
Codes[1]	Operation	Op1c	Op1r	Op2a	or Op3c	Op3r	Op4a	and Op6a	and Op8a	PLa
0 and 2	Compare and load	R_1	-	$D_2(B_2)$	R_3		$D_4(B_4)$	-	-	-
1 and 3	Compare and load	PL	-	$D_2(B_2)$	PL		PL	-	-	$D_4(B_4)$
4 and 6	Compare and swap	R_1	R_1+1	$D_2(B_2)$	-		-	-	-	-

Explanation:

[1] For function codes that are a multiple of 4 (including 0) or one more than a multiple of 4, operands in general registers are in bit positions 32-63 of the registers, and bits 0-31 of the registers are ignored and remain unchanged. For function codes that are two more than a multiple of 4, operands in general registers are in bit positions 0-63 of the registers.

-	Operand, value, or address is not used in the operation.
OpNc	Operand-N comparison value.
OpNr	Operand-N replacement value.
OpNa	Operand-N address.
PL	Operand, value, or address is in the parameter list.
PLa	Parameter-list address.

Figure 7-348. Operand and Address Locations for PERFORM LOCKED OPERATION

the parameter list before the lock is obtained are not necessarily refetched. A serialization function is not performed if the test bit, bit 55 of general register 0, is one.

In the following figures showing the parameter lists for the different function codes, the offsets shown on the left are byte values.

Function Codes 0-3 (Compare and Load)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 1 has the following format:

Parameter List for Function Code 1

0		
8	Operand-1 Comparison Value	
16		
24		
32		
40	Operand 3	
48		
56		
64		Operand-4 ALET
72	Operand-4 Address	

The parameter list used for function code 3 has the following format:

Parameter List for Function Code 3

0	Operand-1 Comparison Value	
8	Operand-1 Comparison Value (continued)	
16		
24		
32	Operand 3	
40	Operand 3 (continued)	
48		
56		
64		Operand-4 ALET
72	Operand-4 Address	

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the third operand is replaced by the fourth operand, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

Function Codes 4-7 (Compare and Swap)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 5 has the following format:

Parameter List for Function Code 5

0	
8	Operand-1 Comparison Value
16	
24	Operand-1 Replacement Value

The parameter list used for function code 7 has the following format:

Parameter List for Function Code 7

0	Operand-1 Comparison Value
8	Operand-1 Comparison Value (continued)
16	Operand-1 Replacement Value
24	Operand-1 Replacement Value (continued)

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

Function Codes 8-11 (Double Compare and Swap)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 9 has the following format:

Parameter List for Function Code 9

0		
8	Operand-1 Comparison Value	
16		
24	Operand-1 Replacement Value	
32		
40	Operand-3 Comparison Value	
48		
56	Operand-3 Replacement Value	
64		Operand-4 ALET
72	Operand-4 Address	

The parameter list used for function code 11 has the following format:

Parameter List for Function Code 11

0	Operand-1 Comparison Value	
8	Operand-1 Comparison Value (continued)	
16	Operand-1 Replacement Value	
24	Operand-1 Replacement Value (continued)	
32	Operand-3 Comparison Value	
40	Operand-3 Comparison Value (continued)	
48	Operand-3 Replacement Value	
56	Operand-3 Replacement Value (continued)	
64		Operand-4 ALET
72	Operand-4 Address	

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the third-operand comparison value is compared to the fourth operand. When the third-operand comparison value is equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the first-operand replacement value is stored at the second-operand location, the third-operand replacement value is stored at the fourth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the third-operand comparison value is not equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the third-operand comparison value is replaced by the fourth operand, and condition code 2 is set.

Function Codes 12-15 (Compare and Swap and Store)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 13 has the following format:

Parameter List for Function Code 13

0		
8	Operand-1 Comparison Value	
16		
24	Operand-1 Replacement Value	
32		
40		
48		
56	Operand 3	
64		Operand-4 ALET
72	Operand-4 Address	

The parameter list used for function code 15 has the following format:

Parameter List for Function Code 15

0	Operand-1 Comparison Value	
8	Operand-1 Comparison Value (continued)	
16	Operand-1 Replacement Value	
24	Operand-1 Replacement Value (continued)	
32		
40		
48	Operand 3	
56	Operand 3 (continued)	
64		Operand-4 ALET
72	Operand-4 Address	

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, the third operand is stored at the fourth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

Function Codes 16-19 (Compare and Swap and Double Store)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 16 has the following format:

Parameter List for Function Code 16

<table>
<tr><td>0</td><td colspan="2"></td></tr>
<tr><td>8</td><td colspan="2"></td></tr>
<tr><td>16</td><td colspan="2"></td></tr>
<tr><td>24</td><td colspan="2"></td></tr>
<tr><td>32</td><td colspan="2"></td></tr>
<tr><td>40</td><td colspan="2"></td></tr>
<tr><td>48</td><td colspan="2"></td></tr>
<tr><td>56</td><td></td><td>Operand 3</td></tr>
<tr><td>64</td><td></td><td>Operand-4 ALET</td></tr>
<tr><td>72</td><td colspan="2">Operand-4 Address</td></tr>
<tr><td>80</td><td colspan="2"></td></tr>
<tr><td>88</td><td></td><td>Operand 5</td></tr>
<tr><td>96</td><td></td><td>Operand-6 ALET</td></tr>
<tr><td>104</td><td colspan="2">Operand-6 Address</td></tr>
</table>

The parameter list used for function code 17 has the following format:

Parameter List for Function Code 17

<table>
<tr><td>0</td><td colspan="2"></td></tr>
<tr><td>8</td><td colspan="2">Operand-1 Comparison Value</td></tr>
<tr><td>16</td><td colspan="2"></td></tr>
<tr><td>24</td><td colspan="2">Operand-1 Replacement Value</td></tr>
<tr><td>32</td><td colspan="2"></td></tr>
<tr><td>40</td><td colspan="2"></td></tr>
<tr><td>48</td><td colspan="2"></td></tr>
<tr><td>56</td><td colspan="2">Operand 3</td></tr>
<tr><td>64</td><td></td><td>Operand-4 ALET</td></tr>
<tr><td>72</td><td colspan="2">Operand-4 Address</td></tr>
<tr><td>80</td><td colspan="2"></td></tr>
<tr><td>88</td><td colspan="2">Operand 5</td></tr>
<tr><td>96</td><td></td><td>Operand-6 ALET</td></tr>
<tr><td>104</td><td colspan="2">Operand-6 Address</td></tr>
</table>

The parameter list used for function code 18 has the following format:

Parameter List for Function Code 18

<table>
<tr><td>0</td><td colspan="2"></td></tr>
<tr><td>8</td><td colspan="2"></td></tr>
<tr><td>16</td><td colspan="2"></td></tr>
<tr><td>24</td><td colspan="2"></td></tr>
<tr><td>32</td><td colspan="2"></td></tr>
<tr><td>40</td><td colspan="2"></td></tr>
<tr><td>48</td><td colspan="2"></td></tr>
<tr><td>56</td><td colspan="2">Operand 3</td></tr>
<tr><td>64</td><td></td><td>Operand-4 ALET</td></tr>
<tr><td>72</td><td colspan="2">Operand-4 Address</td></tr>
<tr><td>80</td><td colspan="2"></td></tr>
<tr><td>88</td><td colspan="2">Operand 5</td></tr>
<tr><td>96</td><td></td><td>Operand-6 ALET</td></tr>
<tr><td>104</td><td colspan="2">Operand-6 Address</td></tr>
</table>

The parameter list used for function code 19 has the following format:

Parameter List for Function Code 19

0	Operand-1 Comparison Value	
8	Operand-1 Comparison Value (continued)	
16	Operand-1 Replacement Value	
24	Operand-1 Replacement Value (continued)	
32		
40		
48	Operand 3	
56	Operand 3 (continued)	
64		Operand-4 ALET
72	Operand-4 Address	
80	Operand 5	
88	Operand 5 (continued)	
96		Operand-6 ALET
104	Operand-6 Address	

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, the third operand is stored at the fourth-operand location, the fifth operand is stored at the sixth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

Function Codes 20-23 (Compare and Swap and Triple Store)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-348 on page 7-341.

The parameter list used for function code 20 has the following format:

Parameter List for Function Code 20

0		
8		
16		
24		
32		
40		
48		
56		Operand 3
64		Operand-4 ALET
72	Operand-4 Address	
80		
88		Operand 5
96		Operand-6 ALET
104	Operand-6 Address	
112		
120		Operand 7
128		Operand-8 ALET
136	Operand-8 Address	

PERFORM LOCKED OPERATION

The parameter list used for function code 21 has the following format:

Parameter List for Function Code 21

0		
8	Operand-1 Comparison Value	
16		
24	Operand-1 Replacement Value	
32		
40		
48		
56	Operand 3	
64		Operand-4 ALET
72	Operand-4 Address	
80		
88	Operand 5	
96		Operand-6 ALET
104	Operand-6 Address	
112		
120	Operand 7	
128		Operand-8 ALET
136	Operand-8 Address	

The parameter list used for function code 22 has the following format:

Parameter List for Function Code 22

0		
8		
16		
24		
32		
40		
48		
56	Operand 3	
64		Operand-4 ALET
72	Operand-4 Address	
80		
88	Operand 5	
96		Operand-6 ALET
104	Operand-6 Address	
112		
120	Operand 7	
128		Operand-8 ALET
136	Operand-8 Address	

The parameter list used for function code 23 has the following format:

Parameter List for Function Code 23

<table>
<tr><td>0</td><td colspan="2">Operand-1 Comparison Value</td></tr>
<tr><td>8</td><td colspan="2">Operand-1 Comparison Value (continued)</td></tr>
<tr><td>16</td><td colspan="2">Operand-1 Replacement Value</td></tr>
<tr><td>24</td><td colspan="2">Operand-1 Replacement Value (continued)</td></tr>
<tr><td>32</td><td colspan="2"></td></tr>
<tr><td>40</td><td colspan="2"></td></tr>
<tr><td>48</td><td colspan="2">Operand 3</td></tr>
<tr><td>56</td><td colspan="2">Operand 3 (continued)</td></tr>
<tr><td>64</td><td></td><td>Operand-4 ALET</td></tr>
<tr><td>72</td><td colspan="2">Operand-4 Address</td></tr>
<tr><td>80</td><td colspan="2">Operand 5</td></tr>
<tr><td>88</td><td colspan="2">Operand 5 (continued)</td></tr>
<tr><td>96</td><td></td><td>Operand-6 ALET</td></tr>
<tr><td>104</td><td colspan="2">Operand-6 Address</td></tr>
<tr><td>112</td><td colspan="2">Operand 7</td></tr>
<tr><td>120</td><td colspan="2">Operand 7 (continued)</td></tr>
<tr><td>128</td><td></td><td>Operand-8 ALET</td></tr>
<tr><td>136</td><td colspan="2">Operand-8 Address</td></tr>
</table>

The first-operand comparison value is compared to the second operand. When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, the third operand is stored at the fourth-operand location, the fifth operand is stored at the sixth-operand location, the seventh operand is stored at the eighth-operand location, and condition code 0 is set.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

Locking

A lock is obtained at the beginning of the operation and released at the end of the operation. The lock obtained is represented by a program lock token (PLT) whose logical address is specified in general register 1 as already described.

A PLT is a value produced by a model-dependent transformation of the PLT logical address. Depending on the model, the PLT may be derived directly from the PLT logical address or, when DAT is on, from the real address that results from transformation of the PLT logical address by DAT. If DAT is used, access-register translation (ART) precedes DAT in the access-register mode.

A PLT selects one of a model-dependent number of locks within the configuration. Programs being executed by different CPUs can be assured of specifying the same lock only by specifying PLT logical addresses that are the same and that can be transformed to the same real address by the different CPUs.

Since a model may or may not use ART and DAT when forming a PLT, access-exception conditions that can be encountered during ART and DAT may or may not be recognized as exceptions. There is no accessing of a location designated by a PLT, but an addressing exception may be recognized for the location. A protection exception is not recognized for any reason during processing of a PLT logical address.

The CPU can hold one lock at a time.

When PERFORM LOCKED OPERATION is executed by this CPU and is to use a lock that is already held by another CPU due to the execution of a PERFORM LOCKED OPERATION instruction by the other CPU, the execution by this CPU is delayed until the lock is no longer held. An excessive delay can be caused only by a machine malfunction and is a machine-check condition.

The order in which multiple requests for the same lock are satisfied is undefined.

A nonrecoverable failure of a CPU while holding a lock may result in a machine check, entry into the check-stop state, or system check stop. The machine check is processing backup if all operands are undamaged or processing damage if register operands are damaged. If a machine check or the check-stop state is the result, either no storage operands have been changed or else all storage operands that were due to be changed have been correctly changed, and, in either case, the lock has been released. If the storage operands are not in either their correct original state or their correct final state, the result is system check stop.

Storage-Operand References

The accesses to the even-numbered storage operands appear to be word concurrent, as observed by other CPUs, for function codes that are a multiple of 4 or doubleword concurrent for function codes that are one, 2, or 3 more than a multiple of 4. The accesses to the doublewords in the parameter list appear to be doubleword concurrent, as observed by other CPUs, regardless of the function code.

As observed by other CPUs, all storage operands may be tested for access exceptions before a lock is obtained. (A channel program cannot observe a lock.)

As observed by other CPUs, in all operations except the compare-and-swap operation (which does not have a fourth operand), the fourth operand is accessed while the lock is held only if a comparison of the first-operand comparison value to the second operand while the lock is held has indicated equality. In these operations, the fourth operand is accessed before the lock is held only if a comparison of the first-operand comparison value to the second operand has indicated equality and only if, when DAT is on, an INVALIDATE PAGE TABLE ENTRY instruction executed by another CPU after the fetch of the second operand will not be the cause of a page-translation exception recognized for the fourth operand, which it will if it sets to one the page-invalid bit in the page-table entry for the fourth operand when this CPU does not have a TLB entry corresponding to that page-table entry. In the compare-and-swap-and-double-store and compare-and-swap-and-triple-store operations, the sixth operand, and also the eighth operand in the triple-store operation, are treated the same as the fourth operand described above. The reason for this specification about INVALIDATE PAGE TABLE ENTRY is given in programming note 7.

Provided that accessing of an operand is not prohibited as described in the preceding paragraph, store-type access exceptions may be recognized for the fourth, sixth, or eighth operands even when a store does not occur because of the results of a comparison. A storage-alteration PER event is recognized, and a change bit is set, only if a store occurs.

When a comparison is made between an operand comparison value and an operand before the lock is obtained and indicates inequality, the lock still is obtained. The condition code is set only as a result of a comparison made while the lock is held. When condition code 1 or 2 is set, the first-operand comparison value or third-operand comparison value is replaced only by means of a fetch of the second operand or fourth operand, respectively, made while the lock is held, as observed by other CPUs.

In those cases when a store is performed to the second-operand location and one or more of the fourth-, sixth-, and eighth-operand locations, the store to the second-operand location is always performed last, as observed by other CPUs and by channel programs.

Stores into the parameter list may be performed while the lock is held or after it has been released.

Access exceptions may be recognized for parameter-list locations even when the locations are not required in the operation. The locations are those beginning at offset 0 and extending up through the last location defined for the function code used.

For the compare-and-load and compare-and-swap operations, the operation is suppressed on all addressing and protection exceptions.

When a nonrecoverable failure of a CPU while holding a lock results in a machine check or entry into the check-stop state, either no storage operands have been changed or else all storage operands that were due to be changed have been correctly changed. The latter may be accomplished by repeating stores that were performed successfully before the failure. Therefore, there may be two single-access store references (possibly the store part of an update reference and then a store reference) to the store-type operands, with the first value stored equal to the second value stored.

Resulting Condition Code:

When test bit is zero:

0 All comparisons equal; replacement value or values stored or loaded
1 First-operand comparison not equal; first-operand comparison value replaced
2 -- (all operations except double compare and swap)
2 First-operand comparison equal but third-operand comparison not equal; third-operand comparison value replaced (double compare and swap)
3 --

When test bit is one:

0 Function code valid
1 --
2 --
3 Function code invalid

Program Exceptions:

- Access (for all function codes, fetch, except addressing and protection for PLT location, program lock token, model-dependent; for function codes 0-3, fetch, operand 2; for function codes 4-23, fetch and store, operand 2; for odd-numbered function codes, fetch and store, parameter list; for function codes 16, 18, 20, and 22, fetch, parameter list; for function codes 0-3, fetch, operand 4; for function codes 8-11, fetch and store, operand 4; for function codes 12-23, store, operand 4; for function codes 16-23, store, operand 6; for function codes 20-23, store, operand 8)
- Specification
- Transaction constraint

Programming Notes:

1. In configurations that support the transactional-execution facility, a transaction may provide benefits over the use of PERFORM LOCKED OPERATION, as follows:

   a. Transactional execution may provide improved performance over an equivalent code path that uses PLO.

   b. Transactional execution does not require the specification of a program lock token in general register 1.

   c. Transactional execution does not require the use of a parameter list for more complex operations.

   d. Transactional execution provides a much broader scope of operations that can be performed, all of which appear to execute in a block-concurrent manner as observed by other CPUs and the channel subsystem.

   e. The use of classic interlocked-access techniques on one CPU can correctly coexist with transactional execution on another CPU. This coexistence is not possible using PLO, as explained in programming note 4, below.

   If a program that uses PLO is changed to use transactional execution, then all occurrences of PLO that designate the same storage locations as the transaction should be changed to use transactional accesses to those locations if predictable storage results are to be obtained.

2. An example of the use of the PERFORM LOCKED OPERATION instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

3. When the contents of storage locations are changed by PERFORM LOCKED OPERATION instructions that are executed concurrently by different CPUs and that use the same lock, the changes to operands not in the parameter list will be completed by one of the CPUs before they are begun by the other CPU, depending on which CPU first obtains the lock.

4. The compare-and-swap functions of PERFORM LOCKED OPERATION are not performed by means of interlocked-update references. Concurrent store references by another CPU to the storage operands, even if they are interlocked-update references, will interfere unpredictably, in terms of the resulting register and storage contents, with the intended operation of PERFORM LOCKED OPERATION. All changes to the contents of the storage locations must be made by PERFORM LOCKED OPERATION instructions that use the same lock, if predictable storage results are to be obtained.

5. Because a nonrecoverable failure of a CPU while executing PERFORM LOCKED OPERATION may cause two stores of the same value to a store-type operand, a concurrent store made by another CPU to the same operand but not by executing PERFORM LOCKED OPERATION may be lost.

6. When programs in different address spaces are using the same lock when DAT is on, the programs must ensure that they are using PLT logical addresses that are the same and that will be translated to the same real address regardless of the address space in which a translation occurs. Otherwise, the programs may in fact use different locks.

7. The section “Storage-Operand References” on page 7-347 contains a specification concerning the INVALIDATE PAGE TABLE ENTRY (IPTE) instruction. The need for the specification is

shown by the following example that is possible without the specification.

a. CPU 1 begins to execute a PERFORM LOCKED OPERATION instruction with function code 8, which is referred to as PLO.DCS. Operand 2 is a location, Qtail, containing the address (the first-operand comparison value) of the last element, element X, on a queue, and operand 4 is a location in that element containing the address (0, the third-operand comparison value) of the next (nonexisting) element on the queue. The purpose of the PLO instruction is to enqueue an element by placing the address of the element (the first-operand and third-operand replacement values) in both operand 2 and operand 4. With the lock not held, the PLO instruction fetches operand 2 and compares it, with an equal result, to the first-operand comparison value.

b. CPU 2 completely executes a PLO.DCS instruction to dequeue element X, which is the only element on the queue, from the queue. The PLO instruction stores 0 in Qtail and also in Qhead, which is a location containing the address of the first element on the queue. The program on CPU 2 processes the dequeued element and then invokes the freemain service of the control program to deallocate the storage containing the element. The freemain service uses IPTE to set the page-invalid bit to one in the page-table entry for the page containing element X. The IPTE instruction immediately sets the page-invalid bit to one, and then it waits for the signal that all other CPUs have cleared their TLBs of entries corresponding to the page.

c. CPU 1 attempts to fetch operand 4. CPU 1 does not have a TLB entry for the operand-4 page. CPU 1 signals CPU 2 that the CPU 2 IPTE instruction may proceed.

d. CPU 2 completes its IPTE instruction. The program on CPU 2 sets a software bit in the page-table entry to one to indicate that the page has been freemained and that, therefore, a reference to the page should result in presentation by the control program of an addressing exception to the program making the reference.

e. CPU 1 attempts to do DAT for operand 4 and sees that the page-invalid bit is one. CPU 1 performs a program interruption indicating a page-translation exception. The exception handler sees that the software bit indicating freemained is one, and it presents an addressing exception to the CPU 1 program, which causes an abend of the program.

If CPU 1 had had a TLB entry for the page, its PLO instruction would not have been interrupted, and the comparison of the first-operand comparison value to the second operand while the lock was held would indicate that CPU 2 had changed the second operand. The PLO instruction would set condition code 1. If CPU 1 did not have a TLB entry but IPTE could not set the page-invalid bit to one while CPU 1 was executing an instruction, CPU 1 could successfully translate the operand-4 address and, again, discover while the lock was held that operand 2 had changed. The case when operand 2 points to element X but the freemained bit for the element-X page is one is a programming error.

8. For functions that use a parameter list in the access register mode, the value in the R_3 field of the instruction should be different from that of the B_2 and B_4 fields. Because access register R_3 is modified as a result of an access exception, subsequent re-execution of the instruction (for example, following the resolution of a page-translation exception) may yield unpredictable results if the R_3 field designates the same access register as that of the second operand or parameter list.

9. “Summary of PERFORM LOCKED OPERATION Results” on page 7-351 summarizes the results of the operation.

Op1c=Op2	Op3c=Op4	Cond Code	Action
Function Codes 0-3 (Compare and Load)			
No	-	1	Op2 → Op1c
Yes	-	0	Op4 → Op3
Function Codes 4-7 (Compare and Swap)			
No	-	1	Op2 → Op1c
Yes	-	0	Op1r → Op2
Function Codes 8-11 (Double Compare and Swap)			
No	-	1	Op2 → Op1c
Yes	No	2	Op4 → Op3c
Yes	Yes	0	Op1r → Op2 Op3r → Op4
Function Codes 12-15 (Compare and Swap and Store)			
No	-	1	Op2 → Op1c
Yes	-	0	Op1r → Op2 Op3 → Op4
Function Codes 16-19 (Compare and Swap and Double Store)			
No	-	1	Op2 → Op1c
Yes	-	0	Op1r → Op2 Op3 → Op4
			Op5 → Op6
Function Codes 20-23 (Compare and Swap and Triple Store)			
No	-	1	Op2 → Op1c
Yes	-	0	Op1r → Op2 Op3 → Op4
			Op5 → Op6
			Op7 → Op8

Figure 7-349. Summary of PERFORM LOCKED OPERATION Results

PERFORM PROCESSOR ASSIST

PPA R_1,R_2,M_3 [RRF-c]

'B2E8'	M_3	////	R_1	R_2
0	16	20	24	28 31

The M_3 field contains a 4-bit unsigned binary integer function code specifying the processor-assist function to be performed. The function codes for PERFORM PROCESSOR ASSIST are as follows.

Code	Meaning
0	Reserved
1	Transaction-abort assist
2-14	Reserved
15	In-order-execution assist

The operation of each assist function, and the registers used by the function are as follows:

Transaction-Abort Assist: When the function code in the M_3 field is 1 and the processor-assist facility is installed, the processor is requested to assist following an aborted nonconstrained transaction.

The program is expected to provide an unsigned 32-bit binary integer in bits 32-63 of general register R_1, specifying the number of times the nonconstrained transaction has been repeatedly aborted. Depending on the value of this integer, the processor may take escalating actions to increase the likelihood of successful completion of the transaction in a subsequent execution.

Bits 0-31 of general register R_1 are ignored, and bits 32-63 of the register are unchanged. General register R_2 is ignored, however the R_2 field of the instruction should contain zeros; otherwise, the program may not operate compatibly in the future.

In-order-execution assist: When the function code in the M_3 field is 15 and the PPA-in-order facility is installed, the processor is requested to complete processing all instructions prior to this PPA instruction, as observed by this CPU, before attempting storage-operand references for any instruction after this PPA instruction.

The R_1 and R_2 fields are ignored and the instruction is executed as a no-operation.

The in-order-execution assist does not necessarily perform any of the steps for architectural serialization described in the section “CPU Serialization” on page 5-130.

Reserved: Reserved function codes should not be specified; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (neither the PPA-in-order facility nor the processor-assist facility is installed)
- Transaction constraint

Programming Notes:

1. For the transaction-abort-assist function, a larger value in general register R_1 does not necessarily guarantee successful completion when the transaction is reexecuted, and it may unnecessarily delay the CPU. Therefore, the program should provide an accurate count of the number of times a transaction has been aborted in the register.

   A value of one in bits 32-63 of general register R_1 means that the transaction has been aborted once, a value of two means the transaction has been aborted twice, and so forth.

2. An example of the use of PERFORM PROCESSOR ASSIST is shown in programming note 2 on page 5-106.

3. The processor-assist facility is indicated by facility bit 49.

4. The in-order-execution assist is designed to be used to prevent the out of order execution of conditional paths.

PERFORM RANDOM NUMBER OPERATION

PRNO	R_1,R_2	[RRE]
PPNO	R_1,R_2	[RRE]

'B93C'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are reserved and should contain zeros; otherwise, the instruction may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-350 shows the assigned function codes for PERFORM RANDOM NUMBER OPERATION. All other function codes are unassigned.

Code	Function	Parameter Block Size (bytes)
0	PRNO Query	16
3	PRNO-SHA-512-DRNG	240
112	PRNO-TRNG-Query-Raw-to-Conditioned-Ratio	8
114	PRNO-TRNG	—

Explanation:

— Not applicable to the function.
DRNG Deterministic random-number generation.
TRNG True random-number generation.

Figure 7-350. Function Codes for PERFORM RANDOM NUMBER OPERATION

If bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

The PRNO-query function provides the means of indicating the availability of the other functions.

For the PRNO-SHA-512-DRNG function, bit 56 of general register 0 is the modifier bit. When the modifier bit is zero, a generate operation is performed, and when the modifier bit is one, a seed operation is performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

Depending on the function, a parameter block, first operand, and second operand in storage may be accessed by the instruction. When applicable, general register 1 contains the address of the leftmost byte of the parameter block in storage. When applicable, general registers R_1 and R_2 designate an even-odd pair of general registers corresponding to the first and second operands, respectively. The even-numbered register contains the address of the operand in storage, and the odd-numbered register contains the length of the operand. The storage location corresponding to an operand is only accessed when the length of the corresponding operand is nonzero.

All general registers that contain an address are subject to the current addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address of the storage location, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address of the storage location, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register constitute the address of the storage location. In the access register mode, general register 1, R_1, and R_2 specifies the address space containing the parameter block, first operand, and second operand, respectively.

The odd-numbered registers containing an operand's length are also subject to the current addressing mode. In either the 24- or 31-bit addressing mode, the contents of bit positions 32-63 of the register form a 32-bit unsigned binary integer which specifies the number of bytes in the storage operand, and bit positions 0-31 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register form a 64-bit unsigned binary integer which specifies the number of bytes in the storage operand.

For the PRNO-SHA-512-DRNG function's generate operation, the first-operand length is updated in general register $R_1 + 1$ at the completion of the instruction. The first-operand address in general register R_1 is not updated by the PRNO-SHA-512-DRNG function; however in the 24-bit addressing mode, bits 32-39 may be set to zero or remain unchanged, and in the 31-bit addressing mode, bit 32 may be set to zero or remain unchanged, regardless of the first-operand length.

For the PRNO-TRNG function, the first-operand address, first-operand length, second-operand address, and second-operand length in general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, respectively, are updated at the completion of the instruction. In the 24-bit addressing mode, bits 40-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand, bits 0-31 of the register remain unchanged, and regardless of the operand's length, bits 32-39 of the register may be set to zero or may remain unchanged. In the 31-bit addressing mode, bits 33-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand, bits 0-31 of the register remain unchanged, and regardless of the operand's length, bit 32 of the register may be set to zero or may remain unchanged. In the 64-bit addressing mode, bits 0-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand. In either the 24- or 31-bit addressing mode, bits 32-63 of the odd-numbered register are decremented by the number of bytes processed for the respective operand, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 0-63 of the odd-numbered register are decremented by the number of bytes processed for the respective operand.

Figure 7-351 shows the contents of the general registers just described.

Depending on the function code in general register 0, one or more registers designating the parameter block, first operand, or second operand may not be

D The register is decremented by the number of bytes processed by the instruction.

F Fetch access

I The register is incremented by the number of bytes processed by the instruction. Note, general register R_1 is not incremented for PRNO-SHA-512-DRNG generate operation.

O_1A When the first-operand length is nonzero, the address of the leftmost byte of the first operand; otherwise, not applicable.

O_1L First-operand length.

O_2A When the second-operand length is nonzero, the address of the leftmost byte of the second operand; otherwise, not applicable.

O_2L Second-operand length.

PBA Address of the leftmost byte of the parameter block.

S Store access.

Figure 7-352. Summary of Register Usage for PRNO Functions

When the parameter block overlaps any portion of the storage operands, the results are unpredictable.

When the R_1 or R_2 field is not applicable to a function (as shown in Figure 7-352), any storage location designated by the respective operand is not accessed, and access exceptions and PER zero-address-detection events are not recognized for the location. When an applicable storage-operand length is zero, access exceptions for the storage-operand location are not recognized. However, for functions that access the parameter block, the parameter block is accessed even when the storage-operand length is zero.

As observed by other CPUs and the I/O subsystem, references to the parameter block and storage operands may be multiple-access references, accesses to these locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

A PER storage-alteration event is recognized only for the portion of the parameter block that is stored. For functions that store to the first- or second-operand locations, when a PER storage-alteration event is recognized, fewer than 4K additional bytes are stored into the respective locations before the event is reported. When a PER storage-alteration event is recognized for any combination of the first-operand location, the second-operand location, and the portion of the parameter block that is stored, it is unpredictable which of these locations is indicated in the PER access identification (PAID) and PER ASCE ID (AI). Similarly, when a PER zero-address-detection event is recognized for any combination of the first-operand location, the second-operand location, and the parameter block, it is unpredictable which of these locations is identified in the PAID and AI.

PRNO-Query (PRNO Function Code 0)

The contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$ are ignored by the query function.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-351 on page 7-354.

The parameter block used for the function has the following format:

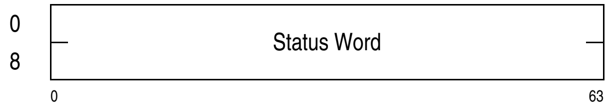

Figure 7-353. Parameter Block for PRNO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PERFORM RANDOM NUMBER OPERATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PRNO-Query function completes; condition code 3 is not applicable to this function.

PRNO-SHA-512-DRNG (PRNO Function Code 3)

Depending on the modifier bit, bit 56 of general register 0, the PRNO-SHA-512-DRNG function performs either a deterministic pseudorandom-number generate operation or a deterministic pseudorandom-number seed operation using the 512-bit secure-hash algorithm (SHA-512).

Deterministic pseudorandom-number generation, also known as deterministic random-bit generation, is defined in Reference [18.] on page xxx; refer to this publication for further description on terms used in this definition. Further description of the secure hash algorithm may be found in Reference [15.] on page xxx.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-351 on page 7-354.

The parameter block used for the function represents the internal state of a deterministic random-number generator and has the following format:

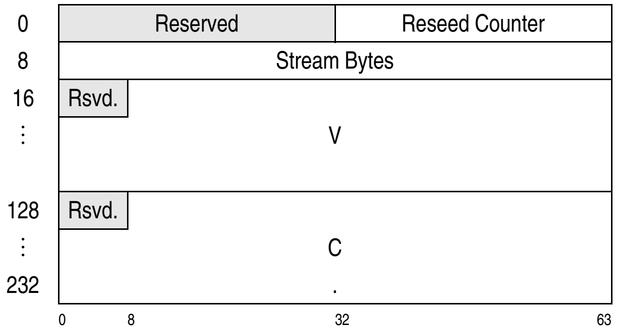

Figure 7-354. Parameter Block for PRNO-SHA-512-DRNG Function

The same parameter block format is used by both the generate operation and the seed operation (including instantiation and reseeding). A parameter block containing all zeros is considered to be not instantiated. The program should zero the parameter block prior to issuing the seed operation to instantiate the parameter block, and subsequently, the program should not alter the contents of the parameter block except to zero it; otherwise, unpredictable results may be produced by the instruction.

Reserved: Bytes 0-3, 16, and 128 of the parameter block are reserved. As observed by other CPUs and the I/O subsystem, the contents of byte 16 may appear to change during the execution of the instruction; however, byte 16 will contain zero when the instruction completes with condition code 0. As observed by other CPUs and the I/O subsystem, the contents of byte 128 may appear to change during the execution of the seed operation, however, byte 128 will contain zero at the completion of the seed operation.

Reseed Counter: Bytes 4-7 of the parameter block contain a 32-bit unsigned binary integer indicating the number of times that the instruction has completed with condition code 0 since the parameter block was last instantiated or reseeded.

When the reseed counter contains zero, the parameter block is considered to be not instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be instantiated with initial values, including setting the reseed counter to a value of one.
- Execution of the generate operation results in a general-operand data exception being recognized.

When the reseed counter contains a nonzero value, the parameter block is considered to be instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be reseeded, including resetting the reseed counter to a value of one.
- Execution of a generate operation that results in condition code 0 causes the reseed counter to be incremented by one; any carry out of bit position 0 of the reseed-counter field is ignored.

Stream Bytes: Bytes 8-15 of the parameter block contain a 64-bit unsigned binary integer. The stream-bytes field is set to zero by the execution of the seed operation when instantiating the parameter block (that is, when the reseed counter is zero); the field is not changed by the execution of the seed operation when the parameter block is already instantiated.

Partial or full completion of a generate operation causes the contents of the stream-bytes field to be incremented by the number of bytes stored into the first operand; any carry out of bit position 0 of the stream-bytes field is ignored.

Value (V): Bytes 17-127 of the parameter block contains an 888-bit value indicating the internal state of the random-number generator represented by the parameter block. V is initialized by the execution of the seed operation when instantiating the parameter block. V is updated by either (a) the execution of the seed operation when the reseed counter is nonzero, or (b) the execution of the generate operation that ends in condition code 0.

Constant (C): Bytes 129-239 of the parameter block contain an 888-bit value indicating the internal state of the random-number generator represented by the block. C is initialized by the execution of the seed operation, and inspected by the generate operation.

PRNO-SHA-512-DRNG Seed Operation

The PRNO-SHA-512-DRNG seed operation instantiates or reseeds a deterministic-pseudorandom-number-generation parameter block using the 512-bit secure-hash algorithm.

Depending on whether the reseed counter in bytes 4-7 of the parameter block is zero or nonzero, an instantiation or reseeding operation is performed, respectively.

- For the instantiation operation, the second operand in storage contains entropy input, nonce, and an optional personalization string, used to form seed material.
- For the reseed operation, the second operand in storage contains entropy input and optional additional input, used to form the seed material.

See Reference [18.] on page xxx for the definition and usage of entropy input, nonce, personalization string, and additional input, and for details on the algorithms used. The length of the second operand in general register $R_2 + 1$ must not exceed 512 bytes, otherwise, a specification exception is recognized.

When performing an instantiation operation, seed material is formed using only the second operand. When performing a reseeding operation, seed material is formed from a concatenation of the value 01 hex, the V field of the parameter block, and the second operand. The formation of the seed material is illustrated in Figure 7-355.

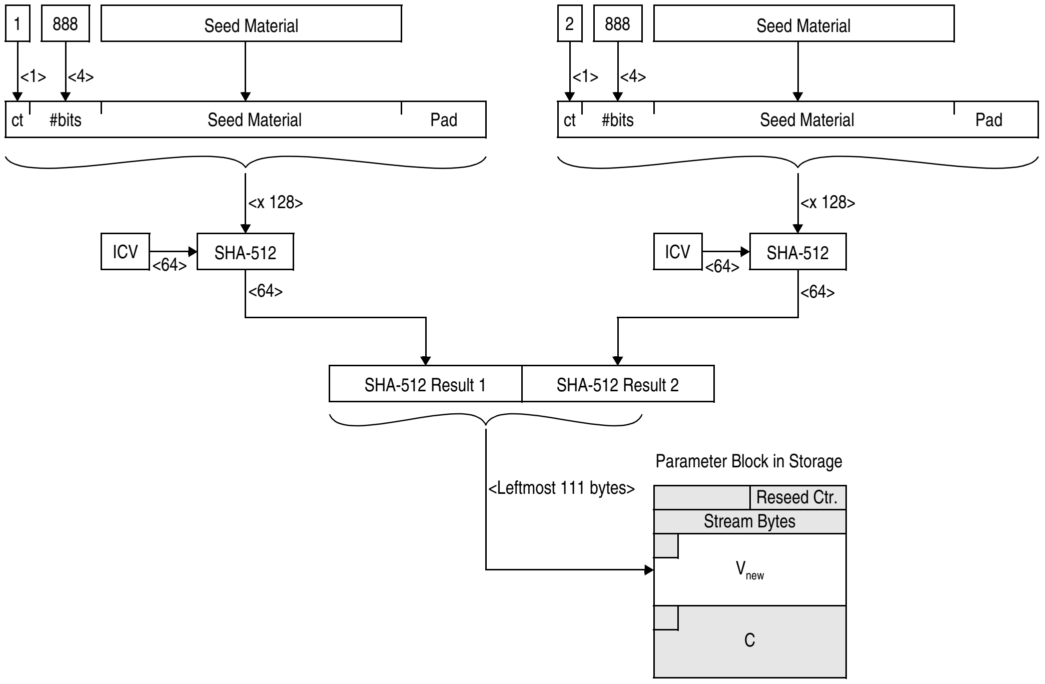
Figure 7-355. PRNO-SHA-512-DRNG Function’s Seed Operation Generation of Seed Material

For either the instantiation or reseeding operation, a new value field (V_{new}) is formed as follows: A one byte counter, four-byte value of 888, the seed material, and padding are used as input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 0-127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, and the seed material). The SHA-512 algorithm is invoked twice to form two 64-bit hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new value field (V_{new}) in the parameter block. The generation of V_{new} is illustrated in Figure 7-356.



Explanation:

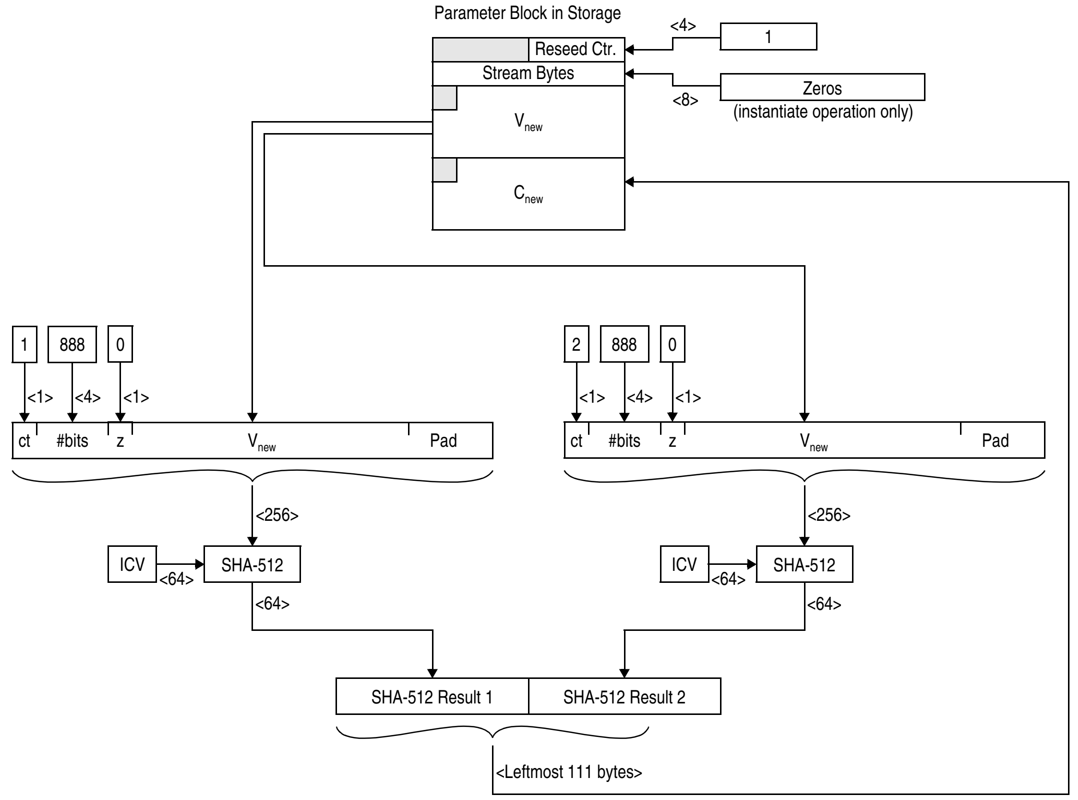
#bits 32-bit count of bits to be produced by the SHA-512 algorithm: 888 bits (378 hex)
<#> Length of the field in bytes.
<x #> Length of the field is a multiple of # bytes.
ct 8-bit counter used by the hash-derivation function (hash_df, defined in Reference [18.] on page xxx).
ICV Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-199.
Pad Variable number of pad bytes, beginning with 80 hex, followed by 0-127 bytes of zeros, followed by a 16-byte binary integer representing the length in bits of the input to the SHA-512 algorithm not including the padding. An appropriate number of zero bytes are inserted such that the length of the input to the SHA-512 algorithm is a multiple of 128 bytes.

Figure 7-356. PRNO-SHA-512-DRNG Function's Seed Operation Formation of New Value (V_{new})

Similar to the formation of the V_{new} field, the new constant field (C_{new}) is formed during both the instantiation or reseeding operation. A one byte counter, four-byte value of 888, one byte value of zero, the V_{new} field, and padding are concatenated to form input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 122 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, one-byte value of zero, and the V_{new} field). The SHA-512 algorithm is invoked twice to form two 64-bit hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new constant field (C_{new}) in the parameter block.

For either the instantiate or reseeding operation, the reseed-counter field in the parameter block is set to a value of one. For the instantiate operation only, the stream-bytes field in the parameter block is set to zeros; the stream-bytes field remains unchanged by a reseeding operation.

The generation of C_{new} and the initialization of the reseed-counter and stream-bytes fields is illustrated in Figure 7-357.



Explanation:

Figure 7-357. PRNO-SHA-512-DRNG Function's Seed Operation Formation of New Constant (C_{new}) and Initialization of the Reseed-Counter and Stream-Bytes Fields

Condition code 0 is set when execution of the PRNO-SHA-512-DRNG function's seed operation completes; condition code 3 is not applicable to the seed operation.

PRNO-SHA-512-DRNG Generate Operation

If the reseed counter in the parameter block is zero, a general-operand data exception is recognized and the operation is suppressed.

General register R_1 contains the address of the *leftmost* byte of the first operand. When the first-operand length in general register $R_1 + 1$ is nonzero, the first operand is formed in right-to-left order in units of 64-byte blocks, except that the rightmost block may contain fewer than 64 bytes. The number of blocks to be stored, including any partial rightmost block, is determined by rounding the first-operand length in general register $R_1 + 1$ up to a multiple of 64 and dividing this value by 64. The blocks of the first operand are numbered from left to right as 0 to n–1, where n–1 represents the rightmost block. The following procedure is performed for each block of the first-operand location, beginning with the rightmost (n–1) block and proceeding to the left.

1. The value (V) from the parameter block is added to the block number being processed, with any overflow from the addition ignored.
2. The 111-byte sum of this addition, concatenated with 17 bytes of padding, are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The 17-byte padding provided to the SHA-512 algorithm consists of a value of 80 hex followed by a 16-byte binary integer value of 888 (the length of V in bits).
3. If the first-operand length in general register $R_1 + 1$ is a multiple of 64, then the resulting 64-byte hashed value is stored in the respective block of the first-operand location, and the length in general register $R_1 + 1$ is decremented by 64.

   If the first-operand length is not a multiple of 64, then the leftmost *m* bytes of the resulting 64-byte hashed value is stored in the rightmost partial block of the first operand, where *m* represents the remainder of the first-operand length divided by 64. In this case, the length in general register $R_1 + 1$ is decremented by *m*.
4. Regardless of whether a full or partial block is stored, the stream-bytes field in bytes 8-15 of the parameter block is incremented by the number of bytes stored into the first-operand location.

The above process is repeated until either the first-operand length in general register $R_1 + 1$ is zero (called normal completion) or a CPU-determined number of blocks has been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The process of generating the deterministic pseudorandom numbers in the first operand is shown in Figure 7-358.

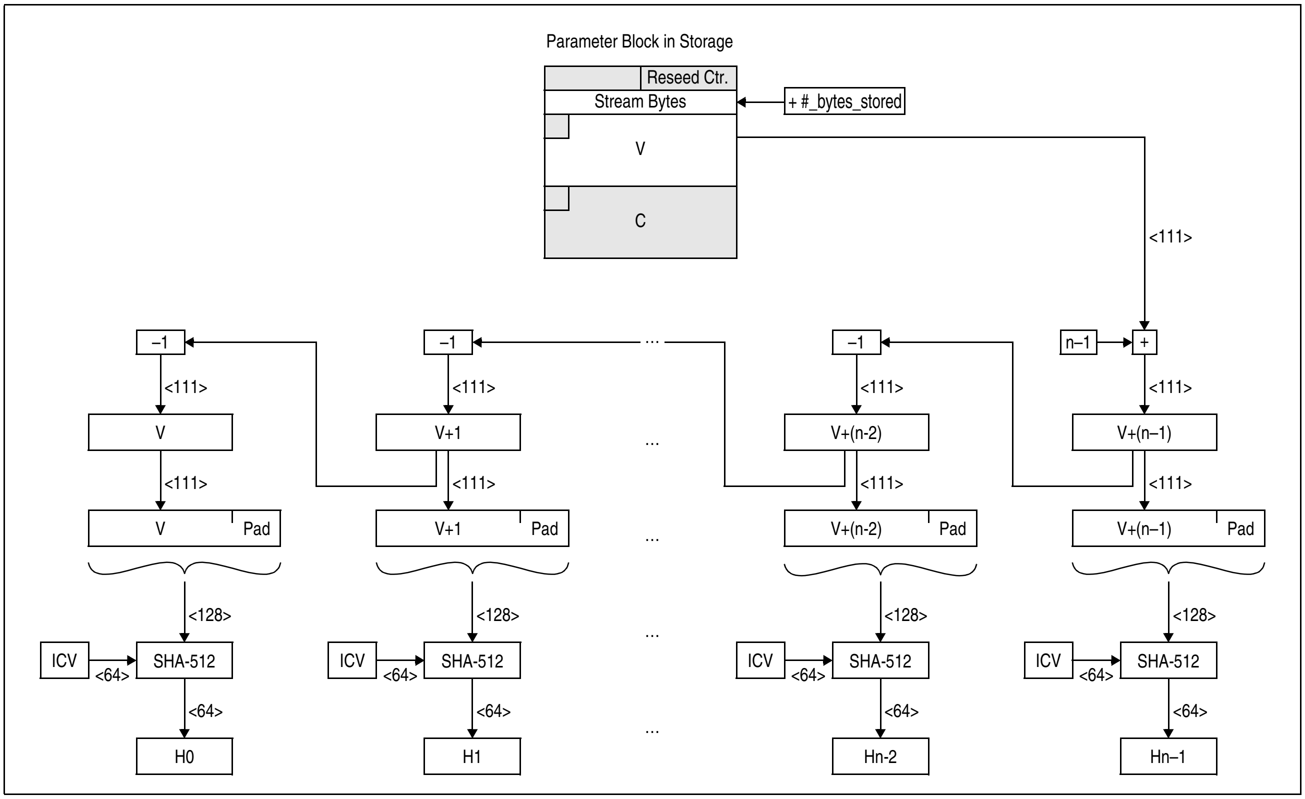

Figure 7-358. PRNO-SHA-512-DRNG Function's Generate Operation Generation of Deterministic Pseudorandom Numbers (Part 1 of 2)

Explanation:

<#> Length of field in bytes.
Hn 64-byte hashed value stored in the first-operand location; the rightmost value (Hn–1) may contain fewer than 64 bytes.
ICV Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-199.
n Number of 64-byte blocks in the first operand; n is equal to the integer quotient of ((length in general register R_1 + 1) + 63) ÷ 64.
Pad Pad bytes, beginning with 80 hex, followed by a 16-byte unsigned binary integer representing the length of V in bits: 888 (378 hex).

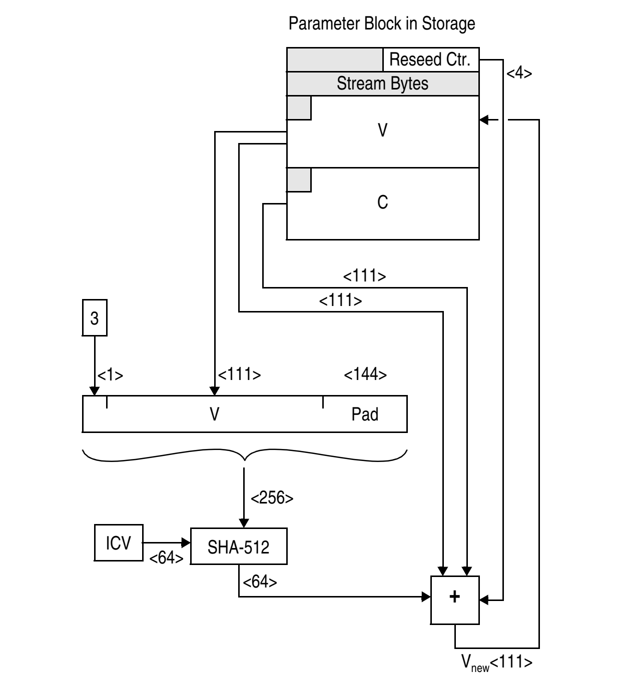
Figure 7-358. PRNO-SHA-512-DRNG Function's Generate Operation Generation of Deterministic Pseudorandom Numbers (Part 2 of 2)

When the first-operand length in general register R_1 + 1 is initially zero, normal completion occurs without storing into the first-operand location; however, the parameter block is updated as described below.

When the pseudorandom-number-generation process ends due to normal completion, the parameter block is updated as described below.

1. A one byte value of 03 hex, 111-byte value (V) from the parameter block, and 144 bytes of padding are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The padding consists of a value of 80 hex, concatenated with 127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte value of 03 hex and the V field). The values of the 4-byte reseed-counter field and the 111-byte value (V) and constant (C) fields in the parameter block, and the 64-byte hashed value (from the above computation) are added. For the purposes of this addition, each value is treated as an unsigned binary integer, extended to the left with zeros as necessary. Any overflow from the addition is ignored, and the resulting 111-byte sum replaces the value field in the parameter block (V_{new}).
2. The 4-byte reseed-counter field in the parameter block is incremented by one.
3. Condition code 0 is set.

Steps 1 and 2 of the normal completion processing are illustrated in Figure 7-359.



Explanation:

<#> Length of field in bytes
ICV Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-199.
Pad Pad bytes, beginning with 80 hex, followed 127 bytes of zeros, followed by a 16-byte unsigned binary integer representing the length of the input to the SHA-512 algorithm not including the padding.

Figure 7-359. PRNO-SHA-512-DRNG Function's Generate Operation Normal Completion

When the pseudorandom-number-generation process ends due to partial completion, the first-operand length in general register R_1 + 1 contains a nonzero multiple of 64, the reseed-counter and value (V) fields in the parameter block are not updated, and condition code 3 is set.

For a generate operation, access exceptions may be reported for a larger portion of the first operand than is processed in a single execution of the instruction. However, access exceptions are not recognized for locations that do not encompass the first operand nor for locations more than 4K bytes from the current location being processed.

For a generate operation, when the operation ends due to normal completion, condition code 0 is set and the resulting value in general register $R_1 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in general register $R_1 + 1$ is nonzero.

PRNO-TRNG-Query-Raw-to-Conditioned Ratio (PRNO Function Code 112)

The PRNO-TRNG-query-raw-to-conditioned ratio function may be used to determine the ratio of raw to conditioned entropy produced when both types of entropy are requested by the PRNO-TRNG function. See Reference [19.] on page xxx for a description of these terms.

The parameter block is stored with two 32-bit unsigned binary integers indicating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-351 on page 7-354. The contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$ are ignored by the function.

The parameter block used for the function has the following format:

0	Raw-Entropy	Conditioned-Entropy
	0	32 63

Figure 7-360. Parameter Block for PRNO-TRNG-Query-Raw-to-Conditioned Ratio

The fields of the parameter block are as follows:

Raw Entropy: The numerator in a fraction designating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

Conditioned Entropy: The denominator in a fraction designating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

The raw-entropy to conditioned-entropy ratio indicates the relative sizes of the first and second operands stored by the PRNO-TRNG function when the operands contain a proportionate number of raw and conditioned bits.

Condition code 0 is set when execution of the PRNO-TRNG-query-raw-to-conditioned function completes; condition code 3 is not applicable to this function.

PRNO-TRNG (PRNO Function Code 114)

A series of hardware-generated random numbers is stored at either or both the first- and second-operand locations. The locations of the operands and addresses used by the instruction are as shown in Figure 7-351 on page 7-354. A parameter block is not used by the PRNO-TRNG function, and general register 1 is ignored.

The R_1 field designates an even-odd pair of general registers. The even-numbered register contains the address of the leftmost byte of the first operand, and the odd-numbered register contains the length of the first operand. The first operand comprises random numbers in the form of raw entropy, produced directly by a hardware source.

The R_2 field designates an even-odd pair of general registers. The even-numbered register contains the address of the leftmost byte of the second operand, and the odd-numbered register contains the length of the second operand. The second operand comprises random numbers extracted from the raw entropy source and then conditioned by an approved algorithm (section 6.4.2 of Reference [19.] on page xxx describes approved algorithms).

The ratio of raw-entropy bits needed to produce conditioned-entropy bits can be determined by the PRNO-TRNG-query-raw-to-conditioned-ratio function. When the lengths of both the first and second operands are nonzero, the raw and conditioned entropy are stored at the first- and second-operand locations, respectively, in the raw-to-conditioned ratio. The number of bytes stored in a single unit of operation is model dependent, and may vary from one execution of the instruction to another.

When the length of the first operand is nonzero but the length of the second operand is zero, the process continues with storing the raw entropy in the first operand only. Similarly, when the length of the second operand is nonzero but the length of the first operand is zero, the process continues with storing the conditioned entropy in the second operand only.

Access exceptions may be reported for a larger portion of the first and second operands than is processed in a single execution of the instruction. However, access exceptions are not recognized for locations that do not encompass the first or second operand nor for locations more than 4K bytes from the current location being processed.

The process continues either until both operand lengths are zero (called normal completion), or until a CPU-determined number of bytes have been stored (called partial completion), whichever occurs first. When the operation ends due to normal completion, condition code 0 is set. When the operation ends due to partial completion, condition code 3 is set. The CPU-determined number of bytes depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bytes is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless recurrence of this no-progress case.

Regardless of whether the operation ends due to normal or partial completion, general registers R_1 and $R_1 + 1$ are incremented and decremented, respectively, by the number of bytes stored into the first operand, and general registers R_2 and $R_2 + 1$ are incremented and decremented, respectively, by the number of bytes stored into the second operand.

If the first and second operands overlap, the results are unpredictable.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following conditions exist:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 or R_2 fields designate an odd-numbered register or general register 0. This exception is recognized regardless of the function code.
3. For the PRNO-SHA-512-DRNG function's seed operation, the length in general register $R_2 + 1$ is greater than 512.

For the PRNO-SHA-512-DRNG function's generate operation, a general-operand data exception is recognized if the reseed counter in the parameter block is zero.

Condition Code:

0 Normal completion
1 --
2 --
3 Partial completion

Program Exceptions:

- Access (store, operand 1; fetch and store, operand 2 and parameter block)
- Data with DXC 0, general operand
- Operation (if the message-security-assist extension 5 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. With the advent of the message-security-assist extension 7, the instruction is capable of producing both true and deterministic random numbers. Thus, the former PERFORM PSEUDORANDOM NUMBER OPERATION (PPNO) instruction is renamed to PERFORM RANDOM NUMBER OPERATION (PRNO) to encompass both types of numbers. Although it is now deprecated, the mnemonic PPNO is retained for compatibility.
3. The following considerations apply to the PRNO-SHA-512-DRNG function:

   a. For the generate operation, when condition code 3 is set, the first operand length in general register $R_1 + 1$ is updated such that the program can simply branch back to the instruction to continue the operation.

b. The seed operation (instantiation and reseeding) and generate operation correspond to the following algorithm specifications in Reference [19.] on page xxx:

   - Section 10.1.1.2: Instantiation of Hash_DRBG
   - Section 10.1.1.3: Reseeding a Hash_DRBG Instantiation
   - Section 10.1.1.4: Generating Pseudorandom Bits Using Hash_DRBG (steps 3–7)

c. If a carry out of bit position 0 of the reseed-counter field occurs during a generate operation, then the counter wraps around to zero; in this case, the parameter block is considered not to be instantiated. Unless a seed operation is performed to reinstantiate the parameter block, a subsequent generate operation will result in a general-operand data exception being recognized.

d. The PRNO-SHA-512-DRNG function does not implement the testing and uninstantiation functions described in Reference [19.] on page xxx. As the parameter block exists in program storage, the program can effect the testing function by directly inspecting the parameter block; similarly, the program can effect the uninstantiation function by zeroing the parameter block.

e. The program is responsible for reseeding the parameter block depending on policy and pseudorandom-number-generation state. For example, reseeding may be required after each generate operation if prediction resistance is required. Reseeding may be appropriate after a preset number of stream bytes is produced. See Reference [18.] on page xxx for further explanation.

f. Even though the generate operation processes the blocks of the first operand in right to left order, it is the address of the leftmost byte of the operand in general register R_1 that is used for PER zero-address detection. If the first-operand address is nonzero, and length of the operand is such that the operand wraps around to location zero, stores to the first-operand location – including stores to location zero – will not result in the recognition of a PER zero-address-detection event.

g. The length in bits of the input to the SHA-512 algorithm is implicitly determined by the instruction; this length is described as occupying the rightmost 16 bytes of the padding field. This differs from the KLMD-SHA-512 function of the COMPUTE LAST MESSAGE DIGEST instruction where the message-bit length (mbl) is explicitly specified in the parameter block, and the padding (p) and mbl are described separately.

h. The initial chaining value (ICV) is described as the initial-hash value (IHV) in Reference [18.] on page xxx.

i. The program may issue a seed operation with the second-operand length in general register $R_2 + 1$ set to zero. However, the results in this case will always be deterministic.

4. The following considerations apply to the PRNO-TRNG function:

   a. Depending on the model, significant performance degradation may be experienced either by requesting excessively large results or by frequently-repeated executions of the instruction.

   b. The PRNO-TRNG function may be useful when implementing a hybrid random-number generator, using the conditioned entropy source from PRNO-TRNG to periodically reseed a deterministic random-number generation (such as that provided by the PRNO-SHA-512-DRNG function).

   c. The conditioned entropy provided by the PRNO-TRNG function may be shared by multiple, independently-seeded deterministic random number generators. Independence may be achieved by a unique program-supplied entropy, nonce, or personalization string when seeding a deterministic random number generator.

   d. The raw entropy provided by the first operand is intended for use by diagnostic programs that test the quality of entropy provided by the function. It is recommended that for normal usage, the first-operand length be set to zero.

e. The ratio of raw-to-conditioned entropy provided by the function is constant across all processors of the same model type. Therefore, once the program has determined the ratio, it need not re-execute the PRNO-TRNG-query-raw-to-conditioned-ratio function unless it is relocated to another model type.

f. Although entropy is produced by the PRNO-TRNG function in the raw-to-conditioned ratio reported by the PRNO-TRNG-query-raw-to-conditioned-ratio function, the program is in no way obliged to request raw and conditioned entropy in that ratio.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in a location defined to be stored for a particular function. See the section “Effects of CPU Retry” on page 11-3 for further details.

POPULATION COUNT

POPCNT $R_1,R_2[,M_3]$ [RRF-c]

'B9E1'	M_3	////	R_1	R_2
0	16		24	28 31

A count of the number of bits in the second operand containing a value of one, is placed into the first operand.

When the miscellaneous-instruction-extensions facility 3 is not installed or bit 0 of the M_3 field is zero, a count of the number of one bits in each of the eight bytes of general register R_2 is placed into the corresponding byte of general register R_1. Each byte of general register R_1 is an 8-bit binary integer in the range of 0-8.

When the miscellaneous-instruction-extensions facility 3 is installed and bit 0 of the M_3 field is one, a count of the total number of one bits in the 64-bit general register R_2 is placed into general register R_1. The result is a 64-bit unsigned integer in the range 0 to 64.

Bits 1-3 of the M_3 field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. If the miscellaneous-instruction-extensions facility 3 is not installed, bit 0 of the M_3 field should also contain zero.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the population-count facility is not installed)

Programming Notes:

1. The condition code is set based on all 64 bits of general register R_1.

2. If the miscellaneous-instruction-extensions facility 3 is installed, bit 0 of the M_3 field should be set to one to compute the total number of one bits in a general register. If the facility is not installed, the total number of one bits in a general register can be computed as shown below. In this example, general register 15 contains the bits to be counted; the result containing the total number of one bits in general register 15 is placed in general register 8. (General register 9 is used as a work register and contains residual values on completion.)

```
POPCNT 8,15
AHHLR  8,8,8
SLLG   9,8,16
ALGR   8,9
SLLG   9,8,8
ALGR   8,9
SRLG   8,8,56
```

If there is a high probability that the results of the POPCNT instruction are zero, a conditional branch instruction may be inserted to skip the adding and shifting operations based on the condition code set by POPCNT.

3. Using techniques similar to that shown in programming note 2, the number of one bits in a word, halfword, or discontiguous bytes of the second operand may be determined.

PREFETCH DATA

PFD $M_1,D_2(X_2,B_2)$ [RXY-b]

'E3'	M_1	X_2	B_2	DL_2	DH_2	'36'
0	8	12	16	20	32	40 47

PREFETCH DATA RELATIVE LONG

PFDRL M_1,RI_2 [RIL-c]

'C6'	M_1	'2'	RI_2	
0	8	12	16	47

Note: In this instruction definition, the name “PREFETCH DATA (RELATIVE LONG)” refers to both the PREFETCH DATA instruction and the PREFETCH DATA RELATIVE LONG instruction.

Subject to the controls specified in the M_1 field, the CPU is signaled to perform one of the following operations:

- Prefetch the second operand into a cache line.
- Release a cache line containing the second operand.

The second operand designates a logical address.

The M_1 field contains a 4-bit unsigned binary integer that is used as a code to signal the CPU as to the intended use of the second operand. The codes are as follows:

Code	Function Performed
1	Prefetch the data at the second-operand address into a cache line for fetch access.
2	Prefetch the data at the second-operand address into a cache line for store access.
6	Release the cache line containing the second operand from store access; retain the data in the cache line for fetch access.
7	Release the cache line containing the second operand from all accesses

All other codes are reserved. Depending on the model, the CPU may not implement all of the prefetch functions. For functions that are not implemented by the CPU, and for reserved functions, the instruction acts as a no-op. Code 0 always acts as a no-op.

No access exceptions or PER storage-alteration events are recognized for the second operand.

Code 2 has no effect on the change bit for the second operand. For all codes, it is model dependent whether any TLB entry is formed for the data that is prefetched.

For PREFETCH DATA, the displacement is treated as a 20-bit signed binary integer.

For PREFETCH DATA RELATIVE LONG, the contents of the RI_2 field are signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

When PREFETCH DATA (RELATIVE LONG) is attempted in a nonconstrained transaction, and the code in the M_1 field is 6 or 7, it is model dependent whether the instruction is restricted; if the instruction is not restricted, it is unpredictable whether the transaction is aborted due to abort code 16. When PREFETCH DATA (RELATIVE LONG) is attempted in a constrained transaction, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

1. PREFETCH DATA (RELATIVE LONG) signals the CPU to perform the specified operation, but it does not guarantee that the CPU will necessarily honor the request.

2. There is no guarantee that storage location will still be in the cache when a subsequent instruction references the location. Likewise, there is no guarantee that when a cache line is released, that the CPU will not subsequently refetch it (independent of any prefetching operations). Rather, PREFETCH DATA (RELATIVE LONG) simply provides hints as to the program’s anticipated use of storage areas.

3. If an exception condition would otherwise be recognized when accessing the second operand, PREFETCH DATA (RELATIVE LONG) is completed with no indication of the exception provided to the program, however, the performance

of PREFETCH DATA (RELATIVE LONG) may be significantly slower than if the exception condition did not exist.

4. A significant delay may be experienced if a storage location has been prefetched and then released, and then a subsequent instruction references the same storage location. Similarly, a delay may be experienced if a storage location has been prefetched for fetch access, and then a subsequent instruction references the same location for storing.

5. On models that implement a unified data and instruction cache, the function performed may affect both subsequent operand accesses and instruction fetches from the second-operand location. On such models, a significant delay may be experienced if the code 7 is used to release data in a cache line from which an instruction is subsequently fetched.

6. On models that implement separate data and instruction caches, codes 1 and 2 cause the second operand to be prefetched into the data cache. Similarly, on such models, codes 6 and 7 cause the second operand to be released from the data cache. However, on certain models with separate data and instruction caches, code 7 may also cause the second operand to be released from the instruction cache, in addition to being released from the data cache.

7. On models that implement separate data and instruction caches, the use of code 2 to prefetch (for storing) a cache line from which instructions will subsequently be fetched may cause significant delays. Similar delays may be experienced for any store operation into a cache line from which instructions are subsequently fetched.

8. The use of PREFETCH DATA (RELATIVE LONG) to prefetch operands that are frequently updated in a multiprocessing environment may actually degrade performance by causing unnecessary contention for the cache line.

9. A prefetch operation consists of fetching a cache line on an integral boundary. The cache line size (and corresponding integral boundary) may be determined by executing EXTRACT CPU ATTRIBUTE.

10. The second operand is fetched into the cache line in model-dependent units, on an integral boundary, the minimum size of which is a doubleword. Thus, at least the rightmost three bits of the second-operand address are assumed to contain zeros, regardless of what is specified by the program.

11. On most models, the unit directly addressed by the second-operand address is prefetched first. The order in which the remaining units of the cache line are prefetched is also model dependent.

12. When PREFETCH DATA RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

ROTATE LEFT SINGLE LOGICAL

RLL $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'1D'
0	8	12	16	20	32	40 47

RLLG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'1C'
0	8	12	16	20	32	40 47

The 32-bit or 64-bit third operand is rotated left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3. For ROTATE LEFT SINGLE LOGICAL (RLL), bits 0-31 of general registers R_1 and R_3 remain unchanged.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

For RLL, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. For RLLG, the operands are in bit positions 0-63 of the registers.

All 32 or 64 bits of the third operand participate in a left shift. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand.

Condition Code: The code remains unchanged.

Program Exceptions: None.

ROTATE THEN AND SELECTED BITS

RNSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'54'
0	8	12	16	24	32	40 47

ROTATE THEN EXCLUSIVE OR SELECTED BITS

RXSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'57'
0	8	12	16	24	32	40 47

ROTATE THEN OR SELECTED BITS

ROSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'56'
0	8	12	16	24	32	40 47

The second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. Depending on the instruction, the selected bits of the rotated second operand are logically ANDed, exclusive ORed, or ORed with the corresponding bits of the first operand, and the results of the logical operation may replace the selected bits of the first operand. The result is indicated by the condition code.

The second operand remains unchanged in general register R_2.

Bits 2-7 of the I_3 field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the I_4 field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_3 field (bit 16 of the instruction) contains the test-results control (T). When the T bit is zero, the results of the logical operation replace the selected bits of the first operand, and the remaining bits of the first operand are unchanged. When the T bit is one, the entire first operand is unchanged.

The condition code is set based on the results of the logical operation, regardless of the setting of the T bit. Only the selected range of bits is used to determine the condition code.

The immediate fields just described are as follows:

I_3 Field

T	/	Starting Bit Position
0	1	2 7

I_4 Field

/ /	Ending Bit Position
0	2 7

I_5 Field

	Rotate Amount
0	2 7

Bit 1 of the I_3 field and bits 0-1 of the I_4 field (bits 17 and 24-25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the

rotated value logically operate upon the corresponding bits of the unrotated register contents.

3. Examples of the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS, and ROTATE THEN OR SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

4. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

5. The I_3 field contains both the test-results control (in bit 0) and the starting bit position value (in bits 2-7). For example, to AND bits 40-43 of register 5 with the corresponding bits of register 7 (no rotation) and simply test the results, the programmer might code:

   ```
   RNSBG    R5,R7,X'80'+40,43,0
   ```

   The X‘80’ represents the test-results control which is added to the starting-bit position to form the I_3 field.

   The high-level assembler (HLASM) provides alternative mnemonics for the test versions of these instructions, as shown below:

   ```
   RNSBGT    R5,R7,40,43,0
   ```

   The “T” suffix to the mnemonic indicates that the specified I_3 field is ORed with a value of X’80’ when generating the object code. The T mnemonic suffix also applies to ROSBG and RXSBG.

6. The High-Level Assembler implements various high-word logical operations by providing extended-mnemonics for the RNSBG, ROSBG, and RXSBG instructions, as shown in Figure 7-361.

Instruction Name	Extended-Mnemonic Syntax	RxSBG Equivalent
AND HIGH (HIGH ← HIGH)	NHHR R_1,R_2	RNSBG R_1,R_2,0,31
AND HIGH (HIGH ← LOW)	NHLR R_1,R_2	RNSBG R_1,R_2,0,31,32
AND HIGH (LOW ← HIGH)	NLHR R_1,R_2	RNSBG R_1,R_2,32,63,32
EXCLUSIVE OR HIGH (HIGH ← HIGH)	XHHR R_1,R_2	RXSBG R_1,R_2,0,31
EXCLUSIVE OR HIGH (HIGH ← LOW)	XHLR R_1,R_2	RXSBG R_1,R_2,0,31,32
EXCLUSIVE OR HIGH (LOW ← HIGH)	XLHR R_1,R_2	RXSBG R_1,R_2,32,63,32
OR HIGH (HIGH ← HIGH)	OHHR R_1,R_2	ROSBG R_1,R_2,0,31
OR HIGH (HIGH ← LOW)	OHLR R_1,R_2	ROSBG R_1,R_2,0,31,32
OR HIGH (LOW ← HIGH)	OLHR R_1,R_2	ROSBG R_1,R_2,32,63,32

Figure 7-361. Extended-Mnemonics Formed Using RNSBG, RXSBG, and ROSBG

ROTATE THEN INSERT SELECTED BITS

RISBG R_1,R_2,I_3,I_4[,I_5] [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'55'

0 8 12 16 24 32 40 47

RISBGN R_1,R_2,I_3,I_4[,I_5] [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'59'

0 8 12 16 24 32 40 47

The second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. The selected bits of the rotated second operand replace the contents of the corresponding bit positions of the first operand. For RISBG, the result is indicated by the condition code.

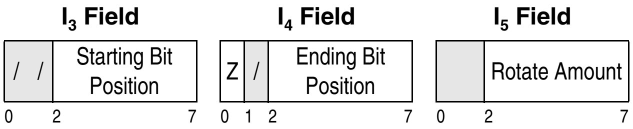
The second operand remains unchanged in general register R_2.

Bits 2-7 of the I_3 field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the I_4 field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_4 field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.

The immediate fields just described are as follows:



Bits 0-1 of the I_3 field and bit 1 of the I_4 field (bits 16-17 and 25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

For the purposes of setting the condition code for RISBG, the result in general register R_1 is treated as being a 64-bit signed binary integer.

Resulting Condition Code:

For RISBG, the condition code is set as follows:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

For RISBGN, the condition code remains unchanged.

Program Exceptions:

- Operation (RISBG, if the general-instructions-extension facility is not installed; RISBGN, if the miscellaneous-instruction-extensions facility 1 is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. When used with the zero-remaining-bits control, ROTATE THEN INSERT SELECTED BITS provides a means of effecting a shift operation.

3. When the R_1 and R_2 fields designate the same register and the Z bit is one, ROTATE THEN INSERT SELECTED BITS may be used to zero a selected range of bits in a register. Note, this technique cannot be used to zero all 64 bits of the register.

4. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.

5. Examples of the use of ROTATE THEN INSERT SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

6. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

7. The I_4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 2-7). For example, to insert bits 40-43 of register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in register 5, the programmer might code:

   ```
   RISBG    R5,R7,40,X'80'+43,0
   RISBGN     R5,R7,40,X'80'+43,0
   ```

   The X‘80’ represents the zero-remaining-bits control which is added to the ending-bit position to form the I_4 field.

   The high-level assembler (HLASM) provides an alternative mnemonic for the zero-remaining-bits versions of the instruction, as shown below:

   ```
   RISBGZ    R5,R7,40,43,0
   RISBGNZ   R5,R7,40,43,0
   ```

The “Z” suffix to the mnemonic indicates that the specified I_4 field is ORed with a value of X’80’ when generating the object code.

ROTATE THEN INSERT SELECTED BITS HIGH

RISBHG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'5D'
0	8	12	16	24	32	40 47

ROTATE THEN INSERT SELECTED BITS LOW

RISBLG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]

'EC'	R_1	R_2	I_3	I_4	I_5	'51'
0	8	12	16	24	32	40 47

The 64-bit second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. The selected bits of the rotated second operand replace the contents of the corresponding bit positions of the first operand.

For ROTATE THEN INSERT SELECTED BITS HIGH, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are unchanged. For ROTATE THEN INSERT SELECTED BITS LOW, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are unchanged.

The second operand remains unchanged in general register R_2.

For ROTATE THEN INSERT SELECTED BITS HIGH, bits 3-7 of the I_3 and I_4 fields (bits 19-23 and 27-31 of the instruction, respectively), with a binary zero appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 31 to bit 0. Thus, the starting and ending bit positions of the selected range of bits are always between 0 and 31.

For ROTATE THEN INSERT SELECTED BITS LOW, bits 3-7 of the I_3 and I_4 fields, with a binary one appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 63 to bit 32. Thus, the starting and ending bit positions of the selected range of bits are always between 32 and 63.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_4 field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.

The immediate fields just described are as follows:

I_3 Field

/ / /	Starting Bit Position
0	3 7

I_4 Field

Z	/ /	Ending Bit Position
0	1	3 7

I_5 Field

	Rotate Amount
0	2 7

Bits 0-2 of the I_3 field and bits 1-2 of the I_4 field (bits 16-19 and 25-26 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

Condition Code: The code remains unchanged

Program Exceptions:

- Operation (if the high-word facility is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the value contained in the register is first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.

3. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

4. The I_4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 2-7). For example, to insert bits 40-43 of register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in the right half of register 5, the programmer might code:

   ```
   RISBLG   R5,R7,40,X'80'+43,0
   ```

   The X‘80’ represents the zero-remaining-bits control which is added to the ending-bit position to form the I_4 field.

   The High-Level Assembler (HLASM) provides alternative mnemonics for the zero-remaining-bits versions of RISBHG and RISBLG in the form of RISBHGZ and RISBLGZ, respectively. The “Z” suffix to the mnemonic indicates that the specified I_4 field is ORed with a value of X’80’ when generating the object code.

   An equivalent to the example shown above using the Z-suffixed mnemonic is as follows:

   ```
   RISBLGZ   R5,R7,40,43,0
   ```

5. On some models, improved performance of RISBHG and RISBLG may be realized by setting the zero-remaining-bits control to one (or using the Z mnemonic suffix).

6. Unlike ROTATE THEN INSERT SELECTED BITS which sets the condition code, ROTATE THEN INSERT SELECTED BITS HIGH and ROTATE THEN INSERT SELECTED BITS LOW do not set the condition code.

7. The High-Level Assembler implements various high-word logical operations by providing extended-mnemonics for the RISBHG and RISBLG instructions, as shown in Figure 7-362.

Instruction Name	Extended-Mnemonic Syntax	RISBHG / RISBLG Equivalent
LOAD (HIGH ← HIGH)	LHHR R_1,R_2	RISBHGZ R_1,R_2,0,31
LOAD (HIGH ← LOW)	LHLR R_1,R_2	RISBHGZ R_1,R_2,0,31,32
LOAD (LOW ← HIGH)	LLHFR R_1,R_2	RISBLGZ R_1,R_2,0,31,32
LOAD LOGICAL HALFWORD (HIGH ← HIGH)	LLHHHR R_1,R_2	RISBHGZ R_1,R_2,16,31
LOAD LOGICAL HALFWORD (HIGH ← LOW)	LLHHLR R_1,R_2	RISBHGZ R_1,R_2,16,31,32
LOAD LOGICAL HALFWORD (LOW ← HIGH)	LLHLHR R_1,R_2	RISBLGZ R_1,R_2,16,31,32
LOAD LOGICAL CHARACTER (HIGH ← HIGH)	LLCHHR R_1,R_2	RISBHGZ R_1,R_2,24,31
LOAD LOGICAL CHARACTER (HIGH ← LOW)	LLCHLR R_1,R_2	RISBHGZ R_1,R_2,24,31,32
LOAD LOGICAL CHARACTER (LOW ← HIGH)	LLCLHR R_1,R_2	RISBLGZ R_1,R_2,24,31,32

Figure 7-362. Extended Mnemonics Formed Using RISBHG and RISBLG

SEARCH STRING

SRST R_1,R_2 [RRE]

'B25E'	////////	R_1	R_2
0	16	24	28 31

The second operand is searched until a specified character is found, the end of the second operand is reached, or a CPU-determined number of bytes have been searched, whichever occurs first. The CPU-determined number is at least 256. The result is indicated in the condition code.

The location of the first byte of the second operand is designated by the contents of general register R_2. The location of the first byte after the second operand is designated by the contents of general register R_1.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register R_2. The contents of access register R_1 are ignored.

The character for which the search occurs is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the specified character has been found in the second operand, the address of the next second-operand byte to be examined equals the address in general register R_1, or a CPU-determined number of second-operand bytes have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified character is found, condition code 1 is set. When the address of the next second-operand byte to be examined equals the address in general register R_1, condition code 2 is set. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set. When the CPU-determined number of second-operand bytes have been examined and the address of the next second-operand byte is in general register R_1, it is unpredictable whether condition code 2 or 3 is set.

When condition code 1 is set, the address of the specified character found in the second operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged. When condition code 2 is set, the contents of general registers R_1 and R_2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R_1 equals the address in general register R_2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R_1 is less than the address in general register R_2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-125.

Resulting Condition Code:

0 --
1 Specified character found; general register R_1 updated with address of character; general register R_2 unchanged
2 Specified character not found in entire second operand; general registers R_1 and R_2 unchanged
3 CPU-determined number of bytes searched; general register R_1 unchanged; general register R_2 updated with address of next byte

Program Exceptions:

- Access (fetch, operand 2)
- Specification
- Transaction constraint

Programming Notes:

1. Examples of the use of the SEARCH STRING instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of bytes that were searched.

3. The R_1 or R_2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

   However, if the program branches back to the SEARCH STRING instruction following condition code 3, specifying R_2 as register 0 is impractical. This is because bits 32-55 of the register will have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search character in bit positions 56-63 of the register also may have been altered.

4. When it is desired to search a string of unknown length for its ending character, and assuming that the specified character in general register 0 need not be preserved, then the R_1 field can designate general register 0 in order to have SEARCH STRING use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 8-bit search character is also used to form the address of the first byte after the second operand.

5. If the program branches back to the SEARCH STRING instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register R_2 will have changed from its initial value, even though the definition states that the register is unchanged when the character is found.

6. If the length of the string (as determined by the difference between the addresses in general registers R_1 and R_2) is 255 characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 256 or more characters, condition code 3 may be set – even if condition code 2 also applies.

SEARCH STRING UNICODE

SRSTU R_1,R_2 [RRE]

'B9BE'	////////	R_1	R_2
0	16	24	28 31

The second operand is searched until a specified two-byte character is found, the end of the second operand is reached, or a CPU-determined number of two-byte characters have been searched, whichever occurs first. The CPU-determined number is at least 256 two-byte characters. The result is indicated in the condition code.

The location of the first two-byte character of the second operand is designated by the contents of general register R_2. When the contents of bit position 63 of general registers R_1 and R_2 are identical (that is, when both addresses are even or both addresses are odd), the location of the first two-byte character after the second operand is designated by the contents of general register R_1. When the contents of bit position 63 of general registers R_1 and R_2 differ (that is, when one address is even and the other is odd), the location of the first two-byte character after the second operand is one more than the contents of general register R_1.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register R_2. The contents of access register R_1 are ignored.

The two-byte character for which the search occurs is specified in bit positions 48-63 of general register 0. Bit positions 32-47 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

Except for the case when the address in general register R_1 equals the address in general register R_2, the operation proceeds from left to right in steps of two bytes and ends as soon as the specified two-byte character has been found in the second operand, the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand (as designated by general register R_1), or a CPU-determined number of second-operand two-byte characters have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified two-byte character is found, condition code 1 is set. When the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand, condition code 2 is set. When a CPU-determined number of second-operand two-byte characters have been examined, condition code 3 is set, except that condition code 2 is set if the conditions for setting it also apply.

When condition code 1 is set, the address of the specified two-byte character found in the second operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next two-byte character to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged. When condition code 2 is set, the contents of general registers R_1 and R_2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R_1 equals the address in general register R_2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R_1 is less than the address in general register R_2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-125.

Resulting Condition Code:

0 --
1 Specified two-byte character found; general register R_1 updated with address of character; general register R_2 unchanged
2 Specified two-byte character not found in entire second operand; general registers R_1 and R_2 unchanged
3 CPU-determined number of two-byte characters searched; general register R_1 unchanged; general register R_2 updated with address of next two-byte character

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of two-byte characters that were searched.

2. The R_1 or R_2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

   However, if the program branches back to the SEARCH STRING UNICODE instruction following condition code 3, specifying R_2 as register 0 is impractical. This is because bits 32-47 of the register may have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search character in bit positions 48-63 of the register also may have been altered.

3. When it is desired to search a string of unknown length for its ending two-byte character, and assuming that the specified two-byte character in general register 0 need not be preserved, then the R_1 field can designate general register 0 in order to have SEARCH STRING UNICODE use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 16-bit search character is also used to form the address of the first byte after the second operand.

4. If the program branches back to the SEARCH STRING UNICODE instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register R_2 will have changed from its initial value, even though the definition states that the register is unchanged when the two-byte character is found.

5. If the length of the string (as determined by the difference between the addresses in general registers R_1 and R_2) is 256 two-byte characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 257 or more two-byte characters, condition code 3 may be set.

SELECT

SELR R_1,R_2,R_3,M_4 [RRF-a]

'B9F0'	R_3	M_4	R_1	R_2
0	16	20	24	28 31

SELGR R_1,R_2,R_3,M_4 [RRF-a]

'B9E3'	R_3	M_4	R_1	R_2
0	16	20	24	28 31

SELECT HIGH

SELFHR R_1,R_2,R_3,M_4 [RRF-a]

'B9C0'	R_3	M_4	R_1	R_2
0	16	20	24	28 31

The second operand is placed unchanged at the first-operand location if the condition code has one of the values specified by M_4; otherwise, the third operand is placed unchanged at the first operand location.

For SELR, all operands are in bits 32-63 in their respective general registers; bits 0-31 of general register R_1 are unchanged. For SELGR, all operands are in bits 0-63 in their respective general registers. For SELFHR, all operands are in bits 0-31 in their respective general registers; bits 32-63 of general register R_1 are unchanged.

The M_4 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	Mask Position Value
0	8
1	4
2	2
3	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the second operand is loaded. If the mask bit selected is zero, the third operand is loaded.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

Programming Notes:

1. SELECT may be used to provide better performance when it is difficult for the CPU to predict the branch condition and also uses fewer instructions. For example, the following two instruction sequences are equivalent.

```
SELR    4,5,6,7             BRC    7,REG5
                            LR     4,6
                            BRC    15,FIN
                       REG5 LR     4,5
                       FIN  DS     0H
```

2. The High-Level Assembler (HLASM) provides the following extended-mnemonic suffixes for the SELECT instructions in place of the M_4 field.

Suffix	Meaning	Effective M_4 Value
E	Equal	B'1000'
L	Low	B'0100'
H	High	B'0010'
NE	Not equal	B'0111'
NL	Not low	B'1011'
NH	Not high	B'1101'
Z	Zero	B'1000'
M	Minus or mixed	B'0100'
P	Plus	B'0010'
O	Overflow or ones	B'0001'
NZ	Not zero	B'0111'
NM	Not minus or not mixed	B'1011'
NP	Not plus	B'1101'
NO	Not overflow or not ones	B'1110'

When the extended mnemonic is coded, the M_4 field must be omitted.

SET ACCESS

SAR R_1,R_2 [RRE]

'B24E'	////////	R_1	R_2
0	16	24	28 31

The contents of bit positions 32-63 of general register R_2 are placed in access register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

SET ADDRESSING MODE

SAM24 [E]

'010C'
0 15

SAM31 [E]

'010D'
0 15

SAM64 [E]

'010E'
0 15

The addressing mode is set by setting the extended-addressing-mode bit, bit 31 of the current PSW, and the basic-addressing-mode bit, bit 32 of the current PSW, as follows:

Instruction	PSW Bit 31	PSW Bit 32	Resulting Addressing Mode
SAM24	0	0	24-bit
SAM31	0	1	31-bit
SAM64	1	1	64-bit

The instruction address in the PSW is updated under the control of the new addressing mode, as follows. The value 2 (the instruction length) is added to the contents of bit positions 64-127 of the PSW, or the value 4 is added if the instruction is the target of EXECUTE, or the value 6 is added if the instruction is the target of EXECUTE RELATIVE LONG. In any case, a carry out of bit position 0 is ignored. Then bits 64-103 of the PSW are set to zeros if the new addressing mode is the 24-bit mode, or bits 64-96 are set to zeros if the new addressing mode is the 31-bit mode.

The instruction is completed only if the new addressing mode and the unupdated instruction address in the PSW are a valid combination. When the new addressing mode is to be the 24-bit mode, bits 64-103 of the unupdated PSW must be all zeros, or, when the new addressing mode is to be the 31-bit mode, bits 64-96 of the unupdated PSW must be all zeros; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, it is unpredictable whether SAM64 is supported. If not supported, attempted execution of SAM64 results in an operation exception.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (SAM64, in the ESA/390-compatibility mode)
- Specification (SAM24 and SAM31 only)
- Trace
- Transaction constraint

Programming Note: Checking the unupdated instruction address prevents completion in two major cases: the instruction is located at address 2^{24} or above and the new addressing mode is to be the 24-bit mode, or the instruction is located at address 2^{31} or above and the new addressing mode is to be the 24-bit or 31-bit mode. In these cases, if the instruction were completed, the updating of the instruction address under the control of the new addressing mode would cause one or more leftmost bits of the address to be set to zeros, which would cause the next instruction to be fetched from other than the next sequential location. This action is sometimes called a “wild branch.” A wild branch still can occur if the instruction is located at $2^{24} - 2$ or $2^{31} - 2$, or at $2^{24} - 4$ or $2^{31} - 4$ if EXECUTE or EXECUTE RELATIVE LONG is used, or at $2^{24} - 6$ or $2^{31} - 6$ if EXECUTE RELATIVE LONG is used.

SET PROGRAM MASK

SPM R_1 [RR]

'04'	R_1	////
0	8	12 15

The first operand is used to set the condition code and the program mask of the current PSW.

Bits 34 and 35 of general register R_1 replace the condition code, and bits 36-39 replace the program mask. Bits 0-33 and 40-63 of general register R_1 are ignored.

Resulting Condition Code:

The code is set as specified by bits 34 and 35 of general register R_1.

Program Exceptions: None.

Programming Notes:

1. Bits 34-39 of the general register may have been loaded from the PSW by execution of BRANCH AND LINK in the 24-bit addressing mode or by execution of INSERT PROGRAM MASK in any addressing mode.
2. SET PROGRAM MASK permits setting of the condition code and the mask bits in either the problem state or the supervisor state.
3. The program should take into consideration that the setting of the program mask can have a significant effect on subsequent execution of the program. Not only do the four mask bits control whether the corresponding interruptions occur, but the HFP-exponent-underflow and HFP-significance masks also determine the result which is obtained.

SHIFT LEFT DOUBLE

SLDA $R_1,D_2(B_2)$ [RS-a]

'8F'	R_1	////	B_2	D_2
0	8	12	16	20 31

The 63-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

The first operand is treated as a 64-bit signed binary integer. The sign bit of the first operand, bit 32 of the even-numbered register, remains unchanged. Bit position 32 of the odd-numbered register contains a numeric bit, which participates in the shift in the same manner as the other numeric bits. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

If one or more bits unlike the sign bit are shifted out of bit position 33 of the even-numbered register, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow
- Specification

Programming Notes:

1. An example of the use of the SHIFT LEFT DOUBLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The eight shift instructions that are in both ESA/390 and z/Architecture provide the following three pairs of alternatives for 32 bits in one general register or, for double, in each of two general registers: left or right, single or double, and signed or logical. The four additional shift instructions in z/Architecture provide left or right, signed

or logical shifts of 64 bits in one general register. The signed shifts differ from the logical shifts in that, in the signed shifts, overflow is recognized, the condition code is set, and the leftmost bit participates as a sign.

3. A zero shift amount in the two signed double-shift operations provides a double-length sign and magnitude test.

4. The base register participating in the generation of the second-operand address permits indirect specification of the shift amount by means of placement of the shift amount in the base register. A zero in the B_2 field indicates the absence of indirect shift specification.

SHIFT LEFT DOUBLE LOGICAL

SLDL $R_1,D_2(B_2)$ [RS-a]

'8D'	R_1	////	B_2	D_2
0	8	12	16	20 31

The 64-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register R_1 + 1.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 32 of the even-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers R_1 and R_1 + 1 remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions:

- Specification

SHIFT LEFT SINGLE

SLA $R_1,D_2(B_2)$ [RS-a]

'8B'	R_1	////	B_2	D_2
0	8	12	16	20 31

SLAK $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'DD'
0	8	12	16	20	32	40 47

SLAG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'0B'
0	8	12	16	20	32	40 47

For SLA, the 31-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SLAK, the 31-bit numeric part of the signed third operand is shifted left the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SLAG, the 63-bit numeric part of the signed third operand is shifted left the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SLA, the first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the left shift.

For SLAK, the first and third operands are treated as 32-bit signed binary integers in bit positions 32-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 31 numeric bits of the third operand participate in the left shift.

For SLAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the left shift.

For SLA, SLAG, or SLAK, zeros are supplied to the vacated bit positions on the right.

If one or more bits unlike the sign bit are shifted out of bit position 33, for SLA or SLAK, or 1, for SLAG, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow
- Operation (SLAK, if the distinct-operands facility is not installed)

Programming Notes:

1. An example of the use of the SHIFT LEFT SINGLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For SHIFT LEFT SINGLE (SLA and SLAK), for numbers with a value greater than or equal to -2^{30} and less than 2^{30}, a left shift of one bit position is equivalent to multiplying the number by 2. For SHIFT LEFT SINGLE (SLAG), the comparable values are -2^{62} and 2^{62}.

3. For SHIFT LEFT SINGLE (SLA and SLAK), shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of the maximum negative number or zero, depending on whether or not the initial contents were negative. For SHIFT LEFT SINGLE (SLAG), a shift amount of 63 causes the same effect.

SHIFT LEFT SINGLE LOGICAL

SLL $R_1,D_2(B_2)$ [RS-a]

'89'	R_1	////	B_2	D_2	
0	8	12	16	20	31

SLLK $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'DF'	
0	8	12	16	20	32	40	47

SLLG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'0D'	
0	8	12	16	20	32	40	47

For SLL, the 32-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SLLK, the 32-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SLLG, the 64-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SLL, the first operand is in bit positions 32-63 of general register R_1. All 32 bits of the operand participate in the left shift.

For SLLK, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. All 32 bits of the third operand participate in the left shift.

For SLLG, the first and third operands are in bit positions 0-63 of general registers R_1 and R_3, respectively. All 64 bits of the third operand participate in the left shift.

For SLL, SLLG, or SLLK, zeros are supplied to the vacated bit positions on the right.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (SLLK, if the distinct-operands facility is not installed)

Programming Note: The rightmost six bits of the second-operand address are treated as a 6-bit unsigned binary integer specifying the number of bit positions to be shifted to the left. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

When the number of bit positions to be shifted is between 32 and 63, SLL and SLLK can be used to zero the rightmost 32 bits of the result in general register R_1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

Because the number of shifted bit positions is limited to 63, SLLG cannot be used to zero all 64 bits of the result.

SHIFT RIGHT DOUBLE

SRDA $R_1,D_2(B_2)$ [RS-a]

'8E'	R_1	////	B_2	D_2	
0	8	12	16	20	31

The 63-bit numeric part of the signed first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

The first operand is treated as a 64-bit signed binary integer. The sign bit of the first operand, bit 32 of the even-numbered register, remains unchanged. Bit position 32 of the odd-numbered register contains a numeric bit, which participates in the shift in the same manner as the other numeric bits. Bits shifted out of bit position 63 of the odd-numbered register are not inspected and are lost. Bits equal to the sign are supplied to the vacated bit positions on the left. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Specification

SHIFT RIGHT DOUBLE LOGICAL

SRDL $R_1,D_2(B_2)$ [RS-a]

'8C'	R_1	////	B_2	D_2	
0	8	12	16	20	31

The 64-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 63 of the odd-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the left. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions:

- Specification

SHIFT RIGHT SINGLE

SRA $R_1,D_2(B_2)$ [RS-a]

'8A'	R_1	////	B_2	D_2
0	8	12	16	20 31

SRAK $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'DC'
0	8	12	16	20	32	40 47

SRAG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'0A'
0	8	12	16	20	32	40 47

For SRA, The 31-bit numeric part of the signed first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-32 of general register R_1 remain unchanged.

For SRAK, the 31-bit numeric part of the signed third operand is shifted right the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SHIFT RIGHT SINGLE (SRAG), the 63-bit numeric part of the signed third operand is shifted right the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SRA, The first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the right shift.

For SRAK, the first and third operands are treated as 32-bit signed binary integers in bit positions 32-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 31 numeric bits of the third operand participate in the right shift.

For SRAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the right shift.

For SRA, SRAG, or SRAK, bits shifted out of bit position 63 are not inspected and are lost. Bits equal to the sign are supplied to the vacated bit positions on the left.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Operation (SRAK, if the distinct-operands facility is not installed)

Programming Notes:

1. A right shift of one bit position is equivalent to division by 2 with rounding downward. When an even number is shifted right one position, the result is equivalent to dividing the number by 2. When an odd number is shifted right one position, the result is equivalent to dividing the *next*

lower number by 2. For example, +5 shifted right by one bit position yields +2, whereas -5 yields -3.

2. For SRA and SRAK, shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of -1 or zero, depending on whether or not the initial contents were negative. For SHIFT RIGHT SINGLE (SRAG), a shift amount of 63 causes the same effect.

SHIFT RIGHT SINGLE LOGICAL

SRL $R_1,D_2(B_2)$ [RS-a]

'88'	R_1	////	B_2	D_2
0	8	12	16	20 31

SRLK $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'DE'
0	8	12	16	20	32	40 47

SRLG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'0C'
0	8	12	16	20	32	40 47

For SRL, the 32-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SRLK, the 32-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SRLG, the 64-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SRL, the first operand is in bit positions 32-63 of general register R_1. All 32 bits of the operand participate in the right shift.

For SRLK, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. All 32 bits of the third operand participate in the right shift.

For SRLG, the first and third operands are in bit positions 0-63 of general registers R_1 and R_3, respectively. All 64 bits of the third operand participate in the right shift.

For SRL, SRLG, or SRLK, bits shifted out of bit position 63 are not inspected and are lost. Zeros are supplied to the vacated bit positions on the left.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (SRLK, if the distinct-operands facility is not installed)

Programming Note: The rightmost six bits of the second-operand address are treated as a 6-bit unsigned binary integer specifying the number of bit positions to be shifted to the right. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

When the number of bit positions to be shifted is between 32 and 63, SRL and SRLK can be used to zero the rightmost 32 bits of the result in general register R_1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

Because the number of shifted bit positions is limited to 63, SRLG cannot be used to zero all 64 bits of the result.

STORE

ST $R_1,D_2(X_2,B_2)$ [RX-a]

'50'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

STY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'50'
0	8	12	16	20	32	40 47

STG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'24'
0	8	12	16	20	32	40 47

STORE RELATIVE LONG

STRL R_1,RI_2 [RIL-b]

'C4'	R_1	'F'	RI_2
0	8	12	16 47

STGRL R_1,RI_2 [RIL-b]

'C4'	R_1	'B'	RI_2
0	8	12	16 47

The first operand is placed unchanged at the second-operand location.

For STORE (ST, STY) and STORE RELATIVE LONG (STRL), the operands are 32 bits, and, for STORE (STG) and STORE RELATIVE LONG (STGRL), the operands are 64 bits.

The displacement for ST is treated as a 12-bit unsigned binary integer. The displacement for STY and STG is treated as a 20-bit signed binary integer.

For STORE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For STORE RELATIVE LONG (STRL), the second operand must be aligned on a word boundary, and for STORE RELATIVE LONG (STGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STY, if the long-displacement facility is not installed; STRL and STGRL, if the general-instructions-extension facility is not installed)
- Specification (STRL, STGRL only)

Programming Notes:

1. For STORE RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.

2. When STORE RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction or into the cache line from which a subsequent instruction may be fetched. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE ACCESS MULTIPLE

STAM $R_1,R_3,D_2(B_2)$ [RS-a]

'9B'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

STAMY $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'9B'
0	8	12	16	20	32	40 47

The contents of the set of access registers starting with access register R_1 and ending with access register R_3 are stored at the locations designated by the second-operand address.

The storage area where the contents of the access registers are placed starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The contents of the access registers are stored in ascending order of their register numbers, starting with access register R_1 and continuing up to and including access register R_3, with access register 0 following access register 15. The contents of the access registers remain unchanged.

The displacement for STAM is treated as a 12-bit unsigned binary integer. The displacement for STAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STAMY, if the long-displacement facility is not installed)
- Specification

STORE CHARACTER

STC $R_1,D_2(X_2,B_2)$ [RX-a]

'42'	R_1	X_2	B_2	D_2

0 8 12 16 20 31

STCY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'72'

0 8 12 16 20 32 40 47

Bits 56-63 of general register R_1 are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement for STC is treated as a 12-bit unsigned binary integer. The displacement for STCY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STCY, if the long-displacement facility is not installed)

STORE CHARACTER HIGH

STCH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C3'

0 8 12 16 20 32 40 47

Bits 24-31 of general register R_1 are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE CHARACTERS UNDER MASK

STCM $R_1,M_3,D_2(B_2)$ [RS-b]

'BE'	R_1	M_3	B_2	D_2

0 8 12 16 20 31

STCMY $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'2D'

0 8 12 16 20 32 40 47

STCMH $R_1,M_3,D_2(B_2)$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'2C'

0 8 12 16 20 32 40 47

Bytes selected from general register R_1 under control of a mask are placed at contiguous byte locations beginning at the second-operand address.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R_1. For STORE CHARACTERS UNDER MASK (STCM, STCMY), the four bytes to which the mask bits correspond are in bit positions 32-63 of general register R_1. For STORE CHARACTERS UNDER MASK (STCMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The bytes corresponding to ones in the mask are placed in the same order at successive and contiguous storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The contents of the general register remain unchanged.

When the mask is not zero, exceptions associated with storage-operand accesses are recognized only for the number of bytes specified by the mask.

When the mask is zero, the single byte designated by the second-operand address remains unchanged. However, on some models, an access exception may be recognized for the location. If accessible, (a) a PER zero-address-detection event may be recognized for the location, and (b) the contents may be fetched and subsequently stored back unchanged at the same storage location; this update appears to be an interlocked-update reference as observed by other CPUs.

The displacement for STCM is treated as a 12-bit unsigned binary integer. The displacement for STCMY and STCMH is treated as a 20-bit signed binary integer.

When STORE CHARACTERS UNDER MASK (STCMH) is attempted in a nonconstrained transaction, the M_3 field is 0, and the code in the R_1 field is 6 or 7, it is model dependent whether the instruction is restricted; if the instruction is not restricted, it is unpredictable whether the transaction is aborted due to abort code 16. When STORE CHARACTER UNDER MASK (STCMH) is attempted in a constrained transaction and the M_3 field is 0, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STCMY, if the long-displacement facility is not installed)
- Transaction constraint (STCMH)

Programming Notes:

1. An example of the use of the STORE CHARACTERS UNDER MASK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. STORE CHARACTERS UNDER MASK (STCM, STCMY), with a mask of 0111 binary may be used to store a three-byte address, for example, in modifying the address in a format-0 CCW.

3. STORE CHARACTERS UNDER MASK (STCM, STCMY) with a mask of 1111, 0011, or 0001 binary performs the same function as STORE (ST), STORE HALFWORD, or STORE CHARACTER, respectively.

4. Using STORE CHARACTERS UNDER MASK with a zero mask may cause any of the following to occur for the byte designated by the second-operand address: a PER storage-alteration event may be recognized; access exceptions may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

5. On certain models, STORE CHARACTERS UNDER MASK with mask field that specifies discontiguous bytes may perform slower than when the mask specifies contiguous bytes.

STORE CLOCK

STCK $D_2(B_2)$ [S]

'B205'	B_2	D_2
0	16	20 31

STORE CLOCK FAST

STCKF $D_2(B_2)$ [S]

'B27C'	B_2	D_2
0	16	20 31

The current value of bits 0-63 of the TOD clock is stored in the eight-byte field designated by the second-operand address, provided the clock is in the set, stopped, or not-set state.

When the clock is stopped, zeros are stored in positions to the right of the rightmost bit position that is incremented when the clock is running. For STORE CLOCK, when the value of a running clock is stored, nonzero values may be stored in positions to the right of the rightmost incremented bit; this is to ensure that a unique value is stored. For STORE CLOCK FAST, when the value of a running clock is stored, bits to the right of the rightmost bit that is incremented are stored as zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.

The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

For STORE CLOCK, a serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.

Resulting Condition Code:

0 Clock in set state
1 Clock in not-set state
2 Clock in error state
3 Clock in stopped state or not-operational state

Program Exceptions:

- Access (store, operand 2)
- Operation (STCKF, if the store-clock-fast facility is not installed)
- Transaction constraint

Programming Notes:

1. Bit position 31 of the clock is incremented every 1.048576 seconds; hence, for timing applications involving human responses, the leftmost clock word may provide sufficient resolution.

2. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK cannot be used for time measurement or indication.

3. Condition code 3 indicates that the clock is in either the stopped state or the not-operational state. These two states can normally be distinguished because an all-zero value is stored when the clock is in the not-operational state.

4. If a problem program written for z/Architecture is to be executed also on a system in the System/370 mode, then the program should take into account that, in the System/370 mode, the value stored when the condition code is 2 is not necessarily zero.

5. Two executions of STORE CLOCK FAST, or an execution of STORE CLOCK FAST and STORE CLOCK, either on the same or different CPUs, do not necessarily return different values of the clock if the clock is running. Similarly, an execution of STORE CLOCK FAST and STORE CLOCK EXTENDED, either on the same or different CPUs, do not necessarily return different values of TOD clock bits 0-63 if the clock is running.

   Two executions of STORE CLOCK FAST, an execution of STORE CLOCK FAST and STORE CLOCK, or an execution of STORE CLOCK FAST and STORE CLOCK EXTENDED on different CPUs, may produce results that make it appear that the TOD clock is running backwards (see Figure 4-13 on page 4-51 for details).

6. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK or STORE CLOCK FAST.

7. Using the standard epoch beginning January 1, 1900, the TOD clock provided by STORE CLOCK and STORE CLOCK FAST will wrap around to zero on September 17, 2042 at 23:53:57.370496 TAI. When the multiple-epoch facility is installed, the STORE CLOCK EXTENDED instruction provides an extended result that does not wrap around to zero at the end of an epoch.

STORE CLOCK EXTENDED

STCKE $D_2(B_2)$ [S]

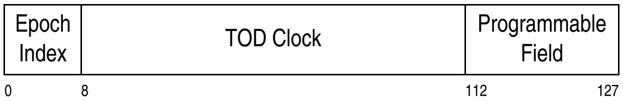
'B278'	B_2	D_2
0	16	20 31

Provided that the clock is in the set, stopped, or not-set state, the following are stored into the 16-byte second operand:

- When the multiple-epoch facility (MEF) is not installed in the configuration, it is unpredictable whether the epoch index or zeros are stored in byte position 0. When the multiple epoch facility is installed in the configuration, the epoch index is stored in byte position 0.

- The current value of the TOD clock is stored in byte positions 1-13.
- The TOD programmable field, bits 16-31 of the TOD programmable register, is stored in byte positions 14 and 15.

The operand just described has the following format:



When the clock is stopped, zeros are stored in the clock value in positions to the right of the rightmost bit position that is incremented when the clock is running. The programmable field still is stored.

When the value of a running clock is stored, the value in bit positions 64-103 of the clock (bit positions 72-111 of the storage operand) is always nonzero; this ensures that values stored by STORE CLOCK EXTENDED are unique when compared with values stored by STORE CLOCK and extended with zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.

The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

A serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.

Resulting Condition Code:

0 Clock in set state
1 Clock in not-set state
2 Clock in error state
3 Clock in stopped state or not-operational state

Program Exceptions:

- Access (store, operand 2)
- Transaction constraint

1. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK EXTENDED cannot be used for time measurement or indication.
2. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK EXTENDED.
3. Programming notes 7-9 beginning on page 4-53 show hex values related to the value of the TOD clock as it is stored by the STORE CLOCK instruction. Notes 4-6, below, are repetitions of those notes except with the text and hex values adjusted so they apply to bits 0-71 of the value stored by STORE CLOCK EXTENDED.
4. The following chart shows the time interval between instants at which various bits of the TOD-clock value stored by STORE CLOCK EXTENDED are stepped. This time value may also be considered as the weighted time value that the bit, when one, represents. The bit numbers are those of the STORE CLOCK EXTENDED operand.

	Stepping Interval			
STCKE Bit	**Days**	**Hours**	**Min.**	**Seconds**
59				0.000 001
55				0.000 016
51				0.000 256
47				0.004 096
43				0.065 536
39				1.048 576
35				16.777 216
31			4	28.435 456
27		1	11	34.967 296
23		19	5	19.476 736
19	12	17	25	11.627 776
15	203	14	43	6.044 416
11	3257	19	29	36.710 656

5. The following chart shows the setting of bits 0-63 of the STORE CLOCK EXTENDED operand for 00:00:00 (0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 27 leap seconds that will have occurred through January, 2017. Each of these leap seconds is inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed.

Year	Month	Day	Leap Sec.	STCKE Value (Hex) Bits 0-63
1900	1	1		0000 0000 0000 0000
1972	1	1		0081 26D6 0E46 0000
1972	7	1	1	0082 0BA9 811E 2400
1973	1	1	2	0082 F300 AEE2 4800
1974	1	1	3	0084 BDE9 7114 6C00
1975	1	1	4	0086 88D2 3346 9000
1976	1	1	5	0088 53BA F578 B400
1977	1	1	6	008A 1FE5 9520 D800
1978	1	1	7	008B EACE 5752 FC00
1979	1	1	8	008D B5B7 1985 2000
1980	1	1	9	008F 809F DBB7 4400
1981	7	1	10	0092 305C 0FCD 6800
1982	7	1	11	0093 FB44 D1FF 8C00

1988	1	1	14	009D DA69 A557 F800
1990	1	1	15	00A1 717D 063E 1C00
1991	1	1	16	00A3 3C65 C870 4000
1992	7	1	17	00A5 EC21 FC86 6400
1993	7	1	18	00A7 B70A BEB8 8800
1994	7	1	19	00A9 81F3 80EA AC00
1996	1	1	20	00AC 3433 6FEC D000
1997	7	1	21	00AE E3EF A402 F400
1999	1	1	22	00B1 962F 9305 1800
2006	1	1	23	00BE 2510 9797 3C00
2009	1	1	24	00C3 870C B9BB 6000
2012	7	1	25	00C9 CC9A 704D 8400
2015	7	1	26	00CF 2D54 B4FB A800
2017	1	1	27	00D1 E0D6 8173 CC00

6. The stepping value of TOD-clock bit position 63, if implemented, is 2^{-12} microseconds, or approximately 244 picoseconds. This value is called a clock unit.

   The following chart shows various time intervals in clock units expressed in hexadecimal notation. The chart shows the values stored in bit positions 0-71 of the STORE CLOCK EXTENDED operand. Bit 71 of the operand represents a clock unit.

Interval	Clock Units (Hex) Bits 0-71
1 microsecond	0010 00
1 millisecond	3E80 00
1 second	00F4 2400 00
1 minute	3938 7000 00
1 hour	000D 693A 4000 00
1 day	0141 DD76 0000 00
365 days	0001 CAE8 C13E 0000 00
366 days	0001 CC2A 9EB4 0000 00
1,461 days*	0007 2CE4 E26E 0000 00

* Number of days in four years, including a leap year. Note that the year 1900 was not a leap year. Thus, the four-year span starting in 1900 has only 1,460 days.

STORE FACILITY LIST EXTENDED

STFLE $D_2(B_2)$ [S]

'B2B0'	B_2	D_2
0	16	20 31

A list of bits providing information about facilities is stored beginning at the doubleword specified by the second operand address.

For the leftmost doublewords in which facility bits are assigned, the reserved bits are stored as zeros. Doublewords to the right of the doubleword in which the highest-numbered facility bit is assigned for a model may or may not be stored. Access exceptions and PER events are not recognized for doublewords that are not stored.

The size of the second operand, in doublewords, is one more than the value specified in bits 56-63 of general register 0. The remaining bits of general register 0 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

When the size of the second operand is large enough to contain all of the facility bits assigned for a model, then the complete facility list is stored in the second operand location, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the model, and condition code 0 is set.

When the size of the second operand is not large enough to contain all of the facility bits assigned for a model, then only the number of doublewords specified by the second-operand size are stored, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the model, and condition code 3 is set.

Figure 4-36, “Assigned Facility Bits” on page 4-99 shows the meanings of the assigned facility bits.

Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Complete facility list stored
1 --
2 --
3 Incomplete facility list stored

Program Exceptions:

- Access (store, second operand)
- Operation (if the store-facility-list-extended facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The performance of STORE FACILITY LIST EXTENDED may be significantly slower than that of simply testing a byte in storage. Programs that need to frequently test for the presence of a facility — for example, dual-path code in which the facility is used in one path but not another — should execute the STORE FACILITY LIST EXTENDED instruction once during initialization. Subsequently, the program may test for the presence of the facility by examining the stored result, using an instruction such as TEST UNDER MASK.

2. When condition code 0 is set, bits 56-63 of general register 0 are updated to contain a value that is one less than the number of doublewords stored. If the program chooses to ignore the results in general register 0, then it should ensure that the entire second operand in storage is set to zero prior to executing STORE FACILITY LIST EXTENDED.

STORE GUARDED STORAGE CONTROLS

STGSC $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3”	R_1	X_2	B_2	DL_2	DH_2	'49'

0 8 12 16 20 32 40 47

The contents of the three guarded-storage registers are stored at the second-operand location. The second operand has the format of a guarded-storage control block (GSCB), as shown in Figure 4-19 on page 4-67.

Access exceptions are recognized for all 32 bytes of the GSCB.

The R_1 field of the instruction is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.

Special Conditions

A special-operation exception is recognized and the instruction is suppressed if the guarded-storage-facility-enablement control, bit 59 of control register 2, is zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, second operand)
- Operation (if the guarded-storage facility is not installed)
- Special operation
- Transaction constraint

STORE HALFWORD

STH $R_1,D_2(X_2,B_2)$ [RX-a]

'40'	R_1	X_2	B_2	D_2

0 8 12 16 20 31

STHY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'70'
0	8	12	16	20	32	40 47

STORE HALFWORD RELATIVE LONG

STHRL R_1,RI_2 [RIL-b]

'C4'	R_1	'7'	RI_2
0	8	12	16 47

Bits 48-63 of general register R_1 are placed unchanged at the second-operand location. The second operand is two bytes in length.

The displacement for STH is treated as a 12-bit unsigned binary integer. The displacement for STHY is treated as a 20-bit signed binary integer.

For STORE HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

Access (store, operand 2)

Operation (STHY if the long-displacement facility is not installed; STHRL, if the general-instructions-extension facility is not installed.)

Programming Notes:

1. For STORE HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.

2. When STORE HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE HALFWORD HIGH

STHH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'C7'
0	8	12	16	20	32	40 47

Bits 16-31 of general register R_1 are placed unchanged at the second-operand location. The second operand is two bytes in length.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE HIGH

STFH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'CB'
0	8	12	16	20	32	40 47

The first operand is placed unchanged at the second-operand location. The first operand is in bits 0-31 of general register R_1, and the second operand is 32 bits in storage.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE MULTIPLE

STM $R_1,R_3,D_2(B_2)$ [RS-a]

'90'	R_1	R_3	B_2	D_2	
0	8	12	16	20	31

STMY $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'90'	
0	8	12	16	20	32	40	47

STMG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'24'	
0	8	12	16	20	32	40	47

The contents of bit positions of the set of general registers starting with general register R_1 and ending with general register R_3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For STORE MULTIPLE (STM, STMY), the contents of bit positions 32-63 of the general registers are stored in successive four-byte fields beginning at the second-operand address. For STORE MULTIPLE (STMG), the contents of bit positions 0-63 of the general registers are stored in successive eight-byte fields beginning at the second-operand address.

The general registers are stored in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

The displacement for STM is treated as a 12-bit unsigned binary integer. The displacement for STMY and STMG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STMY, if the long-displacement facility is not installed)

Programming Note: An example of the use of the STORE MULTIPLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

STORE MULTIPLE HIGH

STMH $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'26'	
0	8	12	16	20	32	40	47

The contents of the high-order halves, bit positions 0-31, of the set of general registers starting with general register R_1 and ending with general register R_3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, the contents of bit positions 0-31 are stored in successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers are ignored.

The general registers are stored in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)

Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

STORE ON CONDITION

STOC $R_1,D_2(B_2),M_3$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'F3'	
0	8	12	16	20	32	40	47

STOCG $R_1,D_2(B_2),M_3$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'E3'	
0	8	12	16	20	32	40	47

STORE HIGH ON CONDITION

STOCFH $R_1,D_2(B_2),M_3$ [RSY-b]

'EB'	R_1	M_3	B_2	DL_2	DH_2	'E1'
0	8	12	16	20	32	40 47

The first operand is placed unchanged at the second-operand location if the condition code has one of the values specified by M_3; otherwise, the second operand remains unchanged.

For STOC and STOCFH, the first and second operands are 32 bits, and for STOCG, the first and second operands are 64 bits. For STOC, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are ignored. For STOCFH, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are ignored.

The M_3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Instruction Bit Number of Mask	12	13	14	15
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the store is performed. If the mask bit selected is zero, the store is not performed.

The displacement is treated as a 20-bit signed binary integer.

When the condition specified by the M_3 field is not met (that is, store operation is not performed), it is model dependent whether any or all of the following occur for the second operand: (a) an access exception is recognized, (b) the change bit is set, or (c) a PER storage-alteration or zero-address-detection event is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the load/store-on-condition facility 1 is not installed; STOCFH, if the load/store-on-condition facility 2 is not installed)

Programming Notes:

1. When the M_3 field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M_3 field contains all ones and no exception condition exists, the store operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional store, respectively.

2. When the condition specified by the M_3 field is not met, it is model dependent whether the second operand is brought into the cache.

3. STORE ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a STORE instruction, except that STORE ON CONDITION does not provide an index register. For example, assuming the storage location is accessible, the following two instruction sequences are equivalent.

```
STOCG  15,256(7),8  |       BC    7,SKIP
                    |       STG   15,256(0,7)
                    |  SKIP DS    0H
```

   On models that implement predictive branching, the combination of the BRANCH ON CONDITION and STORE instructions may perform somewhat better than the STORE ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the STORE ON CONDITION instruction may provide significant performance improvement.

4. See programming note 4 on page 7-284 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

STORE PAIR TO QUADWORD

STPQ $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'8E'
0	8	12	16	20	32	40 47

The quadword first operand is stored at the second-operand location. The store at the second-operand location appears to be quadword concurrent as observed by other CPUs. The left doubleword of the first operand is in general register R_1, and the right doubleword is in general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Specification
- Transaction constraint

Programming Notes:

1. The STORE MULTIPLE (STM or STMG) instruction does not necessarily provide quadword-concurrent access.

2. The performance of STORE PAIR TO QUADWORD on some models may be significantly slower than that of STORE MULTIPLE (STMG). Unless quadword consistency is required, STMG should be used instead of STPQ.

STORE REVERSED

STRVH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'3F'	
0	8	12	16	20	32	40	47

STRV $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'3E'	
0	8	12	16	20	32	40	47

STRVG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'2F'	
0	8	12	16	20	32	40	47

The first operand is placed at the second-operand location with the left-to-right sequence of the bytes reversed.

For STORE REVERSED (STRVH), the first operand is two bytes in bit positions 48-63 of general register R_1. For STORE REVERSED (STRV), the first operand is four bytes in bit positions 32-63 of general register R_1. For STORE REVERSED (STRVG), the first operand is eight bytes in bit positions 0-63 of general register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)

Programming Notes:

1. The instruction can be used to convert two, four, or eight bytes from a "little-endian" format to a "big-endian" format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

'B9E9'	R_3	////	R_1	R_2	
0	16	20	24	28	31

Register-and-storage formats:

S $R_1,D_2(X_2,B_2)$ [RX-a]

'5B'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

SY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'5B'
0	8	12	16	20	32	40 47

SG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'09'
0	8	12	16	20	32	40 47

SGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'19'
0	8	12	16	20	32	40 47

For S, SG, SGF, SGFR, SGR, SR, and SY, the second operand is subtracted from the first operand, and the difference is placed at the first-operand location. For SGRK and SRK, the third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

For S, SR, SRK, and SY, the operands and the difference are treated as 32-bit signed binary integers. For SG, SGR, and SGRK, they are treated as 64-bit signed binary integers. For SGFR and SGF, the second operand is treated as a 32-bit signed binary integer, and the first operand and the difference are treated as 64-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for S is treated as a 12-bit unsigned binary integer. The displacement for SY, SG, and SGF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2 of S, SY, SG, and SGF only)
- Fixed-point overflow
- Operation (SY, if the long-displacement facility is not installed; SRK, SGRK, if the distinct-operands facility is not installed)

Programming Notes:

1. For SR and SGR, when R_1 and R_2 designate the same register, subtracting is equivalent to clearing the register.
2. Subtracting a maximum negative number from itself gives a zero result and no overflow.

SUBTRACT HALFWORD

SH $R_1,D_2(X_2,B_2)$ [RX-a]

'4B'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

SHY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'7B'
0	8	12	16	20	32	40 47

SGH $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'39'
0	8	12	16	20	32	40 47

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. The first operand and the difference are treated as 32-bit signed binary integers. For SGH, the first operand and the difference are treated as 64-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for SH is treated as a 12-bit unsigned binary integer. The displacement for SGH and SHY is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2)
- Fixed-point overflow
- Operation (SHY, if the long-displacement facility is not installed; SGH, if the miscellaneous-instruction-extensions facility 2 is not installed)

Programming Note: The function of a SUBTRACT HALFWORD IMMEDIATE instruction, which is an instruction not provided, can be obtained by using an ADD HALFWORD IMMEDIATE instruction with a negative I_2 field.

SUBTRACT HIGH

SHHHR R_1,R_2,R_3 [RRF-a]

'B9C9'	R_3	////	R_1	R_2
0	16	20	24	28 31

SHHLR R_1,R_2,R_3 [RRF-a]

'B9D9'	R_3	////	R_1	R_2
0	16	20	24	28 31

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit signed binary integers.

The first and second operands are in bits 0-31 of general registers R_1 and R_2, respectively; bits 32-63 of general register R_1 are unchanged, and bits 32-63 of general register R_2 are ignored. For SHHHR, the third operand is in bits 0-31 of general register R_3; bits 32-63 of the register are ignored. For SHHLR, the third operand is in bits 32-63 of general register R_3; bits 0-31 of the register are ignored.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow
- Operation (if the high-word facility is not installed)

SUBTRACT LOGICAL

Register-and-register formats:

SLR R_1,R_2 [RR]

'1F'	R_1	R_2
0	8	12 15

SLGR R_1,R_2 [RRE]

'B90B'	////////	R_1	R_2
0	16	24	28 31

SLGFR R_1,R_2 [RRE]

'B91B'	////////	R_1	R_2
0	16	24	28 31

SLRK R_1,R_2,R_3 [RRF-a]

'B9FB'	R_3	////	R_1	R_2
0	16	20	24	28 31

SLGRK R_1,R_2,R_3 [RRF-a]

'B9EB'	R_3	////	R_1	R_2
0	16	20	24	28 31

Register-and-storage formats:

SL $R_1,D_2(X_2,B_2)$ [RX-a]

'5F'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

SLY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'5F'
0	8	12	16	20	32	40 47

SLG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'0B'
0	8	12	16	20	32	40 47

SLGF $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'1B'
0	8	12	16	20	32	40 47

SUBTRACT LOGICAL IMMEDIATE

SLFI R_1,I_2 [RIL-a]

'C2'	R_1	'5'	I_2
0	8	12	16 47

SLGFI R_1,I_2 [RIL-a]

'C2'	R_1	'4'	I_2
0	8	12	16 47

For SUBTRACT LOGICAL (SL, SLG, SLGF, SLGFR, SLGR, SLR, SLY) and for SUBTRACT LOGICAL IMMEDIATE, the second operand is subtracted from the first operand, and the difference is placed at the first-operand location. For SUBTRACT LOGICAL (SLGRK and SLRK), the third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

For SUBTRACT LOGICAL (SL, SLR, SLRK, and SLY) and for SUBTRACT LOGICAL IMMEDIATE (SLFI), the operands and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL (SLG, SLGR, and SLGRK), they are treated as 64-bit unsigned binary integers. For SUBTRACT LOGICAL (SLGFR, SLGF) and for SUBTRACT LOGICAL IMMEDIATE (SLGFI), the second operand is treated as a 32-bit unsigned binary integer, and the first operand and the difference are treated as 64-bit unsigned binary integers.

The displacement for SL is treated as a 12-bit unsigned binary integer. The displacement for SLY, SLG, and SLGF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 --
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

Program Exceptions:

- Access (fetch, operand 2 of SL, SLY, SLG, and SLGF only)
- Operation (SLY, if the long-displacement facility is not installed; SLFI and SLGFI, if the extended-immediate facility is not installed; SLRK and SLGRK, if the distinct-operands facility is not installed)

Programming Notes:

1. Logical subtraction is performed by adding the one's complement of the second operand and a value of one to the first operand. The use of the one's complement and the value of one instead of the two's complement of the second operand results in a carry when the second operand is zero.

2. SUBTRACT LOGICAL differs from SUBTRACT only in the meaning of the condition code and in the absence of the interruption for overflow.

3. A zero difference is always accompanied by a carry out of bit position 0 for 64-bit results or bit position 32 for 32-bit results, and, therefore, no borrow.

4. The condition-code setting for SUBTRACT LOGICAL can also be interpreted as indicating the presence or absence of a carry, as follows:

   1 Result not zero; no carry
   2 Result zero; carry
   3 Result not zero; carry

SUBTRACT LOGICAL HIGH

SLHHHR R_1,R_2,R_3 [RRF-a]

'B9CB'	R_3	////	R_1	R_2
0	16	20	24	28 31

SLHHLR R_1,R_2,R_3 [RRF-a]

'B9DB'	R_3	////	R_1	R_2
0	16	20	24	28 31

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit unsigned binary integers.

The first and second operands are in bits 0-31 of general registers R_1 and R_2, respectively; bits 32-63 of general register R_1 are unchanged, and bits 32-63 of general register R_2 are ignored. For SLHHHR, the third operand is in bits 0-31 of general register R_3; bits 32-63 of the register are ignored. For SLHHLR, the third operand is in bits 32-63 of general register R_3; bits 0-31 of the register are ignored.

Resulting Condition Code:

0 --
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

Program Exceptions:

- Operation (if the high-word facility is not installed)

SUBTRACT LOGICAL WITH BORROW

Register-and-register formats:

SLBR R_1,R_2 [RRE]

'B999'	////////	R_1	R_2
0	16	24	28 31

SLBGR R_1,R_2 [RRE]

'B989'	////////	R_1	R_2
0	16	24	28 31

Register-and-storage formats:

SLB $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'99'
0	8	12	16	20	32	40 47

SLBG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'89'
0	8	12	16	20	32	40 47

The second operand and the borrow are subtracted from the first operand, and the difference is placed at the first-operand location. For SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), the operands, the borrow, and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG), they are treated as 64-bit unsigned binary integers.

Resulting Condition Code:

0 Result zero; borrow
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

Program Exceptions:

- Access (fetch, operand 2 of SLB and SLBG only)

Programming Notes:

1. A borrow is represented by a zero value of bit 18 of the current PSW. Bit 18 is the leftmost bit of the two-bit condition code in the PSW. Bit 18 is set to zero by an execution of a SUBTRACT LOGICAL or SUBTRACT LOGICAL WITH BORROW instruction that produces a borrow into the leftmost bit position of the 32-bit or 64-bit result.

2. Logical subtraction with borrow is performed by adding the one's complement of the second operand and bit 18 of the current PSW to the first operand. Therefore, when bit 18 is one, indicating no borrow, the addition is the same as for SUBTRACT LOGICAL.

3. Condition code zero is set for SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), when the maximum 32-bit unsigned binary integer, $2^{32} - 1$, is subtracted from zero when PSW bit 18 indicates a borrow. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG) condition code zero is set when the maximum 64-bit unsigned binary integer, $2^{64} - 1$, is subtracted from zero when PSW bit 18 indicates a borrow.

4. SUBTRACT and SUBTRACT LOGICAL may provide better performance than SUBTRACT LOGICAL WITH BORROW, depending on the model.

SUPERVISOR CALL

SVC I [I]

'0A'	I
0	8 15

The instruction causes a supervisor-call interruption, with the I field of the instruction providing the rightmost byte of the interruption code.

Bits 8-15 of the instruction, with eight zeros appended on the left, are placed in the supervisor-call interruption code that is stored in the course of the interruption. See “Supervisor-Call Interruption” on page 6-57.

A serialization and checkpoint-synchronization function is performed.

Condition Code: The code remains unchanged and is saved as part of the old PSW. A new condition code is loaded as part of the supervisor-call interruption.

Program Exceptions:

- Transaction constraint

TEST ADDRESSING MODE

TAM [E]

'010B'
0 15

The extended-addressing-mode bit and basic-addressing-mode bit, bits 31 and 32 of the current PSW, respectively, are tested, and the result is indicated in the condition code.

Resulting Condition Code:

0 PSW bits 31 and 32 zeros (indicating 24-bit addressing mode)
1 PSW bit 31 zero and bit 32 one (indicating 31-bit addressing mode)
2 --
3 PSW bits 31 and 32 ones (indicating 64-bit addressing mode)

Program Exceptions:

- Transaction constraint

Programming Note: The case when PSW bit 31 is one and bit 32 is zero causes an early PSW specification exception to be recognized.

TEST AND SET

TS D_2(B_2) [SI]

'93'	////////	B_2	D_2
0	8	16	20 31

The leftmost bit (bit position 0) of the byte located at the second-operand address is used to set the condition code, and then the byte is set to all ones.

Bits 8-15 of the instruction are ignored.

The byte in storage is set to all ones as it is fetched for the testing of bit 0. This update appears to be an interlocked-update reference as observed by other CPUs.

A serialization function is performed before the byte is fetched and again after the storing of all ones.

Resulting Condition Code:

0 Leftmost bit zero
1 Leftmost bit one
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Transaction constraint

Programming Notes:

1. TEST AND SET may be used for controlled sharing of a common storage area by programs operating on different CPUs. This instruction is provided primarily for compatibility with programs written for System/360. The instructions COMPARE AND SWAP and COMPARE DOUBLE AND SWAP provide functions which are more suitable for sharing among programs on a single CPU or for programs that may be interrupted. See the description of these instructions and the associated programming notes for details.

2. TEST AND SET does not interlock against storage accesses by channel programs. Therefore, the instruction should not be used to update a location into which a channel program may store, since the channel-program data may be lost.

TEST UNDER MASK (TEST UNDER MASK HIGH, TEST UNDER MASK LOW)

TM $D_1(B_1),I_2$ [SI]

'91'	I_2	B_1	D_1

0 8 16 20 31

TMY $D_1(B_1),I_2$ [SIY]

'EB'	I_2	B_1	DL_1	DH_1	'51'

0 8 16 20 32 40 47

TMHH R_1,I_2 [RI-a]

'A7'	R_1	'2'	I_2

0 8 12 16 31

TMHL R_1,I_2 [RI-a]

'A7'	R_1	'3'	I_2

0 8 12 16 31

TMH R_1,I_2 [RI-a]
TMLH R_1,I_2 [RI-a]

'A7'	R_1	'0'	I_2

0 8 12 16 31

TML R_1,I_2 [RI-a]
TMLL R_1,I_2 [RI-a]

'A7'	R_1	'1'	I_2

0 8 12 16 31

A mask is used to select bits of the first operand, and the result is indicated in the condition code.

TEST UNDER MASK is a new name of, and TMLH and TMLL are new mnemonics for, the ESA/390 instructions TEST UNDER MASK HIGH (TMH) and TEST UNDER MASK LOW (TML), respectively.

In TEST UNDER MASK (TM, TMY), the byte of immediate data, I_2, is used as an eight-bit mask. The bits of the mask are made to correspond one for one with the bits of the byte in storage designated by the first-operand address.

A mask bit of one indicates that the storage bit is to be tested. When the mask bit is zero, the storage bit is ignored. When all storage bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

Access exceptions associated with the storage operand are recognized for one byte even when the mask is all zeros.

In TEST UNDER MASK (TMHH, TMHL, TMLH, TMLL), the contents of the I_2 field are used as a 16-bit mask. For each instruction, the bits of the mask are made to correspond one for one with 16 bits of the first operand as follows:

Instruction	Bits Tested
TMHH	0-15
TMHL	16-31
TMLH (or TMH)	32-47
TMLL (or TML)	48-63

A mask bit of one indicates that the first-operand bit is to be tested. When the mask bit is zero, the first-operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are mixed zeros and ones, condition code 1 is set if the leftmost selected bit is zero, or condition code 2 is set if the leftmost selected bit is one. When the selected bits are all ones, condition code 3 is set.

The displacement for TM is treated as a 12-bit unsigned binary integer. The displacement for TMY is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Selected bits all zeros; or mask bits all zeros
1 Selected bits mixed zeros and ones (TM and TMY only)
1 Selected bits mixed zeros and ones, and leftmost is zero (TMHH, TMHL, TMLH, TMLL)
2 -- (TM and TMY only)
2 Selected bits mixed zeros and ones, and leftmost is one (TMHH, TMHL, TMLH, TMLL)
3 Selected bits all ones

Program Exceptions:

- Access (fetch, operand 1, TM and TMY only)
- Operation (TMY, if the long-displacement facility is not installed)

Programming Notes:

1. An example of the use of the TEST UNDER MASK (TM) instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the mask for TMHH, TMHL, TMLH, or TMLL selects exactly two bits, the two selected bits effectively are loaded into the condition code.

TRANSACTION ABORT

TABORT $D_2(B_2)$ [S]

'B2FC'	B_2	D_2

0 16 20 31

If the CPU is in the nonconstrained transactional-execution mode, the transaction is aborted.

The second-operand address is not used to address data; instead, the address specified by the B_2 and D_2 fields forms the transaction abort code which is placed in the transaction diagnostic block during abort processing. Address computation for the second-operand address follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

Aborting of a transaction by the TABORT instruction consists of performing steps 1-7 of the section “Transaction Abort Processing” on page 5-102. The condition code in the transaction-abort PSW is set to either 2 or 3, depending on whether bit 63 of the second-operand address is zero or one, respectively.

A serialization function is implicitly performed by the abort processing.

When TRANSACTION ABORT is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A specification exception is recognized and the operation is suppressed if the second-operand address is between 0 and 255.

A special-operation exception is recognized and the operation is suppressed if the CPU is not in the transactional-execution mode at the beginning of the instruction.

If the CPU is in the constrained transactional-execution mode, a transaction-constraint program exception condition is recognized.

Condition Code: The code remains unchanged. However, the condition code of the transaction-abort PSW will be set by the subsequent transaction-abort processing.

Program Exceptions:

- Execute
- Operation (transactional-execution facility not installed)
- Special-operation
- Specification
- Transaction constraint

Programming Notes:

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode; Attempted execution of a TRANSACTION ABORT in this case results in a special-operation exception.
2. Abort codes 0-255 are reserved for transactions that are implicitly aborted by the CPU. See “Transaction Abort Conditions” on page 5-100 for details.
3. Program interruptions are subject to the effective program-interruption filtering control.
4. Execution of TABORT may result in significant performance degradation, potentially causing high contention which, in turn, can lead to other abort conditions.
5. Following the TABORT instruction, program execution continues at the instruction designated by the transaction-abort PSW.

TRANSACTION BEGIN (TBEGIN)

TBEGIN $D_1(B_1),I_2$ [SIL]

'E560'	B_1	D_1	I_2

0 16 20 32 47

Execution of the TRANSACTION BEGIN (TBEGIN) instruction causes the CPU either to enter or to remain in the nonconstrained transactional-execution mode.

When the B_1 field is nonzero, the following applies;

- When the transaction nesting depth is initially zero, the first-operand address designates the location of the 256-byte transaction diagnostic block, called the TBEGIN-specified TDB, into which various diagnostic information may be stored if the transaction is aborted (see “Transaction Diagnostic Block (TDB)” on page 5-93). When the CPU is in the primary-space mode or access-register mode, the first-operand address designates a location in the primary address space. When the CPU is in the secondary-space or home-space mode, the first-operand address designates a location in the secondary or home address space, respectively. When DAT is off, the TDBA designates a location in real storage.

  Store accessibility to the first operand is determined. If accessible, the logical address of the operand is placed into the transaction-diagnostic-block address (TDBA), and the TDBA is valid.

- When the CPU is already in the nonconstrained transactional-execution mode, the TDBA is not modified, and it is unpredictable whether the first operand is tested for accessibility.

When the B_1 field is zero, no access exceptions are detected for the first operand, and, for the outermost TBEGIN instruction, the TDBA is invalid.

The I_2 field contains various controls for the instruction and has the following format:

GRSM	/ / / /	A	F	PI FC
0	8	12	13	14 15

The bits of the I_2 field are defined as follows:

General Register Save Mask (GRSM): Bits 0-7 of the I_2 field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM of the outermost TBEGIN instruction is zero, the corresponding register pair is not saved. When a bit in the GRSM of the outermost TBEGIN instruction is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TBEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a transaction aborts.

The general register save mask is ignored on all TBEGINs except for the outermost one.

Allow AR Modification (A): The A control, bit 12 of the I_2 field, controls whether the transaction is allowed to modify an access register. The effective allow-AR-modification control is the logical AND of the A control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

Allow Floating-Point Operation (F): The F control, bit 13 of the I_2 field, controls whether the transaction is allowed to execute any floating-point instruction (that is, any instruction defined in Chapters 9, 18, 19, or 20) or any vector instruction (that is, any instruction defined in Chapters 21, 22, 23, 24, or 25). The effective allow-floating-point-operation control is the logical AND of the F control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective F control is zero, then (a) the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to execute a floating-point or vector instruction, and (b) the data-exception code (DXC) in byte 2 of the floating-point control register (FPCR) will not be set by any data-exception program-exception condition. If the effective F control is one, then (a) the transaction will not be aborted if an attempt is made to execute a floating-point or vector instruction (absent any other abort condition), and (b) the DXC or VXC in the FPCR may be set by a data-exception or vector-exception program-exception condition.

Program-Interruption-Filtering Control (PIFC): Bits 14-15 of the I_2 field are the program-interruption-filtering control (PIFC). The PIFC controls whether certain classes of program-exception conditions that occur while the CPU is in the transactional-execution mode result in an interruption. See “Program-Interruption Filtering on a Transaction Abort" on page 5-104 for a description of these classes.

The effective PIFC is the highest value of the PIFC in the TBEGIN instruction for the current nesting level and for all outer levels. When the effective PIFC is zero, all program-exception conditions result in an interruption. When the effective PIFC is one, program-exception conditions having a transactional-execution class of 1 and 2 result in an interruption. When the effective PIFC is two, program-exception conditions having a transactional-execution class of 1 result in an interruption. A PIFC of 3 is reserved.

Bits 8-11 of the I_2 field (bits 40-43 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

TRANSACTION BEGIN (TBEGIN) Processing

Execution of the TRANSACTION BEGIN (TBEGIN) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-363 on page 7-404 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if either of the following is true.
   a. The program-interruption-filtering control, bits 14-15 of I_2 field of the instruction, contains the value 3.
   b. The first-operand address does not designate a doubleword boundary. It is model dependent whether a specification exception is recognized when the first-operand address does not designate a doubleword boundary if either the B_1 field is zero or the transaction-nesting depth is nonzero.
4. If the CPU is in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. When the B_1 field is nonzero, the following applies:
   - If the CPU is not in the transactional-execution mode (that is, the transaction nesting depth is zero), then the following occurs:
     – Store accessibility to the first operand is determined. If the first operand cannot be accessed for stores, then an access exception is recognized and the operation is either nullified, suppressed, or terminated, depending on the specific access-exception condition.
     – Any PER storage-alteration or zero-address-detection event for the first operand is recognized.
   - If the CPU is already in the transactional-execution mode, it is unpredictable whether (a) store accessibility to the first operand is determined, and (b) PER storage-alteration or zero-address-detection events are detected for the first operand.

   If the B_1 field is zero, then the first operand is not accessed.
6. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See "Transaction Abort Processing" on page 5-102 for details on the handling of a transaction abort.
7. If the CPU is not in the transactional-execution mode, the following occurs:
   a. If the B_1 field is nonzero, the first-operand address is placed in the transaction-diagnostic-block address, and the transaction-diagnostic-block address is valid. If the B_1 field is zero, the transaction-diagnostic-block address is invalid.
   b. The transaction-abort PSW is set from the contents of the current PSW. The instruction address of the transaction-abort PSW designates the next-sequential instruction (that is, the instruction following the outermost TBEGIN).
8. An effective value of the allow-AR-modification (A) control, bit 12 of the I_2 field of the instruction, is determined. The effective A control is the logi-

cal AND of the A control in the TBEGIN instruction for the current level and for all outer levels.

9. An effective value of the allow-floating-point-operation (F) control, bit 13 of the I_2 field of the instruction, is determined. The effective F control is the logical AND of the F control in the TBEGIN instruction for the current level and for all outer levels.

10. An effective value of the program-interruption-filtering control (PIFC), bits 14-15 of the I_2 field of the instruction, is determined. The effective PIFC value is highest value in the TBEGIN instruction for the current level and for all outer levels.

11. If the CPU is not in the transactional-execution mode, the contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.

12. A value of one is added to the transaction nesting depth, and the instruction completes by setting condition code 0. If the transaction nesting depth transitions from zero to one, the CPU enters the nonconstrained transactional-execution mode; otherwise, the CPU remains in the nonconstrained transactional-execution mode.

When TBEGIN is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See “Event-Suppression Control (ES)” on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

Resulting Condition Code:

0 Transaction initiation successful
1 – (see programming notes 3 and 4)
2 – (see programming notes 3 and 4)
3 – (see programming notes 3 and 4)

Program Exceptions:

- Access (store, first operand)
- Execute
- Operation (transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to reserved PIFC value.
8.B	Specification exception due to first-operand address not on a doubleword boundary.
8.C	Access exception (when B_1 field is nonzero).
8.D	Abort due to exceeding maximum transaction nesting depth.
9	Condition code 0 due to normal completion.

Figure 7-363. Priority of Execution: TRANSACTION BEGIN (TBEGIN)

Programming Notes:

1. When the B_1 field is nonzero, the following applies:

   - An accessible transaction diagnostic block (TDB) must be provided when an outermost transaction is initiated – even if the transaction never aborts.

   - Since it is unpredictable whether accessibility of the TDB is tested for nested transactions, an accessible TDB should be provided for any nested TBEGIN instruction.

   - The performance of any TBEGIN in which the B_1 field is nonzero, and the performance of any abort processing that occurs for a transaction that was initiated by an outermost TBEGIN in which the B_1 field is nonzero, may be slower than when the B_1 field is zero.

2. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The I_2 field should designate all register pairs that provide input values that are changed by the transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when the abort handler is entered.

3. The TRANSACTION BEGIN (TBEGIN) instruction is expected to be followed by a conditional branch instruction that will determine whether the transaction was successfully initiated. See programming note 3 on page 5-103 for a complete explanation of each condition code.

4. If a transaction is aborted due to conditions that do not result in an interruption, the instruction designated by the transaction-abort PSW receives control (that is, the instruction following the outermost TRANSACTION BEGIN [TBEGIN]). In addition to the condition code set by the TRANSACTION BEGIN (TBEGIN) instruction, condition codes 1-3 are also set when a transaction aborts.

   Therefore, the instruction sequence following the outermost TRANSACTION BEGIN (TBEGIN) instruction should be able to accommodate all four condition codes, even though the TBEGIN instruction only sets code 0. See the explanation of abort condition codes in programming note 3 on page 5-103.

5. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

6. While in the nonconstrained transactional-execution mode, a program may call a service function which may alter access registers, floating-point registers (including the floating-point control register), or vector registers. Although such a service routine may save the altered registers on entry and restore them at exit, the transaction may be aborted prior to normal exit of the routine. If the calling program makes no provision for preserving these registers while the CPU is in the nonconstrained transactional-execution mode, it may not be able to tolerate the service function's alteration of the registers.

   To prevent inadvertent alteration of access registers while in the nonconstrained transactional-execution mode, the program can set the allow-AR-modification control, bit 12 of the I_2 field of the TRANSACTION BEGIN instruction, to zero. Similarly, to prevent the inadvertent alteration of the floating-point registers or vector registers, the program can set the allow-floating-point-operation control, bit 13 of the I_2 field of the TBEGIN instruction, to zero.

7. Program-interruption conditions recognized during the execution of TRANSACTION BEGIN (TBEGIN) instruction are subject to the effective program-interruption filtering control set by any outer TBEGIN instructions. Program-interruption conditions recognized during the execution of the outermost TBEGIN instruction are not subject to filtering.

8. In order to update multiple storage locations in a serialized manner, conventional code sequences may employ a lock word (semaphore). If (a) transactional execution is used to implement updates of multiple storage locations, (b) the program also provides a “fall-back” path to be invoked if the transaction aborts, and (c) the fall-back path employs a lock word, then the transactional-execution path should also test for the availability of the lock, and, if the lock is unavailable, end the transaction by means of the TRANSACTION END instruction and branch to the fall-back path. This ensures consistent access to the serialized resources, regardless of whether they are updated transactionally.

   Alternatively, the program could abort if the lock is unavailable, however the abort processing may be significantly slower than simply ending the transaction via TEND.

9. If the effective program-interruption filtering control (PIFC) is greater than zero, the CPU filters most data-exception program interruptions. If the effective allow-floating-point-operation (F) control is zero, the data-exception code (DXC) will not be set in the floating-point control register as a result of an abort due to a data-exception program-exception condition. In this scenario (filtering applies and the effective F control is zero), the only location in which the DXC can be inspected is in the TBEGIN-specified TDB. If the program's abort handler needs to inspect the DXC in such a situation, general register B_1 should be nonzero, such that a valid transaction-diagnostic-block address (TDBA) is set.

10. If a PER storage-alteration or zero-address-detection condition exists for the TBEGIN-specified TDB of the outermost TBEGIN instruction, and PER event suppression does not apply, the PER event will be recognized during the execution of the instruction, thus causing the transac-

tion to be aborted immediately, regardless of whether any other abort condition exists.

TRANSACTION BEGIN (TBEGINC)

TBEGINC $D_1(B_1),I_2$ [SIL]

'E561'	B_1	D_1	I_2	
0	16	20	32	47

Execution of the TRANSACTION BEGIN (TBEGINC) instruction causes the CPU to enter the constrained transactional-execution mode or remain in the nonconstrained transactional-execution mode.

The first-operand address is not used to access storage. The B_1 field, bits 16-19 of the instruction, must contain zeros; otherwise, a specification exception is recognized.

The I_2 field contains various controls for the instruction and has the following format:

GRSM	/ / / /	A	/	/	/
0	8	12	13	14	15

The bits of the I_2 field are defined as follows:

General Register Save Mask (GRSM): Bits 0-7 of the I_2 field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM is zero, the corresponding register pair is not saved. When a bit in the GRSM is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TRANSACTION BEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a constrained transaction aborts.

When TBEGINC is used to continue execution in the nonconstrained transactional-execution mode, the general register save mask is ignored.

Allow AR Modification (A): The A control, bit 12 of the I_2 field, controls whether the transaction is allowed to modify an access register. The effective allow-AR-modification control is the logical AND of the A control in the TBEGINC instruction for the current nesting level and for any outer TBEGIN or TBEGINC instructions.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

Bits 8-11 and 13-15 of the I_2 field (bits 40-43 and 45-47 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

TRANSACTION BEGIN (TBEGINC) Processing

Execution of the TRANSACTION BEGIN (TBEGINC) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-364 on page 7-407 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if the B_1 field, bits 16-19 of the instruction, is nonzero.
4. If the CPU is already in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See “Transaction Abort Processing” on page 5-102 for details on the handling of a transaction abort.
6. If the transaction nesting depth is zero, then the following is performed:

   a. The transaction-diagnostic-block address is considered to be invalid.

   b. The transaction-abort PSW is set from the contents of the current PSW, except that the instruction address of the transaction-abort PSW designates the TBEGINC instruction (rather than the next-sequential instruction).

   c. The contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.

7. An effective value of the allow-AR-modification (A) control, bit 12 of the I_2 field of the instruction, is determined. The effective A control is the logical AND of the A control in the TBEGINC instruction for the current level and for any outer TRANSACTION BEGIN instructions.

8. If the transaction nesting depth is zero, then it is set to one, and the CPU enters the constrained transactional-execution mode. The effective allow-floating-point-operation and program-interruption-filtering controls (F and PIFC, respectively) are set to zero.

   If the transaction nesting depth is nonzero, then it is incremented by one, and the CPU remains in the nonconstrained transactional-execution mode. In this case, the effective value of the allow-floating-point-operation control is set to zero, and the effective value of the program-interruption-filtering control is unchanged. See “Allow Floating-Point Operation (F)” on page 7-402 and “Program-Interruption-Filtering Control (PIFC)” on page 7-402 for a description of these controls.

9. The instruction completes by setting condition code 0.

When TBEGINC is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See “Event-Suppression Control (ES)” on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

Resulting Condition Code:

0 Transaction initiation successful
1 –
2 –
3 –

Program Exceptions:

- Execute
- Operation (constrained transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to the B_1 field containing a nonzero value.
8.B	Abort due to exceeding transaction nesting depth.
9	Condition code 0 due to normal completion.

Figure 7-364. Priority of Execution: TRANSACTION BEGIN (TBEGINC)

Programming Notes:

1. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The I_2 field should designate all register pairs that provide input values that are changed by a constrained transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when constrained transaction is reexecuted.

2. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

3. Figure 7-365 on page 7-408 illustrates the results of the TRANSACTION BEGIN instruction (both TBEGIN and TBEGINC) based on the current transaction nesting depth and, when the TND is nonzero, whether the CPU is in the non-

constrained or constrained transactional-execution mode.

		TND > 0	
Instruction	TND = 0	NTX Mode	CTX Mode
TBEGIN	Enter the nonconstrained transactional-execution mode	Continue in the nonconstrained transactional-execution mode	Transaction-constraint exception
TBEGINC	Enter the constrained transactional-execution mode	Continue in the nonconstrained transactional-execution mode	Transaction-constraint exception

Explanation:

CTX	CPU is in the constrained transactional-execution mode
NTX	CPU is in the nonconstrained transactional-execution mode
TND	Transaction nesting depth at the beginning of the instruction

Figure 7-365. Operation of TRANSACTION BEGIN based on Transaction Nesting Depth and Transactional-Execution Mode

TRANSACTION END

TEND [S]

'B2F8'	////////////////
0	16 31

If the CPU is in the transactional-execution mode, the transaction nesting depth is decremented. If the transactional nesting depth is zero following the decrementing, all store accesses made by the transaction are committed, the CPU leaves the transactional-execution mode, and the instruction completes.

The effective allow-floating-point-operation (F) control, allow-AR-modification (A) control, and program-interruption-filtering control (PIFC) are reset to their respective values prior to the TRANSACTION BEGIN instruction that initiated the level being ended.

If the CPU is in the transactional-execution mode at the beginning the operation, the condition code is set to 0; otherwise, the condition code is set to 2.

A serialization function is performed at the completion of the operation.

When TRANSACTION END is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

Resulting Condition Code:

0 CPU in the transactional-execution mode at the beginning of the operation
1 –
2 CPU not in the transactional-execution mode at the beginning of the operation
3 –

Program Exceptions:

- Execute
- Operation (transactional-execution facility not installed)
- Special operation

Programming Notes:

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode. Attempted execution of a TRANSACTION END in this case results in a special-operation exception.

2. PER instruction-fetching and transaction-end events that are recognized at the completion of the outermost TRANSACTION END instruction do not result in the transaction being aborted. See “Event-Suppression Control (ES)” on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION END.

TRANSLATE

TR $D_1(L,B_1),D_2(B_2)$ [SS-a]

'DC'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The bytes of the first operand are used as eight-bit arguments to reference a list designated by the second-operand address. Each function byte selected from the list replaces the corresponding argument in the first operand.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte.

The operation proceeds until the first-operand field is exhausted. The list is not altered unless an overlap occurs.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the corresponding function byte.

Access exceptions are recognized only for those bytes in the second operand which are actually required.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the TRANSLATE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. TRANSLATE may be used to convert data from one code to another code.
3. The instruction may also be used to rearrange data. This may be accomplished by placing a pattern in the destination area, by designating the pattern as the first operand of TRANSLATE, and by designating the data that is to be rearranged as the second operand. Each byte of the pattern contains an eight-bit number specifying the byte destined for this position. Thus, when the instruction is executed, the pattern selects the bytes of the second operand in the desired order.
4. Because each eight-bit argument byte is added to the initial second-operand address to obtain the address of a function byte, the list may contain 256 bytes. In cases where it is known that not all eight-bit argument values will occur, it is possible to reduce the size of the list.
5. Significant performance degradation is possible when the second-operand address of TRANSLATE designates a location that is less than 256 bytes to the left of a 4 K-byte boundary. This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary.
6. The fetch and subsequent store accesses to a particular byte in the first-operand field do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”
7. The storage-operand references of TRANSLATE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

TRANSLATE AND TEST

TRT $D_1(L,B_1),D_2(B_2)$ [SS-a]

'DD'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the next byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this register remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of this register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the rightmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

The contents of access register 1 always remain unchanged.

Access exceptions are recognized only for those bytes in the second operand which are actually required. Access exceptions are not recognized for those bytes in the first operand which are to the right of the first byte for which a nonzero function byte is obtained.

Resulting Condition Code:

0 All function bytes zero
1 Nonzero function byte; first-operand field not exhausted
2 Nonzero function byte; first-operand field exhausted
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Transaction constraint

Programming Notes:

1. An example of the use of the TRANSLATE AND TEST instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. TRANSLATE AND TEST may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

TRANSLATE AND TEST EXTENDED

TRTE $R_1,R_2[,M_3]$ [RRF-c]

'B9BF'	M_3	////	R_1	R_2
0	16	20	24	28 31

TRANSLATE AND TEST REVERSE EXTENDED

TRTRE $R_1,R_2[,M_3]$ [RRF-c]

'B9BD'	M_3	////	R_1	R_2
0	16	20	24	28 31

The argument characters of the first operand are used to select function codes from a function-code table designated by general register 1. For TRANSLATE AND TEST EXTENDED, the argument characters are processed in a left-to-right direction; for TRANSLATE AND TEST REVERSE EXTENDED, the argument characters are processed in a right-to-left direction. When a nonzero function code is selected, it is inserted in general register R_2, the related argument address is placed in general register R_1, and the first-operand length in general register R_1 + 1 is decremented by the number of bytes processed. The operation proceeds until a nonzero function code is encountered, the end of the first operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first. The result is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

General register $R_1 + 1$ contains the length of the first operand in bytes.

Operation of the instruction is subject to controls specified in the M_3 field, bits 16-19 of the instruction. The M_3 field has the following format:

A	F	L	/
0	1	2	3

The bits of the M field are defined as follows:

- ***Argument-Character Control (A):*** The A bit, bit 0 of the M_3 field, controls the size of the argument characters in the first operand. When the A bit is zero, the argument characters are one byte in length. When the A bit is one, the argument characters are two bytes in length.

  When the A bit is one, the first-operand length in general register $R_1 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

- ***Function-Code Control (F):*** The F bit, bit 1 of the M_3 field, controls the size of the function codes in the function-code table designated by general register 1. When the F bit is zero, a function code is one byte in length. When the F bit is one, a function code is two bytes in length.

- ***Argument-Character Limit (L):*** The L bit, bit 2 of the M_3 field, controls whether argument characters with a value greater than 255 are used to select function codes. When the L bit is zero, argument character values are unlimited. When the L bit is one, an argument character with a value greater than 255 is not used to select a function code; rather, the function code is assumed to contain zeros.

  When the A bit of the M_3 field is zero, the L bit is ignored.

- ***Unassigned:*** Bit 3 of the M_3 field is unassigned and should contain zero; otherwise, the program may not operate compatibly in the future.

Figure 7-366 summarizes the size of the function-code table based on the A, F, and L bits.

			Table Size
A bit	**F bit**	**L bit**	**(bytes)**
0	0	–	256
0	1	–	512
1	0	0	65,536
1	1	0	131,072
1	0	1	256
1	1	1	512

Explanation:

– Not applicable

Figure 7-366. Function-Code Table Size

The location of the first argument character in the first operand is designated by the contents of general register R_1. The location of the leftmost byte of the function-code table is designated by the contents of general register 1. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer.

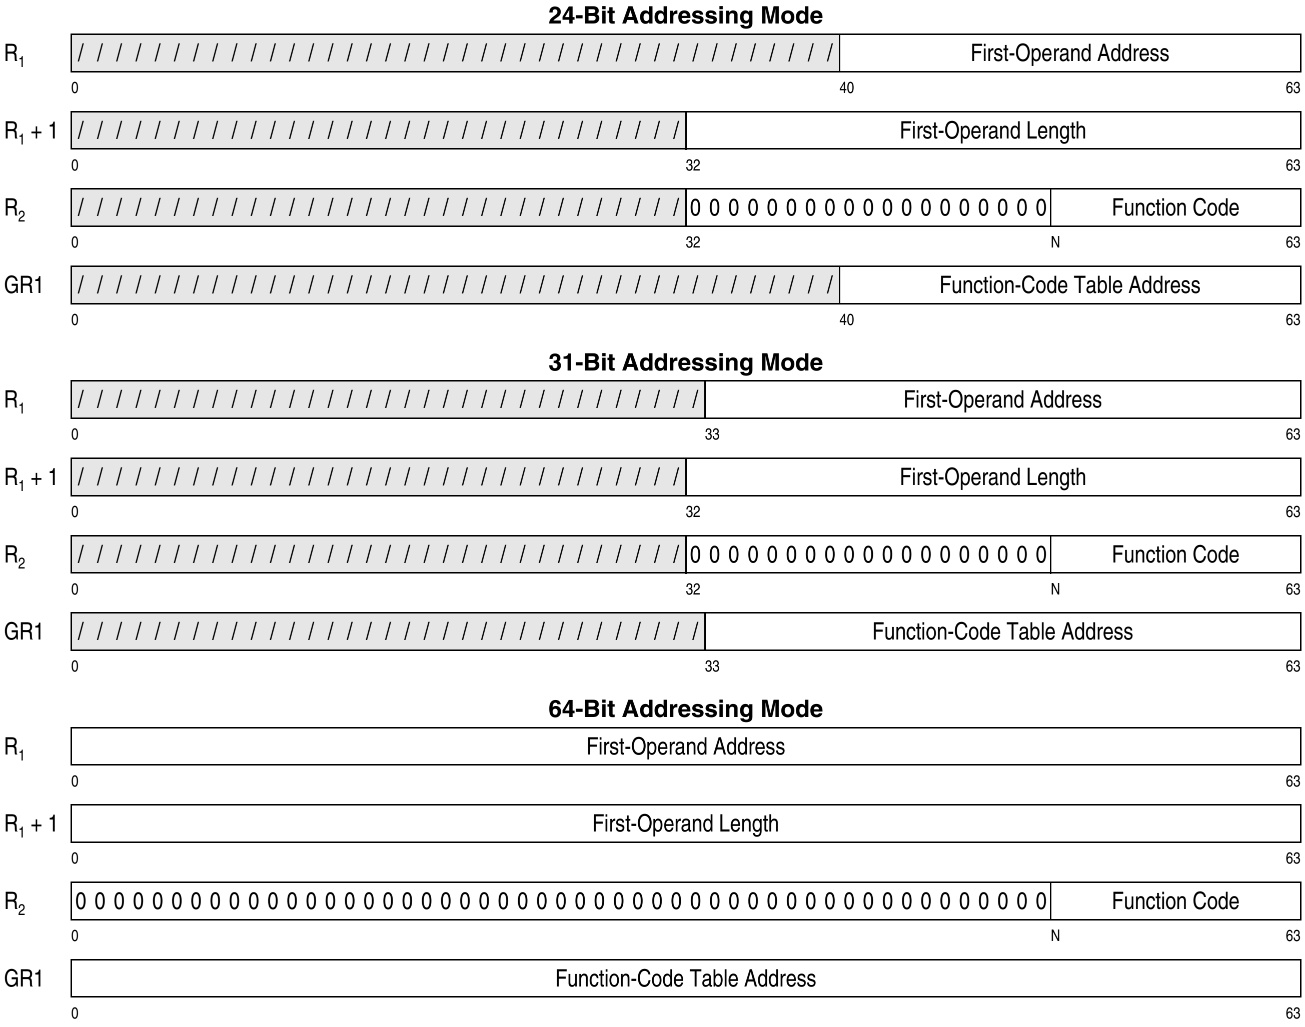
The handling of the argument-character address in general register R_1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The function-code table is treated as being on a doubleword boundary. The handling of the function-code-table address in general register 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-60 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register constitute the address. In all addressing modes, bit positions 61-63 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

When a nonzero function code is selected, it is inserted into either bits 56-63 or bits 48-63 of general register R_2, depending on whether the F bit of the M_3

field is zero or one, respectively. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-55 (F=0) or 32-47 (F=1) of the register are set to zero. In the 64-bit addressing mode, bits 0-55 (F=0) or 0-47 (F=1) are set to zero.

The contents of the registers just described are shown in Figure 7-367.



Explanation:

N 56 when the F-bit = 0; 48 when the F-bit = 1

Figure 7-367. Register Contents for TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED

The argument characters of the first operand are selected one by one for processing, proceeding in a left-to-right direction for TRANSLATE AND TEST EXTENDED, or in a right-to-left direction for TRANSLATE AND TEST REVERSE EXTENDED. Depending on the A bit of the M_3 field, the argument characters are treated as either eight-bit or sixteen-bit unsigned binary integers, extended with zeros on the left.

When the F bit of the M_3 field is zero, the argument character is added to the function-code-table address in general register 1 to form the address of the selected 8-bit function code. When the F bit is one, the argument character, extended on the right with a binary 0, is added to the function-code-table address in general register 1 to form the address of the selected 16-bit function code. These additions follow the rules for address arithmetic.

When both the A and L bits are one, and the value of the argument character is greater than 255, then the function-code table is not accessed. The function code is assumed to contain zero in this case.

When the selected function code contains zero, or when the function code is assumed to contain zero, processing continues with the next argument character in the first operand. The operation proceeds until a nonzero function code is selected, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.

When the first-operand location is exhausted without having selected a nonzero function code, general register R_1 is either incremented or decremented by the first operand length in general register $R_1 + 1$; general register $R_1 + 1$ is set to zero; general register R_2 is set as though a function code of zero was selected; and condition code 0 is set. For TRANSLATE AND TEST EXTENDED, general register R_1 is incremented by the first operand length; for TRANSLATE AND TEST REVERSE EXTENDED, general register R_1 is decremented by the first operand length. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-63 of the register are set to zeros; in the 64-bit addressing mode, bits 0-63 of general register R_2 are set to zeros.

When a nonzero function code is selected, the function code replaces bits 56-63 or bits 48-63 of general register R_2, depending on whether the F bit is zero or one, respectively; depending on the addressing mode, the remaining bits in general register R_2 are set to zeros; the address of the argument character used to select the nonzero function code is placed in general register R_1; general register $R_1 + 1$ is decremented by the number of first-operand bytes processed prior to selecting the nonzero function byte; and condition code 1 is set. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-55 (F=0) or 32-47 (F=1) are set to zero; in the 64-bit addressing mode, bits 0-55 (F=0) or 0-47 (F=1) are set to zeros.

When a CPU-determined number of bytes have been processed, general register R_1 is either incremented or decremented by the number of bytes in the first operand that were processed, general register $R_1 + 1$ is decremented by this number, and condition code 3 is set. For TRANSLATE AND TEST EXTENDED, general register R_1 is incremented by the number of bytes processed; for TRANSLATE AND TEST REVERSE EXTENDED, general register R_1 is decremented by the number of bytes processed. Condition code 3 may be set even when the first-operand location is exhausted or when the next argument character to be processed selects a nonzero function byte. In these cases, condition code 0 or 1 will be set when the instruction is executed again.

When the R_2 field designates the same register as register R_1, the updated first-operand address is placed in the register. When the R_2 field designates the same register as register R_1+1, the updated first-operand length is placed in the register.

When general register R_1 is updated in the 24-bit or 31-bit addressing mode, bits 32-39, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, and R_2 always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the portion of the first operand beyond the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

Access exceptions for any byte of the function-code table specified by general register 1 may be recognized, even if not all bytes are used.

Special Conditions

A specification exception is recognized for any of the following conditions:

1. The R_1 field designates an odd-numbered register.

2. The A bit of the M_3 field is one and the first operand length in general register $R_1 + 1$ is odd.

Resulting Condition Code:

0 Entire first operand processed without selecting a nonzero function code
1 Nonzero function code selected
2 --
3 CPU-determined number of bytes processed

Program Exceptions:

- Access (fetch, operand 1 and the function-code table)
- Operation (if the parsing-enhancement facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue processing. The program need not determine the number of bytes that were processed.

2. The storage-operand references of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

3. The following example illustrates the use of TRANSLATE AND TEST EXTENDED to parse a buffer of 16-bit Unicode argument characters for delimiters such as those used in common markup languages. Because the Unicode representation of such delimiters is in the range of 0000 - 00FF hex, a limited function-code table is used (the L bit of the M_3 field is one).

   In this example, the variable BUFFER is used to hold the 16-bit characters to be parsed. If a delimiting character is not found, control passes to the label NOTFND. If a delimiting character is found, the function code placed in general register R_2 is used as an index to the branch table that passes control to a specific processing routine (not shown).

        DC    X'00,00,00,00,18,1C,20,24'  38-3F
        DC    192X'00'                    40-FF
BUFFER  DS    CL8192           Buffer of 16-bit chars.
```

   Note, the branch to label NOT_FND does not result from a function-code-table entry of zeros. Rather, the branch is taken when the first operand is exhausted without selecting a nonzero function-code-table entry.

4. As an alternative to treating the selected function-code value as a table index (as shown in programming note 3, above), the function-code value may be used directly as a branch offset.

5. The performance of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be significantly slower if the program modifies the function-code table prior to execution of the instruction.

6. In the assembler syntax, the M_3 operand is considered to be optional. When the M_3 field is not coded, it is considered to contain zeros by the assembler.

TRANSLATE AND TEST REVERSE

TRTR $D_1(L,B_1),D_2(B_2)$ [SS-a]

'D0'	L	B_1	D_1	B_2	D_2
0	8	16	20	32 36	47

The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first-operand address designates the rightmost byte of the first operand. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding from right to left. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the preceding byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this register remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, and bits 0-32 of this register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the leftmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

The contents of access register 1 always remain unchanged.

Access exceptions can be recognized for any byte in either the first or in the second operand.

Resulting Condition Code:

0 All function bytes zero
1 Nonzero function byte; first-operand field not exhausted
2 Nonzero function byte; first-operand field exhausted
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Operation (if the extended-translation facility 3 is not installed)
- Transaction constraint

Programming Note:

TRANSLATE AND TEST REVERSE may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

TRANSLATE EXTENDED

TRE R_1,R_2 [RRE]

'B2A5'	////////	R_1	R_2
0	16	24	28 31

The bytes of the first operand are compared to a test byte in general register 0 and, unless an equal comparison occurs, are used as eight-bit arguments to reference a 256-byte translation table designated by the second-operand address. Each function byte selected from the second operand replaces the corresponding argument in the first operand. The operation proceeds until a first-operand byte equal to the test byte is encountered, the end of the first operand is reached, or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The test byte is in bit positions 56-63 of general register 0, and the contents of bit positions 0-55 of this register are ignored.

The contents of the registers just described are shown in Figure 7-368.

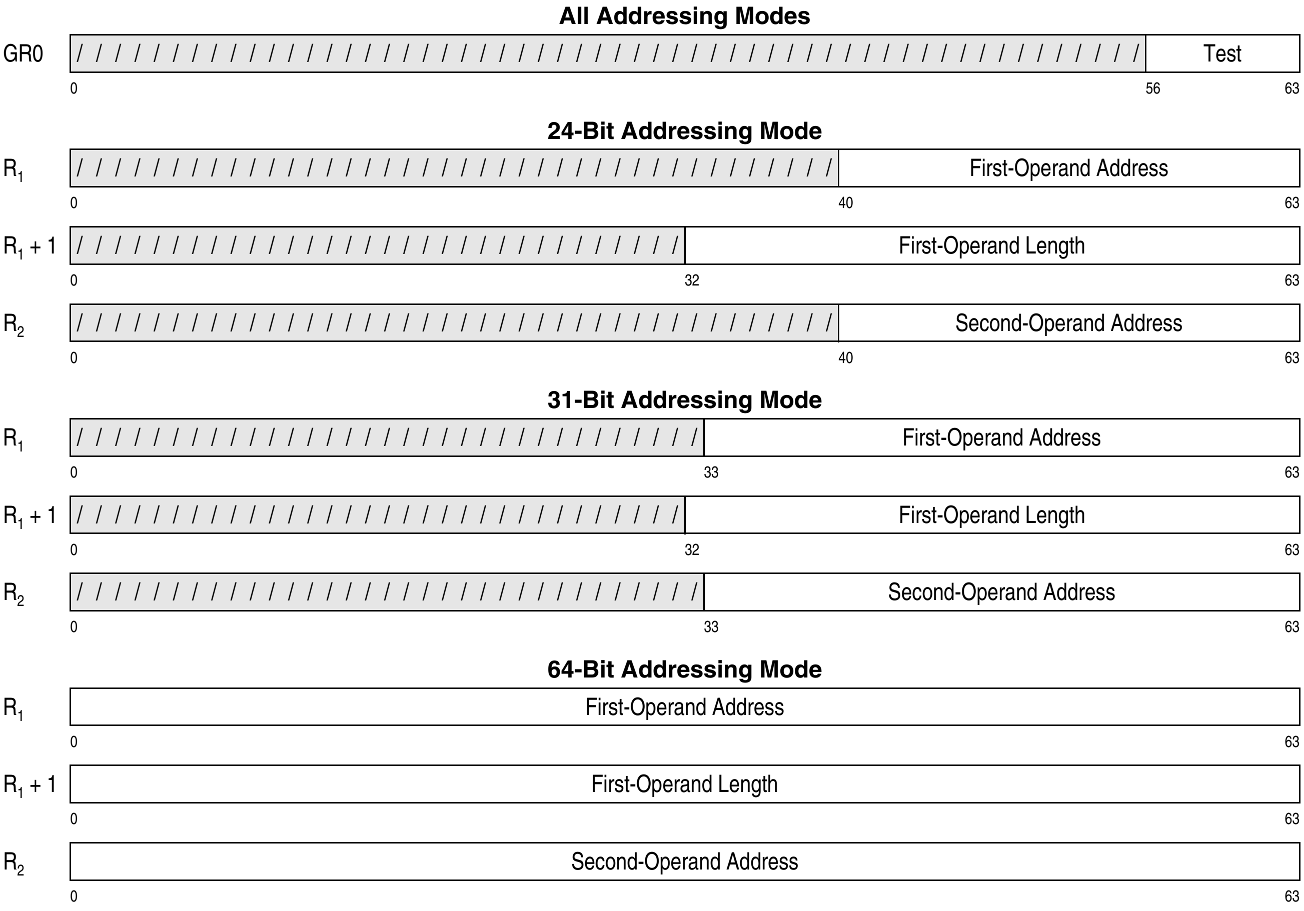

Figure 7-368. Register Contents for TRANSLATE EXTENDED

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is first compared to the test byte in general register 0. If the result is an equal comparison, the operation is completed. If the argument byte is not equal to the test byte, the argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte. The second operand is not altered unless an overlap occurs.

The operation proceeds until a first-operand byte equal to the test byte is encountered, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.

When the first-operand location is exhausted without finding a byte equal to the test byte, condition code 0 is set. When a first-operand byte equal to the test byte is encountered, condition code 1 is set. When a CPU-determined number of bytes have been processed, condition code 3 is set. Condition code 3 may be set even when the first-operand location is exhausted or when the next byte to be processed is equal to the test byte. In these cases, condition code 0 or 1, respectively, will be set when the instruction is executed again.

If the operation is completed with condition code 0, the contents of general register R_1 are incremented by the contents of general register $R_1 + 1$, and then the contents of general register $R_1 + 1$ are set to zero. If the operation is completed with condition code 1, the contents of general register $R_1 + 1$ are decremented by the number of bytes processed before the first-operand byte equal to the test byte was encountered, and the contents of general register R_1 are incremented by the same number, so that general register R_1 contains the address of the equal byte. If the operation is completed with condition code 3, the contents of general register $R_1 + 1$ are decremented by the number of bytes processed, and the contents of general register R_1 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be processed. When general register R_1 is updated in the 24-bit or 31-bit addressing mode, bits 32-39 of it, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_2 register is the same register as the R_1 or $R_1 + 1$ register, the results are unpredictable.

When R_1 or R_2 is zero, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portion of the first operand to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

Access exceptions for all 256 bytes of the second operand may be recognized, even if not all bytes are used.

Access exceptions are not recognized if the R_1 field is odd. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

Resulting Condition Code:

0 Entire first operand processed without finding a byte equal to the test byte
1 First-operand byte is equal to the test byte
2 --
3 CPU-determined number of bytes processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of bytes that were translated.

2. The instruction can improve performance by being used in place of a TRANSLATE AND TEST instruction that locates an escape character, fol-

lowed by a TRANSLATE instruction that translates the bytes preceding the escape character.

3. The storage-operand references of TRANSLATE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

TRANSLATE TWO TO TWO

TRTT R_1,R_2[,M_3] [RRF-c]

'B990'	M_3	////	R_1	R_2
0	16	20	24	28 31

The characters of the second operand are used as arguments to select function characters from a translation table designated by the address in general register 1.

When the ETF2-enhancement facility is not installed, or when the test-character-comparison control is zero, each function character selected from the translation table is compared to a test character in general register 0, and, unless an equal comparison occurs, is placed at the first-operand location. The operation proceeds until a selected function character equal to the test character is encountered, the end of the second operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first.

When the ETF2-enhancement facility is installed and the test-character-comparison control is one, test-character comparison is not performed. Each function character selected from the translation table is placed at the first operation location. The operation proceeds until the end of the second operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first.

The result is indicated in the condition code.

When the ETF2-enhancement facility is installed, the M_3 field has the following format:

/	/	/	C
0			3

The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

- ***Test-Character-Comparison Control (C):*** The C bit, bit 3 of the M_3 field, controls test-character comparison. When the C bit is zero, test-character comparison is performed. When the C bit is one, test-character comparison is not performed.

When the ETF2-enhancement facility is not installed, the M_3 field is ignored. When the ETF2-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The lengths of the operand and test characters are as follows:

- For TRANSLATE ONE TO ONE, the second-operand, first-operand, and test characters are single bytes.

- For TRANSLATE ONE TO TWO, the second-operand characters are single bytes, and the first-operand and test characters are double bytes.

- For TRANSLATE TWO TO ONE, the second-operand characters are double bytes, and the first-operand and test characters are single bytes.

- For TRANSLATE TWO TO TWO, the second-operand, first-operand, and test characters are double bytes.

For TRANSLATE ONE TO ONE and TRANSLATE TWO TO ONE, the test character is in bit positions 56-63 of general register 0. For TRANSLATE ONE TO TWO and TRANSLATE TWO TO TWO, the test character is in bit positions 48-63 of general register 0.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 0-63 of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer. The length of the first-operand location is considered to be the same as that of the second operand for TRANSLATE ONE TO ONE and TRANSLATE TWO TO TWO, twice that for TRANSLATE ONE TO TWO, and one half that for TRANSLATE TWO TO ONE.

For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the length in general register $R_1 + 1$ must be an even number of bytes; otherwise, a specification exception is recognized.

The translation table is treated as being on a doubleword boundary for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO. For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the translation table is treated as follows:

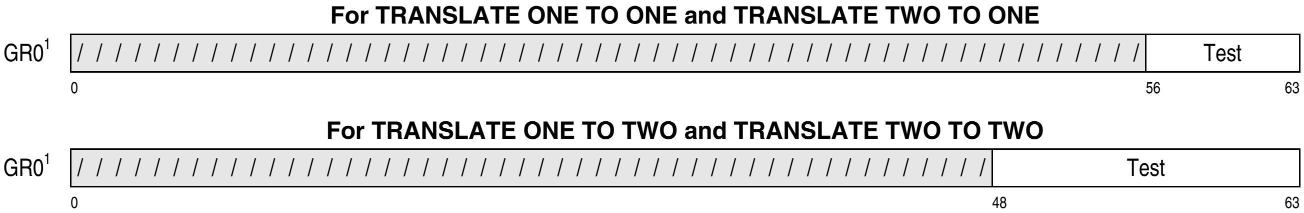
- When the ETF2-enhancement facility is not installed, the translation table is treated as being on a 4 K-byte boundary.
- When the ETF2-enhancement facility is installed, the translation table is treated as being on a doubleword boundary.

The rightmost bits of the register that are not used to form the address, which are bits 61-63 in the doubleword case and bits 52-63 in the 4 K-byte case, are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The handling of the addresses in general registers R_1, R_2, and 1 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 and 40-60 or 40-51 of 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of registers R_1 and R_2 and 33-60 or 33-51 of 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of registers R_1 and R_2 and 0-60 or 0-51 of 1 constitute the address.

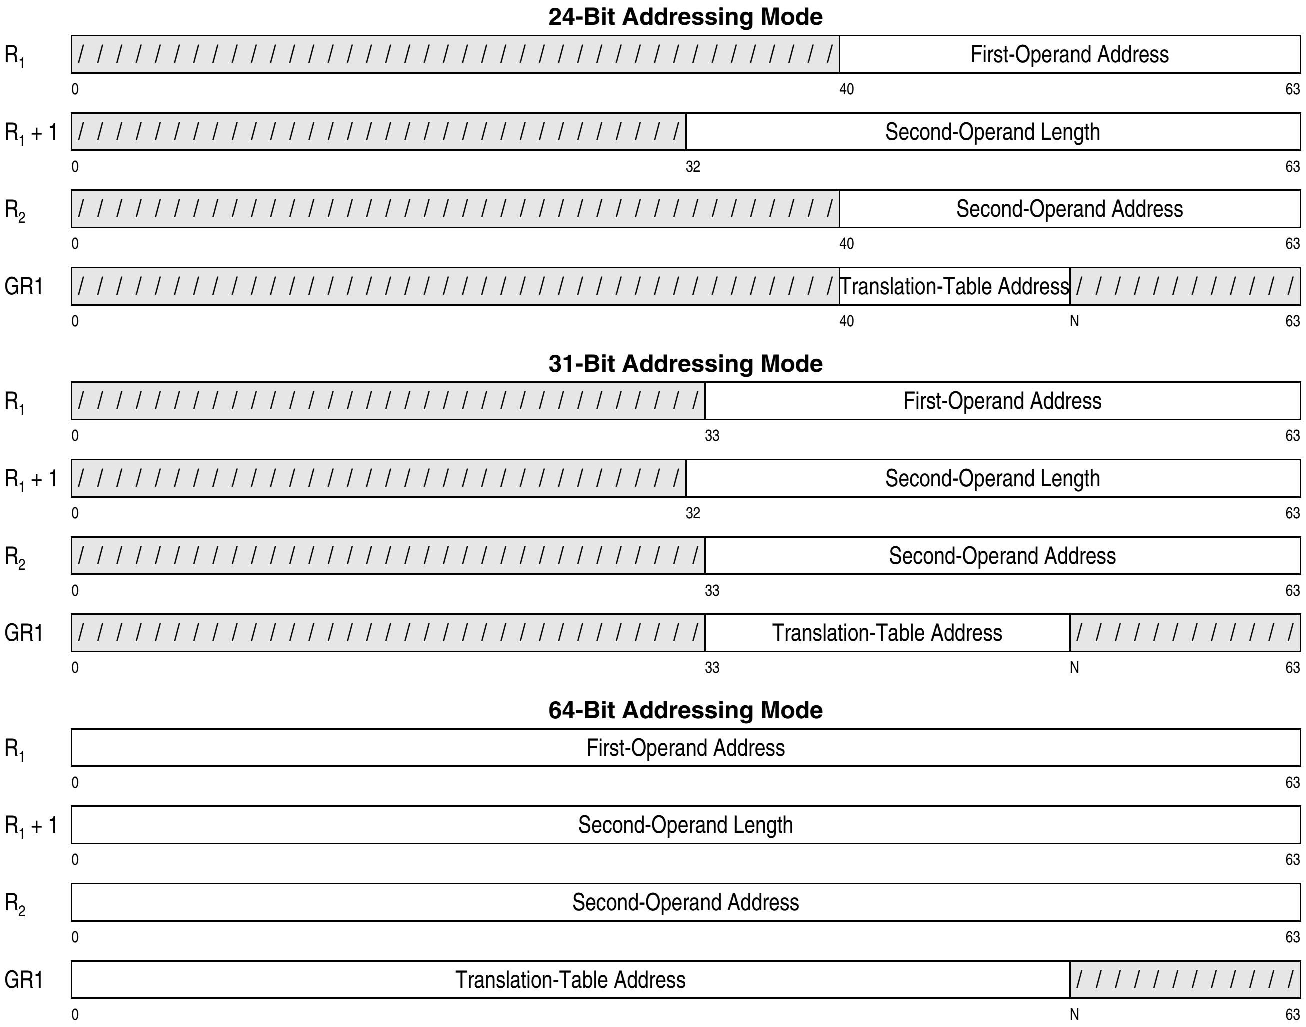
The contents of the registers just described are shown in Figure 7-369.



For TRANSLATE ONE TO ONE and TRANSLATE TWO TO ONE

For TRANSLATE ONE TO TWO and TRANSLATE TWO TO TWO

Figure 7-369. Register Contents for TRANSLATE ONE TO ONE, TRANSLATE ONE TO TWO, TRANSLATE TWO TO ONE, and TRANSLATE TWO TO TWO (Part 1 of 2)



Explanation:

[1] When the ETF2-enhancement facility is not installed, or when the C bit, bit 3 of the M3 field, is zero, test-character comparison is performed. When the ETF2-enhancement facility is installed and the C bit is one, test-character comparison is not performed, and general register 0 is ignored.

N When the ETF2-enhancement facility is not installed, N is 61 for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO, and N is 52 for TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO. When the ETF2-enhancement facility is installed, N is 61.

Figure 7-369. Register Contents for TRANSLATE ONE TO ONE, TRANSLATE ONE TO TWO, TRANSLATE TWO TO ONE, and TRANSLATE TWO TO TWO (Part 2 of 2)

In the access-register mode, the contents of access registers R_1, R_2, and 1 are used for accessing the first operand, second operand, and translation table, respectively.

The length of the translation table designated by the address contained in general register 1 is as follows:

- For TRANSLATE ONE TO ONE, the translation-table length is 256 bytes; each of the 256 function characters is a single byte.
- For TRANSLATE ONE TO TWO, the translation-table length is 512 bytes; each of the 256 function characters is a double byte.
- For TRANSLATE TWO TO ONE, the translation-table length is 65,536 (64K) bytes; each of the 64K function characters is a single byte.
- For TRANSLATE TWO TO TWO, the translation-table length is 131,072 (128K) bytes; each of the 64K function characters is a double byte.

The characters of the second operand are selected one by one for translation, proceeding left to right. Each argument character is added to the initial translation-table address. The addition is performed following the rules for address arithmetic, with the argument character treated as follows:

- For TRANSLATE ONE TO ONE, the argument character is treated as an eight-bit unsigned binary integer extended on the left with 56 zeros.
- For TRANSLATE ONE TO TWO, the argument character is treated as an eight-bit unsigned binary integer extended on the right with a zero and on the left with 55 zeros.
- For TRANSLATE TWO TO ONE, the argument character is treated as a 16-bit unsigned binary integer extended on the left with 48 zeros.
- For TRANSLATE TWO TO TWO, the argument character is treated as a 16-bit unsigned binary integer extended on the right with a zero and on the left with 47 zeros.

The rightmost bits of the translation-table address that are ignored (61-63 or 52-63) are treated as zeros during this addition.

The sum is used as the address of the function character.

When the ETF2-enhancement facility is not installed, or when the test-character-comparison control is zero, processing is as follows. Each function character selected as described above is first compared to the test character in general register 0. If the result is an equal comparison, the operation is completed. If the function character is not equal to the test character, the function character is placed in the next available character position in the first operand, that is, the first function character is placed at the beginning of the first-operand location, and each successive function character is placed immediately to the right of the preceding character. The second operand and the translation table are not altered unless an overlap occurs.

The operation proceeds until a selected function character equal to the test character is encountered, the second-operand location is exhausted, or a CPU-determined number of second-operand characters have been processed.

When the ETF2-enhancement facility is installed and the test-character-comparison control is one, processing is as described above, except that no test-character comparison is performed.

When a selected function character equal to the test character is encountered, condition code 1 is set. When the second-operand location is exhausted without finding a selected function character equal to the test character, condition code 0 is set. When a CPU-determined number of characters have been processed, condition code 3 is set. Condition code 3 may be set even when the next character to be processed results in a function character equal to the test character or when the second-operand location is exhausted. In these cases, condition code 1 or 0, respectively, will be set when the instruction is executed again. When the ETF2-enhancement facility is installed and the test-character-comparison control is one, condition code 1 does not apply.

If the operation is completed with condition code 0, the contents of general register R_2 are incremented by the contents of general register $R_1 + 1$, and the contents of general register R_1 are incremented as follows:

- For TRANSLATE ONE TO ONE and TRANSLATE TWO TO TWO, the same as for general register R_2.
- For TRANSLATE ONE TO TWO, by twice the amount for general register R_2.
- For TRANSLATE TWO TO ONE, by one half the amount for general register R_2.

The contents of general register $R_1 + 1$ are then set to zero.

If the operation is completed with condition code 1, the contents of general register $R_1 + 1$ are decremented by the number of second-operand bytes processed before the character that selected a function character equal to the test character was encountered, and the contents of general register R_2 are incremented by the same number, so that general register R_2 contains the address of the character that selected a function character equal to the test character. The contents of general register R_1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

If the operation is completed with condition code 3, the contents of general register $R_1 + 1$ are decremented by the number of second-operand bytes processed, and the contents of general register R_2 are incremented by the same number, so that the instruction, when reexecuted, contains the address of the next character to be processed. The contents of general register R_1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, the bits in bit positions 32-39 of them that are not part of the address may be set to zeros or may remain unchanged from their original values. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, and R_2 always remain unchanged.

The contents of general registers 0 and 1 remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When any of the following conditions are true, the results are unpredictable:

- Either the R_1 or $R_1 + 1$ registers are the same register as the R_2 register.
- The R_1 register is register 0,
- The R_2 register is register 0, and either the ETF2-enhancement facility is not installed, or the facility is installed and the C bit is zero.
- The R_2 register is register 1.
- Any of the first and second operands and the translation table overlaps another of them.

Access exceptions for the portion of the first or second operand to the right of the last character processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last character processed.

Access exceptions for all characters of the translation table may be recognized even if not all characters are used.

Access exceptions are not recognized if the R_1 field is odd. When the length of the second operand is zero, no access exceptions for the first or second operand are recognized, and access exceptions for the translation table may or may not be recognized.

Resulting Condition Code:

0 Entire second operand processed; if test-character comparison was performed, no resulting function character was equal to the test character
1 Second-operand character found resulting in a function character equal to the test character (applicable only when test-character comparison is performed)
2 --
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2 and translation table; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. These instructions differ from the TRANSLATE EXTENDED instruction by having the following attributes:
   - Depending on the instruction used, the sets of argument characters and function characters each can contain single-byte or double-byte characters.
   - The test character is compared to a resulting function character instead of to an argument character.
   - The argument (source) and function (destination) operands are different operands.
2. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of characters that were translated.

3. The storage operand references of these instructions may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

UNPACK

UNPK $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'F3'	L_1	L_2	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The format of the second operand is changed from signed-packed-decimal to zoned, and the result is placed at the first-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits and sign are placed unchanged in the first-operand location, using the zoned format. Zone bits with coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the second operand. The sign and digits are not checked for valid codes.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first-operand field is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time and as if the first result byte were stored immediately after fetching the first operand byte. The entire rightmost second-operand byte is used in forming the first result byte. For the remainder of the field, information for two result bytes is obtained from a single second-operand byte, and execution proceeds as if the leftmost four bits of the byte were to remain available for the next result byte and need not be refetched. Thus, the result is as if two result bytes were to be stored immediately after fetching a single operand byte.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the UNPACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. A field that is to be unpacked can be destroyed by improper overlapping. To save storage space for unpacking by overlapping the operands, the rightmost byte of the first operand must be to the right of the rightmost byte of the second operand by the number of bytes in the second operand minus 2. If only one or two bytes are to be unpacked, the rightmost bytes of the two operands may coincide.

3. The storage-operand references of UNPACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

UNPACK ASCII

UNPKA $D_1(L_1,B_1),D_2(B_2)$ [SS-a]

'EA'	L_1	B_1	D_1	B_2	D_2	
0	8	16	20	32	36	47

The format of the second operand is changed from signed-packed-decimal to ASCII, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to ASCII characters by extending them on the left with 0011 binary, and the ASCII characters are then placed at the first operand location. The digits are not checked for valid codes.

The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost byte position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes. The second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L_1 field. The first-operand length must not exceed 32 bytes (L_1 must be less than or equal to 31); otherwise, a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 bytes, the leftmost byte is set to ASCII zero, 30 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0 Sign is plus
1 Sign is minus
2 --
3 Sign is invalid

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Note:

1. The following example illustrates the use of the instruction to unpack to ASCII digits:

```
ASDIGITS  DS     CL31
PKDIGITS  DS     0PL16
          DC     X'1234567890'
          DC     X'1234567890'
          DC     X'1234567890'
          DC     X'1C'
           ⋮
          UNPKA  ASDIGITS(31),PKDIGITS
```

2. The storage-operand references of UNPACK ASCII may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

UNPACK UNICODE

UNPKU $D_1(L_1,B_1),D_2(B_2)$ [SS-a]

'E2'	L_1	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The format of the second operand is changed from signed-packed-decimal to Unicode Basic Latin, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to two-byte Unicode characters by extending them on the left with 000000000011 binary (003 hex), and the Unicode characters are then placed at the first operand location. The digits are not checked for valid codes. The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost character position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes; the second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L_1 field. The first-operand length must not exceed 32 characters or 64 bytes (L_1 must be less than or equal to 63 and must be odd); otherwise a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 characters, the leftmost character is set to Unicode Basic Latin zero, 0030 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0 Sign is plus
1 Sign is minus
2 --
3 Sign is invalid

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

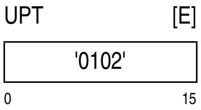
1. The following example illustrates the use of the instruction to unpack to European numbers:

```
UNDIGITS  DS     CL62
PKDIGITS  DS     0PL16
          DC     X'1234567890'
          DC     X'1234567890'
          DC     X'1234567890'
          DC     X'1C'
          UNPKU  UNDIGITS(62),PKDIGITS
```

2. The storage-operand references of UNPACK UNICODE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

UPDATE TREE



The nodes of a tree in storage are examined successively on a path toward the base of the tree, and contents of general register 0, conceptually followed on the right by contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0. The first half of a node and general register 0 contain a codeword, which is for use in sort/merge algorithms.

If the codeword in general register 0 equals the codeword in a node, the contents of the node are placed in general registers 2 and 3.

General register 4 contains the base address of the tree, and general register 5 contains the index of a node whose parent node will be examined first.

In the access-register mode, access register 4 specifies the address space containing the tree.

This instruction may be interrupted between units of operation. The condition code is unpredictable if the instruction is interrupted.

The size of a node, the size of a codeword, and the participation of bits 0-31 of general registers 1-5 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, a node is eight bytes, a codeword is four bytes, and bits 0-31 are ignored and remain unchanged. In the 64-bit addressing mode, a node is 16 bytes, a codeword is eight bytes, and bits 0-31 are used in and may be changed by the operation.

Operation in the 24-Bit or 31-Bit Addressing Mode

In the 24-bit or 31-bit addressing mode, the doubleword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of bit positions 32-63 of general register 0, conceptually followed on the right by the contents of bit positions 32-63 of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in bit positions 32-63 of general register 0.

Bit positions 32-63 of general register 4 contain the base address of the tree, and bit positions 32-63 of general register 5 contain the index of a node whose parent node will be examined first. The base address is eight less than the address of the root node of the tree. The initial contents of bit positions 32-63 of general registers 4 and 5 must be a multiple of 8; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of bit positions 32-63 of general register 5 right logically one position and then setting bit 61 to zero. However, bits 32-63 of general register 5 remain unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 61 to zero, bits 32-63 of general register 5 are all zeros, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 32 of general register 0 is tested. If bit 32 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 32 of general register 0 is zero, the sum of bits 32-63 of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

Bits 32-63 of general register 0 are logically compared with the contents of the first word of the currently addressed node. If the register operand is low, the contents of bit positions 32-63 of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, bit positions 32-63 of general register 2, conceptually followed on the right by bit positions 32-63 of general register 3, are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first word of the node is less than or equal to the value in bit positions 32-63 of the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Operation in the 64-Bit Addressing Mode

In the 64-bit addressing mode, the quadword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of general register 0, conceptually followed on the right by the contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0.

General register 4 contains the base address of the tree, and general register 5 contain the index of a node whose parent node will be examined first. The base address is 16 less than the address of the root node of the tree. The initial contents of general registers 4 and 5 must be a multiple of 16; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of general register 5 right logically one position and then setting bit 60 to zero. However, general register 5 remains unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 60 to zero, the contents of general register 5 are zero, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 0 of general register 0 is tested. If bit 0 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 0 of general register 0 is zero, the sum of the contents of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

The contents of general register 0 are logically compared with the contents of the first doubleword of the currently addressed node. If the register operand is low, the contents of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, general registers 2 and 3 are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first doubleword of the node is less than or equal to the value in the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Specifications Independent of Addressing Mode

Access exceptions are recognized only for one node at a time. Access exceptions, change-bit action, and PER storage alteration do not occur for subsequent nodes until the previous node has been successfully compared and updated, and they also do not occur if a specification-exception condition exists.

Resulting Condition Code:

0 Equal compare values at currently addressed node
1 No equal compare values found on path, or no comparison made
2 --
3 In 24-bit or 31-bit mode, bits 32-63 of general register 5 nonzero and bits 32-63 of general register 0 negative; in 64-bit mode, general register 5 nonzero and general register 0 negative

Program Exceptions:

- Access (fetch and store, nodes of tree)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of UPDATE TREE is given in “Sorting Instructions” in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For use in sorting in the 24-bit or 31-bit addressing mode, when equal compare values have been found, the contents of bit positions 32-63 of general registers 1 and 3 can be appropriate (depending on the contents of the tree) for the subsequent execution of COMPARE AND FORM CODEWORD. The contents of bit positions 32-63 of general register 2, shifted right 16 bit positions, can be similarly appropriate, and they can provide for minimal recomparison of partially equal keys. The same applies in the 64-bit addressing mode except to the contents of bit positions 0-63 of the registers and with the contents of bit positions 0-63 of general register 2 shifted right 48 bit positions. Refer to “Sorting Instructions” on page A-53 for a discussion of trees and their use in sorting.

3. The program should avoid placing a nonzero value in bit positions 32-38 of general register 5 when in the 24-bit addressing mode. If any bit in bit positions 32-38 is a one, the nodes of the tree will not be examined successively.

4. When bits 32-63 of general register 0 are negative in the 24-bit or 31-bit addressing mode, or when bits 0-63 are negative in the 64-bit mode, and provided that the tree has been updated properly previously, the node represented by general registers 0 and 1 either is the node or is equal to the node (equal keys) that would be selected if the unit of operation continued. In this case, ending the unit of operation and setting condition code 3 is a faster means of selecting an appropriate node because it does not require further examination and updating of the tree.

5. Setting condition code 3 provides improved performance when the replacement record is equal to the old winner and, more importantly (since the first case can be detected by means of the condition code of CFC), when the update path contains a negative codeword, indicating equality with the old winner.

6. In those cases when the codeword in the node is less than or equal to the codeword in general register 0, depending on the model, the contents of the node may be fetched and subsequently

stored back. As a result, any of the following may occur for the storage location containing the node: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

7. Special precautions should be taken when UPDATE TREE is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

8. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

9. The storage-operand references for UPDATE TREE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

10. Figure 7-370 on page 7-429 is a summary of the operation of UPDATE TREE in the 24-bit or 31-bit addressing mode, and Figure 7-371 on page 7-430 is a summary of the operation in the 64-bit addressing mode.

Protection of Cryptographic Keys

When the message-security-assist extension 3 is installed, two wrapping-key registers and two wrapping-key-verification-pattern registers are provided for each configuration. The two wrapping-key registers consist of a 192-bit DES wrapping-key (WK_d) register and a 256-bit AES wrapping-key (WK_a) register. The two wrapping-key-verification-pattern registers consist of a 192-bit DES wrapping-key-verification-pattern (WK_dVP) register and a 256-bit AES wrapping-key-verification-pattern (WK_aVP) register.

WK_d is used to protect user DES or TDES keys, and WK_dVP is used to verify the value of WK_d. WK_a is used to protect user AES keys, and WK_aVP is used to verify the value of WK_a. Whenever the contents of the WK_d or WK_a register are changed, the contents of the corresponding verification-pattern register are also changed.

When the message-security-assist extension 9 is installed, the 256-bit AES wrapping key (WK_a) register and the 256-bit AES wrapping-key-verification-pattern (WK_eVP) register are also used to protect ECC keys.

Each time a clear reset is performed, a new set of wrapping keys and their associated verification patterns are generated. The contents of the two wrapping-key registers are kept internal to the model so that no program, including the operating system, can directly observe their clear value.

The following instructions provide functions supporting encrypted cryptographic keys:

- CIPHER MESSAGE
- CIPHER MESSAGE WITH AUTHENTICATION
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- COMPUTE DIGITAL SIGNATURE AUTHENTICATION
- COMPUTE MESSAGE AUTHENTICATION CODE
- PERFORM CRYPTOGRAPHIC COMPUTATION

For each of these instructions, a program-specified DES or AES wrapping-key-verification-pattern in the parameter block is compared with the respective wrapping-key-verification-pattern register. the instruction completes with condition code 1 if the two do not match.

A privileged program may use the PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION (PCKMO) instruction to encrypt DES or TDES keys using WK_d or to encrypt AES or ECC keys using WK_a. A privileged program may also use PCKMO to inspect the current DES or AES wrapping-key-verification pattern used to encrypt the respective key.

Programming Notes:

1. Upon condition code 1, the program should reimport the cryptographic key for encrypting it under the appropriate wrapping key before the operation is resumed.
2. Even though the architecture defines that a new set of wrapping keys are generated upon a clear reset, condition code 1 could occur at any time for message-security-assist functions using an encrypted key because the application may be relocated to another system with a different set of wrapping keys.
3. The sections “Protection of DES Keys” on page 7-432, “Protection of AES Keys” on page 7-434, and “Protection of ECC Keys” on page 7-436 illustrate encryption and decryption algorithms in support of encrypted cryptographic keys. The encryption algorithms are used by the PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION instruction when encrypting a cryptographic key, and the decryption algorithms are used by the various message-security-assist instructions that support the use of encrypted keys.

Symbols Used in Subsequent Descriptions

The following symbols are used in the subsequent description. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxx. Further description of the AES standard may be found in Reference [14.] on page xxx.

Protection of ECC Keys

When the message-security-assist extension 9 is installed, user ECC keys may be protected using the 256-bit AES wrapping key. ECC keys and any necessary padding are encrypted together.

Figure 7-378 on page 7-437 shows the encryption and decryption for ECC P256 and Ed25519 keys. On the left hand side of the figure encryption of a 256-bit (P256), or 255-bit key and 1 bit zero pad (Ed25519) is encrypted to a 256-bit encrypted key. On the right hand side decryption of the 256-bit key is shown. Encryption and decryption uses the 256-bit AES wrapping key. The Ed25519 key is right aligned in the 256-bit field and padded with 1 bit zero on the left.

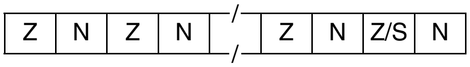
The decimal instructions of this chapter perform arithmetic and editing operations on decimal data. Additional operations on decimal data are also provided by several instructions in Chapter 7, “General Instructions,” several instructions in Chapter 20, “Decimal-Floating-Point Instructions,” and several instructions in Chapter 25, “Vector Decimal Instructions.” Generally, decimal operands reside in storage. For some of the instructions described in Chapter 20, decimal operands may reside in a general register or general register pair. For some of the instructions described in Chapter 25, decimal operands may reside in a vector register. The storage fields for decimal operands residing in storage may start on any byte boundary and may have variable lengths. The decimal operands residing in general registers and vector registers have fixed lengths.

Decimal-Number Formats

Decimal numbers may be represented in several formats, including zoned, signed-packed-decimal and unsigned-packed-decimal. These formats are of variable length; most instructions used to operate on these formats specify the length of their operands and results. Each byte of a format consists of a pair of four-bit codes; the four-bit codes include decimal-digit codes, sign codes, and a zone code.

Zoned Format



In the zoned format, the rightmost four bits of a byte are called the numeric bits (N) and normally consist of a code representing a decimal digit. The leftmost four bits of a byte are called the zone bits (Z), except for the rightmost byte of a decimal operand, where these bits may be treated either as a zone or as a sign (S).

Decimal digits in the zoned format may be part of a larger character set, which includes also alphabetic and special characters. The zoned format is, therefore, suitable for input, editing, and output of numeric data in human-readable form. There are no decimal-arithmetic instructions which operate directly on decimal numbers in the zoned format; such numbers must first be converted to the signed-packed-decimal format or one of the DFP formats.

The editing instructions produce a result of up to 256 bytes; each byte may be a decimal digit in the zoned format, a message byte, or a fill byte.

Packed-Decimal Formats

There are two packed-decimal formats, signed-packed, and unsigned-packed.

Signed-Packed-Decimal Format

D	D	D	D	/ /	D	D	D	S

In the signed-packed-decimal format, each byte contains two decimal digits (D), except for the rightmost byte, which contains a sign (S) to the right of a decimal digit. Decimal arithmetic is performed with operands in the signed-packed-decimal format and generates results in the signed-packed-decimal format.

The signed-packed-decimal operands and results of decimal-arithmetic instructions may be up to 16 bytes (31 digits and sign), except that the maximum length of a multiplier or divisor is eight bytes (15 digits and sign). In division, the sum of the lengths of the quotient and remainder may be from two to 16 bytes. The editing instructions can fetch as many as 256 decimal digits from one or more decimal numbers of variable length, each in the signed-packed-decimal format. CONVERT FROM PACKED and CONVERT TO PACKED may have signed-packed-decimal operands up to 18 bytes (34 digits and sign).

Unsigned-Packed-Decimal Format

D	D	D	D	/ /	D	D	D	D

In the unsigned-packed-decimal format, each byte contains two decimal digits (D) and there is no sign. The unsigned-packed-decimal format can be used as the source operand of the editing instructions, as the second operand of MOVE WITH OFFSET, and is also used by the decimal floating-point (DFP) instructions CONVERT FROM PACKED, CONVERT FROM UNSIGNED PACKED, CONVERT TO PACKED, and CONVERT TO UNSIGNED PACKED.

Decimal Codes

The decimal digits 0-9 have the binary encoding 0000-1001.

The preferred sign codes are 1100 for plus and 1101 for minus. These are the sign codes generated for the results of the decimal-arithmetic instructions and the CONVERT TO DECIMAL instruction. The instructions PACK ASCII and PACK UNICODE supply an implied positive sign (1100 binary). The DFP instructions CONVERT TO PACKED, CONVERT TO SIGNED PACKED, and CONVERT TO ZONED include a plus sign-code selection bit. The plus sign can be encoded as either 1100 or 1111. The sign codes generated for vector decimal instruction results are either preferred sign codes 1100 for positive and 1101 for negative or can be forced to positive with sign code 1111.

Alternate sign codes are also recognized as valid in the sign position: 1010, 1110, and 1111 are alternate codes for plus, and 1011 is an alternate code for minus. Alternate sign codes are accepted for any decimal source operand, but are not generated in the completed result of a decimal-arithmetic instruction , vector decimal-arithmetic instruction, CONVERT TO DECIMAL, or VECTOR CONVERT TO DECIMAL. This is true even when an operand remains otherwise unchanged, such as when adding zero to a number. An alternate sign code is, however, left unchanged by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, UNPACK, VECTOR PACK ZONED and VECTOR UNPACK ZONED.

When an invalid sign or digit code is detected, a general-operand data exception is recognized. For CONVERT TO BINARY, the decimal-arithmetic instructions, the decimal floating-point instructions CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, and CONVERT FROM ZONED, the vector decimal-arithmetic instructions, and the vector decimal instruction VECTOR CONVERT TO BINARY, the operation is suppressed.

For the editing instructions EDIT and EDIT AND MARK, an invalid sign code is not recognized. It is model dependent whether the operation is suppressed or terminated for a general-operand data exception due to an invalid digit code. No validity checking is performed by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, PACK ASCII, PACK UNICODE, and UNPACK. The instructions UNPACK ASCII and UNPACK UNICODE do not check for invalid digit codes; invalid sign codes are recognized, but are not reported as a general-operand data exception, instead condition code 3 is set.

The zone code 1111 is generated in the left four bit positions of each byte representing a zone and a decimal digit in zoned-format results. Zoned-format results are produced by EDIT, EDIT AND MARK, and UNPACK. For EDIT and EDIT AND MARK, each result byte representing a zoned-format decimal digit contains the zone code 1111 in the left four bit positions and the decimal-digit code in the right four bit positions. For UNPACK, zone bits with a coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign.

The zone code 0011 is generated in the leftmost four bit positions of each byte representing a zone for a decimal digit in ASCII format. ASCII formats are produced by CONVERT TO ZONED when the zone-control bit is one and by UNPACK ASCII.

The meaning of the decimal codes is summarized in Figure 8-1.

Code	Recognized As	
(Binary)	Digit	Sign
0000	0	Invalid
0001	1	Invalid
0010	2	Invalid
0011	3	Invalid *
0100	4	Invalid
0101	5	Invalid
0110	6	Invalid
0111	7	Invalid
1000	8	Invalid
1001	9	Invalid
1010	Invalid	Plus
1011	Invalid	Minus
1100	Invalid	Plus (preferred)
1101	Invalid	Minus (preferred)
1110	Invalid	Plus
1111	Invalid	Plus (zone)

Explanation:

* The zone code 0011 binary is generated in the leftmost four bit positions of each byte representing a decimal digit in the ASCII format.

Figure 8-1. Summary of Digit and Sign Codes

Programming Note: Since 1111 is both the zone code and an alternate code for plus, unsigned (positive) decimal numbers may be represented in the zoned format with 1111 zone codes in all byte positions. The result of the PACK instruction converting such a number to the signed-packed-decimal format may be used directly as an operand for decimal instructions.

Decimal Operations

The decimal instructions in this chapter consist of two classes, the decimal-arithmetic instructions and the editing instructions.

Decimal-Arithmetic Instructions

The decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison, and shifting.

Operands of the decimal-arithmetic instructions are in the signed-packed-decimal format and are treated as signed decimal integers. A decimal integer is represented in true form as an absolute value with a separate plus or minus sign. It contains an odd number of decimal digits, from one to 31, and the sign; this corresponds to an operand length of one to 16 bytes.

A decimal zero normally has a plus sign, but multiplication, division, and overflow may produce a zero value with a minus sign. Such a negative zero is a valid operand and is treated as equal to a positive zero by COMPARE DECIMAL.

The lengths of the two operands specified in the instruction need not be the same. If necessary, the shorter operand is considered to be extended with zeros on the left. Results, however, cannot exceed the first-operand length as specified in the instruction.

When a carry or leftmost nonzero digits of the result are lost because the first-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

The operands of decimal-arithmetic instructions should not overlap at all or should have coincident rightmost bytes. In ZERO AND ADD, the operands may also overlap in such a manner that the rightmost byte of the first operand (which becomes the result) is to the right of the rightmost byte of the second operand. For these cases of proper overlap, the result is obtained as if operands were processed right to left. Because the codes for digits and signs are verified during the performance of the arithmetic, improperly overlapping operands are recognized as general-operand data exceptions. However, in ZERO AND ADD when the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, the entire second operand may be fetched, depending on the model, before any storing occurs, which will cause a general-operand data exception not to be recognized. See “Interlocks within a Single Instruction” on page 5-116 for how overlap is detected in the access-register mode.

Programming Note: A signed-packed-decimal number in storage may be designated as both the first and second operand of ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, SUBTRACT DECIMAL, or ZERO AND ADD. Thus, a decimal number may be added to itself, compared with itself, and so forth; SUBTRACT DECIMAL may be used to set a decimal field in storage to zero; and, for MULTIPLY DECIMAL, a decimal number may be squared in place. In these cases, the lengths of the two operands are not necessarily equal and may, depending on the instruction, be prohibited from being equal.

Editing Instructions

The editing instructions are EDIT and EDIT AND MARK. For these instructions, only the first operand (the pattern) has an explicitly specified length. The second operand (the source) is considered to have as many digits as necessary for the completion of the operation.

Overlapping operands for the editing instructions yield unpredictable results.

Execution of Decimal Instructions

During the execution of a decimal instruction, all bytes of the operands are not necessarily accessed concurrently, and the fetch and store accesses to a single location do not necessarily occur one immediately after the other. Furthermore, for decimal instructions, data in source fields may be accessed more than once, and intermediate values may be placed in the result field that may differ from the original operand and final result values. (See “Storage-Operand Consistency” on page 5-125.) Thus, in a multiprocessing configuration, an instruction such as ADD DECIMAL cannot be safely used to update a shared storage location when the possibility exists that another CPU may also be updating that location.

Other Instructions for Decimal Operands

In addition to the decimal-arithmetic instructions in this chapter, (which operate on decimal numbers in the signed-packed-decimal format) several other instructions are provided for operating on decimal data in the zoned, signed-packed-decimal, or unsigned-packed-decimal format.

The editing instructions (described in this chapter) convert decimal numbers in either the signed-packed-decimal or unsigned-packed-decimal format to the zoned format. Zoned results of up to 256 bytes in length can be produced.

CONVERT TO DECIMAL and CONVERT TO BINARY (described in Chapter 7) provide conversion between signed-binary-integer formats and decimal numbers in the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO SIGNED PACKED and CONVERT FROM SIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO UNSIGNED PACKED and CONVERT FROM UNSIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the unsigned-packed-decimal format. Unsigned-packed-decimal operands of up to 16 bytes in length (32 digits) can be processed.

MOVE WITH OFFSET (described in Chapter 7) operates on data in the packed format. (The first operand is treated as signed-packed decimal and the second operand as unsigned-packed decimal.) Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

PACK, UNPACK, PACK ASCII, UNPACK ASCII, PACK UNICODE, and UNPACK UNICODE provide conversion between zoned or character data and signed-packed-decimal data. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

MOVE NUMERICS and MOVE ZONES (described in Chapter 7) operate on data in the zoned format. Operands are not checked for valid codes. Zoned operands of up to 256 bytes in length can be processed.

The vector decimal instructions (described in Chapter 25) provide register-to-register decimal-arithmetic operations of addition, subtraction, multiplication, division, comparison, and shifting of data in the packed-decimal format.

VECTOR CONVERT TO BINARY and VECTOR CONVERT TO DECIMAL (described in Chapter 25) provide register-to-register conversion between signed-packed-decimal format and binary-integer (signed and unsigned) format numbers. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

VECTOR PACK ZONED and VECTOR UNPACK ZONED (described in Chapter 25) provide conversion between a zoned format storage operand and a signed-packed-decimal format register operand. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

General-Operand Data Exception

A general-operand data exception is recognized when any of the following is true:

1. The sign or digit codes are invalid in the operands of the decimal instructions, vector decimal-arithmetic instructions, or in CONVERT TO BINARY (described in Chapter 7, “General Instructions”), in CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, and CONVERT FROM ZONED (described in Chapter 20, “Decimal-Floating-Point Instructions”), or in VECTOR CONVERT TO BINARY (described in Chapter 25, “Vector Decimal Instructions”).
2. The operand fields in ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, and SUBTRACT DECIMAL overlap in a way other than with coincident rightmost bytes; or operand fields in ZERO AND ADD overlap, and the rightmost byte of the second operand is to the right of the rightmost byte of the first operand. On some models, the improper overlap of operands for ZERO AND ADD is not recognized as a general-operand data exception; instead, the operation is performed as if the entire second operand were fetched before any byte of the result is stored.
3. The multiplicand in MULTIPLY DECIMAL has an insufficient number of leftmost zeros.
4. COMPRESSION CALL encounters errors in its dictionaries.
5. The reseed counter is zero for a PERFORM RANDOM NUMBER OPERATION instruction’s PRNO-SHA-512-DRNG generate operation.

A general-operand data exception causes the operation to be suppressed, except that, for EDIT and EDIT AND MARK, and COMPRESSION CALL, the operation may be suppressed or terminated. In the case of EDIT and EDIT AND MARK, and COMPRESSION CALL, an invalid sign code cannot occur.

Note: In earlier versions of the architecture, the general-operand data exception was known as the decimal-operand data exception.

Instructions

The decimal instructions and their mnemonics, formats, and operation codes are listed in Figure 8-2 on page 8-6. The figure also indicates when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For ADD DECIMAL, for example, AP is the mnemonic and $D_1(L_1,B_1),D_2(L_2,B_2)$ the operand designation.

Programming Note: The decimal instruction TEST DECIMAL is available when the extended-translation facility 2 is installed.

Name	Mne- monic	Characteristics													Op Code	Page
ADD DECIMAL	AP	SS-b	C		¤^{9}	A		Dg	DF			ST	B_1	B_2	FA	8-6

Explanation:

¤^{9} Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
A Access exceptions for logical addresses.
B_1 B_1 field designates an access register in the access-register mode.
B_2 B_2 field designates an access register in the access-register mode.
C Condition code is set.
DF Decimal-overflow exception.
Dg General-operand data exception.
DK Decimal-divide exception.
E2 Extended-translation facility 2.
G1 Instruction execution includes the implied use of general register 1.
RSL RSL instruction format.
SP Specification exception.
SS SS instruction format.
ST PER storage-alteration event.

Figure 8-2. Summary of Decimal Instructions

ADD DECIMAL

AP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'FA'	L_1	L_2	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The second operand is added to the first operand, and the resulting sum is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

Addition is algebraic, taking into account the signs and all digits of both operands. All sign and digit codes are checked for validity.

If the first operand is too short to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

The sign of the sum is determined by the rules of algebra. In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given either a positive or negative sign, as determined by what the sign of the correct sum would have been.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Note: An example of the use of the ADD DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

COMPARE DECIMAL

CP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'F9'	L_1	L_2	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

Comparison is algebraic and follows the procedure for decimal subtraction, except that both operands remain unchanged. When the difference is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

Overflow cannot occur because the difference is discarded.

All sign and digit codes are checked for validity.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Data with DXC 0, general operand
- Transaction constraint

Programming Notes:

1. An example of the use of the COMPARE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.

3. A negative zero and a positive zero compare equal.

DIVIDE DECIMAL

DP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'FD'	L_1	L_2	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The first operand (the dividend) is divided by the second operand (the divisor). The resulting quotient and remainder are placed at the first-operand location. The operands and results are in the signed-packed-decimal format.

The quotient is placed leftmost in the first-operand location. The number of bytes in the quotient field is equal to the difference between the dividend and divisor lengths (L_1 - L_2). The remainder is placed rightmost in the first-operand location and has a length equal to the divisor length. Together, the quotient and remainder fields occupy the entire first operand; therefore, the address of the quotient is the address of the first operand.

The divisor length cannot exceed 15 digits and sign (L_2 not greater than seven) and must be less than the dividend length (L_2 less than L_1); otherwise, a specification exception is recognized.

The dividend, divisor, quotient, and remainder are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the dividend and divisor are checked for validity.

The sign of the quotient is determined by the rules of algebra from the dividend and divisor signs. The sign of the remainder has the same value as the dividend sign. These rules hold even when the quotient or remainder is zero.

Overflow cannot occur. If the divisor is zero or the quotient is too large to be represented by the number of digits specified, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The decimal-divide exception is indicated only if the sign codes of both the dividend and divisor are valid, and only if the digit or digits used in establishing the exception are valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal divide
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the DIVIDE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The dividend cannot exceed 31 digits and sign. Since the remainder cannot be shorter than one digit and sign, the quotient cannot exceed 29 digits and sign.

3. The condition for a decimal-divide exception can be determined by a trial comparison. The leftmost digit of the divisor is aligned one digit to the right of the leftmost dividend digit, with rightmost zeros appended up to the length of the dividend. When the divisor, so aligned, is less than or equal to the dividend, ignoring signs, a divide exception is indicated.

4. If a general-operand data exception does not exist, a decimal-divide exception occurs when the leftmost dividend digit is not zero.

EDIT

ED $D_1(L,B_1),D_2(B_2)$ [SS-a]

'DE'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The edited result replaces the first operand.

The length field specifies the length of the first operand, which may contain bytes of any value.

The length of the source is determined by the operation according to the contents of the pattern. The source normally consists of one or more decimal numbers, each in the signed-packed-decimal or unsigned-packed-decimal format. The leftmost four bits of each source byte must specify a decimal-digit code (0000-1001); a sign code (1010-1111) is recognized as a general-operand data exception. The rightmost four bits may specify either a sign code or a decimal-digit code. Access and data exceptions and PER zero-address-detection events are recognized only for those bytes in the second operand which are actually required.

The result is obtained as if both operands were processed left to right one byte at a time. Overlapping pattern and source fields give unpredictable results.

During the editing process, each byte of the pattern is affected in one of three ways:

1. It is left unchanged.

2. It is replaced by a source digit expanded to the zoned format.

3. It is replaced by the first byte in the pattern, called the fill byte.

Which of the three actions takes place is determined by one or more of the following: the type of the pattern byte, the state of the significance indicator, and whether the source digit examined is zero.

Pattern Bytes: There are four types of pattern bytes: digit selector, significance starter, field separator, and message byte. Their coding is as follows:

	Code	
Name	**(Binary)**	**(Hex)**
Digit Selector	0010 0000	20
Significance starter	0010 0001	21
Field separator	0010 0010	22
Message byte	Any other	Any other

The detection of either a digit selector or a significance starter in the pattern causes an examination to be made of the significance indicator and of a source digit. As a result, either the expanded source digit or the fill byte, as appropriate, is selected to replace the pattern byte. Additionally, encountering a digit selector or a significance starter may cause the significance indicator to be changed.

The field separator identifies individual fields in a multiple-field editing operation. It is always replaced in the result by the fill byte, and the significance indicator is always off after the field separator is encountered.

Message bytes in the pattern are either replaced by the fill byte or remain unchanged in the result, depending on the state of the significance indicator. They may thus be used for padding, punctuation, or text in the significant portion of a field or for the insertion of sign-dependent symbols.

Fill Byte: The first byte of the pattern is used as the fill byte. The fill byte can have any code and may concurrently specify a control function. If this byte is a digit selector or significance starter, the indicated editing action is taken after the code has been assigned to the fill byte.

Source Digits: Each time a digit selector or significance starter is encountered in the pattern, a new source digit is examined for placement in the pattern field. Either the source digit is disregarded, or it is expanded to the zoned format, by appending the zone code 1111 on the left, and stored in place of the pattern byte.

Execution is as if the source digits were selected one byte at a time. The leftmost four bits of each byte are examined first, and the rightmost four bits, when they represent a decimal-digit code, remain available for the next pattern byte that calls for a digit examination. When the leftmost four bits contain an invalid digit code, a general-operand data exception is recognized, and the operation is either suppressed or terminated.

At the time the left digit of a source byte is examined, the rightmost four bits are checked for the existence of a sign code. When a sign code is encountered in the rightmost four bit positions, these bits are not treated as a decimal-digit code, and a new source byte is fetched from storage when the next pattern byte calls for a source-digit examination.

When the pattern contains no digit selector or significance starter, no source bytes are fetched and examined.

Significance Indicator: The significance indicator is turned on or off to indicate the significance or non significance, respectively, of subsequent source digits or message bytes. Significant source digits replace their corresponding digit selectors or significance starters in the result. Significant message bytes remain unchanged in the result.

The significance indicator, by its on or off state, indicates also the negative or positive value, respectively, of a completed source field and is used as one factor in the setting of the condition code.

The significance indicator is set to off at the start of the editing operation, after a field separator is encountered, or after a source byte is examined that has a plus code in the rightmost four bit positions.

The significance indicator is set to on when a significance starter is encountered whose source digit is a valid decimal digit, or when a digit selector is encountered whose source digit is a nonzero decimal digit, provided that in both instances the source byte does not have a plus code in the rightmost four bit positions.

In all other situations, the significance indicator is not changed. A minus sign code has no effect on the significance indicator.

Result Bytes: The result of an editing operation replaces and is equal in length to the pattern. It is composed of pattern bytes, fill bytes, and zoned source digits.

If the pattern byte is a message byte and the significance indicator is on, the message byte remains unchanged in the result. If the pattern byte is a field separator or if the significance indicator is off when a message byte is encountered in the pattern, the fill byte replaces the pattern byte in the result.

If the digit selector or significance starter is encountered in the pattern with the significance indicator off and the source digit zero, the source digit is considered nonsignificant, and the fill byte replaces the pattern byte. If the digit selector or significance starter is encountered either with the significance indicator on or with a nonzero decimal source digit, then the source digit (a) is considered significant, (b) is changed to the zoned format, and (c) replaces the pattern byte in the result. Examination of the significance indicator occurs prior to the processing of the source digit (which might change the significance indicator).

Condition Code: The sign and magnitude of the last field edited are used to set the condition code. The term “last field” refers to those source digits, if any, in the second operand selected by digit selectors or significance starters after the last field separator; if the pattern contains no field separator, there is only one field, which is considered to be the last field.

If no such source digits are selected, the last field is considered to be of zero length.

Condition code 0 is set when the last field edited is zero or of zero length.

Condition code 1 is set when the last field edited is nonzero and the significance indicator is on. (This indicates a result less than zero if the last source byte examined contained a sign code in the rightmost four bits.)

Condition code 2 is set when the last field edited is nonzero and the significance indicator is off. (This indicates a result greater than zero if the last source byte examined contained a sign code in the rightmost four bits.)

For the purposes of setting condition code 2, the significance indicator is examined after the processing of the last source digit.

Figure 8-3 on page 8-10 summarizes the functions of the EDIT and EDIT AND MARK operations. The leftmost four columns list all the significant combinations of the four conditions that can be encountered in the execution of an editing operation. The rightmost two columns list the action taken for each case — the type of byte placed in the result field and the new setting of the significance indicator.

Conditions				**Results**	
Pattern Byte	**Previous State of Significance Indicator**	**Source Digit**	**Right Four Source Bits Are Plus Code**	**Result Byte**	**State of Significance Indicator at End of Digit Examination**
Digit selector	Off	0	*	Fill byte	Off
		1-9	No	Source digit#	On
			Yes	Source digit#	Off
	On	0-9	No	Source digit	On
			Yes	Source digit	Off
Significance starter	Off	0	No	Fill byte	On
			Yes	Fill byte	Off
		1-9	No	Source digit#	On
			Yes	Source digit#	Off
	On	0-9	No	Source digit	On
			Yes	Source digit	Off
Field separator	*	**	**	Fill byte	Off
Message byte	Off	**	**	Fill byte	Off
	On	**	**	Message byte	On

Explanation:

*	No effect on result byte or on new state of significance indicator.
**	Not applicable because source is not examined.
#	For EDIT AND MARK only, the address of the rightmost such result byte is placed in general register 1.

Figure 8-3. Summary of Editing Functions

Resulting Condition Code:

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Transaction constraint

Programming Notes:

1. Examples of the use of the EDIT instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. Editing includes sign and punctuation control, and the suppression of leading zeros by replacing them with blanks, or the protection of leading zeros from malicious alteration by replacing them with asterisks or other characters. It also facilitates programmed blanking of all-zero fields. Several fields may be edited in one operation, and numeric information may be combined with text.

3. In most cases, the source is shorter than the pattern because each four-bit source digit produces an eight-bit byte in the result.

4. The total number of digit selectors and significance starters in the pattern always equals the number of source digits edited.

5. If the fill byte is a blank, if no significance starter exists in the pattern, and if the source digit examined for each digit selector is zero, the editing operation blanks the result field.

6. The resulting condition code indicates whether or not the last field is all zeros and, if nonzero, reflects the state of the significance indicator. The significance indicator reflects the sign of the source field only if the last source byte examined contains a sign code in the rightmost four bits. For multiple-field editing operations, the condition code reflects the sign and value only of the field following the last field separator.

7. Significant performance degradation is possible when the second-operand address of an EDIT instruction designates a location that is closer to the left of an access boundary than the length of the first operand of that instruction (for the purposes of this discussion, an access boundary is 4 K-bytes, except when fetch-protection override applies in which case it is 2 K-bytes). This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary. The second operand of EDIT, while normally shorter than the first operand, can in the extreme case have the same length as the first.

EDIT AND MARK

EDMK $D_1(L,B_1),D_2(B_2)$ [SS-a]

'DF'	L	B_1	D_1	B_2	D_2
0	8	16	20	32	36 47

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The address of the first significant result byte of the rightmost (or only) field is inserted in general register 1. The edited result replaces the pattern.

EDIT AND MARK is identical to EDIT, except for the additional function of inserting the address of the result byte in general register 1 if the result byte is a zoned source digit and the significance indicator was off before the examination of the source bytes. If no result byte meets the criteria, general register 1 remains unchanged; if more than one result byte meets the criteria, the address of the rightmost such result byte is inserted.

In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of the register are not changed. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of the register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

The contents of access register 1 remain unchanged.

See Figure 8-3 on page 8-10 for a summary of the EDIT and EDIT AND MARK operations.

Resulting Condition Code:

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Transaction constraint

Programming Notes:

1. Examples of the use of the EDIT AND MARK instruction are given Appendix A, “Number Representation and Instruction-Use Examples.”

2. EDIT AND MARK facilitates the programming of floating currency-symbol insertion. Using appropriate source and pattern data, the address inserted in general register 1 is one greater than the address where a floating currency-sign would be inserted.

3. No address is inserted in general register 1 when the significance indicator is turned on as a result of encountering a significance starter with the corresponding source digit zero. To ensure that general register 1 contains a proper address when this occurs, the address of the pattern byte that immediately follows the appropriate significance starter could be placed in the register beforehand.

4. When multiple fields are edited with one execution of the EDIT AND MARK instruction, the address, if any, inserted in general register 1 applies to the rightmost field edited for which the criteria were met.

5. See also the programming note under EDIT regarding performance degradation due to a possible trial execution.

MULTIPLY DECIMAL

MP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'FC'	L_1	L_2	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The product of the first operand (the multiplicand) and the second operand (the multiplier) is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The multiplier length cannot exceed 15 digits and sign (L_2 not greater than seven) and must be less than the multiplicand length (L_2 less than L_1); otherwise, a specification exception is recognized.

The multiplicand must have at least as many bytes of leftmost zeros as the number of bytes in the multiplier; otherwise, a general-operand data exception is recognized. This restriction ensures that no product overflow occurs.

The multiplicand, multiplier, and product are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the multiplicand and multiplier are checked for validity. The sign of the product is determined by the rules of algebra from the multiplier and multiplicand signs, even if one or both operands are zeros.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the MULTIPLY DECIMAL instruction is given Appendix A, “Number Representation and Instruction-Use Examples.”

2. The product cannot exceed 31 digits and sign. The leftmost digit of the product is always zero.

SHIFT AND ROUND DECIMAL

SRP $D_1(L_1,B_1),D_2(B_2),I_3$ [SS-c]

'F0'	L_1	I_3	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The first operand is shifted in the direction and for the number of decimal-digit positions specified by the second-operand address, and, when shifting to the right is specified, the absolute value of the first operand is rounded by the rounding digit, I_3. The first operand and the result are in the signed-packed-decimal format.

The first operand is considered to be in the signed-packed-decimal format. Only its digit portion is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result replaces the first operand. Nothing is stored outside of the specified first-operand location.

The second-operand address, specified by the B_2 and D_2 fields, is not used to address data; bits 58-63 of that address are the shift value, and the leftmost bits of the address are ignored.

The shift value is a six-bit signed binary integer, indicating the direction and the number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

Shift Value (Binary)	Amount and Direction
011111	31 digits to the left
000001	One digit to the left
000000	No shift
111111	One digit to the right
100000	32 digits to the right

For a right shift, the I_3 field, bits 12-15 of the instruction, is used as a decimal rounding digit. The first operand, which is treated as positive by ignoring the sign, is rounded by decimally adding the rounding digit to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The result of this addition is then shifted right. Except for validity checking and the participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs. Overflow cannot occur for a right shift, with or without rounding, or when no shifting is specified.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, the sign of the result is the same as the original sign but with the preferred sign code.

A general-operand data exception is recognized when the first operand does not have valid sign and digit codes or when the rounding digit is not a valid digit code. The validity of the first-operand codes is checked even when no shift is specified, and the validity of the rounding digit is checked even when no addition for rounding takes place.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Notes:

1. Examples of the use of the SHIFT AND ROUND DECIMAL instruction are given in Appendix A, "Number Representation and Instruction-Use Examples."
2. SHIFT AND ROUND DECIMAL can be used for shifting up to 31 digit positions left and up to 32 digit positions right. This is sufficient to clear all digits of any decimal number even with rounding.
3. For right shifts, the rounding digit 5 provides conventional rounding of the result. The rounding digit 0 specifies truncation without rounding.
4. When the B_2 field is zero, the six-bit shift value is obtained directly from bits 42-47 of the instruction.

SUBTRACT DECIMAL

SP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'FB'	L_1	L_2	B_1	D_1	B_2	D_2

0 8 12 16 20 32 36 47

The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

SUBTRACT DECIMAL is executed the same as ADD DECIMAL, except that the second operand is considered to have a sign opposite to the sign in storage. The second operand in storage remains unchanged.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

TEST DECIMAL

TP $D_1(L_1,B_1)$ [RSL-a]

'EB'	L_1	////	B_1	D_1	////////	'C0'
0	8	12	16	20	32	40 47

The first operand is tested for valid decimal digits and a valid sign code, and the result is indicated in the condition code. The operand is in the signed-packed-decimal format.

Resulting Condition Code:

0 All digit codes and the sign valid
1 All digit codes valid and sign invalid
2 At least one digit code invalid and sign valid
3 At least one digit code invalid and sign invalid

Program Exceptions:

- Access (fetch, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Transaction constraint

ZERO AND ADD

ZAP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]

'F8'	L_1	L_2	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The second operand is placed at the first-operand location. The operation is equivalent to an addition to zero. The operand and result are in the signed-packed-decimal format.

Only the second operand is checked for valid sign and digit codes. Extra zeros are supplied on the left for the shorter operand if needed.

If the first operand is too short to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given the sign of the second operand but with the preferred sign code.

The two operands may overlap, provided the rightmost byte of the first operand is coincident with or to the right of the rightmost byte of the second operand. In this case, the result is obtained as if the operands were processed right to left. When the operands overlap and the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, then, depending on the model, either a general-operand data exception is recognized or the result is obtained as if the entire second operand were fetched before any byte of the result is stored.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Note: An example of the use of the ZERO AND ADD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

Floating-point instructions are used to perform calculations on operands having a wide range of magnitude and to obtain results scaled to preserve precision.

Floating-point operands have formats based on three radixes: 2, 10, or 16. These radix values lead to the terminology “binary,” “decimal,” and “hexadecimal” floating point (BFP, DFP, and HFP), respectively. The formats are also based on three operand lengths: short (32 bits), long (64 bits), and extended (128 bits). Short operands require less storage than long or extended operands. On the other hand, long and extended operands permit greater precision in computation.

Sign Bit

All floating-point data have a sign bit. The sign bit is zero for plus and one for minus.

Finite Floating-Point Numbers

A finite floating-point number has three components: a sign bit, an exponent, and a significand. The magnitude (an unsigned value) of the number is the product of the significand and the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The significand consists of a string of digits, where each digit is an integral value from zero to one less than the radix (2, 10, or 16). (Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The number of digit positions in the significand is called the precision of the floating-point number. The significand has an implied radix point, which, depending on the view, may be considered to be on the left, to the right of the leftmost digit, on the right, or elsewhere.

The exponent, a signed value, is represented as an unsigned binary value by adding a bias; the result, for BFP and DFP, is called the biased exponent; for HFP, it is called the characteristic. The value of the bias depends on the view. In the *fraction view*, the radix point is considered to be the left of the significand. In the *left-units view*, the radix point is considered to be to the right of the leftmost digit. In the *right-units view*, the radix point is considered to be on the right of the significand. By choosing the appropriate bias, any finite floating-point number can be considered in any of these views, or even in another view. For the first three of these views, the bias is called the *fraction-view bias, left-units-view bias,* and *right-units-view bias,* respectively. Except where otherwise indicated, HFP is defined in terms of the fraction view, BFP terms of the left-units view, and DFP in terms of the right-units view.

For HFP, the significand is considered to be a fraction with the implied radix point on the left. In this view, the significand is referred to as the fraction. For BFP, the significand consists of an implicit unit digit to the left of an implied radix point and an explicit fraction field to the right. For DFP, the significand is considered to be an integer with the implied radix point on the right.

Infinities

BFP and DFP data include an infinite numeric datum, called infinity. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. An infinity has a sign bit. In comparisons, infinities of the same sign compare equal, $+\infty$ compares greater than any finite number, and $-\infty$ compares less than any finite number.

Not-A-Number (NaN)

BFP and DFP data types include a nonnumeric datum, called not-a-number (or NaN). A NaN is produced in place of a numeric result after an invalid operation when there is no IEEE trap action. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area. A NaN has a sign bit, a NaN-type bit, and a payload.

Signaling and Quiet NaNs

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the NaN-type bit.

For BFP, the NaN-type bit is the leftmost bit of the fraction field, and is called the QNaN bit: a BFP NaN is an SNaN, or a QNaN, depending on whether the QNaN bit is zero, or one, respectively. For DFP, the NaN-type bit is in bit position 6 in all three formats, and is called the SNaN bit: a DFP NaN is a QNaN, or an SNaN, depending on whether the SNaN bit is zero, or one, respectively.

Payload

NaNs include diagnostic information called the payload. For BFP, the payload has two fewer bits than the precision and is considered to be a left-aligned bit-reversed binary integer. For DFP, the payload has one fewer digit than the precision and is considered to be a right-aligned decimal integer.

For both BFP and DFP the payload of a NaN is considered to be an unsigned integer. Let p represent the precision, in digits, of a particular format. For DFP, bit 6 of the format is called the SNaN bit and the p-1 digits in the trailing significand field are the numeric value of the payload. For BFP, the leftmost bit in the fraction field is called the QNaN bit and the remaining p-2 bits of the fraction field are the numeric value of the payload.

The numeric value of the BFP NaN payload is bit-reversed. That is, the first bit to the right of the QNaN bit is considered to have a value of one, the next bit a value of two, and so on, with each bit having a value of twice the value of the bit to its left.

Propagation of NaNs

Normally, QNaNs are just propagated during computations so that they will remain visible at the end; while an SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by inverting the NaN-type bit, and setting the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Default QNaN

A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a payload of zeros.

Programming Notes:

1. The program can generate and assign values to the payload of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format truncates digits from the payload. For BFP, bits are truncated on the right; for DFP, digits are truncated on the left. For the PFPO-convert-floating-point-radix operation, payloads are preserved, except that payloads larger than the capacity of the target format are replaced by the default QNaN (payload zero).

2. Depending on the application, the program may or may not desire that an SNaN signal the IEEE invalid-operation exception. The sign-handling instructions LOAD COMPLEMENT, LOAD NEGATIVE, and LOAD POSITIVE do not signal the invalid-operation exception but, instead, treat SNaNs like any other data. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option.

3. The instructions LOAD LENGTHENED and LOAD ROUNDED change the precision of a floating-point datum. The BFP versions of these instructions signal the invalid-operation exception when the operand is an SNaN. The DFP instructions have a modifier bit to control whether the exception is signaled.

Floating-Point Number Representations

Hexadecimal-Floating-Point (HFP)

Hexadecimal-floating-point (HFP) operands have formats which provide for exponents that specify powers of the radix 16 and significands that are hexadecimal numbers. The exponent range is the same for the short, long, and extended formats.

The results of most operations on HFP data are truncated to fit into the target format, but there are instructions available to round the result when converting to a narrower format. Additionally, the PERFORM FLOATING POINT OPERATION instruction provides rounding methods when converting to an HFP format from BFP or DFP.

For HFP operands, the implicit unit digit of the significand is always zero. Since the value of the significand and fraction are the same, HFP operations are described in terms of the fraction, and the term significand is not used.

Either normalized or unnormalized numbers may be used as operands for any HFP or DFP operation, where, for HFP, a normalized number is one having a nonzero leftmost fraction digit, or, for DFP, a normalized number is one having a nonzero leftmost significand digit. Most HFP instructions generate normalized results for greatest precision. HFP add and subtract instructions that generate unnormalized results are also available. When the HFP-unnormalized-extensions facility is installed, the MULTIPLY UNNORMALIZED and MULTIPLY AND ADD UNNORMALIZED instructions also generate unnormalized results.

Binary Floating-Point (BFP)

Binary-floating-point (BFP) operands have formats which provide for exponents that specify powers of the radix 2 and significands that are binary numbers. The exponent range differs for different formats, the range being greater for the longer formats. In the long and extended formats, the exponent range is significantly greater for BFP data than for HFP data.

The results of operations performed on BFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable BFP rounding mode; however, explicit rounding modes may be specified in various BFP instructions.

There are no unnormalized operands for BFP operations. For normal BFP numbers, the implicit unit digit of the significand is one. For values too small in magnitude to be represented in normalized form, the implicit unit digit is zero. These numbers are called *subnormal* numbers.[1] Unlike the HFP and DFP formats, where the same value can have multiple representations in a given format because of the possibility of unnormalized numbers, the BFP format does not allow such redundancy.

Decimal Floating-Point (DFP)

Decimal-floating-point (DFP) operands have formats which provide for exponents that specify powers of the radix 10 and significands that are decimal numbers. The exponent range differs for different formats, the range being greater for the longer formats. The exponent range is greater for DFP data than for BFP data.

The results of operations performed on DFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable DFP rounding mode; however, explicit rounding modes may be specified in various DFP instructions.

Like HFP, DFP numbers can be normalized or unnormalized. Either normalized or unnormalized numbers may be used as operands for any DFP operation. For DFP, a normalized number is one having a nonzero leftmost significand digit. Because of the possibility of unnormalized numbers, the same value can have multiple representations in a given DFP format. The representations having the same value are called members of a cohort. Unlike HFP, DFP instructions generate normalized results for greater precision only when the result is inexact. When the result is exact, most DFP instructions produce a value in the form that preserves information called the quantum.

Canonical DFP Data

A *canonical DFP number* has only canonical declets, that is, the digits in the trailing-significand field are encoded using only the preferred DPD codes.

A *canonical DFP infinity* has bit 6 and all bits to the right of this in the format set to zeros.

A *canonical DFP NaN* has zeros in all bits to the right of the NaN-type bit in the combination field and only canonical declets in the trailing significand field.

Noncanonical DFP numbers, infinities, and NaNs are accepted as source operands, but all DFP results are canonical.

Comparison of Floating-Point Number Representations

Floating-Point Number Ranges

Figure 9-1 shows the range of numbers, in decimal form, that can be represented in different floating-point formats.

	Type	Short	Long	Extended
Nmax	HFP	$\pm 7.2\times 10^{+75}$	$\pm 7.2\times 10^{+75}$	$\pm 7.2\times 10^{+75}$
	BFP	$\pm 3.4\times 10^{+38}$	$\pm 1.8\times 10^{+308}$	$\pm 1.2\times 10^{+4932}$
	DFP	$\pm 1.0\times 10^{+97}$	$\pm 1.0\times 10^{+385}$	$\pm 1.0\times 10^{+6145}$

Figure 9-1. Decimal Approximations of Number Ranges for HFP, BFP, and DFP Formats

[1] Subnormal numbers were previously called *denormalized* numbers.

	Type	Short	Long	Extended
Nmin	HFP	$\pm5.4\times10^{-79}$	$\pm5.4\times10^{-79}$	$\pm5.4\times10^{-79}$
	BFP	$\pm1.2\times10^{-38}$	$\pm2.2\times10^{-308}$	$\pm3.4\times10^{-4932}$
	DFP	$\pm1.0\times10^{-95}$	$\pm1.0\times10^{-383}$	$\pm1.0\times10^{-6143}$
Dmin	HFP	$\pm5.1\times10^{-85}$	$\pm1.2\times10^{-94}$	$\pm1.7\times10^{-111}$
	BFP	$\pm1.4\times10^{-45}$	$\pm4.9\times10^{-324}$	$\pm6.5\times10^{-4966}$
	DFP	$\pm1.0\times10^{-101}$	$\pm1.0\times10^{-398}$	$\pm1.0\times10^{-6176}$

Explanation:

Dmin Smallest (in magnitude) representable subnormal (BFP or DFP) or nonzero unnormalized (HFP) number.
Nmax Largest (in magnitude) representable number.
Nmin Smallest (in magnitude) representable normal (BFP or DFP) or normalized (HFP) number.

Values are decimal approximations for all of the HFP, BFP, and DFP formats.

Figure 9-1. Decimal Approximations of Number Ranges for HFP, BFP, and DFP Formats

Equivalent Floating-Point Number Representations

The exponent of an HFP number is represented in the format as an unsigned seven-bit binary integer called the characteristic. The characteristic is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63.

The exponent of a BFP or DFP datum is represented in the format as an unsigned binary integer called the biased exponent. The biased exponent is obtained by adding a bias to the exponent value. The number of bit positions containing the biased exponent, the value of the bias, and the exponent range depend on the data format (short, long, or extended) and are shown for the three formats in Figure 19-4 on page 19-3 and the three DFP formats in Figure 20-3 on page 20-6. Biased exponents are similar to the characteristics of the HFP format, except that, for BFP, special meanings are attached to biased exponents of all zeros and all ones. This is discussed in the section “Classes of BFP Data” on page 19-4.

In each of the three BFP or HFP formats, the binary or hexadecimal point of a number, respectively, is considered to be to the left of the leftmost fraction digit. To the left of the point there is an implied unit digit, which is considered to be zero for HFP numbers or, for BFP numbers, one for normal numbers and zero for zeros and subnormal numbers.

Figure 9-2 on page 9-6 and Figure 9-3 on page 9-7 give examples of the closest representation of the same numbers in the BFP, DFP, and HFP formats, with BFP and DFP values being rounded to nearest and HFP values being truncated.

The figures do not necessarily show the results of conversions exactly. Rounding errors may make a small difference. Also, Figure 9-2 on page 9-6 shows corresponding rounded short-format numbers, not the long HFP results of conversion from short BFP operands.

Figure 9-3. Examples of Floating-Point Numbers in Long Format

Effective Width

The resolution of a floating-point format may be described in terms of the spacing between adjacent representable numbers in the format. This is called an ulp (unit in the last place). Thus, for example, when rounding to nearest, the maximum error is 1/2 ulp. The magnitude of an ulp is directly related to the precision of the format. Another way to measure the resolution of the format in the vicinity of a particular value is in terms of relative spacing, which is simply the value of an ulp divided by the value of the number. Relative spacing may be converted to a form called effective width, which is very similar to precision. The *effective width* (W_x) for any particular normalized floating-point value, v, is defined as:

$$W_x(v) = \log_x(v/u)$$

Where:

u Value of a unit in the last position (ulp).
v Value of the number.
W_x Effective width represented in base x.
x Any arbitrary base.

When effective width is measured using the native base for a particular format, it differs from the precision (p) of the format as shown in the following relation:

$p-1 \le W_b \le p$

Where:

b Native base of a particular format.
p Precision of the format.
W_b Effective width for any normalized value represented in the native base b of the format.

The following figure shows the maximum and minimum values of the effective width for normalized numbers for all supported floating-point formats.

		W_2		W_{10}	
Length	**Radix**	**Max**	**Min**	**Max**	**Min**
Short	HFP	24.00	20.00	7.22	6.02
	BFP	24.00	23.00	7.22	6.92
	DFP	23.25	19.93	7.00	6.00
Long	HFP	56.00	52.00	16.86	15.65
	BFP	53.00	52.00	15.95	15.65
	DFP	53.15	49.83	16.00	15.00
Extended	HFP	112.00	108.00	33.72	32.51
	BFP	113.00	112.00	34.02	33.72
	DFP	112.95	109.62	34.00	33.00

Explanation:

W_2 effective width represented in base 2.
W_{10} effective width represented in base 10.

Figure 9-4. Maximum and Minimum Effective Width

Programming Note: The following example using a 3-digit decimal significand, may be helpful in understanding the concept of effective width and the maximum and minimum values. Consider the three adjacent representable numbers, Va, Vb, and Vc, as shown in the following figure:

Symbol or Formula	Value
Va	9.99
Vb	10.0
Vc	10.1
Vb-Va	0.01
Vc-Vb	0.1

The distance between points Va and Vb (Vb-Va) represents a resolution of one part in a thousand; whereas, the distance between points Vb and Vc (Vc-Vb) represents a resolution of one part in a hundred. In the first case, the effective width is three digits; in the second case, it is only two digits. For other values in the format, the effective width lies between these two extremes.

Floating-Point Data in Storage

All floating-point data formats appear in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also the section “Storage Addressing” on page 3-2.)

Most of the floating-point instructions are defined in detail in this publication in Chapter 18, “Hexadecimal-Floating-Point Instructions,” Chapter 19, “Binary-Floating-Point Instructions,” and Chapter 20, “Decimal-Floating-Point Instructions.” This chapter, Chapter 9, defines in detail instructions called floating-point-support (FPS) instructions. The FPS instructions either have operands that may be in any floating-point format or have the function of converting between formats. This chapter also provides summary information about all of the floating-point instructions.

Registers And Controls

Floating-Point Registers

All floating-point instructions (FPS, BFP, DFP, and HFP) use the same 16 floating-point registers. The floating-point registers are identified by the numbers 0-15 and are designated by a four-bit R field in floating-point instructions. Each floating-point register is 64 bits long and can contain either a short (32-bit) or a long (64-bit) floating-point operand.

A short floating-point datum requires only the leftmost 32 bit positions of a floating-point register. The rightmost 32 bit positions of the register are ignored when the register is the source of an operand in the short format, and they remain unchanged when a short result is placed in the register.

A datum in the extended (128-bit) format occupies a register pair. Register pairs are formed by coupling the 16 registers as follows: 0 and 2, 4 and 6, 8 and 10, 12 and 14, 1 and 3, 5 and 7, 9 and 11, and 13 and 15.

Each of the eight pairs is referred to by the number of the lower-numbered register of the pair.

Additional Floating-Point (AFP) Registers

Floating-point registers 0, 2, 4, and 6 are ones that were originally available on ESA/390 models. The remaining 12 floating-point registers (1, 3, 5, and 7-15) were added to ESA/390 and are referred to as the additional floating-point (AFP) registers. The AFP registers can be used only if bit 45 of control register 0, the AFP-register-control bit, is one. Attempting to use an AFP register when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1).

Valid Floating-Point-Register Designations

Any installed register may be designated by an instruction to specify the register location of a short or long floating-point operand.

An instruction specifying a floating-point operand in the extended format must designate register 0, 1, 4, 5, 8, 9, 12, or 13; otherwise, a specification exception is recognized.

Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. An overview of the FPC register is shown in Figure 9-5. Details are shown in Figure 9-6 and in Figure 9-8. (In Figure 9-6, the abbreviations “IM” and “SF” are based on the terms “interruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

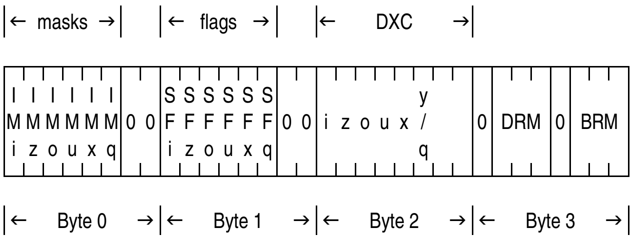

Figure 9-5. FPC Register Overview

Byte	Bit(s)	Name	Abbr.
0	0	IEEE-invalid-operation mask	IMi
0	1	IEEE-division-by-zero mask	IMz
0	2	IEEE-overflow mask	IMo
0	3	IEEE-underflow mask	IMu
0	4	IEEE-inexact mask	IMx
0	5	Quantum-exception mask	IMq
0	6-7	(Unassigned)	0

[2] Used when the floating-point extension facility is installed. However, bits 5-7 may be used by the other architecture mode of the configuration. (See the section, “Impacts on ESA/390 and ESA/390-Compatibility Mode”, for details.)

— Does not apply

Figure 9-8. BFP Rounding Mode

IEEE Masks and Flags

When the floating-point extension facility is installed, the FPC register contains six IEEE mask bits and six IEEE flag bits that each correspond to one of the six IEEE exceptions that may be recognized when an IEEE computational instruction is executed. When the floating-point extension facility is not installed, the quantum exception is not recognized; the mask bit FPC 0.5 and the status flag bit FPC 1.5 corresponding to the quantum exception are unsupported and are zeros.

The mask bits, when one, in the FPC register cause an interruption to occur if an exception is recognized. If the mask bit for an exception is zero, the recognition of the exception causes the corresponding flag bit to be set to one. Thus, a flag bit indicates whether the corresponding exception has been recognized at least once since the program last set the flag bit to zero. Except for PFPO, the mask bits are ignored, and the flag bits remain unchanged, when exceptions are recognized for floating-point-support (FPS) and HFP instructions.

The IEEE flag bits in the FPC register are set to zero only by explicit program action, initial CPU reset, clear reset, or power-on reset.

Note: The quantum exception is not part of the IEEE Standard 754-2008 (see Reference [20.] on page xxx). However, since this data exception with its mask and status flag in the FPC is handled very much like the five IEEE exceptions, this architecture lists the quantum exception among the IEEE exceptions.

FPC DXC Byte

Byte 2 of the FPC register contains the data-exception code (DXC), which is an eight-bit code indicating the specific cause of a data exception. When the AFP-register-control bit, bit 45 of control register 0, is one and a program interruption causes the DXC to be placed at real location 147, the DXC is also placed in the DXC field of the FPC register. The DXC field in the FPC register remains unchanged when the AFP-register-control bit is zero or when any other program exception is reported. The DXC is described in “Data-Exception Code (DXC)” on page 6-17.

The DXC is a code, meaning it should be treated as an integer rather than as individual bits. However, when bits 6 and 7 are zero, bits 0-5 are bit significant; bits 0-4 (i, z, o, u, and x) are trap flags and correspond to the same bits in bytes 0 and 1 of the FPC register (IEEE masks and IEEE flags), and bit 5 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude. When the floating-point extension facility is installed, DXC bit 5 (q) is also the quantum-exception trap flag. The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit.

Operations on the FPC Register

The following unprivileged instructions allow problem-state programs to operate on the FPC register:

EXTRACT FPC (DXC 2)
LOAD FPC (DXC 2)

LOAD FPC AND SIGNAL (DXC 3)
SET BFP ROUNDING MODE (DXC 2)
SET DFP ROUNDING MODE (DXC 3)
SET FPC (DXC 2)
SET FPC AND SIGNAL (DXC 3)
STORE FPC (DXC 2)

These instructions are subject to the AFP-register-control bit, bit 45 of control register 0. An attempt to execute any of the above instructions when the AFP-register-control bit is zero results in a data exception. The term (DXC 2) or (DXC 3) after the name indicates the type of exception: that is, BFP-instruction data exception, (DXC 2), or DFP-instruction data exception, (DXC 3), respectively.

Programming Note: The use of DXC 2 and DXC 3 for these floating-point-support (FPS) instructions is rather arbitrary, but assuming a valid operating system, these exceptions are never reported to the user, as the operating system will set bit 45 of control register 0 to one and re-issue the instruction.

AFP-Register-Control Bit

Bit 45 of control register 0 is the AFP-register-control bit. The AFP registers, the BFP instructions, the DFP instructions, and PFPO can be used successfully only when the AFP-register-control bit is one. Attempting to use one of the 12 additional floating-point registers or executing PFPO when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1). Attempting to execute any BFP instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception (DXC 2). Attempting to execute any DFP instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception (DXC 3).

DXC 2 and 3 are mutually exclusive and are of higher priority than any other DXC. Thus, for example, DXC 2 (BFP instruction) takes precedence over any IEEE exception; and DXC 3 (DFP instruction) takes precedence over any IEEE exception. As another example, if the conditions for both DXC 3 (DFP instruction) and DXC 1 (AFP register) exist, DXC 3 is reported.

If the conditions for both a data exception and a specification exception exist, it is unpredictable which exception is reported.

The initial value of the AFP-register-control bit is zero.

IEEE Computational Operations

Notes:

1. The following section primarily discusses the BFP and DFP formats, however the topics on rounding also discuss the HFP format, as indicated in the text.

2. The description of binary-floating-point operations in this document is based on the original *IEEE Standard for Binary Floating-Point Arithmetic* (IEEE Std. 754-1985). The current *IEEE Standard for Floating-Point Arithmetic* (see Reference [20.] on page xxx), which encompasses both binary and decimal floating point operations, made various terminology changes from the original standard, as follows:

   - The term *subnormal* replaces the term *denormalized*.

   - The term *exception* functionally replaces the former term *trap*. The term *default handling* (or *default non-stop execution handling*) correspond to the former *nontrap* action. and the term *alternate exception handling* encompasses the former *trap* action, as well as other actions.

   - The term *loss* (as in *loss of accuracy* or *denormalization loss*) is no longer used.

   Because of their pervasive use in the original description of binary floating point, the terms *denormalized*, *trap*, and *nontrap* still appear in this document. It is understood that they refer to the equivalent newer terms. A program-exception condition represents the only IEEE-defined alternate exception handling.

Instructions which operate on BFP or DFP source operands or produce BFP or DFP results and recognize IEEE exceptions are called IEEE computational operations, and the associated operands and results are sometimes referred to as IEEE operands and IEEE results, respectively.

Execution of IEEE computational operations normally follows a certain pattern. Source operands are first tested for special cases and then processed to form a result. The priority for testing of special cases is SNaN, QNaN, infinity, and then finite number.

If a source operand is an SNaN, an IEEE-invalid-operation exception is recognized; and, in the non-trap case, the result is set to the corresponding QNaN.

In the absence of a source SNaN, if a source operand is a QNaN the result is set to that QNaN.

Handling of the case when more than one source operand is a NaN is covered in the individual instruction descriptions.

In the absence of a NaN, if an operand is an infinity, special “infinity arithmetic” rules are followed to produce the result.

Programming Note: PERFORM FLOATING-POINT OPERATION is an IEEE computational operation.

Intermediate Values

In the normal case (when all source operands are finite numbers), first, a *precise intermediate value* is produced, then a *rounded intermediate value*. In the absence of trapped overflow and trapped underflow, the rounded intermediate value is used as the *delivered value*. For trapped overflow and trapped underflow, the rounded intermediate value is divided by a *scale factor* to produce a *scaled value*, which is used as the delivered value. Finally, the delivered value is placed in the target location. For DFP, since the cohort for the delivered value may have multiple members, one member from the cohort must be selected. Selection is performed by choosing the member having a quantum closest to the *preferred quantum* (or for trapped overflow and trapped underflow, a *scaled preferred quantum*.

Precise Intermediate Value

Every IEEE computational operation producing a numeric result computes a value called the *precise intermediate value.* This is the value that would have been computed were both the precision and exponent range unbounded.

Precision-Rounded Value

Except when otherwise specified, the precise intermediate value is rounded to the precision of the target format, but with unbounded exponent range. This process is called *target-precision-constrained rounding*, and the value selected by this type of rounding is called the *precision-rounded value*.

Denormalized Value

For IEEE targets, when the IEEE-underflow trap is disabled and the tininess condition exists, the precise intermediate value is rounded to fit in the destination format (that is, with both precision and exponent range of the target format). This process is called *denormalization rounding* and the value selected by this type of rounding is called the *denormalized value*.

Functionally-Rounded Value

The instructions CONVERT TO FIXED, LOAD FP INTEGER, QUANTIZE, and REROUND, as an integral part of the function, take a source operand and modify it to fit in a subset of the destination format. This process is called *functionally-constrained rounding* and the value selected by this type of rounding is called the *functionally-rounded value*.

Rounded Intermediate Value

In any particular instance, only one of the three rounding processes is performed and the value selected (precision-rounded value, denormalized value, or functionally-rounded value) is generically referred to as the *rounded intermediate value*.

Scaled Value

For both overflow and underflow when the associated trap is enabled, the precision-rounded value is scaled to bring it into the representable exponent range of the target. This is called the *scaled value* and is derived as explained in the next section.

Scale Factor (Ψ)

IEEE-overflow trap action and IEEE-underflow trap action produce a *scaled value* using a *scale factor*. The scaled value (z) is computed from the precision-rounded value (g) using the scale factor (Ψ) as follows:

$z = g \div \Psi$

Unsigned Scaling Exponent (α)

For BFP and DFP instructions, the scale factor (Ψ) is computed using the unsigned scaling exponent (α) and different formulas are used for overflow and underflow.

For overflow:
  $\Psi = b^{+\alpha}$
For underflow:
  $\Psi = b^{-\alpha}$

where b is the radix of the target (2 for BFP and 10 for DFP). The unsigned scaling exponent (α) depends on the type of operation and operand format.

For all BFP operations except LOAD ROUNDED, α depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For BFP LOAD ROUNDED, α depends on the source format, and is 512 for long and 8192 for extended.

For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long and 9216 for extended. For DFP LOAD ROUNDED, α depends on the source format, and is 192 for long and 3072 for extended.

Signed Scaling Exponent (Ω)

For PFPO convert floating-point radix, the scale factor (Ψ) is computed using the signed scaling exponent (Ω) and the formula for the scale factor (Ψ) is the same for overflow and underflow:

$\Psi = b^{\Omega}$

Where b is the radix (2, 10, and 16) for BFP, DFP and HFP, respectively. Thus, for overflow, the signed scaling exponent (Ω) is a positive value, and for underflow it is a negative value.

IEEE Rounding

Rounding takes an input value, and, using the effective rounding method, selects a value from a permissible set. The input value, considered to be infinitely-precise, may be an operand of an instruction or the numeric output from an arithmetic operation. The effective rounding method may be the current rounding method specified in the BFP-rounding-mode or DFP-rounding-mode field of the FPC register; or, for some instructions, an explicit rounding method is specified by a modifier field. For the PFPO-convert-floating-point-radix operation, rounding is specified by a field in an implicit register.

For target-precision-constrained rounding and denormalization rounding, the input is the precise intermediate value. For functionally-constrained rounding, the input is a source operand.

Permissible Set

Rounding selects a value from the permissible set. A permissible set is a set of values, and not representations; thus, for DFP, the selection of a member from the cohort is considered to be performed after rounding. A permissible set differs from the values representable in a particular format in the following ways:

1. A permissible set does not include infinity. Infinity is handled as a special case.

2. For target-precision-constrained rounding, the permissible set is considered to have an unbounded exponent range.

3. For denormalization rounding, the permissible set is limited to the values representable in a particular format.

4. For LOAD FP INTEGER, the permissible set contains only integral values.

5. For QUANTIZE, the permissible set is similar to LOAD FP INTEGER, containing only those values which are integral multiples of the requested quantum.

6. For REROUND, the permissible set contains only those values which can be represented within the requested precision.

Selection of Candidates

If a member of the permissible set is equal in value to the input value, then that member is selected; otherwise, two adjacent candidates with the same sign as the input value are chosen from the permissible set. One candidate, called TZ (toward zero), is the member of the permissible set nearest to and smaller in magnitude than the input value; the other candidate, called AZ (away from zero), is the member of the permissible set nearest to and larger in magnitude than the input value. Which of the two candidates is selected depends on the rounding method.

Ties

Three rounding methods depend on a condition called a “tie.” This condition exists when the two candidates are equidistant from the input value.

Voting Digit and Common-Rounding-Point View

Two rounding methods depend on the value of the voting digit of each candidate. (Each “digit” is an integral value from zero to one less than the radix. Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The voting digit is the units digit of the significand when considered in the common-rounding-point view.

Without changing the value of a floating-point number, the significand may be viewed with the implied radix point in different positions, provided a corresponding adjustment is made to the exponent. In the common-rounding-point view, an implied radix point (called the common rounding point) and an associated exponent are selected for the input value and the two candidates, TZ and AZ. The common-rounding point is selected to satisfy the following requirements:

1. The input value and the two candidates all have the same exponent.
2. The significand of TZ is equal to the significand of the input value truncated at the rounding point.
3. The significand of AZ is one greater in magnitude than the significand of TZ.

Rounding Methods

Figure 9-8 and Figure 9-7 on page 9-10 show the implicit rounding methods available for BFP and DFP operations respectively. The section “Explicit Rounding Methods” on page 9-17 describes rounding methods that may be explicitly specified in an instruction, overriding the implicit rounding method. The rounding methods are as follows:

Round to nearest with ties to even: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one whose voting digit has an even value.

Round toward 0: The candidate that is smaller in magnitude is selected.

Round toward +∞: The candidate that is algebraically greater is selected.

Round toward -∞: The candidate that is algebraically less is selected.

Round to nearest with ties away from 0: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is larger in magnitude.

Round to nearest with ties toward 0: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is smaller in magnitude.

Round away from 0: The candidate that is greater in magnitude is selected.

Round to prepare for shorter precision: For a BFP or HFP permissible set, the candidate selected is the one whose voting digit has an odd value. For a DFP permissible set, the candidate that is smaller in magnitude is selected, unless its voting digit has a value of either 0 or 5; in that case, the candidate that is greater in magnitude is selected.

Programming Notes:

1. The two candidates are defined as: “nearest to and smaller” and “nearest to and larger”. Note that the simpler definition, “the two closest values,” is incorrect, as it is possible that the two closest values to the input value can be on the same side (toward zero). To illustrate this, Figure 9-9 on page 9-15 gives an example of rounding the integer value 10,000,003 to DFP short. Several members in the permissible set near this value are shown in three views: left-units view, right-units view, and integer view. The fourth column shows the distance of each member from the input value. In this example, the four closest members are all smaller in magnitude than the input value. Although the example is shown using DFP, corresponding examples can be shown for both BFP and HFP. In the extreme case, the number of members in the permissible set which are closer than candidate AZ, is 2, 10, and 16, for BFP, DFP, and HFP, respectively.
2. Except for rounding methods using the voting digit, rounding can normally be considered to be performed using values independent of the representation and the view. Figure 9-10 on page 9-16 is an example, using the instruction LOAD FP INTEGER, to illustrate the concepts of different representations, views, rounding point, common-rounding-point view, and voting digit. In the example, the input value (source operand) is 29.5 and the two candidates are 29 and 30. The figure shows all three of these values using the left-units, right-units, and common-rounding-point views in both decimal and binary representations. Note that as shown in the left-units and right-units view columns, the rightmost digit is

odd for both TZ and AZ. (But as represented in all BFP formats, these values would have an even rightmost digit; and as represented in DFP formats, these values could have an even or odd rightmost digit, depending on the quantum.) The voting digit can be identified in the common-rounding-point view as the digit to the immediate left of the rounding point. In both the decimal and binary representations, candidate TZ has an odd voting digit and candidate AZ has an even voting digit.

LOAD FP INTEGER produces consistent results between decimal and binary for five of the six rounding methods currently supported by the BFP instruction; for the round-to-prepare-for-shorter-precision rounding method, this is not always the case. Figure 9-11 on page 9-16 shows results of LOAD FP INTEGER for several input values for all eight rounding methods. Only in the round-to-prepare-for-shorter-precision method are the results different for decimal and binary.

3. An example of LOAD ROUNDED (long to short DFP) is shown in Figure 9-12 on page 9-16 In this example, the integer 99,999,995 is rounded from DFP long to DFP short. The cohort for candidate TZ in this case, has only one member and is odd. The cohort of candidate AZ has seven members, one of which is odd and the other six are even. The common-rounding-point view makes it clear that in this case, candidate AZ should be considered to be even.

4. The rightmost digit and the voting digit of a candidate are not necessarily the same digit. Figure 9-13 on page 9-16 and Figure 9-14 on page 9-17 give two examples using the instruction REROUND (long DFP). In both examples, the requested significance is one (Result Digits=1). The input value is 95 in the first example and 150 in the second example. Note that candidate AZ in the first example is the same value as candidate TZ in the second example. In the first example, this member is considered to be even, and in the second example it is considered to be odd.

Value in Permissible Set			Distance from 10000003	Notes

Explicit Rounding Methods

The floating-point-support instruction CONVERT HFP TO BFP includes an M_3 modifier field which can specify any of six rounding methods. One HFP instruction (CONVERT TO FIXED); three BFP instructions (CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER); and five DFP instructions (CONVERT TO FIXED, LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND) also include either an M_3 modifier field or a similar M_4 modifier field. When the floating-point extension facility is installed, four more BFP instructions (CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, and LOAD ROUNDED) and seven more DFP instructions (ADD, CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, DIVIDE, MULTIPLY, and SUBTRACT) also include an M_3 or M_4 modifier field.

The handling of an M_3 or M_4 value of zero depends on the type of instruction. For BFP instructions, an M_3 or M_4 value of zero causes rounding to be performed according to the current BFP rounding mode specified in the FPC register. For DFP instructions, an M_3 or M_4 value of zero causes rounding to be performed according to the current DFP rounding mode specified in the FPC register. The floating-point-support instruction CONVERT HFP TO BFP and the HFP instruction CONVERT TO FIXED treat an M_3 value of zero the same as five; that is, round toward zero.

For PERFORM FLOATING POINT OPERATION (PFPO), any of the rounding methods described in this section may be explicitly specified, or the program may specify the current BFP or DFP rounding method (in the floating-point-control register). The program-specified rounding method is used by PFPO regardless of whether the target-operand format is BFP, DFP or HFP.

Summary of Rounding Action

Figure 9-15 on page 9-17 summarizes the rounding action for floating-point-support (FPS), BFP, DFP, and HFP instructions.

Instruction	Rounding Action For			
	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.
ADD	—	—	CBRM	MDD
ADD NORMALIZED	—	GD	—	—
ADD UNNORMALIZED	—	GD	—	—
CONVERT BFP TO HFP	E	—	—	—
CONVERT FROM FIXED	—	RTZ	MBB	MDD
CONVERT FROM LOGICAL	—	—	MA	MD
CONVERT HFP TO BFP	MC	—	—	—
CONVERT TO FIXED	—	M	MB	MD
CONVERT TO LOGICAL	—	—	MA	MD

Explanation:

CBRM	Rounded according to current BFP rounding mode.
E	Result is exact, no rounding is required.
GD	Round using a guard digit; see the instruction definition. This is almost, but not quite, round toward 0.
M	Rounding is specified by a modifier field in the instruction. Five rounding methods are supported.

Figure 9-15. Comparison of Rounding Action (Part 1 of 2)

	Rounding Action For			
Instruction	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.

MA Rounding is specified by a modifier field in the instruction. Six rounding methods are supported; current BFP rounding mode can also be specified.

MB Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding modes are supported; current BFP rounding mode can also be specified.

MBB When the floating-point extension facility is not installed, rounding is specified by the current BFP rounding mode; four rounding modes are supported. When the floating-point extension facility is installed, rounding is specified by a modifier field in the instruction; six rounding modes are supported; current BFP rounding mode can also be specified.

MBD Rounding is specified by a field in general register 0. Eight rounding methods are supported; current BFP rounding mode and current DFP rounding mode can also be specified.

MC Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding modes are supported; current BFP rounding mode cannot be specified.

MD Rounding is specified by a modifier field in the instruction. Eight rounding methods are supported; current DFP rounding mode can also be specified.

MDD When the floating-point extension facility is not installed, rounding is specified by the current DFP rounding mode. When the floating-point extension facility is installed, rounding is specified by a modifier field in the instruction; eight rounding modes are supported; current DFP rounding mode can also be specified.

RNTA Round to nearest with ties away from 0.

RTZ Round toward 0.

IEEE Exceptions

This section defines handling of IEEE exceptions for most IEEE computational operations. For some instructions the action may differ from the general rules; including, for example, a special controls to suppress recognition of certain IEEE exceptions. These differences are described in the individual instruction descriptions.

The action taken for each IEEE exception is controlled by a mask bit in the FPC register. When an IEEE exception is recognized, one of two actions is taken:

- If the corresponding mask bit in the FPC register is zero, a default action, called IEEE nontrap action, is taken, as specified for each condition, and the corresponding flag bit in the FPC register is set to one. Program execution then continues normally.
- If the corresponding mask bit in the FPC register is one, an action, called IEEE trap action, is taken for that exception, a program interruption for a data exception occurs, and the operation is suppressed or completed, depending on the exception, and the data-exception code (DXC) assigned for that exception is provided. For PFPO, a control bit in GR0 can select alternate exception handling, where overflow or underflow can be reflected by completion with a distinguished condition code, avoiding the interruption.

Concurrent IEEE Exceptions

IEEE-overflow or IEEE-underflow exception, IEEE-inexact exception, and quantum exception can coincide concurrently.

When the action for IEEE overflow (or underflow) is a nontrap action, the IEEE-overflow (or IEEE-underflow) flag bit in the FPC register is set to one and then the action for IEEE inexact (which could be a nontrap or trap action) occurs.

When the action for IEEE overflow (or underflow) is a trap action, the inexact exception is not recognized and not reported directly; instead, the DXC is set to indicate whether the result is exact, inexact and truncated, or inexact and incremented.

When the action for all concurrent IEEE exceptions, except the quantum exception, is a nontrap action, the flag bits in the FPC register corresponding to these nontrap concurrent exceptions are set to one, and then the action for the quantum exception (which could be a nontrap or trap action) occurs.

When the action for any concurrent IEEE exception, except the quantum exception, is a trap action, the quantum exception is not recognized, not reported directly, and not indicated in the DXC.

IEEE Invalid Operation

An IEEE-invalid-operation exception is recognized when, in the execution of an IEEE computational operation, any of the following occurs:

1. An SNaN is encountered in an IEEE computational operation.
2. A QNaN is encountered in an unordered-signaling comparison (COMPARE AND SIGNAL with a QNaN operand).
3. An IEEE difference is undefined (addition of infinities of opposite sign, or subtraction of infinities of like sign).
4. An IEEE product is undefined (zero times infinity).
5. An IEEE quotient is undefined (DIVIDE instruction with both operands zero or both operands infinity).
6. A BFP remainder is undefined (DIVIDE TO INTEGER with a dividend of infinity or a divisor of zero).
7. A BFP square root is undefined (negative nonzero operand).
8. Any other IEEE computational operation whose result is either undefined or not representable in the target format.

Even though an invalid-operation condition exists, the exception is not recognized if recognition of the exception is suppressed by means of an IEEE-invalid-operation-exception control (XiC).

IEEE-Invalid-Operation Nontrap Action: IEEE-invalid-operation nontrap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed and the IEEE-invalid-operation flag bit in the FPC register is set to one. The result of the operation depends on the type of operation and the operands.

If the instruction performs a comparison, the comparison result is *unordered*.

If the instruction is one that produces an IEEE result and none of the operands is a NaN, the result is the default QNaN.

If the instruction is one that produces an IEEE result and one of the operands is a NaN, that operand becomes the result unchanged, except that an SNaN is first converted to the corresponding QNaN and, for DFP, NaNs are canonicalized.

IEEE-Invalid-Operation Trap Action: IEEE-invalid-operation trap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

IEEE Division-By-Zero

An IEEE-division-by-zero exception is recognized when in IEEE division the divisor is zero and the dividend is a nonzero finite number.

IEEE-Division-By-Zero Nontrap Action: IEEE-division-by-zero nontrap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is zero. The operation is completed and the IEEE-division-by-zero flag bit in the FPC register is set to one. The result is set to an infinity with a sign that is the exclusive or of the dividend and divisor signs.

IEEE-Division-By-Zero Trap Action: IEEE-division-by-zero trap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 40 hex.

IEEE Overflow

An IEEE-overflow exception is recognized for an IEEE target when the precision-rounded value of an IEEE computational operation is greater in magnitude than the largest finite number (Nmax) representable in the target format.

IEEE-Overflow Nontrap Action: IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. The result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward +∞, the result is +∞. if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.
4. For round toward -∞, the result is the largest positive finite number if the sign is plus or -∞. if the sign is minus.

IEEE-Overflow Trap Action: IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor, and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The delivered value is equal to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

IEEE Underflow

An IEEE-underflow exception is recognized for an IEEE target when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the result value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The result value is inexact if it is not equal to the precise intermediate value.

IEEE-Underflow Nontrap Action: IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one. The result is set to the denormalized value or Nmin. For DFP targets, the cohort member with the smallest quantum is selected.

IEEE-Underflow Trap Action: IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 10, 18, or 1C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The result is set to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

IEEE Inexact

An IEEE-inexact exception is recognized when, for an IEEE computational operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs. When the inexact condition exists, the delivered value and the result are said to be inexact.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if recognition of the exception is suppressed by means of an IEEE-inexact-exception control (XxC) or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

IEEE-Inexact Nontrap Action: IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, except for QUANTIZE and REROUND, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and another IEEE nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both exceptions are set to one.

IEEE-Inexact Trap Action: IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

Quantum Exception

A quantum exception is recognized when floating-point extension facility is installed and when, for an IEEE computational operation, a quantum-exception condition exists, recognition of the exception is not suppressed, and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For computational operations except DIVIDE, LOAD FP INTEGER, PERFORM FLOATING-POINT OPERATION, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum is different from the preferred quantum.

For DIVIDE, a quantum-exception condition exists (1) when the delivered DFP result is inexact, or (2) when the dividend is a finite number and the divisor is an infinity, or (3) when the delivered DFP result is exact and is a finite number, the delivered quantum is the maximum quantum and is not the preferred quantum, and the rightmost significand digit is zero, or (4) when the delivered DFP result is exact and is a finite number, the delivered quantum is the minimum quantum and is greater than the preferred quantum. Note that the maximum quantum is the value of 1 x 10^{Qmax} and the minimum quantum is the value of 1 x 10^{Qmin}, where Qmax and Qmin are the maximum and minimum right-units-view exponents, respectively.

For LOAD FP INTEGER, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is a finite number, but the delivered quantum is different from the quantum of the source operand (the second operand for LOAD FP INTEGER, and the third operand for QUANTIZE and REROUND).

For PERFORM FLOATING-POINT OPERATION, a quantum-exception condition exists when the delivered quantum exceeds the preferred quantum of 1.

When floating-point extension facility is not installed, no quantum exception is recognized by executing any instruction.

Even though a quantum-exception condition exists, the exception is not recognized if recognition of the exception is suppressed or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum-exception condition is not reported.

Quantum-Exception Nontrap Action: Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the quantum-exception flag bit in the FPC register is set to one. The delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When a quantum-exception nontrap action and other concurrent IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all exceptions are set to one.

Quantum-Exception Trap Action: Quantum-exception trap action occurs when the quantum-exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 04 hex.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value, and the delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the other IEEE nontrap exceptions are set to one, and the quantum-exception trap action takes place.

Programming Notes:

1. IEEE traps are reported by means of a program interruption for a data exception with a data-exception code.[1] The use of data exception provides the application program with a convenient interface since this exception is one of the original 15 exceptions in the System/360 architecture and is supported by most control programs that support the z/Architecture.

2. ANSI/IEEE Standard 754-2008 includes recommendations for the trap handler (see Reference [20.] on page xxx). When a system traps, the trap handler should be able to determine:

   a. Which exception(s) were recognized on this operation.

   b. The kind of operation that was being performed.

   c. The destination's format.

   d. For overflow, underflow, and inexact exceptions, the correctly rounded result, including information that might not fit in the destination's format.

   e. For invalid-operation and divide-by-zero exceptions, the operand values.

   Items a and d are supplied as part of the interruption action. Items b, c, and e can be obtained starting with the instruction address in the old PSW and from this finding the instruction (which indicates the operation and format) and then the operands.

3. The description of underflow is one of the most difficult parts of the standard to understand. This is because:

   a. For tininess, ANSI/IEEE Standard 754-2008 provides two options for detection for BFP formats: “after rounding” or “before rounding”. For DFP formats, tininess detection occurs before rounding.

   b. Implementation of the trap is optional.

   c. The conditions to signal underflow are different depending on whether or not the trap is taken.

   Each of the above items is discussed below.

   a. Detection of tininess after or before rounding differs only for the case when “rounding” would increase the magnitude of the result to exactly ±Nmin. It must be noted, however, that the action which ANSI/IEEE Standard 754-2008 here calls “rounding” is not the rounding to produce the delivered result but

[1] PFPO provides an option for trap action without the program interruption.

rounding to compute an intermediate value having the precision of the result but "as though the exponent range were unbounded". In fact, it is possible that the delivered result may not be tiny even though the intermediate value "after rounding" is tiny.

The option selected in the z/Architecture (and the Power architecture) is to detect tininess before rounding.

b. Although ANSI/IEEE Standard 754-2008 does not require traps to be implemented for underflow or the other IEEE exceptions, it does state that "with each exception should be associated a trap under user control". Since it also defines "should" as "that which is strongly recommended as being in keeping with the intent of the standard", the z/Architecture provides traps by means of program interruptions.

c. When the underflow trap is enabled, underflow is to be signaled when tininess is detected regardless of loss of accuracy. When the underflow trap is not enabled, the underflow flag bit is to be set only when both tininess and loss of accuracy have been detected. Add and subtract can result in tiny or inexact results, but not both. Thus, when underflow is disabled, add and subtract never set the underflow flag bit.

Suppression of Certain IEEE Exceptions

For IEEE-invalid-operation exception, IEEE-inexact exception, and quantum exception, a special control may be provided for an IEEE computational operation to control whether recognition of the exception is suppressed. These controls are called IEEE-invalid-operation-exception control (XiC), IEEE-inexact-exception control (XxC), and quantum-exception control (XqC), respectively.

When a special control is zero, recognition of the designated exception is not suppressed, and normal handling of the exception is performed. And, when the exception is recognized, it further depends on the mask bit in the FPC register to determine if a trap action occurs.

When a special control is one, recognition of the designated exception is suppressed, and no trap or nontrap action for the exception occurs. This suppression affects only recognition of the exception for setting the status flag or for causing the trap action. For example, the IEEE-inexact-exception control (XxC) has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition. Also, it has no effect on recognition of a quantum exception, which may depend on the actual inexact condition regardless of the setting of IEEE-inexact-exception control.

Multiple exception controls may be provided to a single IEEE computational operation. In this case, the effect and setting of each control is independent of other controls. The specific exception controls that are provided are described in the individual instruction descriptions.

IEEE Same-Radix Format Conversion

The instructions LOAD LENGTHENED and LOAD ROUNDED perform conversions of data between the short, long, and extended formats, where the source and target operands are in the same radix. (For mixed-radix conversions, see PFPO.) For BFP and DFP formats, same-radix conversion involves adjustments to both the significand and the biased exponent. Conversion to a narrower format requires rounding of the significand and an IEEE-inexact exception may result.

When converting to a narrower format, adjustment of the biased exponent causes IEEE underflow if the resultant left-units-view (LUV) exponent would be less than the minimum LUV exponent (Emin), or IEEE overflow if the resultant LUV exponent would be greater than the maximum LUV exponent (Emax) for the new format.

Programming Notes:

1. When a NaN is converted to a narrower format, for BFP the appropriate number of payload bits on the right (or for DFP, the appropriate number of payload digits on the left) are simply dropped with no indication. This is unlike the conversion of nonzero numbers, where the loss of nonzero sig-

nificand digits causes an IEEE-inexact exception. Thus, programs which encode NaN payloads for specific purposes must ensure that the distinguishing bits (or digits) are placed in the left part of the payload for BFP and in the right part of the payload for DFP.

2. For BFP, converting a NaN to a narrower format cannot turn the NaN into an infinity because an SNaN either causes an interruption or turns into a QNaN, and all QNaNs have a leftmost fraction bit of one.

IEEE Comparison

Comparisons are always exact and cannot cause IEEE-overflow or IEEE-underflow exceptions.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, +∞. equals +∞, and -∞. equals -∞.

A NaN compares as *unordered* with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Two sets of instructions are provided: COMPARE and COMPARE AND SIGNAL. In the absence of QNaNs, these instructions work the same. These instructions work differently only when both of the following are true:

- Neither operand of the instruction is an SNaN
- At least one operand of the instruction is a QNaN

In this case, COMPARE simply sets condition code 3, but COMPARE AND SIGNAL recognizes the IEEE-invalid-operation exception. If any operand is an SNaN, both instructions recognize the IEEE-invalid-operation exception.

The action when the IEEE-invalid-operation exception is recognized depends on the IEEE-invalid-operation mask bit in the FPC register. If the mask bit is zero, then the instruction execution is completed by setting condition code 3, and the IEEE-invalid-operation flag in the FPC register is set to one. If the mask bit is one, then the exception is reported as a program interruption for a data exception with DXC 80 hex (IEEE invalid operation).

Programming Note: A compiler can select either COMPARE or COMPARE AND SIGNAL for a comparison, depending on whether it is desired that a QNaN to be recognized as an exception.

Condition Codes for IEEE Instructions

For those operations which set the condition code to indicate the value of an IEEE result, condition codes 0, 1, and 2 are set to indicate that the result is a zero of either sign, less than zero, or greater than zero, respectively. The condition-code setting depends only on an inspection of the rounded result. For comparison operations, condition codes 0, 1, and 2 indicate equal, low, or high, respectively. These settings are the same as for the HFP instructions.

Condition code 3 can also be set. After an arithmetic operation, condition code 3 indicates a NaN result of either sign. After a comparison, it indicates that a NaN was involved in the comparison (the unordered condition). See Figure 9-16.

CC	Arithmetic	Comparison
0	±0	Equal
1	<0	Low
2	>0	High
3	±NaN	Unordered

Figure 9-16. Condition Codes

Instructions

The floating-point-support instructions and their mnemonics and operation codes are listed in Figure 9-17 on page 9-25. The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All floating-point-support instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the floating-point instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for floating-point instructions to represent operand-format length, as follows:

D	Long
E	Short
X	Extended

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using LOAD (short), for example, LER is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The following additional floating-point-support instruction is available when the decimal-floating-point facility is installed:
   - SET DFP ROUNDING MODE (SRNMT)
2. The following additional floating-point-support instructions are available when the floating-point-support-sign-handling facility is installed:
   - COPY SIGN (CPSDR)
   - LOAD COMPLEMENT (LCDFR)
   - LOAD NEGATIVE (LNDFR)
   - LOAD POSITIVE (LPDFR)
3. The following additional floating-point-support instructions are available when the FPR-GR-transfer facility is installed:
   - LOAD FPR FROM GR (LDGR)
   - LOAD GR FROM FPR (LGDR)
4. The following additional floating-point-support instructions are available when the IEEE-exception-simulation facility is installed:
   - LOAD FPC AND SIGNAL (LFAS)
   - SET FPC AND SIGNAL (SFASR)
5. The following additional floating-point-support instructions are available when the long-displacement facility is installed:
   - LOAD (LDY, LEY)
   - STORE (STDY, STEY)
6. The following additional floating-point-support instruction is available when the PFPO facility is installed:
   - PERFORM FLOATING POINT OPERATION (PFPO)
7. The following additional floating-point-support instruction and features are available when the floating-point extension facility is installed:
   - A new floating-point-support instruction, SET BFP ROUNDING MODE (SRNMB), is added.
   - A new exception, the quantum exception, is defined for some computational operations.
   - Bit 5 of the floating-point-control (FPC) register is assigned to the quantum-exception mask
   - Bit 13 of the FPC register is assigned to the quantum-exception flag.
   - Data-exception code (DXC) 04 (hex) is assigned to the quantum exception.
   - DXC 07 (hex) is assigned to the simulated quantum exception.
   - The BFP-rounding-mode field in the FPC register is changed to 3 bits to support one additional BFP rounding mode, round to prepare for shorter precision.
   - One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT HFP TO BFP.
   - For PFPO with a DFP result, bit 58 of general register 0 is assigned to be the DFP quantum-permission control.

Figure 9-17. Summary of Floating-Point-Support Instructions (Part 3 of 3)

CONVERT BFP TO HFP

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
THDER	'B358'	Short BFP operand, long HFP result
THDR	'B359'	Long BFP operand, long HFP result

The second operand (the source operand) is converted from the binary-floating-point (BFP) format to the hexadecimal-floating-point (HFP) format, and the normalized result is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

For numeric operands, the sign of the result is the sign of the source operand. If the source operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

When, for THDR, the characteristic of the result would be negative, the result is made all zeros but with the same sign as that of the source operand, and condition code 1 or 2 is set to indicate the sign of the source operand.

When, for THDR, the characteristic of the hexadecimal intermediate result is too large to fit into the target format, the result is set to all ones (that is, the largest-in-magnitude representable finite number) but with the same sign as that of the source operand, and condition code 3 is set.

See Figure 9-18 for a detailed description of the results of this instruction.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

Program Exceptions:

- Data with DXC 1, AFP register
- Transaction constraint

Programming Notes:

1. The BFP-to-HFP conversion instructions are summarized in Figure 9-19.
2. CONVERT BFP TO HFP (THDER) converts BFP operands in the short format to HFP operands in the long format, rather than converting short to short, to retain full precision. Using this long HFP

result subsequently as a short operand requires no extra conversion steps.

Source Operand (a)	Results
-∞ ≤ a < -Hmax	T(-Hmax), cc3
-Hmax ≤ a ≤ -Hmin	T(r), cc1
-Hmin < a < 0	T(-0)[1], cc1
-0	T(-0), cc0
+0	T(+0), cc0
0 < a < +Hmin	T(+0)[2], cc2
+Hmin ≤ a ≤ +Hmax	T(r), cc2
+Hmax < a ≤ +∞	T(+Hmax), cc3
NaN	T(+Hmax), cc3

Explanation:

[1] Condition code 1 is set to indicate the source was less than zero.

[2] Condition code 2 is set to indicate the source was greater than zero.

ccn Condition code is set to n.

r The value derived when the BFP source value a is converted to the HFP format. This result is always exact.

Hmax Largest (in magnitude) representable number in the target HFP format.

Hmin Smallest (in magnitude) representable normalized number in the target HFP format.

T(x) The value x is placed at the target operand location.

Figure 9-18. Results: CONVERT BFP TO HFP

		Source		Target			Overflow,
			Significant		Significant		Underflow
Instruction	Mnemonic	Format	Bits	Format	Bits	Result	Possible
CONVERT BFP TO HFP	THDER	BFP short	24	HFP long	53-56	Exact	No
	THDR	BFP long	53	HFP long	53-56	Exact	Yes
CONVERT HFP TO BFP	TBEDR	HFP long	53-56	BFP short	24	Rounded	Yes
	TBDR	HFP long	53-56	BFP long	53	Rounded	No

Figure 9-19. Summary of BFP-to/from-HFP Conversion Instructions

CONVERT HFP TO BFP

Mnemonic R_1,M_3,R_2 [RRF-e]

Op Code	M_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
TBEDR	'B350'	Long HFP operand, short BFP result
TBDR	'B351'	Long HFP operand, long BFP result

The second operand (the source operand) is converted from the hexadecimal-floating-point (HFP) format to the binary-floating-point (BFP) format, and the result rounded according to the rounding method specified by the M_3 field is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

The M_3 field contains a modifier specifying a rounding method, as follows:

M_3	**Effective Rounding Method**
0	Round toward 0
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

A modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

The sign of the result is the sign of the second operand. If the second operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

See Figure 9-20 on page 9-29 for a detailed description of the results of this instruction.

If the M_3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Overflow

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification
- Transaction constraint

Programming Notes:

1. The HFP-to-BFP conversion instructions are summarized in Figure 9-19 on page 9-28.

2. Conversion to short BFP data requires HFP operands in the long format; a short HFP operand should be extended to long by ensuring that the right half of the register is cleared. Thus, the entire register should be cleared before loading a short HFP operand into it for conversion to BFP. This avoids unrepeatable rounding errors in the BFP result due to data left over from previous use.

Precision Rounded Source Operand (g)	Results
g < -Nmax	See Part 2 of this figure.
-Nmax ≤ g ≤ -Nmin	T(r), cc1
-Nmin < g ≤ -Dmin	T(d*), cc1
-Dmin < g < 0	T(d)[1], cc1
-0	T(-0), cc0
+0	T(+0), cc0
0 < g < +Dmin	T(d)[2], cc2
+Dmin ≤ g < +Nmin	T(d*), cc2
+Nmin ≤ g ≤ +Nmax	T(r), cc2
+Nmax < g	See Part 2 of this figure.

Figure 9-20. (Part 1 of 2) Results: CONVERT HFP to BFP

Precision Rounded Source Operand (g)	Results for Rounding Method Specified in M_3					
	Round to Nearest with Ties away from 0	Round to Nearest with Ties to Even	Round to Prepare for Shorter Precision	Round toward 0	Round toward +∞	Round toward -∞
g < -Nmax	T(-∞), cc3	T(-∞), cc3	T(-Nmax), cc3	T(-Nmax), cc3	T(-Nmax), cc3	T(-∞), cc3
+Nmax < g	T(+∞), cc3	T(+∞), cc3	T(+Nmax), cc3	T(+Nmax), cc3	T(+∞), cc3	T(+Nmax), cc3

Figure 9-20. (Part 2 of 2) Results: CONVERT HFP to BFP

Precision Rounded Source Operand (g)	Results for Rounding Method Specified in M_3					
	Round to Nearest with Ties away from 0	Round to Nearest with Ties to Even	Round to Prepare for Shorter Precision	Round toward 0	Round toward $+\infty$	Round toward $-\infty$

Explanation:

1	Condition code 1 is set for this case, even when the rounded result is zero.
2	Condition code 2 is set for this case, even when the rounded result is zero.
*	The rounded value, in the extreme case, may be Nmin.
ccn	Condition code is set to n.
d	The denormalized value derived when the HFP source value a is rounded to the format of the target using the rounding method specified in the M_3 field.
g	The precision-rounded value. The value derived when the HFP source value is rounded to the precision of the target, but assuming an unbounded exponent range.
r	The value derived when the HFP source value is rounded to the format of the target using the rounding method specified in the M_3 field.
Dmin	Smallest (in magnitude) representable subnormal number in the target BFP format.
Nmax	Largest (in magnitude) representable finite number in the target BFP format.
Nmin	Smallest (in magnitude) representable normal number in the target BFP format.
T(x)	The value x is placed at the target operand location.

Figure 9-20. (Part 2 of 2) Results: CONVERT HFP to BFP

COPY SIGN

CPSDR R_1,R_3,R_2 [RRF-b]

'B372'	R_3	////	R_1	R_2
0	16	20	24	28 31

The second operand is placed at the first-operand location with the sign bit set to the sign of the third operand. The first, second, and third operands are each in a 64-bit floating-point register. The sign bit of the second operand and bits 1-63 of the third operand are ignored.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. COPY SIGN is radix independent and can be used to operate on HFP, BFP, or DFP operands or even to copy the sign between operands having different radixes.
2. Since the sign is in the same bit position (the leftmost bit) in all widths for all radixes, the third operand can be a short, long, or extended format.
3. COPY SIGN can be used in conjunction with LOAD (LDR) to copy the sign of an operand in the extended format.

EXTRACT FPC

EFPC R_1 [RRE]

'B38C'	////////	R_1	////
0	16	24	28 31

The contents of the FPC (floating-point-control) register are placed in bit positions 32-63 of the general register designated by R_1. Bit positions 0-31 of the general register remain unchanged.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Transaction constraint

LOAD

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	Op Code	Operands
LER	'38'	Short
LDR	'28'	Long

Mnemonic2 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic2	Op Code	Operands
LXR	'B365'	Extended

Mnemonic3 R_1,D_2(X_2,B_2) [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic3	Op Code	Operands
LE	'78'	Short
LD	'68'	Long

Mnemonic4 R_1,D_2(X_2,B_2) [RXY-a]

Op Code	R_1	X_2	B_2	DL_2	DH_2	Op Code
0	8	12	16	20	32	40 47

Mnemonic4	Op Code	Operands
LEY	'ED64'	Short
LDY	'ED65'	Long

The second operand is placed unchanged at the first-operand location.

The operation is performed without inspecting the contents of the second operand; no arithmetic exceptions are recognized.

For LXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

The displacement for LE and LD is treated as a 12-bit unsigned binary integer. The displacement for LEY and LDY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LE, LD, LEY, and LDY)
- Data with DXC 1, AFP register
- Operation (LEY and LDY, if the long-displacement facility is not installed)
- Specification (LXR only)
- Transaction constraint

Programming Note: Data can be loaded into the vector registers from the little endian format using the extended mnemonics LERV and LDRV for the VLLEBRZ instruction (see page 21-8).

LOAD COMPLEMENT

LCDFR R_1,R_2 [RRE]

'B373'	////////	R_1	R_2
0	16	24	28 31

The second operand is placed at the first-operand location with the sign bit inverted. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. LOAD COMPLEMENT (LCDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.

2. LOAD COMPLEMENT (LCDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD FPC

LFPC D_2(B_2) [S]

'B29D'	B_2	D_2
0	16	20 31

The four-byte second operand in storage is loaded into the FPC (floating-point-control) register.

Bits corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 2, BFP instruction
- Specification
- Transaction constraint

Programming Notes:

1. When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.
2. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.
3. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

LOAD FPC AND SIGNAL

LFAS $D_2(B_2)$ [S]

'B2BD'	B_2	D_2
0	16	20 31

First, flags of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is the second operand in storage.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 3, DFP instruction

- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint

Enabled[1] Signaling Flags Bit 0 1 2 3 4 5	DXC (Binary)
1 – – – – –	1000 0011
0 1 – – – –	0100 0011
0 0 1 – – –	0010 w011
0 0 0 1 – –	0001 w011
0 0 0 0 1 –	0000 1011
0 0 0 0 0 1	0000 0111[2]

Explanation:

[1] The logical AND of the corresponding bit in the source masks and the signaling flags.

[2] Is only supported when the floating-point extension facility is installed.

– Don't care.

w Bit 4 of the signaling flags.

Figure 9-21. DXC for Simulated-IEEE-Exception Trap Action

	Resulting FPC Register Contents				
Trap	Masks	Flags	DXC	DRM	BRM
No	S	OR	S	S	S
Yes	S	OR	Xg	S	S

Explanation:

DRM DFP rounding mode

DXC Data-exception code

OR Set to the logical OR of signaling flags and source flags.

S Set to the contents of the corresponding field in the source operand.

Trap Simulated-IEEE-exception trap action. This action occurs when the logical AND of the signaling flags and source masks is nonzero.

Xg DXC for simulated IEEE exception. See Figure 9-21

Figure 9-22. Result: LFAS and SFASR

Programming Notes:

1. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.

2. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

3. The IEEE-exception-simulation instructions (LOAD FPC AND SIGNAL and SET FPC AND SIGNAL) are provided to facilitate program simulation of IEEE operations not provided directly in the machine. These instructions permit the simulation routine to restore the caller's masks, flags, and rounding modes; and, when appropriate, to simulate IEEE exceptions, including traps when enabled.

4. On entry, the simulation routine should first save the FPC register contents (containing the caller's masks, flags, and rounding modes), disable all traps, clear all flags, establish appropriate rounding modes, and then perform the necessary floating-point operations. Finally, the routine should set the current flags (called signaling flags) appropriately, and invoke either LOAD FPC AND SIGNAL or SET FPC AND SIGNAL.

5. When a program interruption for a data exception occurs, and both bit 6 and 7 of the DXC are ones, it indicates to the trap handler that the interruption was caused by a simulated-IEEE-exception trap action. The remaining bits of the DXC indicate the type of IEEE exception. Additional information required by the trap handler can be determined by the contents of a trap-information block, located by convention, at a fixed offset from the location where the instruction causing the trap resides.

   The following shows an example of this scheme. The block and the code below are inserted at an appropriate place where a trap can occur. In this example, the LOAD FPC AND SIGNAL instruction is used, and the caller's FPC register contents are at the location, SAVEDFPC.

```
          BC     15,LOADPFC
         ┌──────────────────┐
         │       Trap       │
         │    Information   │
         │       Block      │
         └──────────────────┘
LOADFPC   LFAS   SAVEDFPC
```

The trap information block can contain the designation of floating-point registers and general registers containing the information (or addresses of the information) for the following types of items:

a. The operation being simulated

b. Format and values of source operands

c. Format and value of the result

d. Any additional information useful to the trap handler.

LOAD FPR FROM GR

LDGR R_1,R_2 [RRE]

'B3C1'	////////	R_1	R_2

0 16 24 28 31

The second operand is placed at the first-operand location. The second operand is in a general register, and the first operand is in a floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

LOAD GR FROM FPR

LGDR R_1,R_2 [RRE]

'B3CD'	////////	R_1	R_2

0 16 24 28 31

The second operand is placed at the first-operand location. The second operand is in a floating-point register, and the first operand is in a general register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

LOAD NEGATIVE

LNDFR R_1,R_2 [RRE]

'B371'	////////	R_1	R_2

0 16 24 28 31

The second operand is placed at the first-operand location with the sign bit set to one. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. LOAD NEGATIVE (LNDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.

2. LOAD NEGATIVE (LNDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD POSITIVE

LPDFR R_1,R_2 [RRE]

'B370'	////////	R_1	R_2

0 16 24 28 31

The second operand is placed at the first-operand location with the sign bit set to zero. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. LOAD POSITIVE (LPDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.

2. LOAD POSITIVE (LPDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD ZERO

Mnemonic R_1 [RRE]

Op Code	////////	R_1	////
0	16	24	28 31

Mnemonic	Op Code	Operands
LZER	'B374'	Short
LZDR	'B375'	Long
LZXR	'B376'	Extended

All bits of the first operand are set to zeros.

For LZXR, The R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LZXR only)
- Transaction constraint

Programming Note: LOAD ZERO sets all bits of a register to zeros, which produces a positive zero value in the BFP, DFP, and HFP formats. For DFP, addition of an all-zero value to any normal value, X, normalizes X.

PERFORM FLOATING-POINT OPERATION

PFPO [E]

'010A'
0 15

The operation specified by the function code in general register 0 is performed and the condition code is set to indicate the result. When there are no exceptional conditions, condition code 0 is set. When an IEEE nontrap exception is recognized, condition code 1 is set. When an IEEE trap exception with alternate action is recognized, condition code 2 is set. In the absence of suppression, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The PERFORM FLOATING-POINT OPERATION (PFPO) instruction is subject to the AFP-register-control bit, bit 45 of control register 0. For PFPO to be executed successfully, the AFP-register-control bit must be one; otherwise, an AFP-register data exception, DXC 1, is recognized.

Bit 32 of general register 0 is the test bit. When bit 32 is zero, the function specified by bits 33-63 of general register 0 is performed; each field in bits 33-63 must be valid and the combination must be a valid and installed function; otherwise a specification exception is recognized. When bit 32 is one, the function specified by bits 33-63 is not performed; rather, the condition code is set to indicate whether these bits specify a valid and installed function; the condition code is set to 0 if the function is valid and installed, or to 3 if the function is invalid or not installed. This definition is written as if the test bit is zero except when stated otherwise.

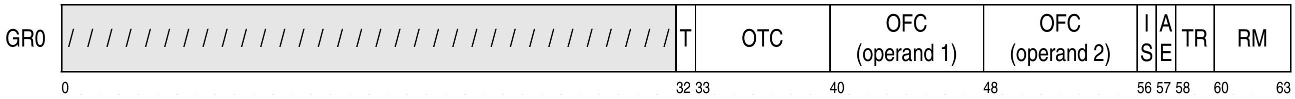
Bits 33-39 of GR0 specify the operation type. Only one operation type is currently defined: 01, hex, is the PFPO-convert-floating-point-radix operation.

For the PFPO-convert-floating-point-radix operation, other fields in general register 0 include first-operand format, second operand format, control flags, and rounding method. The second operand is converted to the format of the first operand and placed at the first-operand location, a return code is placed in bits 32-63 of general register 1, and the condition code is set to indicate whether an exceptional condition was recognized. Alternatively, an exceptional condition may be indicated by the recognition of a data exception resulting in either completion or suppression.

The first and second operands are in implicit floating-point registers. The first operand is in floating-point register 0 (paired with floating-point register 2 for extended). The second operand is in floating-point register 4 (paired with floating-point register 6 for extended).

General Register 0 (GR0)

Figure 9-23 illustrates the contents of general register 0; bits 0-31 of the register are ignored.



Explanation:

/	Ignored
T	Test bit (bit 32)
OTC	PFPO-operation-type code (bits 33-39)
OFC	PFPO-operand format code (bits 40-47 for operand 1, bits 48-55 for operand 2)
IS	Inexact-suppression control (bit 56)
AE	Alternate-exception-action control (bit 57)
TR	Target-radix-dependent controls (bits 58-59)
RM	PFPO rounding method (bits 60-63)

Figure 9-23. General Register 0 for PERFORM FLOATING POINT OPERATION

Figure 9-24 illustrates the contents of the PFPO-operation-type code in bits 33-32 of general register 0.

Op Type Code (hex)	Operation
00	Reserved/Invalid
01	PFPO Convert Floating-Point Radix
02-7F	Reserved/Invalid

Figure 9-24. PFPO-Operation-Type Code (GR0 bits 33-39)

Figure 9-25 illustrates the contents of the PFPO-operand-format codes for the first and second operands (in bits 40-47 and 48-55 of general register 0, respectively).

Code (hex)	Format
00	HFP short
01	HFP long
02	HFP extended
03	Reserved/Invalid
04	Reserved/Invalid
05	BFP short
06	BFP long
07	BFP extended
08	DFP short
09	DFP long
0A	DFP extended
0B-FF	Reserved/Invalid

Figure 9-25. PFPO-Operand-Format Codes (GR0 bits 40-47 and 48-55)

Figure 9-26 illustrates the contents of the PFPO-target-radix-dependent controls in bits 58-59 of general register 0.

Radix of Target	GR0 Bit	Meaning
HFP	58	HFP-overflow control
HFP	59	HFP-underflow control
BFP	58	Reserved, must be zero
BFP	59	Reserved, must be zero
DFP	58	Reserved, must be zero when the floating-point extension facility is not installed; it is the DFP quantum-permission control (DQPC) when the facility is installed.
DFP	59	DFP preferred-quantum control (DPQC)

Figure 9-26. PFPO-Target-Radix-Dependent Controls (GR0, bits 58-59)

Figure 9-27 illustrates the PFPO-rounding-method codes in bits 60-63 of general register 0.

Value	Method*
0	According to current DFP rounding mode in bits 25-27 of the floating-point-control register
1	According to current BFP rounding mode in bits 29-31 of the floating-point-control register
2-7	Reserved/Invalid
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision
*	All rounding methods, other than those listed as reserved, are valid for any conversion function, regardless of the radix of the result.

Figure 9-27. PFPO-Rounding Method (GR0 bits 60-63)

Figure 9-28 shows the basic PFPO functions. PFPO basic functions comprise the set of combinations of the operation-type, first-operand-format, and second-operand-format fields which are valid when the PFPO instruction is installed. Other combinations of operation type and format are not valid and will result in either a specification exception being recognized (when the test bit is zero) or condition code 3 (when the test bit is one).

Explanation:

Da	AFP-register data exception.
SP	Specification exception due to invalid PFPO rounding method; for BFP target, specification exception due to nonzero target-radix-dependent controls; for DFP target, specification exception due to nonzero DFP-quantum-permission control when the floating-point-extension facility is not installed.
Xi	IEEE-invalid-operation exception.
Xo	IEEE-overflow exception.
Xq	Quantum exception, if the floating-point extension facility is installed.
Xu	IEEE-underflow exception.
Xx	IEEE-inexact exception.

Figure 9-28. Basic PFPO Functions (GR0 bits 33-55)

In the detailed descriptions that follow there are many references to quantum exceptions. Those apply only when the floating-point extension facility is installed, and bit 58 of general register 0 is one.

Inexact-Suppression Control: Bit 56 of general register 0 is the inexact-suppression control. When the inexact-suppression control is zero, IEEE-inexact exceptions are recognized and reported in the normal manner. When the inexact-suppression control is one, IEEE-inexact exceptions are not recognized, and no trap or nontrap action for the exceptions occurs. The inexact-suppression control has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition.

Alternate-Exception-Action Control: Bit 57 of general register 0 is the alternate-exception-action control. The setting of this control affects the action taken for IEEE-overflow and IEEE-underflow trap exceptions.

When the alternate-exception-action control is zero, IEEE-overflow and IEEE-underflow trap exceptions are reported in the normal manner. That is, the appropriate data exception code (DXC) is placed in byte 2 of the floating-point control register, the operation is completed, and a program interruption for a data exception occurs. (As part of the program interruption, the DXC is stored at location 147.) This is called an *IEEE trap exception with normal action*.

When the alternate-exception-action control is one, the DXC is placed in byte 2 of the floating-point control register, the operation is completed, condition code 2 is set, and program execution continues with the next sequential instruction. (There is no program interruption and the DXC is not stored at location 147.) This is called an *IEEE trap exception with alternate action*.

Target-Radix-Dependent Controls: Bits 58 and 59 comprise controls for a target (first) operand having either the HFP or DFP format, as described below. When the operand-format control for the first operand designates the BFP format, both bits 58 and 59 must contain zeros; otherwise, a specification exception is recognized (when the test bit is zero) or condition code 3 is set (when the test bit is one).

HFP-Overflow Control: Bit 58 of general register 0 is the HFP-overflow control. When the HFP-overflow control is zero, an HFP-overflow condition is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask. When the HFP-overflow control is one, an HFP-overflow condition is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask.

HFP-Underflow Control: For HFP targets, bit 59 of general register 0 is the HFP alternate underflow control. When the HFP-underflow control is zero, HFP underflow causes the result to be set to a true zero with the same sign as the source and underflow is not reported. (The result in this case is inexact and subject to the inexact-suppression control.) When the HFP-underflow control is one, the condition is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask.

DFP Quantum-Permission Control (DQPC): When the floating-point extension facility is installed, for DFP targets, bit 58 of general register 0 is the DFP quantum-permission control (DQPC). If this control is zero, recognition of the quantum exception is suppressed so that no trap or nontrap action for the exception occurs; if the control is one, recognition of the quantum exception is not suppressed.

DFP Preferred Quantum Control (DPQC): For DFP targets, bit 59 of general register 0 is the DFP preferred quantum control (DPQC). For radix conversion with DFP targets, if the delivered value is inexact, the cohort member with the smallest quantum is selected; if the delivered value is exact, selection depends on the value of bit 59 of general register 0, the DFP preferred quantum control (DPQC). When the delivered value is exact and the DPQC bit is zero, the cohort member with the largest quantum is selected. When the delivered value is exact and the DPQC bit is one, the preferred quantum is one and the cohort member with the quantum closest to one is selected.

Return Code

Regardless of what condition code is set, and independent of whether the test bit is one, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged. A return code is also placed in general register 1 when a program interruption occurs for an IEEE trap exception that completes; general register 1 is not updated when a program interruption occurs for an IEEE trap exception that suppresses. Thus, general register 1 is updated on a program interruption for IEEE-overflow, IEEE-underflow, IEEE-inexact, and quantum-exception trap exceptions, but is not updated on a program interruption for an IEEE-invalid-operation trap exception.

Except where otherwise specified, the return code is a value of zero.

Sign Preservation

For PFPO convert floating-point radix, the sign of the result is the same as the sign of the source. The only exception to this is when the source is a NaN and the target is HFP; in this case, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.

Preferred Quantum

For radix conversion with DFP targets, the handling of the quantum is described in “DFP Preferred Quantum Control (DPQC)” on page 9-38.

NaN Conversion

When converting between DFP and BFP, the sign of the NaN is always preserved, and the value of the payload is preserved, when possible. If the value of the source payload exceeds the maximum value of the target payload, the target is set to the default QNaN, but with the same sign as the source.

When traps are disabled, an SNaN is converted to the corresponding QNaN, and the payload is preserved, when possible; that is, SNaN(x) is converted to QNaN(x), where x is the value of the payload. See the section “Propagation of NaNs” on page 9-3 for additional details.

For DFP, both QNaN(0) and SNaN(0) can be represented; but in BFP, there is a representation for QNaN(0), but not for SNaN(0).

Scaled Value and Signed Scaling Exponent (Ω) for PFPO

When, for the PFPO-convert-floating-point-radix operation, IEEE-overflow trap action or IEEE-underflow trap action occurs, the scaled value is computed using the following steps:

$\Psi = b^{\Omega}$
$z = g \div \Psi$

Where Ω is the signed scaling exponent, b is the target radix (2, 10, or 16), Ψ is the scale factor, g is the precision-rounded value, and z is the scaled value.

The signed scaling exponent (Ω) is selected to make the magnitude of the value of the scaled result (z) lie in the range:

$1 \leq |z| < b$.

The value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer, is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The scaled value is used as the delivered value and is placed in the result location. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected. (But it should be noted that for all currently supported conversions where scaling is required, the result is always inexact, so the cohort member with the smallest quantum is selected.) For BFP targets, there are no redundant representations, there is only one member in a cohort. For HFP targets, the result is normalized.

HFP Values

Unnormalized HFP values are accepted on input, but all HFP results are normalized. If an HFP result would be less than the smallest (in magnitude) representable normalized number, an HFP underflow condition exists.

HFP Zero Result

For PFPO-convert-BFP-to-HFP or PFPO-convert-DFP-to-HFP functions, if the source operand is zero, the result has the same sign as that of the source operand, and has all zeros in fraction and characteristic.

HFP Overflow and Underflow for PFPO

For an HFP target of a PFPO-convert-floating-point-radix operation, the handling of overflow and underflow conditions is controlled by the HFP-overflow control and the HFP-underflow control, respectively.

HFP Overflow: An HFP-overflow condition exists when an HFP target precision's largest number (Hmax) is exceeded in magnitude by the precision-rounded value. That is, when the characteristic of a normalized HFP result would exceed 127 and the fraction is not zero.

When the HFP-overflow control is zero, HFP-overflow is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask in the FPC register. This is called an *HFP-overflow-as-IEEE-invalid-operation condition.*

When the HFP-overflow control is one, HFP overflow is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask in the FPC register. This is called an *HFP-overflow-as-IEEE-overflow condition.*

HFP Underflow: An HFP-underflow condition exists when the precision-rounded value is nonzero and less in magnitude than the HFP target precision's smallest normalized number, Hmin. That is, when the characteristic of a normalized HFP result would be less than zero and the fraction is not zero. Reporting of the HFP-underflow condition is subject to the HFP-underflow control. The result in this case, however, is inexact and is subject to the controls for that condition.

When the HFP-underflow control is zero, the HFP-underflow condition is not reported. The result is set to a true zero with the same sign as the source.

When the HFP-underflow control is one, HFP underflow is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask (IMu) in the FPC register. This is called an *HFP-underflow-as-IEEE-underflow condition.* When IMu is zero, the result is set to a true zero with the same sign as the source, and the return code in general register 1 is zero; when IMu is one, the result is set to a scaled value, and the return code is nonzero.

IEEE Exceptions for PFPO

Except where otherwise stated, the following sections on IEEE exceptions apply to both BFP and DFP.

IEEE Invalid Operation: An IEEE-invalid-operation exception is recognized when any of the following occurs:

1. An SNaN is encountered in an IEEE source.
2. In an IEEE-to-HFP conversion, a NaN (QNaN or SNaN) or an infinity is encountered in the IEEE source.
3. An HFP-overflow-as-IEEE-invalid-operation condition exists.

IEEE-invalid-operation exceptions are recognized as either IEEE-invalid-operation nontrap exceptions or IEEE-invalid-operation trap exceptions.

IEEE-Invalid-Operation Nontrap Action: IEEE-invalid-operation nontrap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed, the IEEE-invalid-operation flag bit in the FPC register is set to one, and condition code 1 is set. The result is as follows:

- When the target is IEEE and the source is an IEEE SNaN, the result is the source NaN converted to the corresponding canonical QNaN in the target format.
- When the target is HFP and the source is an IEEE NaN, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.
- When the target is HFP and the source is an IEEE infinity, the result is Hmax with the same sign as the source.
- When an HFP-overflow-as-IEEE-invalid-operation condition exists, the result is Hmax with the same sign as the source.

IEEE-Invalid-Operation Trap Action: IEEE-invalid-operation trap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

IEEE Overflow: For IEEE targets, an IEEE-overflow exception is recognized when the precision-rounded value is greater in magnitude than the largest finite number (Nmax) representable in the target format. For HFP targets, an IEEE-overflow exception is recognized when the HFP-overflow condition exists and the HFP-overflow control is one.

IEEE-Overflow Nontrap Action: IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. For IEEE targets, the result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward +∞, the result is +∞ if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.

4. For round toward -∞, the result is the largest positive finite number if the sign is plus or -∞ if the sign is minus.

For HFP targets, the result is set to the largest representable number in the target HFP format (Hmax) with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-overflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-overflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-overflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-overflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the IEEE-inexact exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively.

When IEEE-overflow nontrap action and quantum-exception trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the quantum exception is reported as a program interruption for a data exception with DXC 04 hex. When in addition an IEEE-inexact nontrap action occurs, the IEEE-inexact flag bit in the FPC register is set to one.

IEEE-Overflow Trap Action: IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

IEEE Underflow: For IEEE targets, an IEEE-underflow exception is recognized when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the result value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The result value is inexact if it is not equal to the precise intermediate value.

For HFP targets, an IEEE-underflow exception is recognized when the HFP-underflow condition exists and the HFP-underflow control is one.

IEEE-Underflow Nontrap Action: IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one.

For IEEE targets, the result is rounded to the denormalized value or Nmin. For DFP targets, the cohort member with the smallest quantum is selected.

For HFP targets, the result is set to a true zero with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-underflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-underflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-underflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-underflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the IEEE-inexact trap exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively.

When IEEE-underflow nontrap action and quantum-exception trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the quantum exception is reported as a program interruption for a data exception with DXC 04 hex. When in addition an IEEE-inexact nontrap action occurs, the IEEE-inexact flag bit in the FPC register is set to one.

IEEE-Underflow Trap Action: IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 10, 18, or 1C hex, depending on whether the result is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

IEEE Inexact: An IEEE-inexact exception is recognized when, for a PFPO-convert-floating-point-radix operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if the inexact-suppression control is one or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

IEEE-Inexact Nontrap Action: IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and an IEEE-overflow or IEEE-underflow nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both exceptions are set to one, and condition code 1 is set. When in addition, a quantum-exception nontrap action occurs, the quantum-exception flag bit in the FPC register is also set to one.

IEEE-Inexact Trap Action: IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

Quantum Exception: A quantum exception is recognized when the floating-point extension facility is installed, and when a quantum-exception condition exists, recognition of the exception is not suppressed (DQPC = 1), and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For a PFPO-convert-floating-point-radix operation with DFP result, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum exceeds the preferred quantum of 1. (See programming note 6.)

When the floating-point extension facility is not installed, no quantum exception is recognized.

Even though a quantum-exception condition exists, the quantum exception is not recognized if recognition of the exception is suppressed (DQPC = 0), or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists, and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum exception is not reported in status flag or DXC.

Quantum-Exception Nontrap Action: Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the quantum-exception flag bit in the FPC register is set to one.

When a quantum-exception nontrap action and another one or two IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all two or three exceptions are set to one, and condition code 1 is set.

Quantum-Exception Trap Action: Quantum-exception trap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 04 hex.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the nontrap exceptions are set to one, and the quantum-exception trap action takes place.

Resulting Condition Code (when test bit is zero):

0 Normal result
1 Nontrap exception
2 Trap exception with alternate action
3 --

Resulting Condition Code (when test bit is one):

0 Function is valid
1 --
2 --
3 Function is invalid

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 1, AFP register
- Data with DXC for IEEE exception
- Operation (if the PFPO facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The PFPO-convert-floating-point-radix operation performs "correct rounding"; that is, the result is accurately obtained from the precise intermediate value using the effective rounding method. This is in contrast to some radix conversion programs, which may produce results with larger rounding errors.

2. Note that a value of zero in the rounding-method field (GR0 bits 60-63) specifies rounding according to the current DFP rounding mode (FPC 3.1-3) regardless of whether the target is DFP, BFP, or HFP. Similarly, a value of one in the rounding-method field specifies rounding according to the current BFP rounding mode (FPC 3.5-7), regardless of the target format.

3. If the program does not supply a default QNaN (payload = zero) as a source, then its presence as a result indicates that the machine either created a new QNaN or the program attempted to convert a payload which was too large for this format.

   If the program restricts payloads to values within the smallest payload capacity of any first-operand format, then payloads are preserved across radix conversions.

4. In the absence of suppression, bits 32-63 of general register 1 are always set to a return code, even though, in most cases, the return code is zero. Future extensions of PFPO may make more use of nonzero return codes. With the current definition, the only nonzero return codes are set for IEEE-overflow trap exceptions and IEEE-underflow trap exceptions. In this case, the value of the signed scaling exponent (Ω), is placed in bits 32-63 of general register 1. For IEEE-inexact trap exceptions, the return code is set to zero, thus indicating that no scaling has occurred.

5. To display a value in scientific notation, many programming languages, calculators, and spread sheets use the letter e (or E) to separate the significand from the exponent. This is referred to as e-form notation. In this document, e-form notation, along with other forms of conventional numeric notation, is used to represent a value without regard to quantum. To indicate that both value and quantum are being represented, a variation of e-form notation, called q-form notation, is used. In q-form notation, the letter q replaces the letter e and the value shown after q is the right-units-view exponent, that is, the base 10 logarithm of the quantum. Thus, for example, the seven members of the cohort for the value 1e6 in the DFP short format are: 1q6, 10q5, 100q4, 1000q3, 10000q2, 100000q1, and 1000000q0.

   As an example of the distinction between e-form and q-form notation, consider the representation of the members of the cohort of zero. The DFP short format, for example, can represent 198 exact powers of 10, ranging in value from 1e-101 to 1e96; but can represent only 192 values for a quantum, ranging from 1e-101 to 1e90. Thus, the 192 members of the cohort for zero range from 0q-101 to 0q90.

   The effect of the DFP preferred quantum control is shown in Figure 9-29.

Rounded Intermediate Value	Result If Inexact	Result If Exact and DPQC = 0	Result If Exact and DPQC = 1
0	0q-101	0q90	0q0
0.125	1250000q-7	125q-3	125q-3
1	1000000q-6	1q0	1q0
10	1000000q-5	1q1	10q0
100	1000000q-4	1q2	100q0
1000	1000000q-3	1q3	1000q0
9999	9999000q-3	9999q0	9999q0
10000	1000000q-2	1q4	10000q0
10001	1000100q-2	10001q0	10001q0
1e5	1000000q-1	1q5	100000q0
1e6	1000000q0	1q6	1000000q0
1e10	1000000q4	1q10	1000000q4
1e15	1000000q9	1q15	1000000q9

Figure 9-29. Effect of DPQC on DFP Short Results

6. When the floating-point extension facility is installed, for a PFPO-convert-floating-point-radix operation with DFP result, if DPQC is zero and the DFP result is finite and exact, no quantum exception is recognized. This is because the operation always delivers the DFP result with the preferred quantum in this case.

7. The test bit (bit 32 of general register 0) provides a means of determining whether any future extensions to the operation-type code, operand-format code, target-radix-dependent controls, rounding method, and various combinations thereof are supported by the CPU.

PFPO Actions

Figure 9-30 summarizes the actions performed by the PFPO-convert-floating-point-radix operation for various target formats.

y Inexact result was incremented in magnitude (bit 5 of the DXC)
Y Yes
Y' Yes (true by virtue of other conditions in this row)

Figure 9-30. Actions for Various PERFORM FLOATING POINT Conditions (Part 2 of 2)

SET BFP ROUNDING MODE

Mnemonic $D_2(B_2)$ [S]

Op Code	B_2	D_2
0	16	20 31

Mnemonic	Op Code	Operands
SRNM	'B299'	2-bit BFP rounding mode
SRNMB	'B2B8'	3-bit BFP rounding mode

The BFP rounding-mode bits in the FPC register are set from the second-operand address.

For SRNM, the second-operand address is not used to address data; instead, bits 30-31 of the FPC register are set to bits 62 and 63, respectively, of the address. Bits other than 62 and 63 of the second-operand address are ignored. When the floating-point extension facility is installed, bit 29 of the FPC register is set to zero.

For SRNMB, the second-operand address is not used to address data; instead, bits 29-31 of the FPC register are set to bits 61-63, respectively, of the address. Bits 0-55 of the second-operand address are ignored, bits 56-60 must be zero, and bits 61-63 must designate a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Operation (SRNMB only if the floating-point extension facility is not installed)
- Specification (SRNMB only)
- Transaction constraint

Programming Note: SRNMB is a complete superset of the functionality of SRNM. It is recommended that newly developed software use the SRNMB instruction exclusively.

SET DFP ROUNDING MODE

SRNMT $D_2(B_2)$ [S]

'B2B9'	B_2	D_2
0	16	20 31

The DFP rounding-mode bits are set from the second-operand address.

The second-operand address is not used to address data; instead, the DFP rounding-mode bits in the FPC register are set with bits 61-63 of the address.

Bits other than 61-63 of the second-operand address are ignored.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the decimal-floating-point-rounding facility is not installed)
- Transaction constraint

SET FPC

SFPC R_1 [RRE]

'B384'	////////	R_1	////
0	16	24	28 31

The contents of bit positions 32-63 of the general register designated by R_1 are placed in the FPC (floating-point-control) register.

All of bits 32-63 corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration. Bits 0-31 of the general register are ignored.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction

- Specification
- Transaction constraint

Programming Notes:

1. When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.

2. See also the programming notes under LOAD FPC.

SET FPC AND SIGNAL

SFASR R_1 [RRE]

'B385'	////////	R_1	////
0	16	24	28 31

First, bits 0-4 of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is in bits 32-63 of the general register designated by R_1; bits 0-31 of the general register are ignored.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21 on page 9-33.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 on page 9-33 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. See also the programming notes under LOAD FPC AND SIGNAL.

2. Bits 0-31 of the general register designated by the R_1 field are reserved for future extension and should be set to zeros.

STORE

Mnemonic $R_1,D_2(X_2,B_2)$ [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic	**Op Code**	**Operands**
STE	'70'	Short
STD	'60'	Long

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXY-a]

Op Code	R_1	X_2	B_2	DL_2	DH_2	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
STEY	'ED66'	Short
STDY	'ED67'	Long

The first operand is placed unchanged in storage at the second-operand location.

The displacement for STE and STD is treated as a 12-bit unsigned binary integer. The displacement for STEY and STDY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC 1, AFP register
- Operation (STEY and STDY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Note: Data can be stored from the vector registers to the little endian format using the extended mnemonics STERV and STDRV for the VSTEBRF and VSTEBRG instructions (see page 21-22).

STORE FPC

STFPC $D_2(B_2)$ [S]

'B29C'	B_2	D_2
0	16	20 31

The contents of the FPC (floating-point-control) register are placed in storage at the second-operand location.

The operand is four bytes in length. All 32 bits of the FPC register are stored.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC 2, BFP instruction
- Transaction constraint

Summary of All Floating-Point Instructions

Figures 9-31 through 9-37 on the following pages show mnemonics for all floating-point instructions (except for PFPO) arranged in various categories of operand format and type of operation. Figure 9-31 shows those instructions which operate on the FPC register. Figure 9-32 on page 9-50 shows the floating-point instructions which have all operands in the same format (same radix and same length), including those FPS (floating-point support) instructions which operate on floating-point operands in a radix-independent manner. Figure 9-33 on page 9-51 and Figure 9-34 on page 9-51 show the floating-point instructions in which all operands are in the same radix but not all of the same length. Figure 9-35 on page 9-51 and Figure 9-36 on page 9-52 show the floating-point instructions in which the source or the result is in a general register. Figure 9-37 on page 9-52 shows the floating-point instructions other than PFPO which perform radix conversion.

Instruction Name	Mnemonic	Type
EXTRACT FPC	EFPC	BFP
LOAD FPC	**LFPC**	BFP
LOAD FPC AND SIGNAL	**LFAS**	DFP
SET BFP ROUNDING MODE	SRNM, SRNMB[1]	BFP
SET DFP ROUNDING MODE	SRNMT	DFP
SET FPC	SFPC	BFP
SET FPC AND SIGNAL	SFASR	DFP
STORE FPC	**STFPC**	BFP

Explanation:

Mnemonics in **bold** indicate a register-and-storage operation.

[1] The instruction is only available if the floating-point extension facility is installed.

BFP The instruction is considered to be part of the BFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception, DXC 2.

DFP The instruction is considered to be part of the DFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception, DXC 3.

Explanation:

Mnemonics in **bold** indicate a register-and-storage operation.

When the last letter of mnemonic is A, the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction.

Impacts on ESA/390 and ESA/390-Compatibility Mode

When the decimal-floating-point facility or the floating-point extension facility is installed in the z/Architecture architectural mode, the behavior of some instructions in the ESA/390 mode and ESA/390-compatibility mode deviates from the definition in the ESA/390 architecture.

The following summarizes the different behavior of affected ESA/390 instructions caused by those two facilities in the z/Architecture architectural mode.

Impacts of the Decimal-Floating-Point Facility

When the decimal-floating-point facility is installed in the z/Architectural architecture mode, it causes the following deviations from the ESA/390 architecture.

- For LOAD FPC (LFPC) and SET FPC (SFPC), if bits 25-27 of the source operand contain a nonzero value, it is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to this nonzero value.

Impacts of the Floating-Point Extension Facility

When the floating-point extension facility is installed in the z/Architectural architecture mode, it causes the following deviations from the ESA/390 architecture.

1. For LOAD FPC (LFPC) and SET FPC (SFPC), if either or both bit 5 and bit 13 of the source operand are one, it is unpredictable whether a specification exception is recognized or the corresponding bit in the FPC register is set to one; if bits 29-31 of the source operand contain all ones, is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to all ones.

2. For CONVERT HFP TO BFP (TBEDR, TBDR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

3. For BFP CONVERT TO FIXED (CFEBR, CFDBR, CFXBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

4. For BFP CONVERT FROM FIXED (CEFBR, CDFBR, CXFBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

5. For BFP DIVIDE TO INTEGER (DIEBR, DIDBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

6. For BFP LOAD FP INTEGER (FIEBR, FIDBR, FIXBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

7. For BFP LOAD ROUNDED (LEDBR, LDXBR, LEXBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

This chapter includes all privileged and semiprivileged instructions described in this publication, except the input/output instructions, which are described in “I/O Instructions” on page 14-1.

Privileged instructions may be executed only when the CPU is in the supervisor state. An attempt to execute a privileged instruction in the problem state generates a privileged-operation exception.

The semiprivileged instructions are those instructions that can be executed in the problem state when certain authority requirements are met. An attempt to execute a semiprivileged instruction in the problem state when the authority requirements are not met generates a privileged-operation exception or some other program-interruption condition depending on the particular requirement which is violated. Those requirements which cause a privileged-operation exception to be generated in the problem state are not enforced when execution is attempted in the supervisor state.

The control instructions and their mnemonics, formats, and operation codes are listed in Figure 10-1 on page 10-3. The figure also indicates which instructions are new in z/Architecture as compared to ESA/390, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

The instructions that are new in z/Architecture are indicated in Figure 10-1 by “N.”

When the operands of an instruction are 32-bit operands, the mnemonic for the instruction does not include a letter indicating the operand length. If there is an instruction with the same name but with 64-bit operands, its mnemonic includes the letter “G.” In Figure 10-1, when there is an instruction with 32-bit operands and another instruction with the same name but with “G” added in its mnemonic, the first instruction has “(32)” after its name, and the other instruction has “(64)” after its name.

For those control instructions which have special rules regarding the handling of exceptional situations, a section called “Special Conditions” is included. This section indicates the type of ending (suppression, nullification, or completion) only for those exceptions for which the ending may vary.

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For LOAD PSW, for example, LPSW is the mnemonic and $D_2(B_2)$ the operand designation.

Programming Notes:

1. The following additional control instructions are available when the DAT-enhancement facility is installed:

   - COMPARE AND SWAP AND PURGE (CSPG)
   - INVALIDATE DAT TABLE ENTRY

   CSPG operates on a doubleword in storage, in contrast to the previously existing instruction COMPARE AND SWAP AND PURGE (CSP), which operates on a word in storage.

2. The long-displacement facility uses new instruction formats, named RSY, RXY, and SIY, to provide 20-bit signed displacements. In connection with the long-displacement facility, all previously existing control instructions of the RSE or RXE format are changed to be of format RSY or RXY, respectively, where the new formats differ from the old by using a previously unused byte, now named DH, in the instructions. When the long-displacement facility is installed, the displacement for an instruction operand address is formed by appending DH on the left of the previous displacement field, now named DL, of the instruction. When the long-displacement facility is not installed, eight zero bits are appended on the left of DL, and DH is ignored.

   The following additional control instruction is available when the long-displacement facility is installed:

   - LOAD REAL ADDRESS (LRAY)

3. The following additional control instructions are available when the ASN-and-LX-reuse facility is installed:

   - EXTRACT PRIMARY ASN AND INSTANCE
   - EXTRACT SECONDARY ASN AND INSTANCE
   - PROGRAM TRANSFER WITH INSTANCE
   - SET SECONDARY ASN WITH INSTANCE

4. The LOAD PAGE TABLE ENTRY ADDRESS control instruction is available when the DAT-enhancement facility 2 is installed.

5. The PERFORM TIMING FACILITY FUNCTION control instruction is available when the TOD-clock-steering facility is installed.

6. The MOVE WITH OPTIONAL SPECIFICATIONS control instruction is available when the move-with-optional-specifications facility is installed.

7. The PERFORM TOPOLOGY FUNCTION control instruction is available when the configuration-topology facility is installed.

8. The PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION control instruction is available when the message-security-assist extension 3 is installed.

9. The RESET REFERENCE BITS MULTIPLE control instruction is available when the reset-reference-bits-multiple facility is installed.

10. The COMPARE AND REPLACE DAT TABLE ENTRY instruction is available when the enhanced-DAT facility 2 is installed.

11. The INSERT REFERENCE BITS MULTIPLE control instruction is available when the insert-reference-bits-multiple facility is installed.

12. The TEST PENDING EXTERNAL INTERRUPTION control instruction is available when the test-pending-external-interruption facility is installed.

Explanation:

¢ Causes serialization and checkpoint synchronization.

¢^{2} Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.

¢^{3} Causes serialization and checkpoint synchronization when the set-key control is one.

¢^{4} Causes serialization and checkpoint synchronization when the KFC value is 4 or 5.

$ Causes serialization.

¤^{1} Restricted from transactional execution.

* PER zero-address-detection not recognized.

A Access exceptions for logical addresses.

A^1 Access exceptions; not all access exceptions may occur; see instruction description for details.

B PER branch event.

B$_1$ B$_1$ field designates an access register in the access-register mode.

B$_2$ B$_2$ field designates an access register in the access-register mode.

BP B$_2$ field designates an access register when PSW bits 16 and 17 have the value 01 binary.

B† B$_1$ field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.

B‡ B$_2$ field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.

C Condition code is set.

C^1 Condition code is set when the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one.

CT Configuration-topology facility.

DE DAT-enhancement facility.

DM Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.

D2 DAT-enhancement facility 2.

E E instruction format.

ED1 Enhanced-DAT facility 1.

ED2 Enhanced-DAT facility 2.

ES Expanded-storage facility.

FC Designation of access registers depends on the function code of the instruction.

G0 Instruction execution includes the implied use of general register 0.

G2 Instruction execution includes the implied use of general register 2.

GM Instruction execution includes the implied use of multiple general registers:
General registers 0 and 1 for MOVE WITH DESTINATION KEY, MOVE WITH SOURCE KEY, PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION, PERFORM TIMING FACILITY FUNCTION, and STORE SYSTEM INFORMATION.
General registers 3, 4, and 14, and, when the ASN-and-LX-reuse facility is installed, general register 15 for PROGRAM CALL.

II Interruptible instruction (for SSKE, the instruction is interruptible when the multiple-block control is one).

IM Insert-reference-bits--multiple facility.

K PER storage-key-alteration event.

L New condition code is loaded.

BRANCH AND SET AUTHORITY

BSA R_1,R_2 [RRE]

'B25A'	////////	R_1	R_2
0	16	24	28 31

If the dispatchable unit is in the base-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in the dispatchable-unit control table (DUCT); the PSW-key mask (PKM), PSW key, and problem-state bit also are saved in the DUCT; the PKM and PSW key are replaced using the contents of general register R_1; the problem-state bit is set to one; bits 32 and 97-127 of the PSW are replaced using the contents of general register R_2; and the dispatchable unit is placed in the reduced-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in the DUCT and replaced from general register R_2, and bit 32 of the PSW is neither saved nor replaced.

If the dispatchable unit is in the reduced-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW are saved in general register R_1 if R_1 is not zero; bits 32 and 97-127 of the PSW and the PKM, PSW key, and problem-state bit are replaced by values saved in the DUCT; and the dispatchable unit is placed in the base-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in general register R_1 if R_1 is not zero, those bits in the PSW are replaced from the DUCT, and bit 32 of the PSW is neither saved nor replaced.

Words 5, 8, and 9 of the DUCT are used by this instruction. The contents of those words are as follows:

5	PSW-Key Mask		PSW Key	RA		P
	0	16	24	28		31

In the 24-Bit or 31-Bit Addressing Mode

8	All Zeros	
	0	31

9	BA	Bits 33-63 of Return Address	
	32	33	63

In the 64-Bit Addressing Mode

8	Bits 0-31 of Return Address	
	0	31

9	Bits 32-63 of Return Address	
	32	63

The fields in words 5, 8, and 9 of the DUCT are allocated as follows:

PSW-Key Mask: Bit positions 0-15 of word 5 contain the PSW-key mask (PKM), bits 32-47 of control register 3, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PKM is restored to control register 3 by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

PSW Key: Bit positions 24-27 of word 5 contain the PSW key, bits 8-11 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PSW key is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Reduced Authority (RA): Bit 28 of word 5 indicates, when zero, that the dispatchable unit associated with the DUCT is in the base-authority state or, when one, that the dispatchable unit is in the reduced-authority state. Bit 28 is set to one by BRANCH AND SET AUTHORITY executed in the base-authority state, and it is set to zero by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Problem State (P): Bit position 31 of word 5 contains the problem-state bit, bit 15 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The problem-state bit is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Basic Addressing Mode (BA): In the 24-bit or 31-bit addressing mode, bit position 0 of word 9 contains the basic-addressing-mode bit, bit 32 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The basic-addressing-mode bit is restored to the PSW from the DUCT by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Return Address: In the 24-bit or 31-bit addressing mode, bit positions 1-31 of word 9 contain bits 33-63 of the updated instruction address, bits 97-127 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. Bits 1-31 of word 9 of the DUCT are restored to bit positions 97-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state. In the 64-bit addressing mode, words 8 and 9 contain the updated instruction address saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The contents of words 8 and 9 are restored to bit positions 64-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

In the 24-bit or 31-bit addressing mode, all zeros are stored in word 8 when saving occurs in the base-authority state. In any addressing mode, all zeros are stored in bit positions 16-23, 29, and 30 of word 5 when saving occurs in the base-authority state.

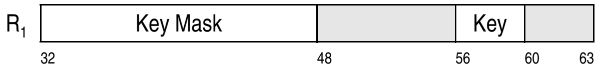
All other fields in words 5, 8, and 9 remain unchanged when bit 28 of word 5 is set to zero in the reduced-authority state.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

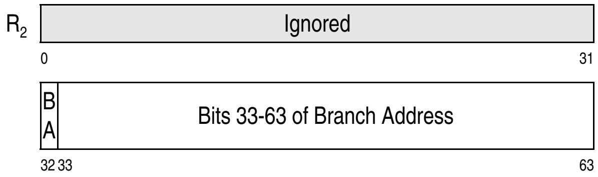
Base-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the base-authority state, as indicated by the reduced-authority bit (RA) in the DUCT being zero, R_2 must be nonzero; otherwise, a special-operation exception is recognized. R_1 may be zero or nonzero.

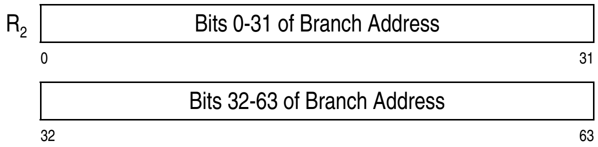
The contents of bit positions 32-63 of general register R_1 and of general register R_2 when the execution of the instruction begins in the base-authority state are as follows:



In the 24-Bit or 31-Bit Addressing Mode



In the 64-Bit Addressing Mode



In any addressing mode, the contents of bit positions 0-31 of general register R_1 are ignored. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general register R_2 are ignored.

In the 24-bit or 31-bit addressing mode, PSW bits 32 and 97-127 are saved in word 9 of the DUCT, and zeros are stored in word 8. In the 64-bit addressing mode, PSW bits 64-127 are saved in words 8 and 9 of the DUCT. In any addressing mode, the PKM, the PSW key, and the problem-state bit are saved in word 5 of the DUCT, the RA bit in word 5 is set to one, and bits 16-23, 29, and 30 of word 5 are set to zeros.

Bits 56-59 of general register R_1 are placed in bit positions 8-11 of the PSW as the new PSW key. In the problem state, the new PSW key must be authorized by the PKM; otherwise, if the new PSW key is not authorized, a privileged-operation exception is recognized.

After the new PSW key has been placed in the PSW, bits 32-47 of general register R_1 are ANDed with the PKM in control register 3, and the result replaces the PKM in control register 3.

The problem-state bit in the PSW is set to one.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R_2 is placed in bit position 32 of the PSW as the new basic-addressing-mode bit. A branch address is generated from bits 33-63 of general register R_2 under the control of the new basic addressing mode, and the result is placed in bit positions 64-127 of the PSW as the new instruction address.

In the 64-bit addressing mode, a branch address is generated from bits 0-63 of general register R_2 and is placed in bit positions 64-127 of the PSW as the new instruction address. Bit 32 of the PSW remains unchanged.

Bits 48-55 and 60-63 of general register R_1 may be used for future extensions and should be zeros; otherwise, the program may not operate compatibly in the future.

Reduced-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the reduced-authority state, as indicated by the reduced-authority (RA) bit in the DUCT being one, R_2 must be zero; otherwise, a special-operation exception is recognized. R_1 may be zero or nonzero. The initial contents of general registers R_1 and R_2 are ignored.

If R_1 is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. If R_1 is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW are placed in bit positions 0-63 of general register R_1. If R_1 is zero, general register 0 remains unchanged.

In the 24-bit or 31-bit addressing mode, bit 0 of word 9 of the DUCT is placed in PSW bit position 32, and bits 1-31 of word 9, with 33 leftmost zeros appended, are placed in PSW bit positions 64-127.

In the 64-bit addressing mode, the contents of words 8 and 9 of the DUCT are placed in PSW bit positions 64-127, and bit 32 of the PSW remains unchanged.

In any addressing mode, the PKM, the PSW key, and the problem-state bit are restored from the DUCT, and the RA bit is set to zero, as previously described. There is no test for whether the restored PSW key is authorized by the restored PKM.

Special Conditions

R_2 must be nonzero in the base-authority state and zero in the reduced-authority state. If either of these rules is violated, a special-operation exception is recognized, and the operation is suppressed.

In the problem state, the execution of the instruction in the base-authority state is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

In the 24-bit or 31-bit addressing mode, the contents of word 9 of the DUCT are not checked for validity before they are loaded into the PSW. If the newly-loaded PSW contains a zero in bit position 32 and the contents of bit positions 97-103 are not zeros, then (a) the instruction is completed, (b) the resulting instruction-length code is 0, (c) a specification-exception is recognized, and (d) a program interruption occurs. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

In the ESA/390-compatibility mode, either (a) an operation exception is recognized, or (b) a special-operation exception is recognized when bit 47 of control register 0 is zero. It is unpredictable which exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (dispatchable-unit control table)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state, base-authority operation only)
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-2 on page 10-10.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
7.C	Operation exception (ESA/390-compatibility mode only)
7.D	Special-operation exception due to bit 47 of control register 0 being zero (ESA/390-compatibility mode only)
8.A	Trace exceptions.
8.B	Protection exception (low-address protection) for access to dispatchable-unit control table.
8.C.1	Addressing exception for access to dispatchable-unit control table.
8.C.2	Special-operation exception due to R_2 being zero in the base-authority state or R_2 being nonzero in the reduced-authority state.
8.C.3	Privileged-operation exception due to selected PSW-key-mask bit being zero (base-authority operation only).
9.	Specification exception due to bit 32 of the newly loaded PSW being zero when bits 97-103 are not all zeros (reduced-authority operation only).

Figure 10-2. Priority of Execution: BRANCH AND SET AUTHORITY

Programming Notes:

1. BRANCH AND SET AUTHORITY can improve performance by replacing to-current-primary forms of PROGRAM TRANSFER (PT-cp) and basic (nonstacking) PROGRAM CALL (PC-cp) instructions. PT-cp and PC-cp are often used (within a single address space) to reduce the authority of the PSW-key mask (PKM) or change from supervisor state to problem state during a calling linkage made by PT-cp and then to restore the PKM authority or supervisor state during a return linkage made by PC-cp. Also, the PSW-key-setting operations of BRANCH AND SET AUTHORITY can be substituted for SET PSW KEY FROM ADDRESS instructions, and, since BRANCH AND SET AUTHORITY combines branching with PSW-key setting, it can be used to change the PSW key when branching from or to a fetch-protected program.

2. Only one base-authority state and one reduced-authority state are available to a dispatchable unit. Nested use of BRANCH AND SET AUTHORITY, that is, use within different subroutine levels, is not possible. The requirement that R_2 must be nonzero in the base-authority state and zero in the reduced-authority state provides detection of an attempt to use BRANCH AND SET AUTHORITY in the base-authority state when the dispatchable unit is already in the reduced-authority state because of a previous use of the instruction in the base-authority state.

3. BRANCH AND SET AUTHORITY in the base authority-state does not save an indication in the DUCT of whether the current addressing mode is the extended (64-bit) addressing mode or a basic (24-bit or 31-bit) addressing mode. The instruction, in either the base-authority state or the reduced-authority state, does not cause a switch between the extended addressing mode and a basic addressing mode. In the reduced-authority state, the contents of words 8 and 9 of the DUCT are interpreted based only on the current addressing mode. If saving occurs in the 31-bit addressing mode and then restoring occurs in the 64-bit addressing mode, bit 0 of word 9 of the DUCT will be used as an address bit instead of as the basic-addressing-mode bit. If saving occurs in the 64-bit addressing mode and then restoring occurs in the 24-bit addressing mode, an early specification exception may be recognized, after the instruction execution is com-

pleted, because bits 97-103 of the PSW may be nonzero when bit 32 is zero.

4. The instruction may be referred to as BSA-ba or BSA-ra depending on whether it is executed in the base-authority state or the reduced-authority state, respectively.

BRANCH AND STACK

BAKR R_1,R_2 [RRE]

'B240'	////////	R_1	R_2
0	16	24	28 31

A linkage-stack branch state entry is formed, and the current PSW, except with an unpredictable PER mask and with the addressing-mode bits and instruction address replaced from the first operand, is placed in the state entry. Subsequently, the updated instruction address in the current PSW is replaced from the second operand. Indications of the current addressing-mode bits and the new instruction address are placed in the state entry, and the PSW-key mask, PASN, SASN, EAX, and contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. When the ASN-and-LX-reuse facility is installed and the ASN-and-LX-reuse control in control register 0 is one, the PASTEIN and SASTEIN also are placed in the state entry. The action associated with an operand is not performed if the R field designating the operand is zero.

When the R_1 field is nonzero, the contents of general register R_1 specify an address referred to as the return address.

When R_1 is nonzero and bit 63 of general register R_1 is zero, the return address is generated from the contents of the register under the control of the basic addressing mode specified by bit 32 of the register: 24-bit mode if bit 32 is zero, or 31-bit mode if bit 32 is one. Bit 32 of the register and the return address are substituted for the basic-addressing-mode bit, bit 32, and the updated instruction address, respectively, in the current PSW when the contents of that PSW are placed in the state entry. The extended-addressing-mode bit, bit 31, is set to zero in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When R_1 is nonzero and bit 63 of general register R_1 is one, the return address is generated from the contents of the register under the control of the 64-bit addressing mode. Bits 0-62 of the return address, with a zero appended on the right, are substituted for the updated instruction address in the current PSW when the contents of that PSW are placed in the state entry. Bits 31 and 32 are set to one in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When the R_1 field is zero, the current PSW is placed in the state entry without any change except for an unpredictable PER mask.

Subsequently, when the R_2 field is nonzero, the instruction address in the current PSW is replaced by the branch address. The branch address is generated from the contents of general register R_2 under the control of the current addressing mode. When the R_2 field is zero, the operation is performed without branching.

The branch state entry is formed and information is placed in it as described in “Stacking Process” on page 5-84.

In the 24-bit or 31-bit addressing mode, bits 33-63 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 33-63 of bytes 144-151 in the state entry, bit 32 of the current PSW is placed in bit position 32 of those bytes, and zeros are placed in bit positions 0-31 of the bytes.

In the 64-bit addressing mode, bits 0-62 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 0-62 of bytes 144-151 in the state entry, and a one is placed in bit position 63 of those bytes.

The entry-type code in the state entry is 0001100 binary.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

Special Conditions

The CPU must be in the primary-space mode or access-register mode; otherwise, a special-operation exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Stack full
- Stack specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-3 on page 10-12.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
7.C	Transaction constraint.
8.A	Trace exceptions (only if R_2 is nonzero).
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry. **Note:** Exceptions 8.B.2-8.B.7 can occur only if there is not enough remaining free space in the current linkage-stack section.
8.B.2	Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.
8.B.3	Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined.
8.B.4	Stack-full exception due to forward-section validity bit in the trailer entry being zero.
8.B.5	Access exceptions (fetch) for entry descriptor of the header entry of the next section. This entry is presumed to be a header entry; its entry-type field is not examined.
8.B.6	Stack-specification exception due to not enough remaining free space in the next section.
8.B.7	Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.
8.B.8	Access exceptions (store) for entry descriptor of the current entry and for the new state entry.

Figure 10-3. Priority of Execution: BRANCH AND STACK (Part 1 of 2)

Figure 10-3. Priority of Execution: BRANCH AND STACK (Part 2 of 2)

Programming Notes:

1. Examples of the use of the BRANCH AND STACK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. In no case does BRANCH AND STACK change the current addressing mode.

3. The effect when the R_1 field is zero is that the return address, which would otherwise be specified by the R_1 general register, is the address of the next sequential instruction. In this case, BRANCH AND STACK provides a program-linkage function that is comparable to the function of BRANCH AND SAVE.

4. BRANCH AND STACK with a nonzero R_1 field is intended for use at or near the entry point of a called program. The program may be called by means of BRANCH AND LINK (BALR) or BRANCH AND SAVE (BAS or BASR) from a program being executed in the 24-bit or 31-bit addressing mode, by means of BRANCH AND SAVE AND SET MODE from a program being executed in any addressing mode, or by means of a BRANCH AND SET MODE instruction located in a “glue module” and being executed in any addressing mode. In all of these cases when the nonzero R_1 field of the calling instruction is the same as the R_1 field of BRANCH AND STACK, and even when the addressing mode was changed during the calling linkage, BRANCH AND STACK correctly saves the addressing mode and return address of the calling program so that the subsequent execution of

PROGRAM RETURN will return correctly to the calling program.

BRANCH IN SUBSPACE GROUP

BSG R_1,R_2 [RRE]

'B258'	////////	R_1	R_2
0	16	24	28 31

Provided that the current primary address space is in the subspace group, if any, associated with the current dispatchable unit, the access-list-entry token (ALET) in access register R_2 is translated by means of a special form of access-register translation (ART) to locate a destination ASN-second-table entry (DASTE). If the DASTE specifies the base space of the subspace group, the primary ASCE (PASCE) in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace of the group, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE. In either case, the following actions also occur.

In the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. Subsequently, the basic-addressing-mode bit and bits 33-63 of the instruction address in the current PSW are replaced from bit positions 32-63 of general register R_2, and bits 0-31 of the register are ignored.

In the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are saved in bit positions 0-63 of general register R_1. Subsequently, the instruction address in the current PSW is replaced from bit positions 0-63 of general register R_2. Bit 32 of the PSW remains unchanged.

In any addressing mode, general register 0 remains unchanged if the R_1 field is zero.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. Also, the secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4

The current primary address space is in the subspace group for the dispatchable unit if the current primary-ASTE origin (PASTEO), bits 33-57 of control register 5, designates the ASTE for the base space of the group. The PASTEO designates the base-space ASTE if the PASTEO is equal to the base-ASTE origin (BASTEO), bits 1-25 of word 0 of the dispatchable-unit control table (DUCT). For determining whether the PASTEO equals the BASTEO, either the PASTEO may be compared to the BASTEO or the entire contents of bit positions 32-63 of control register 5 may be compared to the entire contents of word 0 of the DUCT.

Ordinary ART is described in “Access-Register-Translation Process” on page 5-59. The special ART performed by this instruction is contrasted to ordinary ART as follows:

1. The special ART is performed regardless of whether the CPU is in the access-register mode.
2. If the ALET being translated is 00000000 hex, called ALET 0, the DASTE is the ASTE for the base space. Bit 0 of the DASTE is ignored.
3. If the ALET is 00000001 hex, called ALET 1, the DASTE is the ASTE for the last subspace entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP. That ASTE is designated by the subspace-ASTE origin (SSASTEO), bits 1-25 of word 1 of the DUCT. A special-operation exception is recognized if a subspace has not previously been entered, as indicated by an SSASTEO of all zeros. An ASTE-validity exception is recognized if bit 0 of the DASTE is one. An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the subspace ASTESN (SSASTESN) in word 3 of the DUCT. The DASTE located because of ALET 1 is considered to specify a subspace even if, due to an error, the DASTE is the ASTE for the base space. That is, there is no comparison of the SSASTEO to the BASTEO.
4. If the ALET is other than ALET 0 and ALET 1, an ASTE is located by obtaining its origin from an access-list entry (ALE) in a way similar to ordinary ART, and the DASTE is that located ASTE. In this case, as in ordinary ART:

- An ALET-specification exception is recognized if bits 0-6 of the ALET are not zeros.
- An ALEN-translation exception is recognized if the ALE is outside the effective access list or bit 0 of the ALE is one.
- An ASTE-validity exception is recognized if bit 0 of the DASTE is one.
- An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the ASTESN in the ALE.

The operation differs from ordinary ART in that the ALE sequence number (ALESN) in the ALE is not compared to the ALESN in the ALET, and the private bit in the ALE is treated as zero. Thus, ALE-sequence and extended-authority exceptions cannot occur.

The fetch-only bit in the ALE is ignored.

When the ALET is other than ALET 0 and ALET 1, the special ART may be performed by using the ART-lookaside buffer (ALB).

The DASTE located due to an ALET other than ALET 0 and ALET 1 may be the ASTE for the base space of the subspace group associated with the dispatchable unit. The DASTE is the base-space ASTE if the DASTE origin (DASTEO) obtained from an ALE by ART equals the BASTEO in the DUCT. For determining whether the DASTEO equals the BASTEO, either the DASTEO may be compared to the BASTEO, or the DASTEO with one leftmost and six rightmost zeros appended may be compared to the entire contents of word 0 of the DUCT. If the DASTE is not the base-space ASTE, the DASTE is treated as the ASTE for a subspace of the dispatchable unit's subspace group provided that (1) the subspace-group bit, bit 54, in the ASCE in the DASTE is one, and (2) the DASTE does not specify the base space of another subspace group. The DASTE specifies the base space of another subspace group if the base-space bit, bit 31 of word 0 of the DASTE, is one. A special-operation exception is recognized if either of those two provisions is not met.

If the DASTE specifies the base space of the subspace group, the PASCE in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE, and bits 56 and 57 of the PASCE, the storage-alteration-event bit and space-switch-event-control bit, remain unchanged.

If R_1 is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. If R_1 is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are placed in bit positions 0-63 of general register R_1. If R_1 is zero, general register 0 remains unchanged.

Whether R_2 is nonzero or zero, in the 24-bit or 31-bit addressing mode, bits 32-63 of general register R_2 specify the new basic addressing mode and designate the branch address. Bit 32 of the register specifies the new basic addressing mode and replaces bit 32 of the current PSW, and the branch address is generated from the contents of bit positions 33-63 of the register under the control of the new basic addressing mode.

When R_2 is nonzero or zero in the 64-bit addressing mode, the contents of general register R_2 designate the branch address. The branch address is generated from the contents of the register under the control of the 64-bit addressing mode. Bit 32 of the PSW remains unchanged.

Regardless of the addressing mode, the new value for the PSW is computed before general register R_1 is changed.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. The secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

If the DASTE specifies the base space, the subspace-active bit, bit 0 of word 1 of the DUCT, is set to zero, and bits 1-31 of word 1 remain unchanged. If the DASTE specifies a subspace by means of ALET 1, then (1) the subspace-active bit is set to one,

(2) the SSASTEO in bit positions 1-25 of word 1 remains unchanged, and (3) bits 26-31 of word 1 either are set to zeros or remain unchanged. If the DASTE specifies a subspace by means of an ALET other than ALET 1, then (1) the subspace-active bit is set to one, (2) the DASTEO is stored in bit positions 1-25 of word 1 as the SSASTEO, (3) zeros are stored in bit positions 26-31 of word 1, and (4) the ASTESN in the DASTE is stored in word 3 of the DUCT as the SSASTESN.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

The operation, since it changes a translation parameter in control register 1, causes all copies of prefetched instructions to be discarded, except when in the home-space mode.

Special Conditions

DAT must be on; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the current primary address space is not in a subspace group associated with the current dispatchable unit, if the ALET in access register R_2 is ALET 1 but a subspace has not previously been entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP, or if the ALET used is other than ALET 0 and ALET 1 and the destination ASTE does not specify the base space or a subspace of the subspace group.

The primary space-switch-event-control bit, bit 57 of control register 1 either before or after the operation, does not cause a space-switch-event program interruption to occur.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (dispatchable-unit control table, effective access-list designation, access-list entry, destination ASN-second-table entry)
- ALET specification
- ALEN translation
- ASTE sequence
- ASTE validity
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in the Figure 10-4.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.A	Trace exceptions.
8.B	Protection exception (low-address protection) for access to dispatchable-unit control table.
8.C.1	Addressing exception for access to dispatchable-unit control table.
8.C.2	Special-operation exception due to current primary address space not being in a subspace group associated with the current dispatchable unit (primary-ASTE origin in control register 5 not equal to base-ASTE origin in dispatchable-unit control table).
	Note: Exception 8.C.3.A can occur only if the access-list-entry token (ALET) in access register R_2 is ALET 0.
8.C.3.A	Addressing exception for access to base ASTE (ASTE designated by base-ASTE origin in dispatchable-unit control table).
	Note: Exceptions 8.C.3.B.1-8.C.3.B.4 can occur only if the access-list-entry token (ALET) in access register R_2 is ALET 1.
8.C.3.B.1	Special-operation exception due to subspace-ASTE origin in dispatchable-unit control table being zero.
8.C.3.B.2	Addressing exception for access to subspace ASTE.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 1 of 2)

8.C.3.B.3 ASTE-validity exception due to bit 0 in subspace ASTE being one.

8.C.3.B.4 ASTE-sequence exception due to ASTE sequence number in subspace ASTE not being equal to subspace-ASTE sequence number in dispatchable-unit control table.

Note: Exceptions 8.C.3.C.1-8.C.3.C.9 can occur only if the access-list-entry token (ALET) in access register R_2 is other than ALET 0 and ALET 1.

8.C.3.C.1 ALET-specification exception due to bits 0-6 of ALET not being all zeros.

8.C.3.C.2 Addressing exception for access to effective access-list designation.

8.C.3.C.3 ALEN-translation exception due to access-list entry being outside the list.

8.C.3.C.4 Addressing exception for access to access-list entry.

8.C.3.C.5 ALEN-translation exception due to I bit in access-list entry being one.

8.C.3.C.6 Addressing exception for access to destination ASTE.

8.C.3.C.7 ASTE-validity exception due to bit 0 in destination ASTE being one.

8.C.3.C.8 ASTE-sequence exception due to ASTE sequence number (ASTESN) in access-list entry not being equal to ASTESN in destination ASTE.

8.C.3.C.9 Special-operation exception due to destination-ASTE origin not equal to base-ASTE origin in dispatchable-unit control table and (1) subspace-group bit, bit 54 in address-space-control element in destination ASTE being zero or (2) base-space bit 31, in destination ASTE being one.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 2 of 2)

Programming Notes:

1. See the discussion of BRANCH IN SUBSPACE GROUP in “Subroutine Linkage without the Linkage Stack” on page 5-14. It is intended that there be a separate ASN-second-table entry (ASTE) for each of the base space and each subspace of a subspace group. The ASTEs for the subspaces can be “pseudo” ASTEs as described in the programming note in “Address-Space Number” on page 3-23. A subspace can contain a subset of the storage in the base space by having the DAT tables for the subspace designate a subset of the pages that are designated by the DAT tables for the base space. A dispatchable unit has access to a subspace if an access-list entry designating the ASTE for the subspace is in the primary-space or dispatchable-unit access list of the dispatchable unit.

2. BRANCH IN SUBSPACE GROUP can be used to give control from the base space to a subspace, from a subspace to another subspace, and from a subspace to the base space. The instruction can also be used to give control from the base space to the base space or from a subspace to the same subspace.

3. Since BRANCH IN SUBSPACE GROUP sets the secondary address-space-control element (ASCE) in control register 7 equal to the new primary ASCE in control register 1 (along with setting the secondary ASN in control register 3 equal to the primary ASN in control register 4), the program in an address space given control by BRANCH IN SUBSPACE GROUP does not have access to the calling program’s address space by means of that address space being the secondary address space.

4. When a dispatchable unit has used BRANCH IN SUBSPACE GROUP to enter a subspace and has not subsequently used BRANCH IN SUBSPACE GROUP to return to the base space, the dispatchable unit is said to be “subspace active.” When LOAD ADDRESS SPACE PARAMETERS, PROGRAM CALL, PROGRAM RETURN, PROGRAM TRANSFER, PROGRAM TRANSFER WITH INSTANCE, SET SECONDARY ASN, or SET SECONDARY ASN WITH INSTANCE places an ASCE in control register 1 as the primary ASCE or in control register 7 as the secondary ASCE, and if (1) the ASCE has the subspace-group bit on in it, (2) the dispatchable unit is subspace active, and (3) the ASCE was obtained from the ASN-second-table entry (ASTE) for the base space of the current dispatchable unit, then the instruction (any of the seven named instructions) replaces bits 0-55 and 58-63 of the ASCE in the control register with the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details about the effects of the subspace-group facility on the seven named instructions are given in “Subspace-Replace-

ment Operations” on page 5-70 and in the definitions of the instructions.

5. The use of BRANCH IN SUBSPACE GROUP (BSG) along with PROGRAM CALL (PC) and either PROGRAM TRANSFER (PT) (or PROGRAM TRANSFER WITH INSTANCE) or PROGRAM RETURN (PR) can produce results that may be unexpected. Consider the following sequence of operations:

   a. Start in the base space

   b. BSG to a subspace

   c. PC (the first PC) to an address space that is not in the subspace group.

   d. PC (the second PC) to the base space. Since the dispatchable unit is subspace active, control is given to the subspace.

   e. BSG back to the base space.

   f. PT or PR (paired with the second PC) back to the address space that is not in the subspace group.

   g. PT or PR (paired with the first PC) back to the subspace group. Since the dispatchable unit is no longer subspace active, control is given to the base space even though the first PC was issued in the subspace.

6. BRANCH IN SUBSPACE GROUP does not perform the serialization or checkpoint-synchronization functions, but it does cause all copies of prefetched instructions to be discarded except when in the home-space mode.

7. Unlike the RR-format branch instructions, a value of zero in the R_2 field for BRANCH IN SUBSPACE GROUP designates general register 0, and branching occurs.

8. When the R_2 field designates access register 0, the access register is treated as containing ALET 0 regardless of the contents of the access register.

COMPARE AND REPLACE DAT TABLE ENTRY

CRDTE $R_1,R_3,R_2[,M_4]$ [RRF-b]

'B98F'	R_3	M_4	R_1	R_2	
0	16	20	24	28	31

Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-clearing (LC) control in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.
- When the LC control in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the COMPARE AND REPLACE DAT TABLE ENTRY instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

The first and second operands are compared. If they are equal, the contents of general register $R_1 + 1$ are stored at the second-operand location, and the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the replaced entry in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

If the first and second operands are unequal, the second operand is loaded at the first-operand location. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs. The result of the comparison is indicated by the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The first operand is called the compare value and is contained in bit positions 0-63 of general register R_1.

Bit positions 0-63 of general register $R_1 + 1$ are called the replacement value.

The second operand is a doubleword in storage designated by general registers R_2 and $R_2 + 1$. Bits 59-61 of general register R_2 are the designated-table type (DTT), specifying the bits in general register R_2 that form the origin of a table in storage; the DTT also specifies the bits in general register $R_2 + 1$ that are used as the effective index into the table to locate the second operand, as follows:

DTT (bits 59-61 of Reg. R_2)	Table Type	Table Origin Bits in Reg. R_2	Effective Index Bits in Reg. $R_2 + 1$
000	Page	0-52	44-51
001-011	—	—	—
100	Segment	0-51	33-43
101	Region third	0-51	22-32
110	Region second	0-51	11-21
111	Region first	0-51	0-10

When the DTT is 000 binary, the contents of bit positions 0-52 of general register R_2, with eleven zeros appended on the right, form the table origin, and bits 53-58, 62, and 63 of the register are ignored. When the DTT is 100-111 binary, the contents of bit positions 0-51 of general register R_2, with twelve zeros appended on the right, form the table origin, and bits 52-58, 62, and 63 of the register are ignored. DTT values of 001, 010, and 011 binary are invalid; a specification exception is recognized if the DTT is invalid.

Bits 0-51 of general register $R_2 + 1$ have the format of the region index, segment index, and page index of a virtual address. The part of bits 0-51 normally used by DAT to select an entry in the type of table designated by the DTT is called the effective index. The part of bits 0-51 of general register $R_2 + 1$ to the right of the effective index is ignored. Bit positions 52-53 are reserved for IBM use and must contain zeros; otherwise, results are unpredictable. Bit positions 54-63 of general register $R_2 + 1$ are reserved and must contain zeros; otherwise, a specification exception is recognized.

If R_3 is nonzero, the contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. If R_3 is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-5.

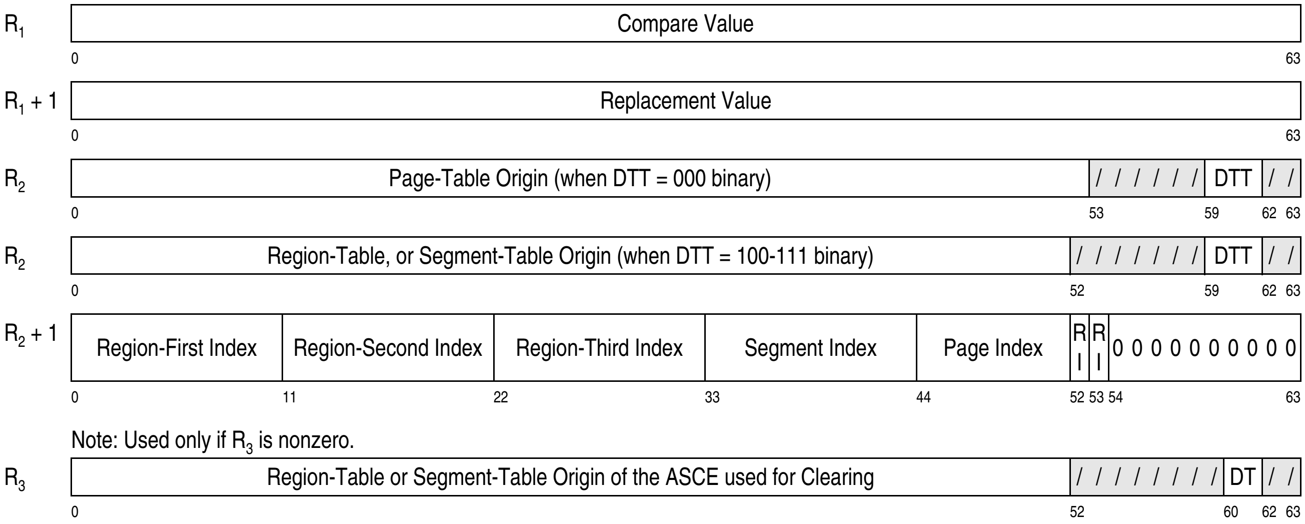


Figure 10-5. Register Contents for COMPARE AND REPLACE DAT TABLE ENTRY

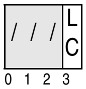
The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved. Reserved bit positions of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- ***Local-Clearing Control (LC):*** The LC bit, bit 3 of the M_4 field controls whether only the TLB in the local CPU is cleared, or whether the TLBs in all CPUs of the configuration are cleared.

When the first and second operands are equal, the contents of general register $R_1 + 1$ are stored at the second-operand location, and the translation-lookaside buffers (TLBs) in the specified CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the original contents of the second operand in storage (that is, the contents of the second operand before it is replaced with the replacement value), and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

Depending on the table type, the table origin in general register R_2 and effective index in general register $R_2 + 1$ designate a table entry in accordance with the rules in “Lookup in a Table Designated by an Address-Space-Control Element” on page 3-57, or “Page-Table Lookup” on page 3-61, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The contents of the table entry are not examined for validity, and no exception conditions are recognized due to the contents of the table entry.

The fetch and store of the table entry are performed as a block-concurrent interlocked update. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

When the first and second operands are equal, this CPU clears selected entries from its TLB. In addition to the clearing of the local CPU, if the LC bit in the M_4 field is zero, all other CPUs in the configuration are signaled to clear selected entries from their TLBs. Each TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective index in general register $R_2 + 1$ matches the corresponding index in the TLB table entry of type designated by the DTT field in bits 59-61 of general register R_2. If the model implements a composite TLB entry that includes the index designated by the DTT field, bits to the left of the effective index in general register $R_2 + 1$ also match any corresponding bits provided in the designated TLB table entry.

- Either the R_3 field is zero , or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

  If the R_3 field is zero, then the condition described in this step does not apply.

- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry, the format control in the replaced entry matches that of the TLB entry.

- If the replaced entry in storage designates a lower-level translation table, the lower-level table origin in the entry matches the table-origin field in the TLB table entry.

- If EDAT-1 applies and the entry replaced in storage is a segment-table entry in which the format control is one, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry in which the format control is one, the segment-frame absolute address or region-frame absolute address, respectively, in the replaced entry matches that of the TLB entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:

- The lower-level TLB table entry was formed through use of the replaced entry in storage or through use of a higher-level TLB table entry formed through use of either the replaced entry in storage or a TLB entry cleared in this process.
- Either the R_3 field is zeroor the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-63 for the meaning of the terminology used here.

  If the R_3 field is zero,, then the condition described in this step does not apply.
- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry, the format control in the replaced entry matches that of the TLB entry.
- If the entry in storage designates a lower-level translation table, the lower-level table origin in the entry matches the table-origin field in the TLB table entry.

When the first and second operands are equal, the execution of COMPARE AND REPLACE DAT TABLE ENTRY is not completed on the CPU which executes it until the following occurs:

1. All entries meeting the criteria specified above have been cleared from the TLB of this CPU. When the LC control in the M_4 field is one, execution of COMPARE AND REPLACE DAT TABLE ENTRY is complete, and the following step is not performed.
2. When the LC control in the M_4 field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits.

The operation does not necessarily have any effect on TLB real-space entries.

Special Conditions

A specification exception is recognized, and the operation is suppressed if any of the following is true:

- Either the R_1 or R_2 field is odd.
- The DTT field, bit positions 59-61 of general register R_2, contain 001, 010, or 011 binary.
- Bit positions 54-63 of general register $R_2 + 1$ contain nonzero values.

It is unpredictable whether a specification exception is recognized if bits 52-53 of general register $R_2 + 1$ contain non-zero values.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by contents of general register $R_1 + 1$
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

Program Exceptions:

- Addressing
- Operation (if the enhanced-DAT facility 2 is not installed)
- Privileged operation
- Protection (fetch and store, region-, segment-, or page-table entry, key-controlled protection and low-address protection)
- Specification
- Transaction constraint

Programming Notes:

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required.

2. When clearing TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.

3. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.

4. The local-clearing control should be specified as one only when either of the following are true; otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

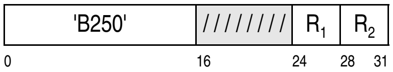
   - The program is running in a uniprocessor configuration.

   - The program is assigned to run on a single CPU and the affinity between the program and that CPU is maintained.

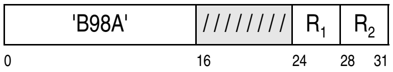
   On some models, use of COMPARE AND REPLACE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

COMPARE AND SWAP AND PURGE

CSP R_1,R_2 [RRE]



CSPG R_1,R_2 [RRE]



The first and second operands are compared. If they are equal, contents of general register $R_1 + 1$ are stored at the second-operand location, and a purging operation is performed. If they are unequal, the second operand is loaded at the first-operand location. The result of the comparison is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For COMPARE AND SWAP AND PURGE (CSP), the first operand is the contents of bit positions 32-63 of general register R_1. The second operand is a word in storage.

For COMPARE AND SWAP AND PURGE (CSPG), the first operand is the contents of bit positions 0-63 of general register R_1. The second operand is a doubleword in storage.

For both CSP and CSPG, the location of the leftmost byte of the second operand is designated by contents of general register R_2.

The purging operation applies to ART-lookaside buffers (ALBs) and translation-lookaside buffers (TLBs) in all CPUs in the configuration. Either ALBs or TLBs, or both ALBs and TLBs, may be selected for purging. All entries are cleared from the selected buffers.

The purging operation is specified by means of bits 62 and 63 of general register R_2. When bit 62 is one, entries are cleared from ALBs. When bit 63 is one, entries are cleared from TLBs. When bits 62 and 63 both are ones, entries are cleared from ALBs and TLBs. When bits 62 and 63 both are zeros, no entries are cleared.

The handling of the address in general register R_2 is dependent on the addressing mode. For CSP in the 24-bit addressing mode, the contents of bit positions 40-61 of general register R_2, with two zeros appended on the right, constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-61 of the register, with two zeros appended on the right, constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-61 of the register, with two zeros appended on the right, constitute the address.

For CSPG in the 24-bit addressing mode, the contents of bit positions 40-60 of general register R_2, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-39 and 61 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-32 and 61 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit position 61 are ignored.

The contents of the registers just described are shown in Figure 10-6 on page 10-22 and Figure 10-7 on page 10-22. When an equal comparison occurs, the contents of bit positions 32-63 of general register R1 + 1 for CSP, or of bit positions 0-63 for CSPG, are stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

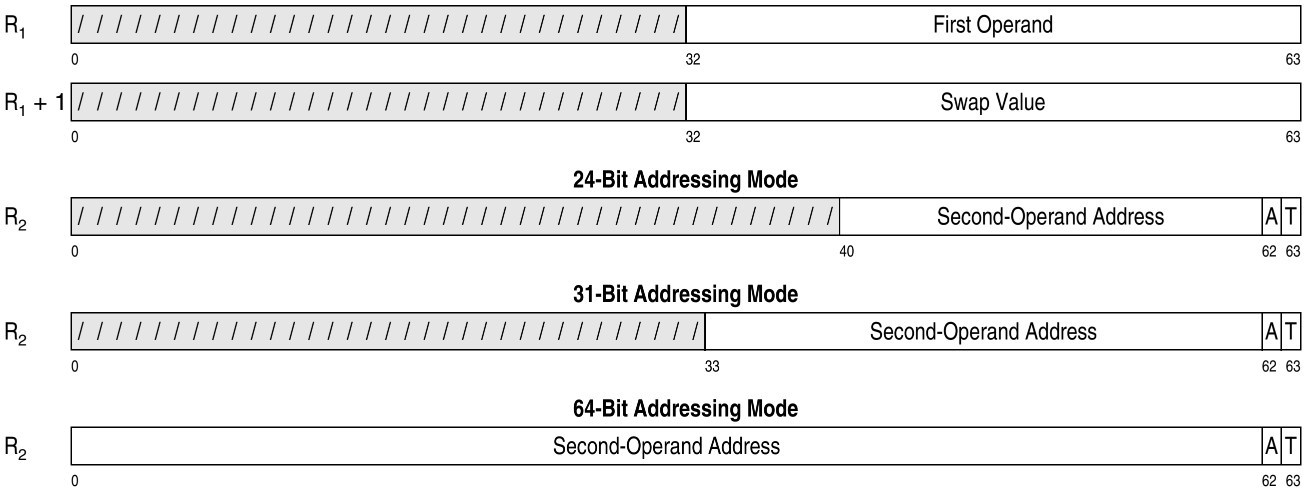


Figure 10-6. Register Contents for COMPARE AND SWAP AND PURGE (CSP)

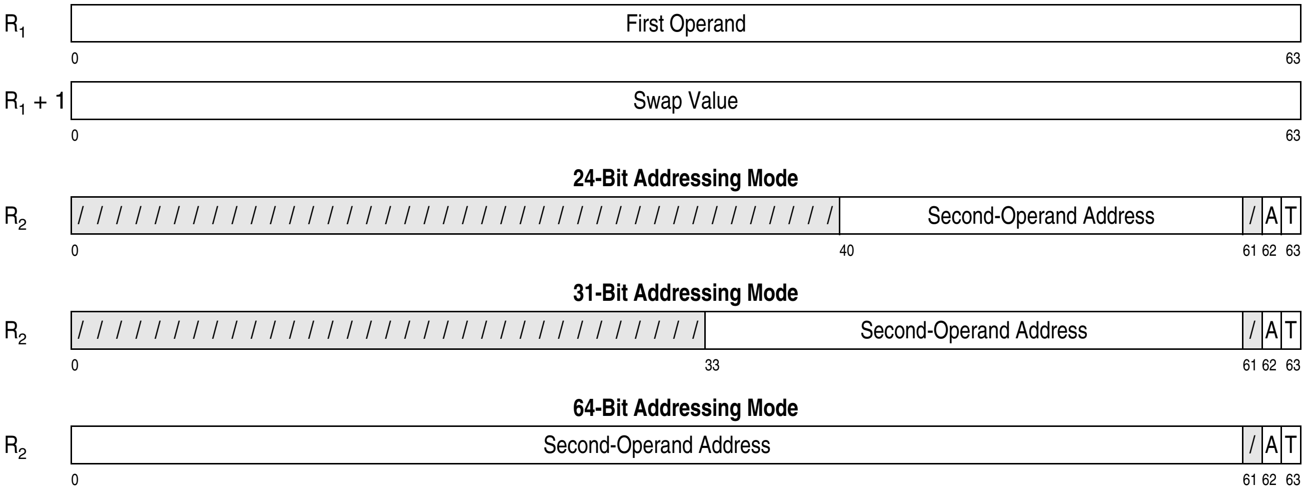

Figure 10-7. Register Contents for COMPARE AND SWAP AND PURGE (CSPG)

When the result of the comparison is unequal, the second-operand is loaded at the first-operand location, bits 0-31 of general register R_1 remain unchanged for CSP only, and the second-operand location remains unchanged. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

When an equal comparison occurs, this CPU clears entries from its ALB and TLB, as specified by bits 62 and 63 of general register R_2, and signals all CPUs in the configuration to clear the same specified entries from their ALBs and TLBs. The ALB entries that are cleared are all ALB access-list designations, access-list entries, ASN-second-table entries, and authority-table entries. The TLB entries that are cleared are all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries, page-table entries, and real-space entries.

Before the TLB purging operation, when bits 62 or 63 of general register R_2 are one, any active transactions on other CPUs in the configuration are aborted with abort code 255, condition code 2.

The execution of COMPARE AND SWAP AND PURGE is not completed on the CPU which executes it until (1) all specified entries have been cleared from the ALB and TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using the specified ALB and TLB entries.

Special Conditions

The R_1 field must designate an even register; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by contents of general register $R_1 + 1$
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if DAT-enhancement facility is not installed, CSPG only)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: COMPARE AND SWAP AND PURGE provides a broadcast form of the PURGE ALB and PURGE TLB instructions, thus making it possible to avoid uses of SIGNAL PROCESSOR.

DIAGNOSE

'83'	
0	8 31

The CPU performs built-in diagnostic functions, or other model-dependent functions. The purpose of the diagnostic functions is to verify proper functioning of equipment and to locate faulty components. Other model-dependent functions may include disabling of failing buffers, reconfiguration of CPUs, storage, and channel paths, and modification of control storage.

Bits 8-31 may be used as in the SI or RS formats, or in some other way, to specify the particular diagnostic function. The use depends on the model.

The execution of the instruction may affect the state of the CPU and the contents of a register or storage location, as well as the progress of an I/O operation. Some diagnostic functions may cause the test indicator to be turned on.

Resulting Condition Code: The code is unpredictable.

Program Exceptions:

- Privileged operation
- Transaction constraint
- Depending on the model, other exceptions may be recognized.

Programming Notes:

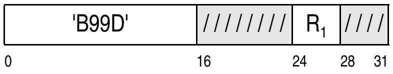
1. Since the instruction is not intended for problem-state-program or control-program use, DIAGNOSE has no mnemonic.

2. DIAGNOSE, unlike other instructions, does not follow the rule that programming errors are distinguished from equipment errors. Improper use of DIAGNOSE may result in false machine-check indications or may cause actual machine malfunctions to be ignored. It may also alter other aspects of system operation, including instruction execution and channel-program operation, to an extent that the operation does not comply with that specified in this publication. As a result of the improper use of DIAGNOSE, the system may be left in such a condition that the power-on reset or initial-microprogram-loading (IML) function must be performed. Since the function performed

by DIAGNOSE may differ from model to model and between versions of a model, the program should avoid issuing DIAGNOSE unless the program recognizes the model number stored by STORE CPU ID.

EXTRACT AND SET EXTENDED AUTHORITY

ESEA R_1 [RRE]



The extended authorization index (EAX), bits 32-47 of control register 8, is saved in bit positions 32-47 of the first operand, and then the EAX in control register 8 is replaced by the contents of bit positions 48-63 of the first operand. Bits 0-31 of the first operand are ignored, and bits 0-31 and 48-63 of the operand remain unchanged.

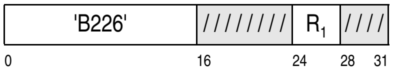
Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

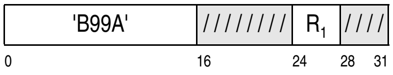
EXTRACT PRIMARY ASN

EPAR R_1 [RRE]



EXTRACT PRIMARY ASN AND INSTANCE

EPAIR R_1 [RRE]



The 16-bit PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register R_1. Bits 32-47 of the general register are set to zeros.

In the EXTRACT PRIMARY ASN AND INSTANCE operation, the PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of general register R_1. In the EXTRACT PRIMARY ASN operation, bits 0-31 of general register R_1 remain unchanged.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, EPAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

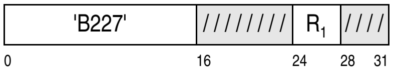
The priority of recognition of program exceptions for the instruction is shown in Figure 10-8.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception if the ASN-and-LX-reuse facility is not installed (EPAIR only).
7.B.2	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-8. Priority of Execution: EXTRACT PRIMARY ASN (AND INSTANCE)

EXTRACT SECONDARY ASN

ESAR R_1 [RRE]



EXTRACT SECONDARY ASN AND INSTANCE

ESAIR R_1 [RRE]

'B99B'	////////	R_1	////
0	16	24	28 31

The 16-bit SASN, bits 48-63 of control register 3, is placed in bit positions 48-63 of general register R_1. Bits 32-47 of the general register are set to zeros.

In the EXTRACT SECONDARY ASN AND INSTANCE operation, the SASTEIN, bits 0-31 of control register 3, is placed in bit positions 0-31 of general register R_1. In the EXTRACT SECONDARY ASN operation, bits 0-31 of general register R_1 remain unchanged.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, ESAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-9.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception if the ASN-and-LX-reuse facility is not installed (ESAIR only).
7.B.2	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-9. Priority of Execution: EXTRACT SECONDARY ASN (AND INSTANCE) (Part 1 of 2)

Figure 10-9. Priority of Execution: EXTRACT SECONDARY ASN (AND INSTANCE) (Part 2 of 2)

EXTRACT STACKED REGISTERS

EREG R_1,R_2 [RRE]

'B249'	////////	R_1	R_2
0	16	24	28 31

EREGG R_1,R_2 [RRE]

'B90E'	////////	R_1	R_2
0	16	24	28 31

Contents of a set of general registers and a set of access registers that were saved in the last state entry in the linkage stack are restored to the registers. Each set of registers begins with register R_1 and ends with register R_2.

For EXTRACT STACKED REGISTERS (EREG), the contents of bit positions 32-63 of the general registers are restored, and the contents of bit positions 0-31 of the registers remain unchanged. For EXTRACT STACKED REGISTERS (EREGG), the contents of bit positions 0-63 of the general registers are restored. In either case, the contents of bit positions 0-31 of the access registers are restored.

For each of the general registers and the access registers, the registers are loaded in ascending order of their register numbers, starting with register R_1 and continuing up to and including register R_2, with register 0 following register 15. The bit positions of each register are loaded from the position in the state entry where the contents of the bit positions were saved when the state entry was created. The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-86. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to references to the linkage stack.

Special Conditions

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-10.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second instruction halfword.

7.B Special-operation exception due to DAT being off or the CPU being in secondary-space mode.

7.C Transaction constraint.

Figure 10-10. Priority of Execution: EXTRACT STACKED REGISTERS (Part 1 of 2)

8. Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.

9. Stack-type exception due to current entry not being a state entry or header entry.

Note: Exceptions 10-14 can occur only if the current entry is a header entry.

10. Access exceptions (fetch) for second word of the header entry.

11. Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

12. Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.

13. Stack-specification exception due to preceding entry being a header entry.

14. Stack-type exception due to preceding entry not being a state entry.

15. Access exceptions (fetch) for the selected contents of the state entry.

Figure 10-10. Priority of Execution: EXTRACT STACKED REGISTERS (Part 2 of 2)

EXTRACT STACKED STATE

ESTA R_1,R_2 [RRE]

'B24A'	////////	R_1	R_2
0	16	24	28 31

Sixty-four or 128 bits of status information in the last state entry in the linkage stack are placed in the pair of general registers designated by the R_1 field. The condition code is set to indicate whether the state entry is a branch state entry or a program-call state entry.

The R_1 field designates the even-numbered register of an even-odd pair of general registers.

Bits 56-63 of general register R_2 are an unsigned binary integer that is used as a code to select the state-entry byte positions, or byte and bit positions, from which information is to be extracted, as shown in Figure 10-11.

Code (Bits 56-63 of GR R_2)	State-Entry Content	State-Entry Byte, or Byte and Bit Positions, Selected
0	PKM, SASN, EAX, and PASN	128-135
1	PSW bits 0-32 and 97-127	136-139, 140.0, and 168-175.33-63 (see text)
2	Branch address or called space and PC number	144-151
3	Modifiable area	152-159
4	PSW bits 0-127	136-143 and 168-175
5	Secondary and primary ASTEIN	176-183

Figure 10-11. EXTRACT STACKED STATE Codes and Extracted State-Entry Fields

For a code of 0, 2, or 3 in bit positions 56-63 of general register R_2, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 32-63 of general register R_1, and the contents of the rightmost four bytes of the status information are placed in bit positions 32-63 of general register $R_1 + 1$. The contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

For a code of 1 in bit positions 56-63 of general register R_2, the contents of bytes 136-139 of the state entry, which are bits 0-31 of the PSW in the state entry, are placed in bit positions 32-63 of general register R_1; the contents of bit position 0 of byte 140 of the entry, which is bit 32 of that PSW, are placed in bit position 32 of general register $R_1 + 1$; and the contents of bit positions 33-63 of bytes 168-175 of the entry, which are bits 97-127 of the PSW, are placed in bit positions 33-63 of general register $R_1 + 1$. However, bit 44 of general register R_1, which corresponds to bit 12 of the PSW in the state entry, is set to one, indicating the extracted PSW is of the short-PSW format (as shown in Figure 4-3 on page 4-8). Also, if bits 0-32 of bytes 168-175 of the state entry are not all zeros, bit 63 of general register $R_1 + 1$ is set to one; otherwise, bit 63 remains with the value loaded from bit position 63 of bytes 168-175 of the state entry. The contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

For a code of 4 in bit positions 56-63 of general register R_2, the contents of bytes 136-143 of the state entry, which are bits 0-63 of the PSW in the state entry, are placed in bit positions 0-63 of general register R_1, and the contents of bytes 168-175 of the state entry, which are bits 64-127 of that PSW, are placed in bit positions 0-63 of general register $R_1 + 1$.

Code 5 in bit positions 56-63 of general register R_2 is valid only if the ASN-and-LX-reuse facility is installed. For code 5, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 0-31 of general register R_1, and the contents of the rightmost four bytes of the status information are placed in bit positions 0-31 of general register $R_1 + 1$. The contents of bit positions 32-63 of general registers R_1 and $R_1 + 1$ remain unchanged.

The format of byte positions 128-183 of the state entry is as follows:

PKM	SASN	EAX	PASN	
128	130	132	134	135

PSW Bits 0-63	
136	143

In a Branch State Entry Made in 24-Bit or 31-Bit Mode

	A	Bits 33-63 of Branch Address
144	148	151

In a Branch State Entry Made in 64-Bit Mode

Bits 0-62 of Branch Address	1
144	151

In a Program-Call State Entry Made When Resulting Mode Is 24 Bit or 31 Bit

Called-Space Id.	0	Numeric Part of PC Number
144	148	151

In a Program-Call State Entry Made When Resulting Mode Is 64 Bit

Called-Space Id.	1	Numeric Part of PC Number

Modifiable Area	
152	159

All Zeros	
160	167

PSW Bits 64-127	
168	175

If ASN-and-LX Reuse Is Enabled; otherwise Unpredictable

Secondary ASTEIN	Primary ASTEIN	
176	180	183

The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-86. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

When the entry-type code in the entry descriptor of the state entry is 0001100 binary, indicating a branch state entry, the condition code is set to 0. When the entry-type code is 0001101 binary, indicating a program-call state entry, the condition code is set to 1.

Key-controlled protection does not apply to references to the linkage stack.

Bits 0-55 of general register R_2 are ignored.

Special Conditions

A specification exception is recognized when R_1 is odd or the code in bit positions 56-63 of general register R_2 is greater than 4 when the ASN-and-LX-reuse facility is not installed or is greater than 5 when the facility is installed.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Branch state entry
1 Program-call state entry
2 --
3 --

Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-12.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
7.C	Transaction constraint.
8.A	Specification exception due to R_1 being odd or bits 56-63 of general register R_2 having a value greater than 4 when the ASN-and-LX-reuse facility is not installed or greater than 5 when the facility is installed.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. **Note**: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Access exceptions (fetch) for second word of the header entry.
8.B.4	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

Figure 10-12. Priority of Execution: EXTRACT STACKED STATE (Part 1 of 2)

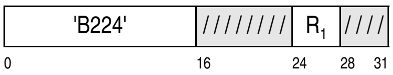
8.B.5	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
8.B.6	Stack-specification exception due to preceding entry being a header entry.
8.B.7	Stack-type exception due to preceding entry not being a state entry.
8.B.8	Access exceptions (fetch) for the selected contents of the state entry.

Figure 10-12. Priority of Execution: EXTRACT STACKED STATE (Part 2 of 2)

Programming Note: The results for a code of 1 in bit positions 56-63 of general register R_2 are intended to provide compatibility with ESA/390. However, the resulting values in bits 32-63 of general registers R_1 correspond to bits 0-31 of the short PSW (shown in Figure 4-3 on page 4-8); that is, the extracted values can indicate a stacked PSW with the extended-addressing control (bit 31) set to one, whereas an ESA/390-format PSW cannot. (It may be that only values of bits in bit positions 0-31 of the PSW are required.) Bit 63 of general register $R_1 + 1$ is set to one if the instruction address in the PSW in the state entry is larger than a 31-bit address.

INSERT ADDRESS SPACE CONTROL

IAC R_1 [RRE]



The address-space-control bits, bits 16 and 17 of the current PSW, are placed in reversed order in bit positions 54 and 55 of general register R_1; that is, bit 16 is placed in bit position 55, and bit 17 is placed in bit position 54. Bits 48-53 of the register are set to zeros, and bits 0-47 and 56-63 of the register remain unchanged. The address-space-control bits are also used to set the condition code.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Resulting Condition Code:

0 PSW bits 16 and 17 zeros (indicating primary-space mode)
1 PSW bit 16 one and bit 17 zero (indicating secondary-space mode)
2 PSW bit 16 zero and bit 17 one (indicating access-register mode)
3 PSW bits 16 and 17 ones (indicating home-space mode)

Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-13.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-13. Priority of Execution: INSERT ADDRESS SPACE CONTROL

Programming Notes:

1. Bits 48-53 of general register R_1 are reserved for expansion for use with possible future facilities. The program should not depend on these bits being set to zeros.

2. INSERT ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL are defined to operate on the seventh byte of a general register so that the address-space-control bits can be saved in the same general register as the PSW

key, which is placed in the eighth byte of general register 2 by INSERT PSW KEY.

INSERT PSW KEY

IPK [S]

'B20B'	////////////////
0	16 31

The four-bit PSW-key, bits 8-11 of the current PSW, is inserted in bit positions 56-59 of general register 2, and bits 60-63 of that register are set to zeros. Bits 0-55 of general register 2 remain unchanged.

Special Conditions

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)
- Transaction constraint

INSERT REFERENCE BITS MULTIPLE

IRBM R_1,R_2 [RRE]

'B9AC'	////////	R_1	R_2
0	16	24	28 31

Beginning with the block designated by the address in general register R_2, the reference bits in the storage keys of the 64 consecutive 4 K-byte blocks are inspected. For each of the 64 blocks, the reference bit is placed in an ascending bit position of general register R_1, beginning with bit position 0 of the register.

General register R_2 designates the first of 64 blocks in absolute storage on a 64-block (256 K-byte) boundary. In the 24-bit addressing mode, bits 40-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-39 and 46-63 of the register are ignored. In the 31-bit addressing mode, bits 33-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-32 and 46-63 of the register are ignored. In the 64-bit addressing mode, bits 0-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 46-63 of the register are ignored.

Because it is an absolute address, the address designating the first storage block is not subject to dynamic address translation or prefixing. The references to the storage keys are not subject to protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Operation (insert-reference-bits-multiple facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: The reference bits provided by the INSERT REFERENCE BITS MULTIPLE instruction provide the control program with a substantially accurate census of the reference bits inspected by the instruction. However, depending on the model, the results returned by the instruction may differ from those provided by the RESET REFERENCE BITS MULTIPLE instruction for the same blocks of storage. Similarly, the results returned by INSERT REFERENCE BITS MULTIPLE may differ from those provided by a series of 64 INSERT STORAGE KEY EXTENDED or RESET REFERENCE BIT EXTENDED instructions for the same blocks of storage.

INSERT STORAGE KEY EXTENDED

ISKE R_1,R_2 [RRE]

'B229'	////////	R_1	R_2
0	16	24	28 31

The storage key for the block that is addressed by the contents of general register R_2 is inserted in general register R_1.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 52-63 of the register are ignored.

The address designating the storage block, being a real address, is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The seven-bit storage key is inserted in bit positions 56-62 of general register R_1, and bit 63 is set to zero. The contents of bit positions 0-55 of the register remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-30 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

INSERT VIRTUAL STORAGE KEY

IVSK R_1,R_2 [RRE]

'B223'	////////	R_1	R_2
0	16	24	28 31

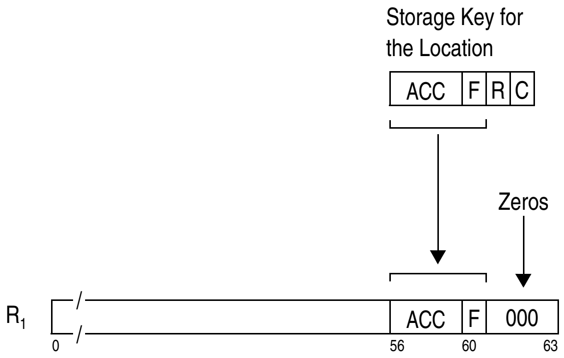
The storage key for the location designated by the virtual address in general register R_2 is inserted in general register R_1.

Selected bits of general register R_2 are used as a virtual address. In the 24-bit addressing mode, the address is specified by bits 40-63 of the register, and bits 0-39 are ignored. In the 31-bit addressing mode, the address is specified by bits 33-63, and bits 0-32 is ignored. In the 64-bit addressing mode, the address is specified by bits 0-63 of the register.

The address is a virtual address and is subject to the address-space-control bits, bits 16 and 17 of the current PSW. The address is treated as a primary virtual address in the primary-space mode, as a secondary virtual address in the secondary-space mode, as an AR-specified virtual address in the access-register mode, or as a home virtual address in the home-space mode. The reference to the storage key is not subject to a protection exception.

Bits 0-4 of the storage key, which are the access-control bits and the fetch-protection bit, are placed in bit positions 56-60 of general register R_1, with bits 61-63 set to zeros. The contents of bit positions 0-55 of the register remain unchanged. The change and reference bits in the storage key are not inspected. The change bit is not affected by the operation. The reference bit, depending on the model, may or may not be set to one as a result of the operation.

The following diagram shows the storage key and the register positions just described.



Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (except for protection, address specified by general register R_2)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-14.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second instruction halfword.

7.B Special-operation exception due to DAT being off.

7.C Transaction constraint.

8. Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero.

9. Access exceptions (except for protection) for address specified by general register R_2.

Figure 10-14. Priority of Execution: INSERT VIRTUAL STORAGE KEY

Programming Notes:

1. Since all bytes in a 4 K-byte block are associated with the same page and the same storage key, bits 52-63 of general register R_2 essentially are ignored. Similarly, since all bytes in a 1 M-byte block are associated with the same segment, bits 44-63 of general register R_2 may be ignored when EDAT-1 applies and the STE-format and ACCF-validity controls are both one. Since all bytes in a 2 G-byte block are associated with the same region, bits 33-63 of general register R_2 may be ignored when EDAT-2 applies and the RTTE-format and ACCF-validity controls are both one.

2. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

INVALIDATE DAT TABLE ENTRY

IDTE $R_1,R_3,R_2[,M_4]$ [RRF-b]

'B98E'	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.

- When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the IDTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

When the clearing-by-ASCE-option bit, bit 52 of general register R_2, is zero, an operation called the invalidation-and-clearing operation is performed, as follows. The designated region-table entry or segment-table entry in storage, or a range of entries beginning with the designated entry, is invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the invalidated entry or entries in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

When the clearing-by-ASCE-option bit is one, an operation called the clearing-by-ASCE operation is performed, as follows. The operation does not perform any invalidation of DAT-table entries in storage, but it does clear, from the TLBs in all CPUs in the configuration, all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries and page-table entries formed to translate addresses in a specified address space.

The two operations are described separately below, before the section “Common Operation.”

The M_4 field has the following format:

/	/	FS	LC
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-1 of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- ***Format-Control Summary (FS):*** When EDAT-2 applies, bit 2 of the M_4 field is the format-control summary (FS) for the invalidation-and-clearing operation. Bit 2 of the M_4 field is ignored for the clearing-by-ASCE operation and when EDAT-2 does not apply.

  The format-control summary applies when the designation type (DT), bits 60-61 of the general register R_1, is 00 or 01 binary; when the DT in general register R_1 is 10 or 11 binary, the format-control summary is ignored. The meaning of the FS bit is as follows:

Value	Meaning
0	The format control is not known to be one in all of the table entries designated by the effective invalidation index and additional-entry count.
1	The format control is one in all of the table entries designated by the effective invalidation index and additional-entry count.

- ***Local-Clearing Control (LC):*** When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M_4 field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When the local-TLB-clearing facility is not installed, bit 3 of the M_4 field is ignored.

Invalidation-and-Clearing Operation

When bit 52 of general register R_2, the clearing-by-ASCE-option bit, is zero, the invalidation-and-clearing operation is specified.

The contents of general register R_1 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. The table origin designates the DAT table in which one or more entries are to be invalidated, and DT specifies the type of that table.

Bits 52-59, 62, and 63 of general register R_1 are ignored.

Bits 0-43 of general register R_2 have the format of the region index and segment index of a virtual address. The part of bits 0-43 normally used by DAT to select an entry in the type of table designated by general register R_1 is called the effective invalidation index.

Bits 60 and 61 of general register R_1 specify a table type and an effective invalidation index as follows:

Bits 60 and 61 of Reg. R_1	Table Type	Effective Invalidation Index in Reg. R_2
11	Region first table	Region first index (bits 0-10)
10	Region second table	Region second index (bits 11-21)
01	Region third table	Region third index (bits 22-32)
00	Segment table	Segment index (bits 33-43)

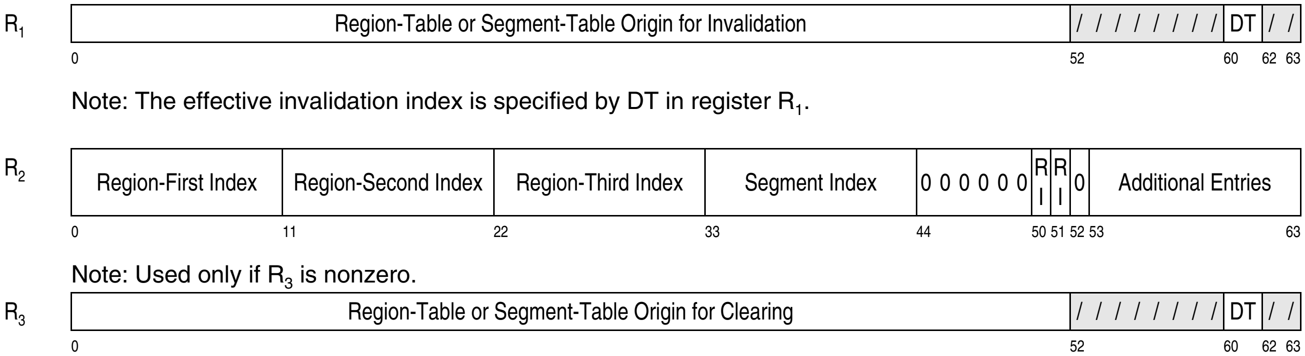
The part of bits 0-43 of general register R_2 to the left (if any) and to the right of the effective invalidation index is ignored.

The table origin in general register R_1 and the effective invalidation index designate a DAT-table entry to be invalidated. Bits 53-63 of general register R_2 are an unsigned binary integer specifying the number of additional table entries to be invalidated. Therefore, the number of entries to be invalidated is 1-2,048, corresponding to a value of bits 53-63.

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized. It is unpredictable if a specification exception is recognized if bits 50 and 51 of general register R_2 contain non-zero values.

If R_3 is nonzero, the contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. If R_3 is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-15.



Note: The effective invalidation index is specified by DT in register R_1.

Note: Used only if R_3 is nonzero.

Figure 10-15. Register Contents for INVALIDATE DAT TABLE ENTRY Invalidation-and-Clearing Operation (Bit 52 of GR R_2 Is Zero)

The table origin in general register R_1 and effective invalidation index in general register R_2 designate a table entry in accordance with the rules in "Lookup in a Table Designated by an Address-Space-Control Element" on page 3-57, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The invalid bit, bit 58, of this doubleword is set to one. During this procedure, the entry is not checked for a format error or for whether the origin, in the entry, of the next-lower-level table would cause an addressing exception. The table-type field in the entry is ignored. If the DT field in bits 60-61 of general register R_1 designates a segment-table entry, the common-segment bit in the entry is ignored. If EDAT-2 applies and the DT field designates a region-third-table entry, the common-region bit in the entry is ignored.

The entire table entry is fetched concurrently from storage. Subsequently, the byte containing the invalid bit is stored. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

If bits 53-63 of general register R_2 are not all zeros, the setting of the invalid bit to one in a region-table or segment-table entry is repeated by adding one to the previously used value of the effective invalidation index, and this is done as many times as are specified by bits 53-63. A carry out of the leftmost bit position of the effective invalidation index is ignored, and wraparound in the table occurs in this case. The contents of general register R_2 remain unchanged.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

After it has set an invalid bit to one, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M_4 field is zero, this CPU signals all other CPUs in the configuration to clear selected entries from their TLBs. Each affected TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective invalidation index in general register R_2 matches the corresponding index in the TLB table entry of type designated by the DT field in bits 60-61 of general register R_1. If the model implements a composite TLB entry that includes the index designated by the DT field, bits to the left of the effective index in general register R_2 also match any corresponding bits provided in the designated TLB table entry. Note that when multiple table entries are invalidated due to bits 53-63 of general register R_2, then the effective invalidation index is incremented, a carry out of the leftmost bit position of the index is lost, and TLB region- or segment-table entries are cleared for each value of the index so obtained.

- Either the R_3 field is zero, or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

  If the R_3 field is zero, then the condition described in this step does not apply.

- If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:

- The lower-level TLB table entry was formed through use of an entry invalidated in storage or through use of a higher-level TLB table entry formed through use of either an entry invalidated in storage or a TLB entry cleared in this process.

- Either the R_3 field is zero or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-63 for the meaning of the terminology used here.

  If the R_3 field is zero, then the condition described in this step does not apply.

- If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Programming Notes:

1. Setting the format-control summary to one may provide improved performance on certain models.

2. When the designation type (DT), bits 60-61 of general register R_1, is 00 binary, the format-control summary applies to the segment-table entries being invalidated. When the DT in general register R_1 is 01 binary, the format-control summary applies to the region-third-table entries being invalidated.

3. The program should only set the format-control summary to one if it can ensure that format control (bit 53 of the table entry) is one in all of the table entries being invalidated. If the format-control summary is set to one, but the format control is not one in all of the table entries being invalidated, incomplete purging of the TLB may occur, resulting in unpredictable results from DAT.

4. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.

Storing in the region- or segment-table entry and the clearing of TLB entries may or may not occur if the invalid bit is already one in the region- or segment-table entry.

When multiple entries are invalidated, clearing of TLB entries may be delayed until all entries have been invalidated.

Clearing-by-ASCE Operation

When bit 52 of general register R_2, the clearing-by-ASCE-option bit, is one, the clearing-by-ASCE operation is specified.

The contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. R_3 may be zero or nonzero, that is, any general register, including register 0, may be designated.

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized. It is unpredictable if a specification exception is recognized if bits 50 and 51 of general register R_2 do not contain zero values.

The contents of general register R_1 and of bit positions 0-43 and 53-63 of general register R_2 are ignored.

The contents of the general registers just described are shown in Figure 10-16.

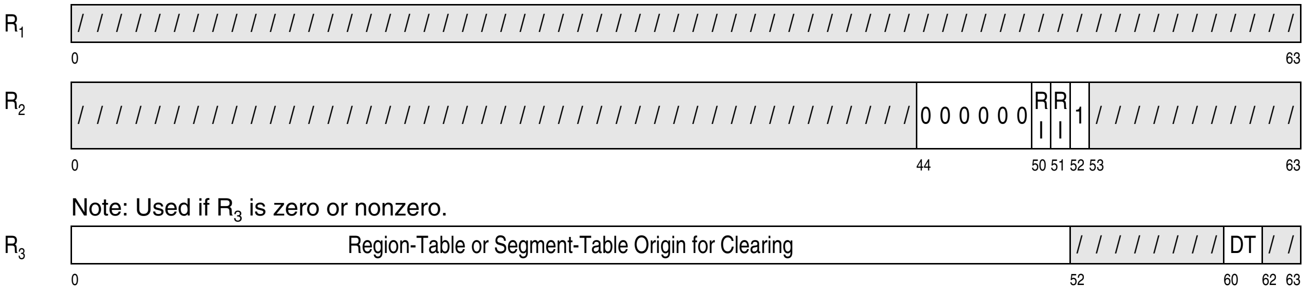


Figure 10-16. Register Contents for INVALIDATE DAT TABLE ENTRY Clearing-by-ASCE Operation (Bit 52 of GR R2 Is One)

The TLBs of the specified CPU or CPUs in the configuration are cleared at all levels of at least those entries for which the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the entry. This ASCE is the one used in the translation during which the entry was formed. See “Formation of TLB Entries” on page 3-63 for the meaning of the terminology used here.

When the clearing-by-ASCE-option bit (bit 52 of general register R_2) is one, the format-control summary bit (bit 2 of the M_4 field) is ignored.

Common Operation

The execution of INVALIDATE DAT TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All entries meeting the criteria specified above have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, execution of INVALIDATE DAT TABLE ENTRY is complete at this point and the following step is not performed.
2. When the local-TLB-clearing facility is not installed, or when the facility is installed and the LC bit in the M_4 field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

The operations do not necessarily have any effect on TLB real-space entries.

Special Conditions

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized.

It is unpredictable whether a specification exception is recognized if bits 44-49 of general register R_2 contain non-zero values.

The operation is suppressed on all addressing and protection exceptions (invalidation-and-clearing operation only).

Resulting Condition Code: The code is unpredictable.

Program Exceptions:

- Addressing (invalidated region- or segment-table entry, invalidation-and-clearing operation only).
- Operation (if the DAT-enhancement facility is not installed)
- Privileged operation
- Protection (fetch and store, region- or segment-table entry, key-controlled protection and low-address protection; invalidation-and-clearing operation only).
- Specification
- Transaction constraint

Programming Notes:

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. When the invalidation-and-clearing operation is performed, some models may clear all TLB entries when the effective invalidation index is not a segment index or may clear an entry regardless of the page-table origin in the entry. When that operation or the clearing-by-ASCE operation is performed, some models may clear a TLB entry regardless of the designation-type field in general register R_3. When either operation is performed, other models may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. When using the clearing-by-ASCE operation to clear TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.

The following notes apply when the invalidation-and-clearing operation is specified.

3. The clearing of TLB entries may make use of the page-table origin in a segment-table entry. Therefore, if the segment-table entry, when in the attached state, ever contained a page-table origin that is different from the current value, copies of entries containing the previous values may remain in the TLB.

4. INVALIDATE DAT TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

5. The address of the DAT-table entry for INVALIDATE DAT TABLE ENTRY is a 64-bit address, and the address arithmetic is performed by following the normal rules for 64-bit address arithmetic, with wraparound at 2^{64} - 1. Also, offset and length fields are not used. Contrast this with implicit translation and the translations for LOAD REAL ADDRESS and STORE REAL ADDRESS, all of which may result either in wraparound or in an addressing exception when a carry occurs out of bit position 0 and which indicate an exception condition when the designated entry does not lie within its table. Accordingly, the DAT tables should not be specified to wrap from maximum storage locations to location 0, and the first designated entry and all additional entries specified by bits 53-63 of general register R_2 should lie within the designated table.

6. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IDTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

   On some models, use of INVALIDATE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

7. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.

INVALIDATE PAGE TABLE ENTRY

IPTE $R_1,R_2[,R_3[,M_4]]$ [RRF-a]

'B221'	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.
- When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the IPTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

The designated page-table entries are invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of the associated entries.

The contents of general register R_1 have the format of a segment-table entry, with only the page-table origin used. The contents of general register R_2 have the format of a virtual address, with only the page index used. The contents of fields that are not part of the page-table origin or page index are ignored.

When the IPTE-range facility is not installed, or when the R_3 field is zero, the single page-table entry designated by the first and second operands is invalidated.

When the IPTE-range facility is installed and the R_3 field is nonzero, bits 56-63 of general register R_3 contain an unsigned binary integer specifying the count of additional page-table entries to be invalidated. Therefore, the number of page-table entries to be invalidated is 1-256, corresponding to a value of 0-255 in bits 56-63 of the register. Bits 0-55 of the register should be set to zero; otherwise, the program may not operate compatibly in the future.

When the IPTE-range facility is installed in the z/Architecture architectural mode, it is unpredictable whether it is installed in the ESA/390-compatibility mode.

The contents of the general registers just described are shown in Figure 10-17 .

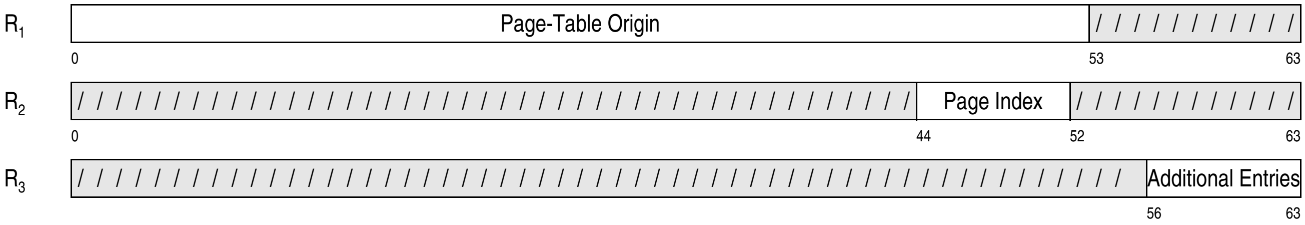

Figure 10-17. Register Contents for INVALIDATE PAGE TABLE ENTRY

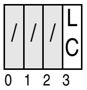
When the IPTE-range facility is not installed, the R_3 field is ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved. Reserved bit positions of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Local-Clearing Control (LC):*** When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M_4 field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When the local-TLB-clearing facility is not installed, bit 3 of the M_4 field is reserved.

The page-table origin and the page index designate a page-table entry, following the dynamic-address-translation rules for page-table lookup. In the z/Architecture architectural mode, the page-table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode, which is specified by bits 31 and 32 of the current PSW. A carry out of bit position 0 as a result of the addition of the page index and page-table origin cannot occur. In the ESA/390-compatibility mode, it is unpredictable whether the page-table origin and page index are treated as in the z/Architecture architectural mode, or the page-table origin is treated as a 31-bit address and the page-table index is multiplied by four (as in the ESA/390 architectural mode). The address formed from these two components is a real or absolute address.

The page-invalid bit of this page-table entry is set to one. During this procedure, the page-table entry is not inspected for whether the page-invalid bit is already one or for format errors. Additionally, the page-frame real address contained in the entry is not checked for an addressing exception. In the z/Architecture architectural mode, the page-invalid bit is bit 53 of the doubleword PTE. In the ESA/390-compatibility mode, it is unpredictable whether the page invalid bit is bit 53 of the doubleword PTE or bit 21 of the word PTE.

When the IPTE-range facility is installed and the R_3 field is nonzero, the instruction is interruptible, and processing is as follows:

1. The invalidation process described above is repeated for each subsequent entry in the page table until either the number of additional entries specified in bits 56-63 of general register R_3 have been invalidated or an interruption occurs.

2. The page-index in bits 44-51 of general register R_2 is incremented by the number of page-table entries that were invalidated; a carry out of bit position 44 of general register R_2 is ignored.

3. The additional-entry count in bits 56-63 of general register R_3 is decremented by the number of page-table entries that were invalidated.

Therefore, whenthe IPTE-range facility is installed, the R_3 field is nonzero, and an interruption occurs (other than one that causes termination), general registers R_2 and R_3 have been updated, so that the instruction, when reexecuted, resumes at the point of interruption.

When the IPTE-range facility is not installed, or when the R_3 field is zero, the contents of registers R_2, and R_3 remain unchanged.

For each page-table entry that is invalidated, the entire page-table entry appears to be fetched concurrently from storage as observed by other CPUs. Subsequently, the byte containing the page-invalid bit is stored. The fetch access to each page-table entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

If no exceptions are recognized, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M_4 field is zero, this CPU signals all CPUs in the configuration to clear selected entries from their TLBs. For each page-table entry invalidated, each affected TLB is cleared of at least those entries that have been formed using all of the following:

- The page-table origin specified by general register R_1

- The page index specified by general register R_2

- The page-frame real address contained in the designated page-table entry

When the local-TLB-clearing facility is installed in the z/Architecture architectural mode, it is unpredictable whether the facility is installed in the ESA/390-compatibility mode.

The execution of INVALIDATE PAGE TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All page-table entries corresponding to the specified parameters have been invalidated.

2. All entries corresponding to the specified parameters have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the execution of INVALIDATE PAGE TABLE entry is complete at this point and the following step is not performed.

3. When the local-TLB-clearing facility is not installed, or when the facility is installed and LC bit in the M_4 field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change

and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

Special Conditions

When the IPTE-range facility is installed, the R_3 field is nonzero, and the page index in general register R_2 plus the additional-entry count in general register R_3 is greater than 255, a specification exception is recognized.

The unit of operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (page-table entry)
- Privileged operation
- Protection (fetch and store, page-table entry, key-controlled protection, and low-address protection)
- Specification
- Transaction constraint

Programming Notes:

1. The selective clearing of entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. Some models may clear all entries which contain the page-frame real addresses obtained from the page-table entries in storage. Others may clear all entries which contain the designated page index (or indices), and some implementations may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. The clearing of TLB entries may make use of the page-frame real addresses in the page-table entries. Therefore, if the page-table entries, when in the attached state, ever contained page-frame real addresses that are different from the current values, copies of entries containing the previous values may remain in the TLB.

3. INVALIDATE PAGE TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

4. When the IPTE-range facility is installed and the R_3 field is nonzero, the following applies:

   a. All of the page-table entries to be invalidated must reside in the same page table. A specification exception is recognized if the page index in general register R_1 plus the additional-entry count in general register R_3 is greater than the maximum page index of 255.

   b. The number of page-table entries that are invalidated by INVALIDATE PAGE TABLE ENTRY may vary from one execution to another.

   c. The instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not use INVALIDATE PAGE TABLE ENTRY to invalidate a page-table entry, the page-frame-real address of which designates the 4 K-byte block containing the instruction or of an execute-type instruction that executes the IPTE.

   d. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

5. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IPTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

On some models, use of INVALIDATE PAGE TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

6. The R_3 and M_4 fields of the instruction are considered to be optional, as indicated by the fields being contained within brackets [ ] in the assembler syntax. When either field is not specified, the assembler places zeros in the corresponding field of the instruction. When the M_4 field is coded but the R_3 field is not required, a zero should be coded to designate the place of the third operand.

LOAD ADDRESS SPACE PARAMETERS

LASP $D_1(B_1),D_2(B_2)$ [SSE]

'E500'	B_1	D_1	B_2	D_2
0	16	20	32	36 47

The first operand contains values to be loaded into control registers 3 and 4, including a secondary ASN (SASN) and a primary ASN (PASN), and, possibly, a secondary ASTE instance number (SASTEIN) and a primary ASTE instance number (PASTEIN). Execution of the instruction consists in performing four major steps: PASN translation, SASN translation, SASN authorization, and control-register loading. Each of these steps may or may not be performed, depending on the outcome of certain tests and on the setting of bits 61-63 of the second-operand address. The first three of these steps, when performed and successful, obtain additional values, that are loaded into control registers 1, 5, and 7. When the first three steps are not successful when performed, no control registers are changed, and the reason is indicated in the condition code.

When the ASN-and-LX-reuse facility is not installed, or is installed but is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the first operand is a doubleword containing a PSW-key mask (PKM), a SASN, an authorization index (AX), and a PASN. When the ASN-and-LX-reuse facility is installed and enabled, the first operand is two consecutive doublewords containing those four values and also a SASTEIN and a PASTEIN.

The primary ASN may be translated by means of the ASN-translation tables to obtain a primary-ASTE (PASTE) origin (PASTEO) and, from the PASTE, a primary ASCE (PASCE). The secondary ASN may be translated by means of the ASN-translation tables to obtain a secondary ASCE (SASCE). If the first operand is two doublewords and PASN or SASN translation occurs, the ASTEIN in the located ASTE is checked for being equal to the PASTEIN or SASTEIN, respectively, in the first operand. An authority check for ensuring that the new AX is authorized to establish the new SASN can be prevented when SASN translation occurs, or it can be required and cause SASN translation even when SASN translation would not otherwise occur. The new AX, which is placed in a control register and is used in SASN authorization if that occurs, is the old AX if PASN translation has not occurred or is the AX in the located PASTE otherwise. However, in either of these cases, the new AX may be the AX specified in the first operand.

A doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Not Enabled

PKM-d	SASN-d	AX-d	PASN-d
0	16	32	48 63

A two-doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Enabled

SASTEIN-d	PKM-d	SASN-d
0	32	48 63

PASTEIN-d	AX-d	PASN-d
64	96	112 127

The “d” stands for designated value and is used to distinguish these fields from other fields with similar names which are referred to in the definition. The current contents of the corresponding fields in the control registers are referred to as SASTEIN-old, PKM-old, SASN-old, etc. The updated contents of the control registers are referred to as SASTEIN-new, PKM-new, SASN-new, etc.

The second-operand address is not used to address data; instead, the rightmost three bits are used to control portions of the operation. The remainder of the second-operand address is ignored. Bits 61-63 of the second-operand address are used as follows:

	Function Specified in Second-Operand Address	
Bit	When Bit Is Zero	When Bit Is One
61	ASN translation performed only when new ASN and old ASN are different.	ASN translation performed.*
62	AX associated with new PASN used.	AX in first operand used.
63	SASN authorization performed.*	SASN authorization not performed.

Explanation:

* SASN translation and SASN authorization are performed only when SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, the SASCE is set equal to the PASCE, the SASTEIN is set equal to the PASTEIN (if ASN-and-LX reuse is enabled), and no authorization is performed.

The operation of LOAD ADDRESS SPACE PARAMETERS is depicted in Figure 10-21 on page 10-49.

Note: In the following sections, the actions involving the PASTEIN and SASTEIN occur only if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0.

PASN Translation and Related Processing

In the PASN-translation process, the PASN-d is translated by means of the ASN first table and the ASN second table. The PASTEO resulting from PASN translation replaces the PASTEO in control register 5. The ASCE in the located ASTE replaces the PASCE in control register 1. When bit 62 of the second-operand address is zero, the AX in the ASTE replaces the AX in control register 4. When bit 62 is one, AX-d replaces the AX in the control register. When ASN-and-LX reuse is enabled, PASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the PASTEIN in control register 4.

When bit 61 of the second-operand address is one, PASN translation is always performed. When bit 61 is zero, PASN translation is performed only if PASN-d is not equal to PASN-old. When bit 61 is zero and PASN-d is equal to PASN-old, the PASCE-old, PASTEO-old, and PASTEIN-old are left unchanged in the control registers and become the PASCE-new, PASTEO-new, and PASTEIN-new, respectively. In this case, if bit 62 is zero, then the AX-old is left unchanged in the control register and becomes the AX-new, or, if bit 62 is one, AX-new is set equal to AX-d.

The PASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 1 is set. Condition code 1 is also set if PASN translation occurs, the ASN-and-LX-reuse facility is enabled, and PASTEIN-d is not equal to the ASTEIN in the ASTE. When a reason for setting condition code 1 does not exist and either the current primary space-switch-event-control bit in control register 1 is one or the space-switch-event-control bit in the ASTE is one, a space-switch event does not occur; instead, condition code 3 is set. When condition code 1 or 3 is set, the control registers remain unchanged.

The contents of the AX, ASCE, and ASTEIN fields in the ASTE which is accessed as a result of the PASN translation are referred to as AX-p, ASCE-p, and ASTEIN-p, respectively. The origin of the ASTE is referred to as PASTEO-p.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-p has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-p, is one, (2) the dispatchable unit is subspace active, and (3) PASTEO-p designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-p, called ASCE-rp, is made, and bits 0-55 and 58-63 of ASCE-rp are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-70. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 1 is set, and the control registers remain unchanged.

SASN Translation and Related Processing

In the SASN-translation process, the SASN-d is translated by means of the ASN first table and the ASN second table. The ASCE field obtained from the ASTE subsequently replaces the secondary ASCE (SASCE) in control register 7. When ASN-and-LX reuse is enabled, SASTEIN-d is compared to the

ASTEIN in the ASTE, and, when equal, replaces the SASTEIN in control register 3.

SASN translation is performed only when, but not necessarily when, SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, SASCE-new and SASTEIN-new are set equal to PASCE-new and PASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to PASTEIN-d; SASTEIN-d is ignored. When SASN-d is not equal to PASN-d and is equal to SASN-old, bit 61 (force ASN translation) is zero, and bit 63 (skip SASN authorization) is one, SASN translation is not performed, and SASCE-old and SASTEIN-old become SASCE-new and SASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to SASTEIN-old; SASTEIN-d is ignored.

SASN translation is performed in each of the following cases:

- SASN-d is not equal to PASN-d or SASN-old.
- SASN-d is not equal to PASN-d but is equal to SASN-old, and either bit 61 (force ASN translation) of the second-operand address is one or bit 63 (skip secondary authority test) of that address is zero. (The translation must be performed when bit 63 is zero in order to obtain the ATO and ATL from the SASTE.)

The SASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 2 is Condition code 2 is also set if SASN translation occurs, the ASN-and-LX-reuse facility is enabled, and SASTEIN-d is not equal to the ASTEIN in the ASTE. When condition code 2 is set, the control registers remain unchanged.

The contents of the ASCE, ATO, ATL and ASTEIN fields in the ASTE which is accessed as a result of the SASN translation are referred to as ASCE-s, ATO-s, ATL-s, and ASTEIN-s, respectively. The origin of the ASTE is referred to as SASTEO-s.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-s has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-s, is one, (2) the dispatchable unit is subspace active, and (3) SASTEO-s designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-s, called ASCE-rs, is made, and bits 0-55 and 58-63 of ASCE-rs are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-70. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 2 is set, and the control registers remain unchanged.

SASN Authorization

SASN authorization is performed when bit 63 of the second-operand address is zero and SASN-d is not equal to PASN-d; it is performed in this case regardless of whether SASN-d is equal to SASN-old. When SASN-d is equal to PASN-d or when bit 63 of the second-operand address is one, SASN authorization is not performed.

SASN authorization is performed by using ATO-s, ATL-s, and the intended value for AX-new. When bit 62 of the second-operand address is zero and PASN translation was performed, the intended value for AX-new is AX-p. When bit 62 of that address is zero and PASN translation was not performed, the AX is not changed, and AX-new is the same as AX-old. When bit 62 of that address is one, the intended value for AX-new is AX-d. SASN authorization follows the rules for secondary authorization as described in “ASN-Authorization Process” on page 3-36. If the SASN is not authorized (that is, the authority-table length is exceeded, or the selected bit is zero), condition code 2 is set, and none of the control registers is updated.

Control-Register Loading

When the PASN-translation and SASN-translation functions and related functions, and the SASN-authorization functions and subspace-replacement operations, if called for in the instruction execution, are performed without encountering any exceptions or exception conditions, the execution is completed by replacing the contents of control registers 1, 3, 4, 5, and 7 with the new values, and condition code 0 is set. The control registers are loaded as follows.

The PSW-key-mask, bits 32-47, and SASN, bits 48-63, in control register 3 are replaced by the contents of the PKM-d and SASN-d fields of the first operand.

If ASN-and-LX reuse is enabled, the SASTEIN, bits 0-31, in control register 3 is replaced as follows:

- When SASN translation is performed, by SASTEIN-d.
- When SASN translation is not performed because SASN-d is equal to PASN-d, by PASTEIN-new.
- When SASN translation is not performed because (1) SASN-d is not equal to PASN-d but is equal to SASN-old, (2) bit 61 (force ASN translation) of the second-operand address is zero, and (3) bit 63 (skip secondary authority test) of the second-operand address is one, the SASTEIN remains unchanged.

When ASN-and-LX reuse is not enabled, bits 0-31 of control register 3 always remain unchanged.

The PASN, bits 48-63 of control register 4, is replaced by the PASN-d of the first operand. If ASN-and-LX reuse is enabled, the PASTEIN, bits 0-31 of control register 4, is replaced by the PASTEIN-d of the first operand; otherwise, bits 0-31 of the register remain unchanged.

The authorization index, bits 32-47 of control register 4, is replaced as follows:

- When bit 62 of the second-operand address is one, by AX-d.
- When bit 62 of the second-operand address is zero and PASN translation is performed, by AX-p.
- When bit 62 of the second-operand address is zero and PASN translation is not performed, the authorization index remains unchanged.

The primary address-space-control element (PASCE) in control register 1 and the primary-ASN-second-table-entry origin (PASTEO) in control register 5 are replaced as follows:

- When PASN translation is performed, the PASCE in control register 1 is replaced by the ASCE-p obtained as a result of PASN translation, except that it is replaced by ASCE-rp if a subspace-replacement operation was performed on ASCE-p. Also, the PASTEO in control register 5 is replaced by PASTEO-p.

  The PASTEO-p is placed in bit positions 33-57 of control register 5, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.
- When PASN translation is not performed, the contents of control registers 1 and 5 remain unchanged.

The secondary address-space-control element (SASCE) in control register 7 is replaced as follows:

- When SASN-d equals PASN-d, by the new contents of control register 1, the PASCE. The new contents may be PASCE-old, ASCE-p, or ASCE-rp.
- When SASN translation is performed, by ASCE-s, or by ASCE-rs if a subspace-replacement operation was performed on ASCE-s.

When SASN-d does not equal PASN-d and SASN translation is not performed, the SASCE remains unchanged.

Other Condition-Code Settings

When PASN translation is called for and cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and PASTEIN-d does not equal the ASTEIN in the ASTE or (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-p, condition code 1 is set, and the control registers are not changed.

When PASN translation is called for and completed and any required PASTEIN-d comparison and subspace-replacement operations on the ASCE-p are also completed, and then either (1) the current primary space-switch-event-control bit, bit 57 of control register 1, is one or (2) the space-switch-event-control bit in the ASTE designated by PASTEO-p is one, condition code 3 is set, and the control registers are not changed.

When SASN translation is called for and the translation cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and SASTEIN-d does not equal the ASTEIN in the ASTE, (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-s, or (3) SASN authorization is called for and the SASN is not authorized, or condition code 2 is set, and the control registers are not changed.

Special Conditions

The instruction can be executed only when the ASN-translation control, bit 44 of control register 14, is one. If the ASN-translation-control bit is zero, a special-operation exception is recognized.

The first operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, one of the following exceptions is recognized: (a) an operation exception, (b) a privileged-operation exception when the CPU is in the problem state, (c) a special-operation exception when bit 44 of control register 14 is zero, or (d) a specification exception when the first operand is not on a doubleword boundary. It is unpredictable which exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Figure 10-20 on page 10-48 and Figure 10-18 on page 10-45 summarize the functions of the instruction.

Resulting Condition Code:

0 Translation and authorization complete; parameters loaded
1 Primary ASN or subspace not available; parameters not loaded
2 Secondary ASN not available or not authorized, or secondary subspace not available; parameters not loaded
3 Space-switch event specified; parameters not loaded

Program Exceptions:

- Access (fetch, operand 1)
- Addressing (ASN-first-table entry, ASN-second-table entry, authority-table entry, dispatchable-unit control table)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-18.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B.1	Privileged-operation exception.
7.B.2	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero.
7.C	Transaction constraint.
7.D	Operation exception (in the ESA/390-compatibility mode)
8.	Specification exception.
9.	Access exceptions for the first operand.
10.	PASN translation and related processing (when performed).
10.1	Addressing exception for access to ASN-first-table entry.
10.2	Condition code 1 due to I bit (bit 0) in ASN-first-table entry being one.
10.3	Addressing exception for access to ASN-second-table entry.
10.4	Condition code 1 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and primary ASTE instance number (PASTEIN) in first operand not being equal to ASTEIN in ASTE.
10.5	Addressing exception for access to dispatchable-unit control table.

Figure 10-18. Priority of Execution: LOAD ADDRESS SPACE PARAMETERS (Part 1 of 2)

10.6 Addressing exception for access to subspace ASN-second-table entry.

10.7 Condition code 1 due to I bit (bit 0) in subspace ASN-second-table entry being one.

10.8 Condition code 1 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

10.9 Condition code 3 due to either the old or new space-switch-event-control bit being one.

11. SASN translation and related processing (when performed).

11.1 Addressing exception for access to ASN-first-table entry.

11.2 Condition code 2 due to I bit (bit 0) in ASN-first-table entry being one.

11.3 Addressing exception for access to ASN-second-table entry.

11.4 Condition code 2 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and secondary ASTE instance number (SASTEIN) in first operand not being equal to ASTEIN in ASTE.

12.A Execution of secondary authorization (when performed).

12.A.1 Condition code 2 due to authority-table entry being outside table.

12.A.2 Addressing exception for access to authority-table entry.

12.A.3 Condition code 2 due to S bit in authority-table entry being zero.

12.B.1 Addressing exception for access to dispatchable-unit control table.

12.B.2 Addressing exception for access to subspace ASN-second-table entry.

12.B.3 Condition code 2 due to I bit (bit 0) in subspace ASN-second-table entry being one.

12.B.4 Condition code 2 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

Figure 10-18. Priority of Execution: LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2)

Programming Notes:

1. Bits 61 and 63 in the second-operand address are intended primarily to provide improved performance for those cases where the associated action is unnecessary.

   When bit 61 is set to zero, the action of the instruction is based on the assumption that the current values for PASCE-old, PASTEO-old, and AX-old are consistent with PASN-old and that SASCE-old is consistent with SASN-old. When this is not the case, bit 61 should be set to one.

   Bit 63, when one, eliminates the SASN-authorization test. The program may be able to determine in certain cases that the SASN is authorized, either because of prior use or because the AX being loaded is authorized to access all address spaces.

2. The SASN-translation and SASN-authorization steps are not performed when SASN-d is equal to PASN-d. This is consistent with the action in SET SECONDARY ASN to current primary (SSAR-cp), which does not perform the translation or ASN authorization.

3. The storage-operand references for LOAD ADDRESS SPACE PARAMETERS may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

4. See Figure 10-19 on page 10-46 for a listing of abbreviations used in this instruction description.

First-Operand Bit Positions when ASN-and-LX Reuse Not Enabled	Abbreviation
0-15	PKM-d
16-31	SASN-d
32-47	AX-d
48-63	PASN-d

Figure 10-19. Summary of Abbreviations for LOAD ADDRESS SPACE PARAMETERS (Part 1 of 2)

First-Operand Bit Positions when ASN-and-LX Reuse Enabled	Abbreviation
0-31	SASTEIN-d
32-47	PKM-d
48-63	SASN-d
64-95	PASTEIN-d
96-111	AX-d
112-127	PASN-d

Control-Register Number.Bit	Abbreviation for	
	Previous Contents	Subsequent Contents
1.0-63	PASCE-old	PASCE-new
3.0-31	SASTEIN-old	SASTEIN-new
3.32-47	PKM-old	PKM-new
3.48-63	SASN-old	SASN-new
4.0-31	PASTEIN-old	PASTEIN-new
4.32-47	AX-old	AX-new
4.48-63	PASN-old	PASN-new
5.33-57	PASTEO-old	PASTEO-new
7.0-63	SASCE-old	SASCE-new

Field in ASN-Second-Table Entry	Abbreviation Used for the Field When Accessed as Part of	
	PASN Translation	SASN Translation
1-29	-	ATO-s
32-47	AX-p	-
48-59	-	ATL-s
64-127	ASCE-p[1]	ASCE-s[1]
352-383	ASTEIN-p	ASTEIN-s

Explanation:

- The field is not used in this case.

[1] ASCE-rp is formed from ASCE-p, and ASCE-rs is formed from ASCE-s, by a subspace-replacement operation.

Figure 10-19. Summary of Abbreviations for LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2)

PASN-d Equals PASN-old	Second-Operand-Address Bits[1]		PASN Translation Performed	Result Field						
	61	62		PASCE-new	AX-new	PASTEO-new	PKM-new	SASN-new	PASN-new	PASTEIN-new
Yes	0	0	No	PASCE-old	AX-old	PASTEO-old	PKM-d	SASN-d	PASN-d	PASTEIN-old

Figure 10-20. Summary of Actions: LOAD ADDRESS SPACE PARAMETERS (Part 1 of 2).

SASN-d Equals PASN-d	SASN-d Equals SASN-old	Second-Operand-Address Bits[1]		SASN Translation Performed	SASN Authorization Performed[3]	Result Field	
		61	63			SASCE-new	SASTEIN-new
Yes	-	-	-	No	No	PASCE-new	PASTEIN-new
No	Yes	0	1	No	No	SASCE-old	SASTEIN-old
No	Yes	1	1	Yes	No	ASCE-s[4]	SASTEIN-d
No	Yes	-	0	Yes	Yes	ASCE-s[4]	SASTEIN-d
No	No	-	1	Yes	No	ASCE-s[4]	SASTEIN-d
No	No	-	0	Yes	Yes	ASCE-s[4]	SASTEIN-d

Explanation:

- Action in this case is the same regardless of the outcome of this comparison or of the setting of this bit.

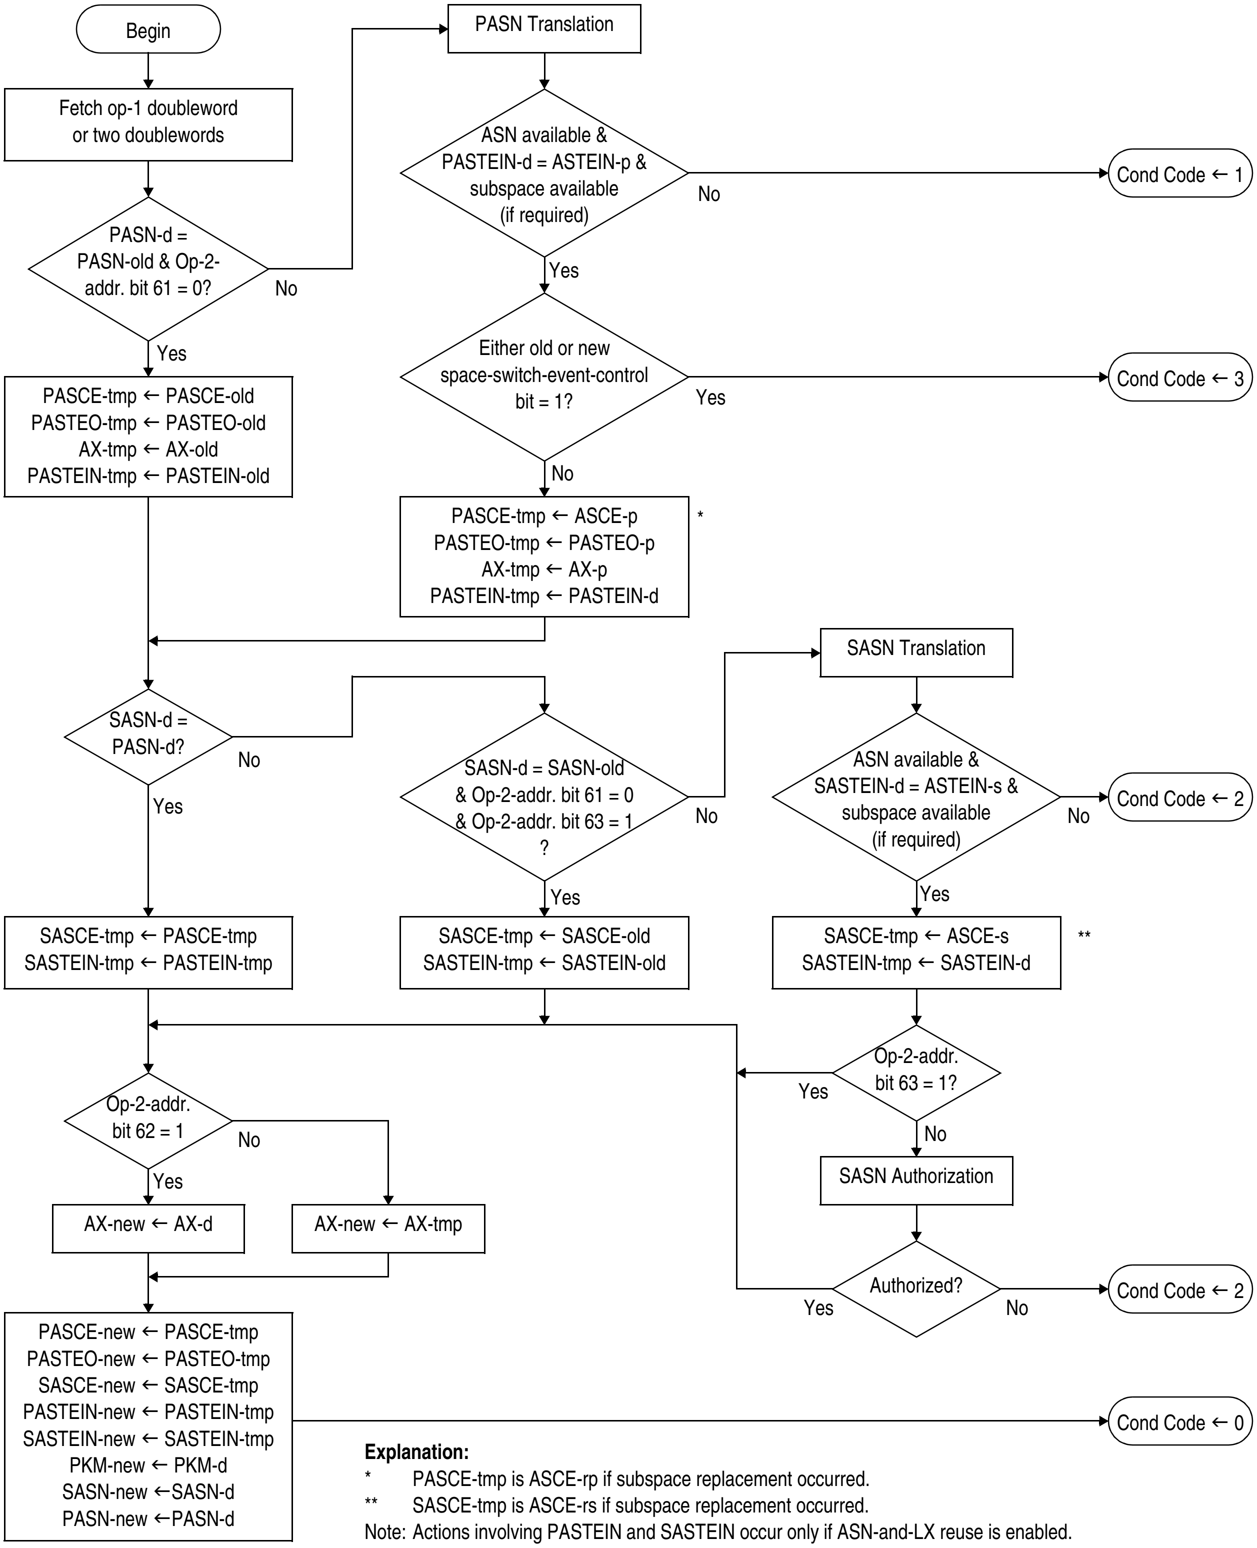
[1] Second-operand-address bits:
61: Force ASN translation.
62: Use AX from first operand.
63: Skip secondary authority test.

[2] PASCE-new is ASCE-rp (a copy of ASCE-p except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

[3] SASN authorization is performed using ATO-s, ATL-s, and AX-new.

[4] SASCE-new is ASCE-rs (a copy of ASCE-s except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

Figure 10-20. Summary of Actions: LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2).



Explanation:

* PASCE-tmp is ASCE-rp if subspace replacement occurred.

** SASCE-tmp is ASCE-rs if subspace replacement occurred.

Note: Actions involving PASTEIN and SASTEIN occur only if ASN-and-LX reuse is enabled.

Figure 10-21. Execution of LOAD ADDRESS SPACE PARAMETERS

LOAD CONTROL

LCTL R$_1$,R$_3$,D$_2$(B$_2$) [RS-a]

'B7'	R$_1$	R$_3$	B$_2$	D$_2$
0	8	12	16	20 31

LCTLG R$_1$,R$_3$,D$_2$(B$_2$) [RSY-a]

'EB'	R$_1$	R$_3$	B$_2$	DL$_2$	DH$_2$	'2F'
0	8	12	16	20	32	40 47

Bit positions of the set of control registers starting with control register R$_1$ and ending with control register R$_3$ are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD CONTROL (LCTL), bit positions 32-63 of the control registers are loaded from successive words beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD CONTROL (LCTLG), bit positions 0-63 of the control registers are loaded from successive doublewords beginning at the second-operand address. The control registers are loaded in ascending order of their register numbers, starting with control register R$_1$ and continuing up to and including control register R$_3$, with control register 0 following control register 15.

The information loaded into the control registers becomes active when instruction execution has ended.

The displacement for LCTL is treated as a 12-bit unsigned binary integer. The displacement for LCTLG is treated as a 20-bit signed binary integer.

Special Conditions

The second operand must be designated on a word boundary for LCTL or on a doubleword boundary for LCTLG; otherwise, a specification exception is recognized.

Attempted execution of LCTLG in the ESA/390-compatibility mode results in an operation exception being recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (LCTLG, in the ESA/390-compatibility mode)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. To ensure that existing programs operate correctly if and when new facilities using additional control-register positions are defined, only zeros should be loaded in unassigned control-register positions.

2. Loading of control registers on some models may require a significant amount of time. This is particularly true for changes in significant parameters.

   For example, the TLB may be cleared of entries as a result of changing or enabling the program-event-recording parameters in control registers 9-11. Where possible, the program should avoid unnecessary loading of control registers. In loading control registers 9-11, most models attempt to optimize for the case when the bits of control register 9 are zeros.

LOAD PAGE TABLE ENTRY ADDRESS

LPTEA R$_1$,R$_3$,R$_2$,M$_4$ [RRF-b]

'B9AA'	R$_3$	M$_4$	R$_1$	R$_2$
0	16	20	24	28 31

General register R$_2$ contains a virtual address that is processed by means of dynamic address translation to locate a page-table entry, the 64-bit real or absolute address of which is returned in general register R$_1$. The M$_4$ field contains a value designating the effective address-space-control element (ASCE) that is used by DAT, as shown in the following table:

M$_4$ Field (binary)	Effective Address-Space-Control Element Used by DAT
0000	Contents of control register 1

M_4 Field (binary)	Effective Address-Space-Control Element Used by DAT
0001	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the R_2 field.
0010	Contents of control register 7
0011	Contents of control register 13
0100	The address-space-control element corresponding to the current address-space-control bits, bits 16 and 17 of the PSW.

When the M_4 field contains 0001 binary, or when the M_4 field contains 0100 binary and bits 16-17 of the PSW contain 01 binary, then access-register translation precedes, as is normal, the dynamic address translation.

The R_3 field is ignored but should be zero to permit possible future extensions.

The virtual address specified by the R_2 field is translated by means of dynamic-address translation, regardless of whether DAT is on or off. ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively. The DAT process completes upon locating the page-table entry. The contents of the page-table entry are not examined for format errors, the I bit is not examined to determine whether the page is invalid, and the page-frame real address is not fetched.

Virtual address computation is performed according to the addressing mode specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses, regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

If the DAT process successfully locates the page-table entry, the 64-bit real or absolute address of the entry is placed in general register R_1, and the condition code is set as follows:

- When EDAT-1 does not apply, the condition code is set based on the DAT-protection bit (P) of the segment-table entry used in the translation. Condition code 0 is set when the P bit is zero; condition code 1 is set when the P bit is one.
- When EDAT-1 applies, the condition code is set based on all of the DAT-protection bits encountered in the translation. If the DAT-protection bit is zero in the segment-table entry and the DAT-protection bits are zero in any and all region-table entries used in the translation, condition code 0 is set. If the DAT-protection bit is one in any region- or segment-table entry used in the translation, condition code 1 is set.

When EDAT-1 applies and the DAT process successfully locates a valid segment-table entry in which the STE-format control is one, bits 0-60 of the segment-table entry address are placed in bit positions 0-60 of general register R_1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the segment-table entry and any region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When EDAT-2 applies and the DAT process successfully locates a valid region-third-table entry in which the RTTE-format control is one, bits 0-60 of the region-third-table entry address are placed in bit positions 0-60 of general register R_1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the region-third-table entry and any higher-level region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When a condition exists that would normally cause one of the exceptions shown in Figure 10-22, processing is as follows:

1. General register R_1 is updated as follows:

   a. Bits 0-60 of the table-entry address are placed in bit positions 0-60 of the register.

   b. When EDAT-1 does not apply, bit 61 of the register is set to zero. When enhanced DAT applies, bit 61 is set to the logical OR of the DAT-protection bits in all valid region-table entries used in the translation; if the DAT process does not require region-table entries, or if no valid region-table entries are encountered, bit 61 is set to zero.

c. The expected table-type bits are placed in bit positions 62-63 of the register. When the region table or segment table containing the invalid entry is directly designated by the address-space-control element, then the expected table-type bits are those contained in the designation-type control (DT) in the ASCE. Otherwise, the expected table-type bits are one less than the value of those bits in the next-higher-level table.

2. The instruction is completed by setting condition code 2.

Exception Name	Cause	Code (hex)	Expected TT Bits
Region first translation	Invalid bit is one in the region-first-table entry selected by the RFX portion of the virtual address.	0039	11
Region second translation	Invalid bit is one in the region-second-table entry selected by the RSX portion of the virtual address.	003A	10
Region third translation	Invalid bit is one in the region-third-table entry selected by the RTX portion of the virtual address.	003B	01
Segment translation	Invalid bit is one in the segment-table entry selected by the SX portion of the virtual address.	0010	00

Figure 10-22. LPTEA Exception Conditions Causing CC2

When a condition exists that would normally cause one of the exceptions shown in Figure 10-23, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, and bits 0-47 of the register are set to zeros; and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (hex)
ALET specification	ALET bits 0-6 not all zeros.	0028
ALEN translation	ALE outside list or I bit is one.	0029
ALE sequence	ALESN in ALET not equal to ALESN in ALE.	002A
ASTE validity	ASTE I bit is one.	002B
ASTE sequence	ASTESN in ALE not equal to ASTESN in ASTE.	002C
Extended authority	ALE P bit not zero, ALEAX not equal to EAX, and secondary bit selected by EAX either outside authority table or zero.	002D
ASCE type	ASCE is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by RFX portion of virtual address outside table.	0039
Region second translation	Region-second-table entry selected by RSX portion of virtual address outside table.	003A
Region third translation	Region-third-table entry selected by RTX portion of virtual address outside table.	003B
Segment translation	Segment-table entry selected by SX portion of virtual address outside table.	0010

Figure 10-23. LPTEA Exception Conditions Causing CC3

Special Conditions

If the M_4 field contains any value other than 0000-0100 binary, a specification exception is recognized.

The address-space-control element used in the translation must not be a real-space designation; otherwise, a special-operation exception is recognized. The exception due to the address-space-control element has priority 9 in Figure 6-8 on page 6-52.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation, the access-list entry, the address-space-second-table entry, or the authority-table entry designates a location which is not available in the configuration. An addressing exception is also recognized when the address used by DAT to fetch a region-table entry or the segment-table entry designates a location which is not available in the configuration.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

A translation-specification exception is recognized if an accessed region-table entry or the segment-table entry has a zero I bit and a format error.

The operation is suppressed on all addressing exceptions.

In the ESA/390-compatibility mode, an operation exception is recognized.

Resulting Condition Code:

0 PTE address returned; P bit is 0 in all DAT-table entries examined

1 PTE address returned; P bit is 1 in any DAT-table entry examined

2 Invalid bit is one in the region- or segment-table entry; EDAT-1 applies, a valid STE was located, and STE FC is 1; or EDAT-2 applies, a valid RTTE was located, and RTTE FC is 1

3 Exception condition exists

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, or segment-table entry)
- Operation (DAT-enhancement facility 2 not installed or in the ESA/390-compatibility mode)
- Privileged operation
- Special operation
- Specification
- Transaction constraint
- Translation specification

Programming Notes:

1. An addressing exception is not recognized if the page-table-entry address returned in general register R_1 is not available in the configuration.

2. When EDAT-1 applies, the STE-format control is one, and no other exception conditions apply, the address of the segment-table entry is placed in general register R_1, and condition code 2 is set. This effectively performs a *load-segment-table-entry-address* function, although no such instruction is defined.

   However, because condition code 2 is also used to indicate an invalid region-table entry or segment-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid STE:

   a. Bit positions 62-63 of general register R_1 must contain 00 binary.

   b. Bit position 58 of the table entry designated by bits 0-60 of general register R_1 must contain zero (indicating a valid table entry).

   c. The table-type field in bit positions 60-61 of the table entry designated by bits 0-60 of general register R_1 must contain 00 binary (designating a segment-table entry).

   The following program fragment illustrates this determination when only EDAT-1 applies. If no branch is taken, then the address in general register 1 is that of a segment-table entry in which the STE-format control is one:

```
LPTEA 1,0,2,4
BRC   8,PTE_WITH_NEITHER_STE_NOR_RTE_PROT
BRC   4,PTE_WITH_PROTECTED_STE_OR_RTE
BRC   1,EXCEPTION_EXISTS
TMLL  1,X'0003'
JNZ   EXCEPTION_EXISTS
NILL  1,X'FFF8'
LURAG 10,1
TMLL  10,X'0020'
JO    EXCEPTION_EXISTS
```

3. When EDAT-2 applies, the RTTE-format control is one, and no other exception conditions apply, the address of the region-third-table entry is placed in general register R_1, and condition code 2 is set. This effectively performs a *load-region-third-table-entry-address* function, although no such instruction is defined.

However, because condition code 2 is also used to indicate an invalid region-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid RTTE:

a. Bit positions 62-63 of general register R_1 must contain 00 binary.

b. Bit position 58 of the table entry designated by bits 0-60 of general register R_1 must contain zero (indicating a valid table entry).

c. The table-type field in bit positions 60-61 of the table entry designated by bits 0-60 of general register R_1 must contain 01 binary (designating a region-third-table entry).

The following program fragment continues the fragment in programming note 2, illustrating this determination when EDAT-2 applies. If no branch is taken, then the address in general register 1 is that of a region-third-table entry in which the RTTE-format control is one:

```
* Further check for EDAT-2
       TMLL   10,X'000C
       JZ     VALID_F1_STE
* Must be valid F1 RTTE
```

4. When condition code 2 is set as a result of locating a valid segment-table entry in which the STE-format control is one, bit 61 of general register R_1 indicates whether DAT protection applies to the segment. Similarly, when condition code 2 is set as a result of locating a valid region-third-table entry in which the RTTE-format control is one, bit 61 of general register R_1 indicates whether DAT protection applies to the region.

5. When EDAT-1 does not apply, only the STE is examined in determining whether condition code 0 or 1 is set. When EDAT applies, all DAT-table entries used in the translation may be examined in determining whether condition code 0 or 1 is to be set.

LOAD PSW

LPSW $D_2(B_2)$ [SI]

'82'	////////	B_2	D_2
0		16	20 31

The current PSW is replaced by a 16-byte PSW formed from the contents of the doubleword at the location designated by the second-operand address. Figure 4-3 on page 4-8 illustrates the contents of the second operand.

Bits 8-15 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit 12 of the doubleword must be one; otherwise, depending on the model, a specification exception may be recognized and the operation suppressed.

Bits 0-11, 13-32, and 33-63 of the doubleword are placed in bit positions 0-11, 13-32, and 97-127 of the current PSW, respectively. Bits 33-96 of the current PSW are set to zeros.

Bit 12 of the doubleword is inverted and then placed in bit 12 of the current PSW. This applies in the z/Architecture architectural mode and in the ESA/390-compatibility mode.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized. A specification exception may be recognized if bit 12 of the operand is zero, depending on the model.

The PSW fields which are to be loaded by the instruction are not checked for validity before they are loaded, except for the optional checking of bit 12. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of bits 0, 2-4, 12, or 25-30 is a one.
- In the ESA/390-compatibility mode, bit 5 of the PSW is one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are both zero, and bits 97-103 are not all zeros.

- Bits 31 and 32 are one and zero, respectively.
- In the ESA/390-compatibility mode, bit 31 is one (recognition of this condition is unpredictable).

In these cases, the operation is completed, and the resulting instruction-length code is 0.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: The second operand of LOAD PSW has the short-PSW format (shown in Figure 4-3 on page 4-8), which is similar to that of an ESA/390-mode PSW (that is, bit 12 of the operand must be 1). When bit 12 of the second operand is zero, a specification exception is recognized, either during the execution of the instruction, or when the instruction completes and the new PSW becomes active.

However, unlike the ESA/390-format PSW in which bit 31 must be zero, bit 31 of the short PSW may be either zero or one in the z/Architecture architectural mode. In the ESA/390-compatibility mode, bit 5 must be zero and it is unpredictable whether bit 31 must be zero.

LOAD PSW EXTENDED

LPSWE $D_2(B_2)$ [S]

'B2B2'	B_2	D_2
0	16	20 31

The current PSW is replaced by the contents of the 16-byte second operand. Figure 4-2 on page 4-5 illustrates the contents of the second operand.

Note: Bit 12 of the second operand is placed unchanged into bit 12 of the current PSW. This applies in the z/Architecture architecture mode and in the ESA/390-compatibility mode.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

It is unpredictable whether LOAD PSW EXTENDED is supported in the ESA/390-compatibility mode. If the instruction is not supported, attempted execution results in an operation exception being recognized.

The value which is to be loaded by the instruction is not checked for validity before it is loaded. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of the unassigned bits (0, 2-4, 25-30, or 33-63) is a one.
- In the ESA/390-compatibility mode, bit 5 of the PSW is one.
- Bit 12 is a one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros.
- Bits 31 and 32 are both zero, and bits 64-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.
- In the ESA/390-compatibility mode, bit 31 is one (recognition of this condition is unpredictable).

In these cases, the operation is completed, and the resulting instruction-length code is zero.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

LOAD REAL ADDRESS

LRA $R_1,D_2(X_2,B_2)$ [RX-a]

'B1'	R_1	X_2	B_2	D_2
0	8	12	16	20 31

LRAY $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'13'
0	8	12	16	20	32	40 47

LRAG $R_1,D_2(X_2,B_2)$ [RXY-a]

'E3'	R_1	X_2	B_2	DL_2	DH_2	'03'
0	8	12	16	20	32	40 47

For LOAD REAL ADDRESS (LRA, LRAY) in the 24-bit or 31-bit addressing mode, if bits 0-32 of the 64-bit real or absolute address corresponding to the second-operand virtual address are all zeros, bits 32-63 of the real or absolute address are placed in bit positions 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. If bits 0-32 of the real address or absolute are not all zeros, a special-operation exception is recognized.

For LRA or LRAY in the 64-bit addressing mode, and for LOAD REAL ADDRESS (LRAG) in any addressing mode, the 64-bit real or absolute address corresponding to the second-operand virtual address is placed in general register R_1.

When EDAT-1 does not apply, or when EDAT-1 applies but the second operand is translated by means of a segment-table entry in which the STE-format control is zero, the address placed in general register R_1 is real. When EDAT-1 applies and the second operand is translated by means of a segment-table entry in which the STE-format control is one, or when EDAT-2 applies and the second operand is translated by means of a region-third-table entry in which the RTTE-format control is one, the address placed in general register R_1 is absolute.

The virtual address specified by the X_2, B_2, and D_2 fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

The displacement for LRA is treated as a 12-bit unsigned binary integer. The displacement for LRAY and LRAG is treated as a 20-bit signed binary integer.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in Figure 10-24.

PSW Bits 16 and 17	Address-Space-Control Element Used by DAT
00	Contents of control register 1
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B_2 field
10	Contents of control register 7
11	Contents of control register 13

Figure 10-24. Address-Space Control used by LOAD REAL ADDRESS

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The virtual-address computation is performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry, if used, are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Condition code 0 is set when both ART, if applicable, and DAT can be completed and a special-operation exception is not recognized, that is, when an address-space-control element can be obtained, the entry in each DAT table lies within the table and has a zero I bit, and, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resulting real or absolute address are zeros. The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

When PSW bits 16 and 17 are 01 binary and an address-space-control element cannot be obtained because of a condition that would normally cause one of the exceptions shown in Figure 10-25, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros	0028
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)	0029
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE	002A
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)	002B
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE	002C
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero	002D

Figure 10-25. Handling of ART-Related Exceptions for LOAD REAL ADDRESS

When ART is completed normally, the operation is continued through the performance of DAT.

When the segment-table entry is outside the table and bits 0-32 of the real or absolute address of the entry are all zeros, bits 32-63 of the entry address are placed in bit positions 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction completes by setting condition code 3. If bits 0-32 of the address are not all zeros, the result is as described in the section “DAT-Related Exceptions for LOAD REAL ADDRESS” on page 10-57.

When the I bit in the segment-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the segment-table entry is placed in general register R_1, and the instruction is completed by setting condition code 1.
- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the segment-table entry are all zeros, bits 32-63 of the real or absolute address of the segment-table entry are placed in bits 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 1.
  - If bits 0-32 of the address of the segment-table entry are not all zeros, the result is as described in the section “DAT-Related Exceptions for LOAD REAL ADDRESS”, below.

When the I bit in the page-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the page-table entry is placed in general register R_1, and the instruction is completed by setting condition code 2.
- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the page-table entry are all zeros, bits 32-63 of the real or absolute address of the page-table entry are placed in bits 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 2.
  - If bits 0-32 of the address of the page-table entry are not all zeros, the result is as described in the section “DAT-Related Exceptions for LOAD REAL ADDRESS”, below.

A segment-table-entry or page-table-entry address placed in general register R_1 is real or absolute in accordance with the type of address that was used during the attempted translation.

DAT-Related Exceptions for LOAD REAL ADDRESS

If a condition exists that would normally cause one of the exceptions shown in the Figure 10-26, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by region-first-index portion of virtual address outside table or invalid.	0039
Region second translation	Region-second-table entry selected by region-second-index portion of virtual address outside table or invalid.	003A
Region third translation	Region-third-table entry selected by region-third-index portion of virtual address outside table or invalid.	003B
Segment translation	Segment-table entry selected by segment-index portion of virtual address outside table (for all instructions and all addressing modes, but only when bits 0-32 of entry address not all zeros); or segment-table entry invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0010
Page translation	Page-table entry selected by page-index portion of virtual address invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0011

Figure 10-26. Handling of DAT-Related Exceptions for LOAD REAL ADDRESS

Special Conditions

In the ESA/390-compatibility mode, an operation exception is recognized.

A special-operation exception is recognized when, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resultant 64-bit real address are not all zeros.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is not available in the configuration.

A translation-specification exception is recognized when an accessed region-table entry or the segment-table entry or page-table entry has a zero **I** bit and a format error, that is, when any of the reasons 1-5 listed in “Translation-Specification Exception” on page 6-46 applies.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Translation available
1 Segment-table entry invalid (**I** bit one) for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros
2 Page-table entry invalid (**I** bit one) for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros
3 Address-space-control element not available, region-table entry outside table or invalid (**I** bit one), segment-table entry outside table, or, for LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros, segment-table entry or page-table entry invalid (**I** bit one)

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, or page-table entry)

- Operation (LRAY, if the long-displacement facility is not installed; LRA, LRAY, LRAG, in the ESA/390-compatibility mode)
- Privileged operation
- Special operation (LRA, LRAY only)
- Transaction constraint
- Translation specification

Programming Notes:

1. Caution must be exercised in the use of LOAD REAL ADDRESS in a multiprocessing configuration. Since INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY may set I bits in storage to one before causing the corresponding entries in TLBs of other CPUs to be cleared, the simultaneous execution of LOAD REAL ADDRESS on this CPU and either INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on another CPU may produce inconsistent results. Because LOAD REAL ADDRESS may access the tables in storage, the region-table entries, segment-table entry or page-table entry may appear to be invalid (condition codes 3, 1, or 2, respectively) even though the corresponding TLB entry has not yet been cleared, and the TLB entry may remain in the TLB until the completion of INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on the other CPU. There is no guaranteed limit to the number of instructions which may be executed between the completion of LOAD REAL ADDRESS and the TLB being cleared of the entry.

   The above cautions for using LOAD REAL ADDRESS also apply when COMPARE AND SWAP AND PURGE or COMPARE AND REPLACE DAT TABLE ENTRY is used to explicitly set the invalid bit in a DAT-table entry.

2. Figure 10-27 on page 10-59 summarizes the resulting contents of general register R_1 and the condition code.

Exception/Cause/ Entry-Address Size or Resultant-Real-Address Size	General Register R_1 Contents and Condition Code

Explanation:

EA1	Bits 0-31 of the entry address.
EA2	Bit 32 of the entry address.
EA3	Bits 33-47 of the entry address.
EA4	Bits 48-63 of the entry address.
RA1	Bits 0-31 of the resultant real address.
RA2	Bit 32 of the resultant real address.
RA3	Bits 33-47 of the resultant real address.
RA4	Bits 48-63 of the resultant real address.
U	Unchanged.

Figure 10-27. Summary of Results: LOAD REAL ADDRESS

3. When the instruction completes with condition code 3, the following applies:
   - Only the rightmost 32 bits of general register R_1 are meaningful, regardless of the addressing mode or instruction executed. The program can determine whether the rightmost bits of general register R_1 contain the address of a DAT-table entry or a program-interruption code based on whether bit 32 of the register is zero or one, respectively.
   - In order to correctly use a DAT-table-entry address returned in general register R_1 in the 64-bit addressing mode, the leftmost 32 bits of the register must be set to zeros.

LOAD USING REAL ADDRESS

LURA R_1,R_2 [RRE]

'B24B'	////////	R_1	R_2
0	16	24	28 31

LURAG R_1,R_2 [RRE]

'B905'	////////	R_1	R_2
0	16	24	28 31

For LOAD USING REAL ADDRESS (LURA), the word at the real-storage location addressed by the contents of general register R_2 is placed in bit positions 32-63 of general register R_1, and the contents of bit positions 0-31 remain unchanged. For LOAD USING REAL ADDRESS (LURAG), the doubleword at that real-storage location is placed in bit positions 0-63 of general register R_1.

In the 24-bit addressing mode, bits 40-63 of general register R_2 designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R_2 designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R_2 designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

Special Conditions

The contents of general register R_2 must designate a location on a word boundary for LURA or on a doubleword boundary for LURAG; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Protection (fetch, operand 2, key-controlled protection)
- Specification
- Transaction constraint

MODIFY STACKED STATE

MSTA R_1 [RRE]

'B247'	////////	R_1	////
0	16	24	28 31

The contents of bit positions 32-63 of the pair of general registers designated by the R_1 field are placed in the modifiable area, byte positions 152-159, of the last state entry in the linkage stack.

The R_1 field designates the even-numbered register of an even-odd pair of general registers.

The last state entry is located as described in “Unstacking Process” on page 5-86. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to the references to the linkage stack, but low-address and DAT protection do apply.

Special Conditions

A specification exception is recognized when R_1 is odd.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-28 on page 10-61.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch and store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
7.C	Transaction constraint.
8.A	Specification exception due to R_1 being odd.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. **Note**: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Access exceptions (fetch) for second word of the header entry.
8.B.4	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

Figure 10-28. Priority of Execution: MODIFY STACKED STATE (Part 1 of 2)

8.B.5 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.

8.B.6 Stack-specification exception due to preceding entry being a header entry.

8.B.7 Stack-type exception due to preceding entry not being a state entry.

8.B.8 Access exceptions (store) for the modifiable area of the state entry.

Figure 10-28. Priority of Execution: MODIFY STACKED STATE (Part 2 of 2)

Programming Note: The modifiable area can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE.

MOVE PAGE

MVPG R_1,R_2 [RRE]

'B254'	////////	R_1	R_2
0	16	24	28 31

The first operand is replaced by the second operand and, optionally, the storage key associated with the 4K-byte block of storage designated by the first operand is set. The first and second operands both are 4K bytes on 4 K-byte boundaries. The results are indicated in the condition code. The accesses to the first-operand location or the second-operand location, but not to both locations, may be performed by using the key specified in general register 0; otherwise, the accesses to an operand location are performed by using the PSW key.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

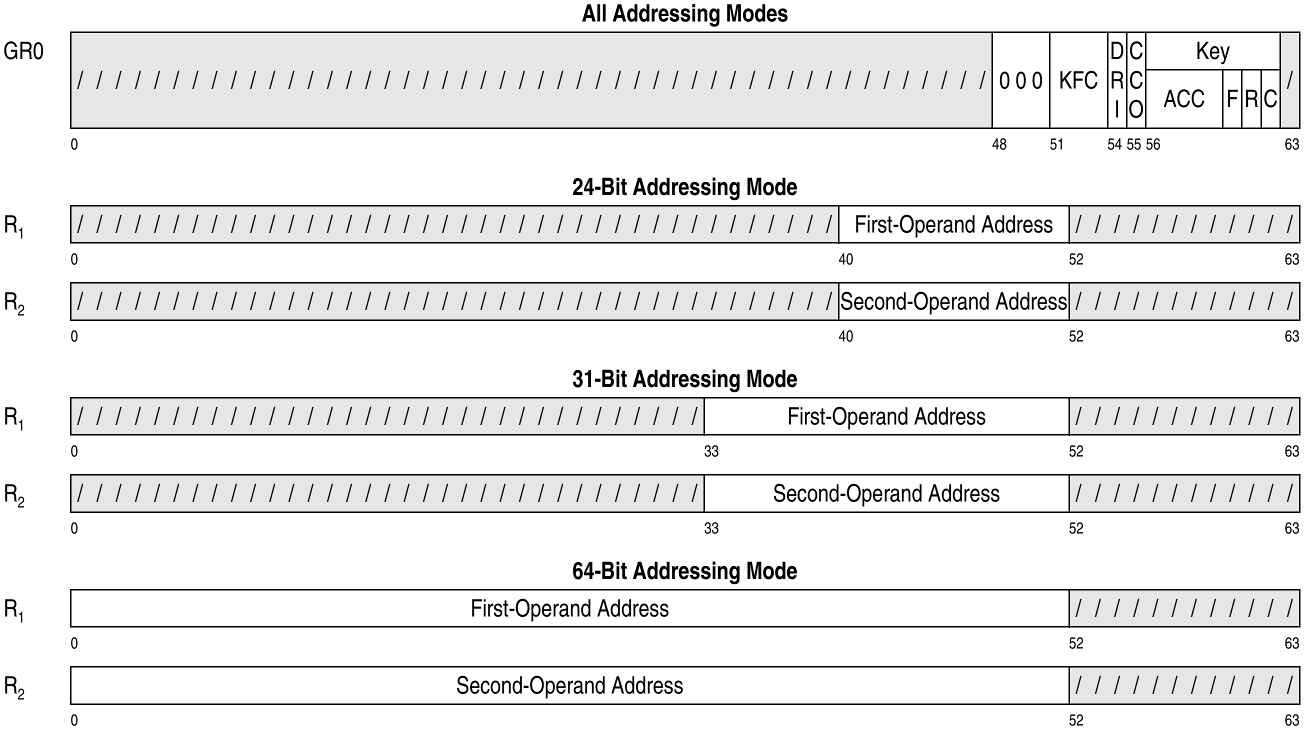
Bits 51-53 of general register 0 contain the key-function control (KFC) which is used to determine how the supplied storage key in bits 56-62 will be used or set.

KFC	Meaning
0	The PSW key is used for accessing both operands. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
1	The PSW key is used for store accesses to the first operand and the supplied ACC key (bits 56-59 of general register 0) is used for fetch accesses to the second operand. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
2	The supplied ACC key (bits 56-59 of general register 0) is used for store accesses to the first operand and the PSW key is used for fetch accesses to the second operand. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
3	Reserved
4	Key-controlled protection does not apply to the first operand. The PSW key is used for fetch accesses to the second operand. The storage key associated with the 4K-byte block of storage designated by the first operand is set to the full key supplied in bits 56-62 of general register 0.
5	Key-controlled protection does not apply to the first operand. The PSW key is used for fetch accesses to the second operand. The storage key associated with the 4K-byte block of storage designated by the first operand is set as follows: the access-control bits (ACC) and fetch-protection bit (F) are copied from the storage key of the second operand and the reference bit (R) and change bit (C) use the value supplied in bits 61-62 of general register 0.
6-7	Reserved

When the move-page-and-set-key facility is not installed, KFC values of 4 and 5 are also reserved. If a reserved value is specified, a specification exception is recognized.

Bit 54 of general register 0 is a destination-reference-intention bit, and bit 55 is a condition-code-option bit. Bits 48-50 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-47 and 63 of general register 0 are ignored. When the move-page-and-set-key facility is not installed, bits 60-62 are also ignored.

The contents of the registers just described are shown in Figure 10-29.



Explanation:

CCO	Condition-code-option bit.
DRI	Destination-reference-intention bit.
Key	Specified access key.
KFC	Key-function control.

Figure 10-29. Register Contents for MOVE PAGE

When 4K bytes have been moved, condition code 0 is set.

When a page-translation-exception condition exists, the exception is not recognized if the condition-code-option bit, bit 55 in general register 0, is one; instead, condition code 1 or 2 is set. Condition code 1 is set if a page-translation-exception condition exists for the first operand and not for the second operand. Condition code 2 is set if a page-translation-exception condition exists for the second operand, regardless of whether the condition exists for the first operand.

When the KFC value is 4 or 5 and the real or absolute addresses (possibly after DAT) of the first and second operands are the same, it is model dependent if an operand exception is recognized.

When an access exception can be recognized for both operands, it is unpredictable for which operand an exception is recognized. If one of the exceptions is a page-translation exception that would cause condition code 1 or 2 to be set, it is unpredictable whether the access exception for the other operand is recognized or condition code 1 or 2 is set.

When the instruction completes by setting condition codes 1 or 2, and a PER zero-address-detection condition also exists for either the first or second operand, it is unpredictable whether the zero-address-detection condition is recognized.

The references to main storage are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

When the storage key is set on the first operand block (KFC values of 4 or 5), a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-120 for a discussion of the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-133 for details on the quiescing operation.

When the KFC value is 4 or 5, serialization and checkpoint-synchronization functions are performed before the operation begins and again after the operation is completed.

Special Conditions

In the problem state, when the KFC value is 1 or 2, the operation is performed only if the access key specified in general register 0 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

When the KFC value is 0, the access key in general register 0 is not tested for validity and a priviliged-operation exception is not recognized. In the problem state, when the move-page-and-set-key facility is installed and the KFC value is 4 or 5, a privleged-operation exception is recognized.

In the problem state, when the KFC value is 3 and the access key in general register 0 is not permitted by the PSW-key mask, it is unpredictable whether a specification exception or a privileged-operation exception is recognized.

KFC values of 6 or 7 always result in a specification exception.

In the ESA/390-compatibility mode, an operation exception is recognized when the configuration is not also operating in the ESA/extended-configuration (ESA/XC) mode . See Reference [12.] on page xxx for details on ESA/XC.

Resulting Condition Code:

0 Data moved and, optionally, key is set
1 Condition-code-option bit one, page-table entry for first operand invalid, and page-table entry for second operand valid
2 Condition-code-option bit one and page-table entry for second operand invalid
3 --

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operand
- Operation (in the ESA/390 compatibility mode when not in ESA/XC mode)
- Privileged operation (access key specified, and selected PSW-key-mask bit is zero in the problem state; KFC values of 4 or 5 in the problem state)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE PAGE, or a loop of MOVE PAGE instructions that moves multiple pages, may provide, on most models, better performance than a MOVE LONG instruction or a loop of MOVE (MVC) instructions that performs the same function. Whether MOVE PAGE provides better performance depends on control-program specifications and the method by which the control program handles page-translation exceptions.

2. The destination-reference-intention bit should be set to one when there is an intention to reference the first operand by means of an instruction other than MOVE PAGE. The bit may allow the control program to process a page-translation exception more efficiently.

3. On most models where the move-page-and-set-key facility is installed and it is desired to both move a page of data and copy or set its key, then using MVPG with KFC values of 4 or 5 will provide better performance compared to a separate move operation followed by a SET STORAGE KEY EXTENDED or PERFORM FRAME MANAGE FUNCTION.

4. When KFC values of 4 or 5 are used, another CPU might briefly observe the reference and

change bits being set to one for the first operand block, before being set to their final value by the key setting operation.

5. The condition code set by the instruction normally need not be examined if the condition-code-option bit is zero or if DAT is off.

6. See the definitions of real locations 162 and 168-175 under "Assigned Storage Locations" in Chapter 3, "Storage" for a description of information stored during a program interruption due to a DAT-related translation exception recognized by MOVE PAGE.

MOVE TO PRIMARY

MVCP $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]

'DA'	R_1	R_3	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

MOVE TO SECONDARY

MVCS $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]

'DB'	R_1	R_3	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The first operand is replaced by the second operand. One operand is in the primary address space, and the other is in the secondary address space. The accesses to the operand in the primary space are performed by using the PSW key; the accesses to the operand in the secondary space are performed by using the key specified by the third operand.

The addresses of the first and second operands are virtual, one operand address being translated by means of the primary address-space-control element and the other by means of the secondary address-space-control element. Operand-address translation is performed in the same way when the address-space-control bits in the current PSW specify either the primary-space mode or the secondary-space mode.

For MOVE TO PRIMARY, movement is to the primary space from the secondary space. The first-operand address is translated by using the primary address-space-control element, and the second-operand address is translated by using the secondary address-space-control element.

For MOVE TO SECONDARY, movement is to the secondary space from the primary space. The first-operand address is translated by using the secondary address-space-control element, and the second-operand address is translated by using the primary address-space-control element.

Bit positions 56-59 of general register R_3 are used as the secondary-space access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R_1 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-30.

24-Bit or 31-Bit Addressing Mode

R_1	/ /	True Length	
	0	32	63

64-Bit Addressing Mode

R_1	True Length	
	0	63

All Addressing Modes

R_3	/ /	Key	/ / / /	
	0	56	60	63

Figure 10-30. Register Contents of MOVE TO PRIMARY and MOVE TO SECONDARY

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. The storage-operand-consistency rules are the same as for MOVE (MVC), except that when the operands overlap in real storage, the use of the common real-storage locations is not necessarily recognized.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

For both MOVE TO PRIMARY and MOVE TO SECONDARY, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Special Conditions

Since the secondary space is accessed, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. A special-operation exception is also recognized when the address-space-control bits in the current PSW specify the access-register or home-space mode.

In the problem state, the operation is performed only if the secondary-space access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the secondary-space access key is valid.

Resulting Condition Code:

0 True length less than or equal to 256
1 --
2 --
3 True length greater than 256

Program Exceptions:

- Access (fetch, primary virtual address, operand 2, MVCS; fetch, secondary virtual address, operand 2, MVCP; store, secondary virtual address, operand 1, MVCS; store, primary virtual address, operand 1, MVCP)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-31.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B	Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero, to DAT being off, or to the CPU being in the access-register or home-space mode.
7.C	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Completion due to length zero.
10.	Access exceptions for operands.

Figure 10-31. Priority of Execution: MOVE TO PRIMARY and MOVE TO SECONDARY

Programming Notes:

1. MOVE TO PRIMARY and MOVE TO SECONDARY can be used in a loop to move a variable number of bytes of any length. See the programming note under MOVE WITH KEY.

2. MOVE TO PRIMARY and MOVE TO SECONDARY should be used only when movement is between different address spaces. The performance of these instructions on most models may be significantly slower than that of MOVE WITH KEY, MOVE (MVC), or MOVE LONG. In addition, the definition of overlapping operands for MOVE TO PRIMARY and MOVE TO SECONDARY is not compatible with the more precise definitions for MOVE (MVC), MOVE WITH KEY, and MOVE LONG.

MOVE WITH DESTINATION KEY

MVCDK $D_1(B_1),D_2(B_2)$ [SSE]

'E50F'	B_1	D_1	B_2	D_2
0	16	20	32	36 47

The first operand is replaced by the second operand. The accesses to the destination-operand location are performed by using the key specified in general register 1, and the accesses to the source-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-32.

GR0	/ /	L	
	0	56	63
GR1	/ /	Key	/ / / /
	0	56	60 63

Figure 10-32. Register Contents of MOVE WITH DESTINATION KEY

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the PSW key, and the store accesses to the first-operand location are performed by using the key specified in general register 1.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

Special Conditions

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

Programming Note: See the programming notes for the MOVE WITH SOURCE KEY instruction.

MOVE WITH KEY

MVCK $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]

'D9'	R_1	R_3	B_1	D_1	B_2	D_2
0	8	12	16	20	32	36 47

The first operand is replaced by the second operand. The fetch accesses to the second-operand location are performed by using the key specified in the third operand, and the store accesses to the first-operand location are performed by using the PSW key.

Bit positions 56-59 of general register R_3 are used as the source access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R_1 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-33.

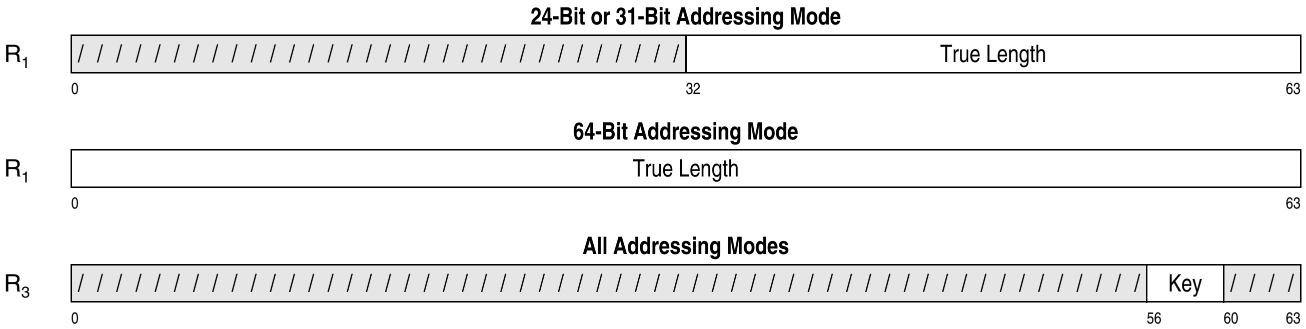


Figure 10-33. Register Contents of MOVE WITH KEY

The first and second operands are of the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. When the storage operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte was fetched. The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

Special Conditions

In the problem state, the operation is performed only if the source access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the source access key is valid.

Resulting Condition Code:

0 True length less than or equal to 256
1 --
2 --
3 True length greater than 256

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-34.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Completion due to length zero.
10.	Access exceptions for operands.

Figure 10-34. Priority of Execution: MOVE WITH KEY

Programming Notes:

1. MOVE WITH KEY can be used in a loop to move a variable number of bytes of any length, as follows:

   ```
   LOOP     MVCK  D1(R1,B1),D2(B2),R3
            BC    8,END
            AHI   B1,256
            AHI   B2,256
            AHI   R1,-256
            B     LOOP
   END      [Any instruction]
   ```

   The above program is for execution in the 24-bit or 31-bit addressing mode. In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

2. The performance of MOVE WITH KEY on most models may be significantly slower than that of the MOVE (MVC) and MOVE LONG instructions. Therefore, MOVE WITH KEY should not be used if the keys of the source and the target are the same.

MOVE WITH OPTIONAL SPECIFICATIONS

MVCOS $D_1(B_1),D_2(B_2),R_3$ [SSF]

'C8'	R_3	'0'	B_1	D_1	B_2	D_2	
0	8	12	16	20	32	36	47

The first operand is replaced by the second operand. Bits in general register 0 determine the address-space-control modes and protection keys that are used to access the first and second operands.

The addresses of the first and second operands are virtual.

Bits 32-47 of general register 0 contain the operand-access control for the first operand (OAC_1), and bits 48-63 of general register 0 contain the operand-access control for the second operand (OAC_2). The operand-access control has the following format.

Key	/ / / /	AS	/ / / /	K	A
0	4	8	10	14	15

Specified-Access Key (Key): Bits positions 0-3 contain the specified-access key that is used to access the operand if the specified-access-key validity bit (K) is one; otherwise, the specified-access key is ignored.

Specified-Address-Space Control (AS): Bit positions 8-9 contain the address-space control that is used to access the operand when the specified-address-space-control validity bit (A) is one; otherwise, the specified-address-space control is ignored. The meaning of bits 8-9 is identical to that of the address-space control in bits 16-17 of the PSW.

Specified-Access-Key Validity Bit (K): Bit 14 controls whether the PSW key or the specified-access key is used to access the operand. When the K bit is zero, the PSW key is used. When the K bit is one, the specified-access key is used.

Specified-Address-Space-Control Validity Bit (A): Bit 15 controls whether the address-space control in the current PSW or the address-space control in the specified-ASC is used to access the operand. When the A bit is zero, the address-space control in the current PSW is used. When the A bit is one, the specified-address-space control is used.

Bits 0-31 of general register 0 are ignored. Bits 4-7 and 10-14 of both operand-access controls (that is, bits 36-39, 42-45, 52-55, and 58-61 of general register 0) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register R_3 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-35.

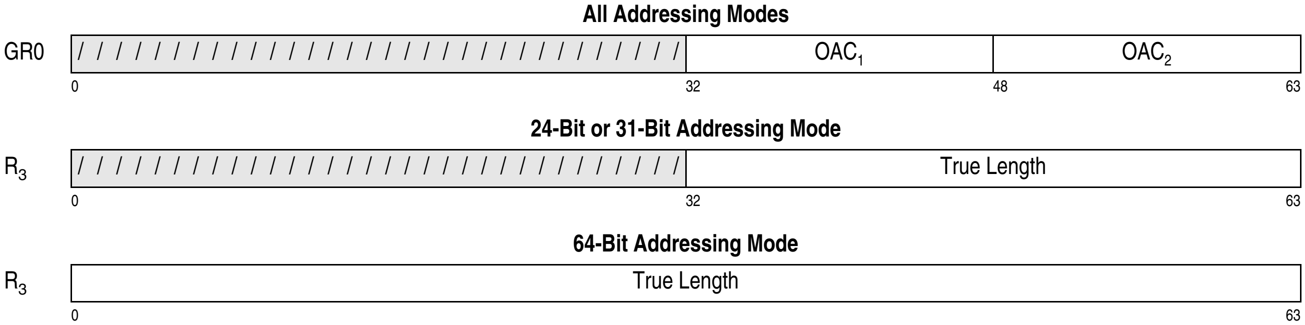

Figure 10-35. Register Contents for MOVE WITH OPTIONAL SPECIFICATIONS

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 4,096, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 4,096 or less, including zero, then the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 4,096, then the effective length is 4,096, and condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand real location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

Special Conditions

A special-operation exception is recognized for any of the following conditions:

- DAT is off.
- The address-space control in OAC$_1$ designates the home-space mode, the address-space-control validity bit in OAC$_1$ is one, and the current PSW is in the problem state (that is, bits 40-41 of general register 0 are 11 binary, bit 47 of the register is one, and bit 15 of the current PSW is one).
- The secondary-space control, bit 37 of control register 0, is zero, and either of the following is true:
  - The A bit of the OAC for either operand is zero, and bits 16-17 of the current PSW are 10 binary.
  - The A bit of the OAC for either operand is one, and the AS bits in the same OAC are 10 binary.

  The secondary-space control is not examined for an operand that is accessed in the secondary-space mode as a result of access-register translation (that is, DAT is on, bits 16-17 of the current PSW are 01 binary, and the access register corresponding to the operand's base register contains an ALET of 00000001 hex).

When MOVE WITH OPTIONAL SPECIFICATIONS is executed in the problem state, and either the first or second operand's specified-access key (from GR0) or the implied-access key (from the PSW) is invalid, a privileged-operation exception is recognized. The validity of an access key is determined as follows:

- The specified-access key in OAC_1 is invalid if the specified-access-key control, bit 46 of general register 0, is one; and the specified-access key, bits 32-35 of the register, designates a PSW-key-mask (PKM) bit position in control register 3 that contains zero.
- The specified-access key in OAC_2 is invalid if the specified-access-key control, bit 62 of general register 0, is one; and the specified-access key, bits 48-51 of the register, designates a PKM bit position that contains zero.
- The implied-access key is invalid if both of the following conditions are true:
  - Either or both bits 46 and 62 of general register 0 are zero.
  - The PSW key, bits 8-11 of the PSW, designates a PKM bit position that contains zero.

In the supervisor state, any value for the implied- or specified-access key is valid.

Resulting Condition Code:

0 True length less than or equal to 4,096
1 --
2 --
3 True length greater than 4,096

Program Exceptions:

- Access (fetch, second operand; store first operand)
- Operation (if the move-with-optional-specifications facility is not installed)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-36.

1.-7.B	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.C.1	Operation exception.
7.C.2	Special-operation exception.
7.C.3	Privileged-operation exception.
7.D	Transaction constraint.
8.	Completion due to length zero.
9.	Access exceptions for operands.

Figure 10-36. Priority of Execution: MOVE WITH OPTIONAL SPECIFICATIONS

Programming Notes:

1. MOVE WITH OPTIONAL SPECIFICATIONS can be used in a loop to move a variable number of bytes of any length.

2. An example of moving 16 K-bytes to the home address space from the secondary address space is shown below. The first operand is accessed using the PSW key, and the second operand is accessed using key 5.

```
        LA      3,OPERAND1
        LA      5,OPERAND2
        LHI     7,16384
        LLILF   0,X'00C15083'
LOOP    MVCOS   0(3),0(5),7
        AHI     3,4096
        AHI     5,4096
        AHI     7,–4096
        BP      LOOP
```

   In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

3. The performance of MOVE WITH OPTIONAL SPECIFICATIONS may be significantly slower than that of individual MOVE (MVC) instructions.

4. When bits 46-47 and 62-63 of general register 0 are all zero, MOVE WITH OPTIONAL SPECIFICATIONS uses the key and address-space control in the current PSW to access both the first and second operands.

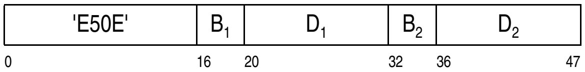
5. In the MVCDK, MVCK, MVCP, MVCS, and MVCSK instructions, one operand is accessed using an implied key from the PSW, and the other operand is accessed using a specified key

in a register. In the problem state, only the specified key is checked for validity in the PSW-key mask (PKM).

When MVCOS is executed in the problem state, the access keys for the first and second operands are both checked for validity in the PKM, regardless of whether the keys are implied or specified.

MOVE WITH SOURCE KEY

MVCSK $D_1(B_1),D_2(B_2)$ [SSE]



The first operand is replaced by the second operand. The accesses to the source-operand location are performed by using the key specified in general register 1, and the accesses to the destination-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-37.

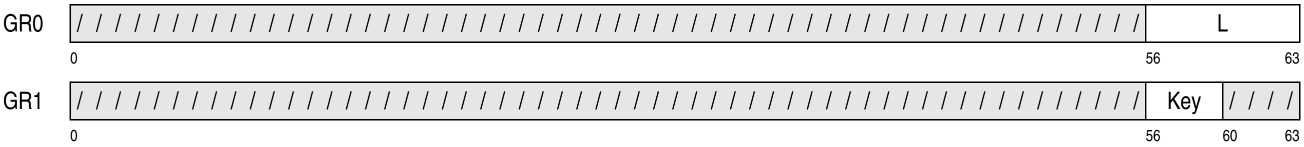


Figure 10-37. Register Contents of MOVE WITH SOURCE KEY

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the key specified in general register 1, and the store accesses to the first-operand location are performed by using the PSW key.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

Special Conditions

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

Programming Notes:

1. When data is to be moved alternately in both directions between two storage areas that are fetch protected by means of different keys, then MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY can be used while leaving the PSW key unchanged; and this may be, on most models, significantly faster than using MOVE WITH KEY along with SET PSW KEY FROM ADDRESS to change the PSW key.

2. MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY should be used only when movement is between storage areas having different keys. The performance of these instructions on most models may be significantly slower than that of the MOVE (MVC) instruction.

3. MOVE WITH SOURCE KEY or MOVE WITH DESTINATION KEY can be used in a loop to move a variable number of bytes as shown in the following example. In the example, the specified

access key, the first-operand address, the second-operand address, and the length of each operand are assumed to be in general registers 1-4, respectively, at the beginning of the example. The length of each operand is treated as a 32-bit signed value, and a negative value is treated as zero.

```
         LTR    4,4
         BC     12,END
         AHI    4,-256
         BC     12,LAST
         LA     0,255
LOOP     MVCSK  0(2),0(3)
         LA     2,256(2)
         LA     3,256(3)
         AHI    4,-256
         BC     2,LOOP
LAST     LA     0,255(4)
         MVCSK  0(2),0(3)
END      [Any instruction]
```

PAGE IN

PGIN R_1,R_2 [RRE]

'B22E'	////////	R_1	R_2
0	16	24	28 31

A page-in operation is performed which transfers a 4 K-byte block to the real-storage location designated by general register R_1 from the expanded-storage block designated by general register R_2.

Bits 32-63 of general register R_2 are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4 K-byte block of expanded storage which is to be transferred. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R_1 are a real address which designates a 4 K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 are ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE IN is not subject to key-controlled storage protection, but low-address protection does apply. PAGE IN is not subject to program-event recording for storage alteration.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

If the page-in operation is completed with no errors, condition code 0 is set.

If the page-in operation encounters an expanded-storage data error, condition code 1 is set. For an expanded-storage data-error condition, the contents of the entire 4 K-byte block in real storage is unpredictable, but this condition does not result in the generation of invalid checking-block codes in real storage.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

Operation of PAGE IN in a Multiple-CPU Configuration

The accesses to main storage and to expanded storage by PAGE IN are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

See also the description under PAGE OUT.

Resulting Condition Code:

0 Page-in operation completed
1 Expanded-storage data error
2 --
3 Expanded-storage block not available

Program Exceptions:

- Addressing (block designated by general register R_1)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Protection (block designated by general register R_1; low-address protection)
- Transaction constraint

PAGE OUT

PGOUT R_1,R_2 [RRE]

'B22F'	////////	R_1	R_2
0	16	24	28 31

A page-out operation is performed which transfers a 4 K-byte block from the real-storage location designated by general register R_1 to the expanded-storage block designated by general register R_2.

Bits 32-63 of general register R_2 are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4 K-byte block of expanded storage which is to be replaced. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R_1 are a real address which designates a 4 K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 is ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE OUT is not subject to key-controlled protection.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Depending on the model, after the data has been written to the expanded-storage block, a read-back-check operation may be performed to determine whether the data was written correctly. If the read-back-check operation determines that the data has been written correctly, condition code 0 is set. If the read-back-check operation encounters an expanded-storage data error, condition code 1 is set.

Most models do not perform the read-back-check operation, and, after the page-out operation is completed, condition code 0 is set.

Regardless of whether condition code 0 or condition code 1 is set, the entire 4 K-byte block is written. Errors, if any, in the block after the block is written are preserved. Thus, if a subsequent execution of PAGE IN addresses the same expanded-storage block, the expanded-storage data error will be detected and condition code 1 will be indicated.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

Operation of PAGE OUT in a Multiple-CPU Configuration

The accesses to main storage and to expanded storage by PAGE OUT are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

If two or more CPUs issue PAGE IN or PAGE OUT instructions at approximately the same instant in time, depending on the model, the operations may be performed one at a time, or the operations may be performed concurrently. Concurrent operation may occur even if the instructions address the same expanded-storage block.

When two or more PAGE OUT instructions addressing the same expanded-storage block are executed concurrently, the resulting values in the expanded-storage block for each group of bytes transferred may be from any of the instructions being executed simultaneously. The number of bytes transferred as a group depends on the model.

Similarly, for concurrent execution of a PAGE IN and a PAGE OUT instruction for the same expanded-storage block, the resulting values for each group of bytes transferred as a result of the execution of the PAGE IN instruction may be either the old or new values from the expanded-storage block.

Concurrent operation of paging instructions does not result in expanded-storage data errors.

Resulting Condition Code:

0 Page-out operation completed
1 Expanded-storage data error
2 --
3 Expanded-storage block not available

Program Exceptions:

- Addressing (block designated by general register R_1)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Transaction constraint

PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION

PCKMO [RRE]

'B928'	////////////////

0 16 31

A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-38 on page 10-75 shows the assigned function codes. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	PCKMO-Query	16	—
1	PCKMO-Encrypt-DEA-Key	32	8
2	PCKMO-Encrypt-TDEA-128-Key	40	8
3	PCKMO-Encrypt-TDEA-192-Key	48	8
18	PCKMO-Encrypt-AES-128-Key	48	16
19	PCKMO-Encrypt-AES-192-Key	56	16
20	PCKMO-Encrypt-AES-256-Key	64	16
32	PCKMO-Encrypt-ECC-P256-Key	64	16
33	PCKMO-Encrypt-ECC-P384-Key	80	16
34	PCKMO-Encrypt-ECC-P521-Key	112	16
40	PCKMO-Encrypt-ECC-Ed25519-Key	64	16
41	PCKMO-Encrypt-ECC-Ed448-Key	96	16

Explanation:

— Not applicable

Figure 10-38. Function Codes for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.

Figure 10-39 shows the contents of general registers 0 and 1.

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by other CPUs and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

PCKMO-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

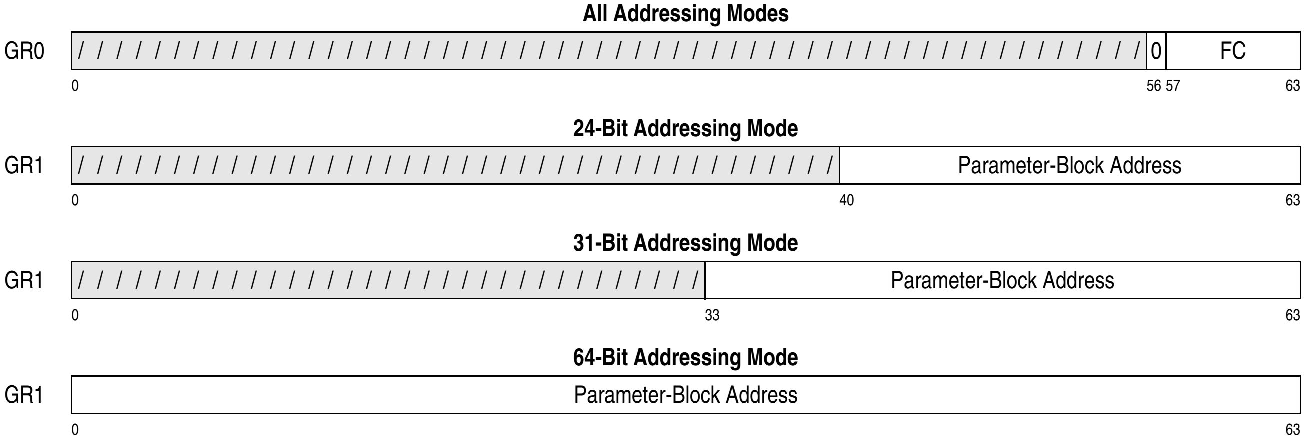

Figure 10-39. General Register Assignment for PCKMO

The parameter block used for the function has the following format:

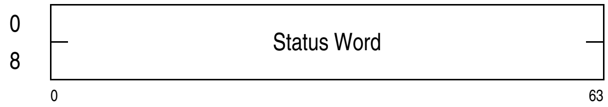

Figure 10-40. Parameter Block for PCKMO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PCKMO instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

PCKMO-Encrypt-DEA-Key (Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

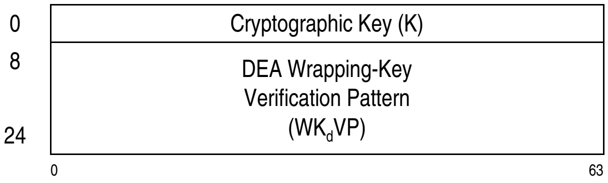

Figure 10-41. Parameter Block for PCKMO-Encrypt-DEA-Key

The 8-byte cryptographic key, K, in byte offsets 0-7 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-7 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 8-31 of the parameter block.

PCKMO-Encrypt-TDEA-128-Key (Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

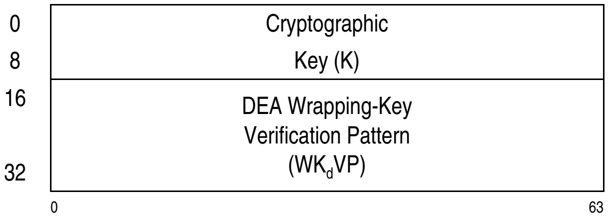

Figure 10-42. Parameter Block for PCKMO-Encrypt-TDEA-128-Key

The 16-byte cryptographic key, K, in byte offsets 0-15 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-15 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 16-39 of the parameter block.

PCKMO-Encrypt-TDEA-192-Key (Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

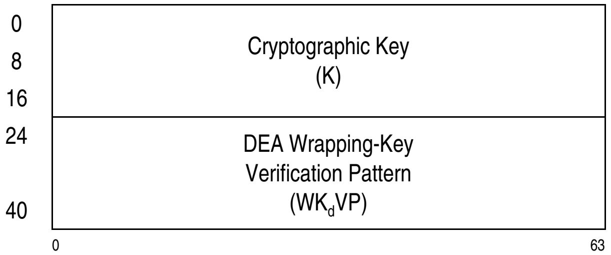

Figure 10-43. Parameter Block for PCKMO-Encrypt-TDEA-192-Key

The 24-byte cryptographic key, K, in byte offsets 0-23 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-23 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 24-47 of the parameter block.

PCKMO-Encrypt-AES-128-Key (Function Code 18)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

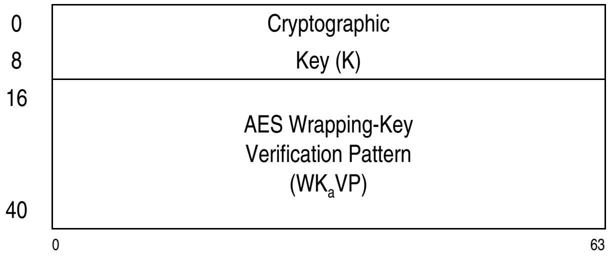

Figure 10-44. Parameter Block for PCKMO-Encrypt-AES-128-Key

The 16-byte cryptographic key, K, in byte offsets 0-15 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-15 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 16-47 of the parameter block.

PCKMO-Encrypt-AES-192-Key (Function Code 19)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

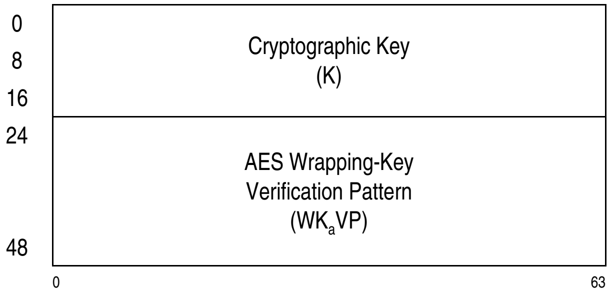

Figure 10-45. Parameter Block for PCKMO-Encrypt-AES-192-Key

The 24-byte cryptographic key, K, in byte offsets 0-23 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-23 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 24-55 of the parameter block.

PCKMO-Encrypt-AES-256-Key (Function Code 20)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

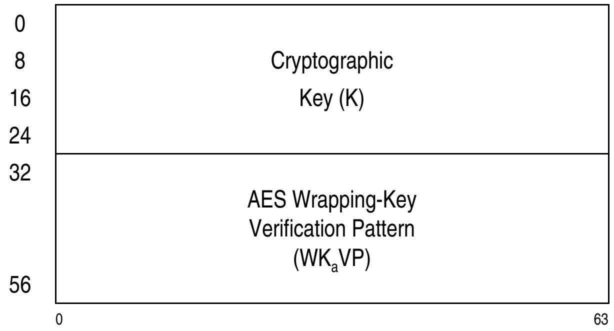

Figure 10-46. Parameter Block for PCKMO-Encrypt-AES-256-Key

The 32-byte cryptographic key, K, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-ECC-P256-Key (Function Code 32)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

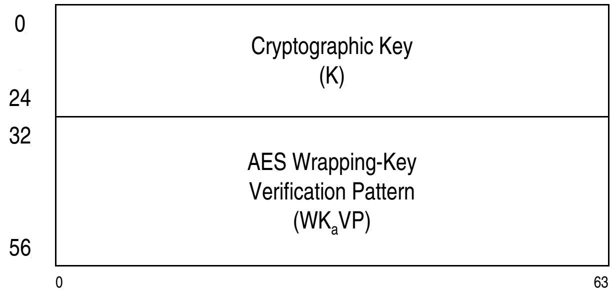

Figure 10-47. Parameter Block for PCKMO-Encrypt-ECC-P256-Key

The 32-byte cryptographic key, K, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-ECC-P384-Key (Function Code 33)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

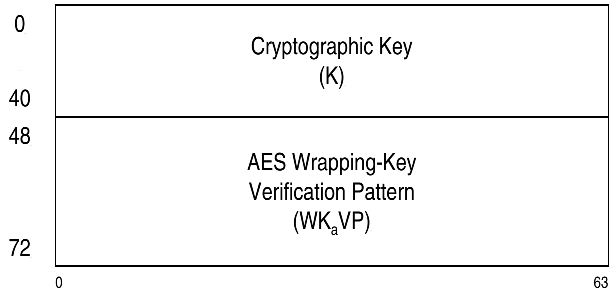

Figure 10-48. Parameter Block for PCKMO-Encrypt-ECC-P384-Key

The 48-byte cryptographic key, K, in byte offsets 0-47 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-47 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 48-79 of the parameter block.

PCKMO-Encrypt-ECC-P521-Key (Function Code 34)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

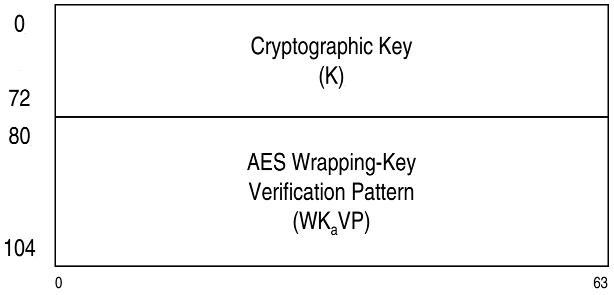

Figure 10-49. Parameter Block for PCKMO-Encrypt-ECC-P521-Key

The 521 bit cryptographic key, K, is right aligned in byte offsets 14-79 of the parameter block with padding in bytes 0 to 13 and part of byte 14. The programmer must pad with zeros in byte 14 or unpredictable results are possible when using this key. Bytes 0 to 79 are encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-79 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 80-111 of the parameter block.

PCKMO-Encrypt-ECC-Ed25519-Key (Function Code 40)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

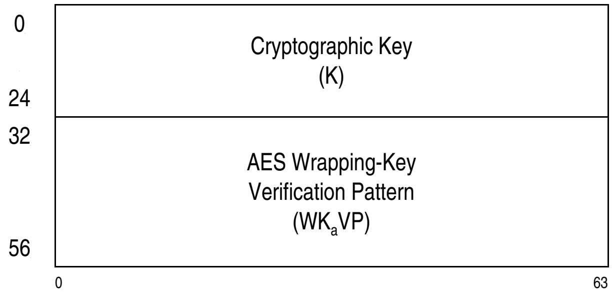

Figure 10-50. Parameter Block for PCKMO-Encrypt-ECC-Ed25519-Key

The 255 bit cryptographic key, K, is right aligned in byte offsets 0-31 of the parameter block and has a 1 bit zero pad. The programmer must use a zero for the padding or unpredictable results are possible when using this key. The whole 32 byte field is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-ECC-Ed448-Key (Function Code 41)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-39 on page 10-76.

The parameter block used for the function has the following format:

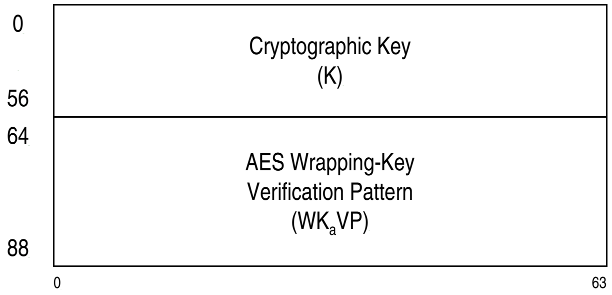

Figure 10-51. Parameter Block for PCKMO-Encrypt-ECC-Ed448-Key

Bytes 0 to 63 of the paramater block are encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-431 for the encryption algorithm.) The 56-byte cryptographic key, K, is in byte offsets 8-63 of the parameter block and padding is in bytes 0-7. The result is placed back in byte offsets 0-63 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 64-95 of the parameter block.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Condition Code: The code remains unchanged.

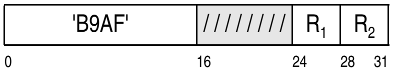
Program Exceptions:

- Access (fetch, parameter block; store, parameter block)
- Operation (if the message-security-assist extension 3 is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: Each set of PCKMO-Encrypt-DEA-Key functions, PCKMO-Encrypt-AES-Key functions, and PCKMO-Encrypt-ECC-Key functions can be independently disabled by an external means. When a set is disabled, functions in the set appear as if they were not installed.

PERFORM FRAME MANAGEMENT FUNCTION

PFMF R$_1$,R$_2$ [RRE]



Subject to the controls in the first-operand register, a frame-management function is performed for the storage frame designated by the second-operand address.

The contents of general register R$_1$ are as follows:

Frame-management function indications: Bit positions 44-47 of general register R$_1$ contain the frame-management function indications (FMFI), as follows:

Reserved: Bits 44 and 45 are reserved and must contain zeros; otherwise, a specification exception is recognized.

Set-Key Control (SK): Bit 46 controls whether the storage key for each 4 K-byte block in the frame is set from bits 56-62 of general register R$_1$. When the SK control is zero, the keys are not set; when the SK control is one, the keys are set.

Clear-Frame Control (CF): Bit 47 controls whether the frame is set to zeros. When the CF control is zero, no clearing operation is performed. When the CF control is one, the frame is cleared to zeros.

Usage Indication (UI): Bit position 48 of general register R$_1$ contains the usage indication (UI). When bit 48 is zero, it indicates that the program does not anticipate immediate usage of the frame. When bit 48 is one, it indicates that program anticipates usage of the frame in the near future.

Frame-Size Code (FSC): Bits 49-51 of general register R$_1$ contain the frame-size code (FSC), as follows:

FSC	Meaning
0	4 K-byte frame
1	1 M-byte frame
2	2 G-byte frame
3-7	Reserved

Reference-Bit Update Mask (MR): When the set-key control, bit 46 of general register R$_1$, is one, bit 53 of general register R$_1$ controls whether updates to the reference bit in the storage key may be bypassed, as described below. When the set-key control is zero, bit 53 of general register R$_1$ is ignored.

Change-Bit Update Mask (MC): When the set-key control, bit 46 of general register R$_1$, is one, bit 54 of general register R$_1$ controls whether updates to the change bit in the storage key may be bypassed. When the set-key control is zero, bit 54 of general register R$_1$ is ignored.

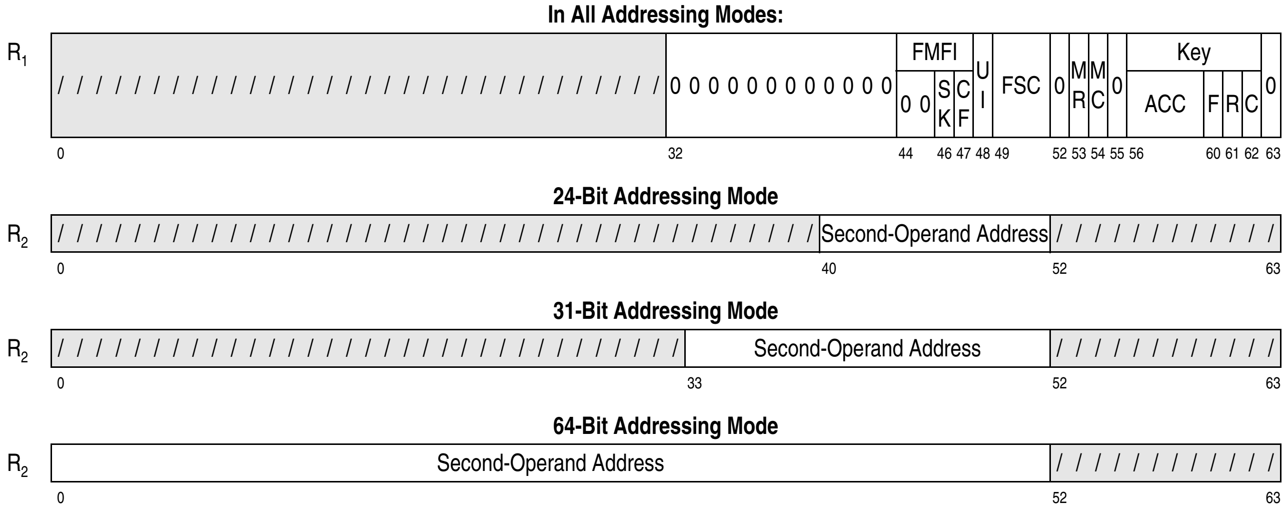
When the conditional-SSKE facility is installed, the handling of the MR and MC bits is identical to the handling of the corresponding bits of the M$_3$ field of the SET STORAGE KEY EXTENDED instruction (described on page 10-133), except that general register R$_1$ is not updated with the contents of the previous key, and the condition code is not changed. When the conditional-SSKE facility is not installed, the MR and MC bits are ignored.

Key: When the set-key control, bit 46 of general register R$_1$, is one, bits 56-62 of the register contain the storage key to be set for each 4 K-byte block in the frame, with the access-protection bits, fetch-protection bit, reference bit, and change bit in bit positions 56-59, 60, 61, and 62, respectively. When the set-key control is zero, bits 56-62 of general register R$_1$ are ignored.

Bit positions 0-31 general register R$_1$ are ignored. Bit positions 32-45, 55, and 63 of general register R$_1$ are reserved and must contain zeros. When the nonquiescing key-setting facility is not installed, bit position 52 of general register R_1 is also reserved and must contain zero. If any reserved bit position in general register R_1 does not contain zeros, a specification exception is recognized. When the nonquiescing key-setting facility is installed, bit position 52 of general register R_1 is ignored.

General register R_2 contains the real or absolute address of the storage frame upon which the frame-management function is to be performed. When the frame-size code designates a 4 K-byte block, the second-operand address is real; when the frame-size code designates a 1 M-byte or 2 G-byte block the second-operand address is absolute. The handling of the address in general register R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of the register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

The contents of the registers just described are shown in Figure 10-52.



Explanation:

ACC	Access-protection bits of the storage key
C	Change bit of the storage key
CF	Clear-frame control
F	Fetch-protection bit of the storage key
FMFI	Frame-management function indication
FSC	Frame-size code
MC	Change-bit-update mask
MR	Reference-bit-update mask
R	Reference bit of the storage key
SK	Set-key control
UI	Usage indication

Figure 10-52. Register Contents for PERFORM FRAME-MANAGEMENT FUNCTION

When the frame-size code is 0, the specified frame-management functions are performed for the 4 K-byte frame specified by the second operand. General register R_2 is unmodified in this case.

When the frame-size code is 1, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 1 M-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1 M-byte boundary.

When the enhanced-DAT facility 2 is installed and the frame-size code is 2, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 2 G-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 2 G-byte boundary. When the enhanced-DAT facility 2 is not installed, a frame-size code of 2 is reserved.

PERFORM FRAME MANAGEMENT FUNCTION is interruptible. When the frame-size code is 1 or 2, an interruption may occur between the processing of successive 4 K-byte blocks. When both the clear-frame and set-key controls are one, an interruption may also occur between the clearing and key-setting operations for an individual 4 K-byte block.

When the frame-size code is 1 or 2, processing is as follows:

- When both the clear-frame and set-key functions are specified, both functions are completed for a 4 K-byte block before proceeding to the next block.
- When an interruption occurs (other than one that follows termination), the second-operand address in general register R_2 is updated by the number of 4 K-byte blocks completely processed, so the instruction, when reexecuted, resumes at the point of interruption.
- When the instruction completes without interruption, the second-operand address in general register R_2 is updated to the next 1 M-byte boundary (FSC=1) or 2 G-byte boundary (FSC=2).
- In any of the above cases, bit 52-63 of general register R_2 are unchanged.

When the CPU is in the 24-bit addressing mode and the frame-size code is 1, bits positions 32-39 of general register R_2 are set to zeros and bits 0-31 of the register are unchanged. When the CPU is in the 24-bit addressing mode and the frame-size code is 2, a specification exception is recognized.

When the CPU is in the 31-bit addressing mode, and the frame-size code is either 1 or 2, bit position 32 of general register R_2 is set to zero and bits 0-31 of general register R_2 are unchanged.

When the clear-frame control is one, references to main storage within the second operand may be multiple-access references and are not necessarily performed in a left-to-right direction as observed by other CPUs and by channel programs. The clear operation is not subject to key-controlled protection; however low-address protection applies regardless of whether the frame-size code designates a 4 K-byte, 1 M-byte, or 2 G-byte frame (that is, regardless of whether the second-operand address is real or absolute).

When the set-key control is one, the operation for each 4 K-byte block is similar to that described in “SET STORAGE KEY EXTENDED” on page 10-133, except that when the keys for multiple blocks are set, the condition code and the contents of general register R_1 are unchanged.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the seven bits of all storage keys to be set are the same as bits 56-62 of general register R_1, or when the MR and MC bits allow all the storage keys to remain unchanged, it is unpredictable whether the serialization and checkpoint-synchronization functions are performed after the operation completes. See “SET STORAGE KEY EXTENDED” on page 10-133 for details on the cases where setting of the key may be bypassed.

When the set-key control is one, and the nonquiescing key-setting facility is not installed, a quiescing operation is performed. When the set-key control is one, and the nonquiescing key-setting facility is installed, a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-120 for a discussion of the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-133 for details on the quiescing operation.

Provided that there is no other access to the storage by other CPUs or the channel subsystem, the final results of the instruction reflect the specified key value, including the specified R and C values when MR and MC are zero, respectively. Subject to this constraint, it is unpredictable whether the clear-frame or the set-key operation is performed first when both of the respective controls are one. When both the clear-frame and set-key controls are one, and either the MR or MC bit is also one, and the clear operation is performed first, the storage key that is compared with bits 56-62 of general register R_1 in the set-key operation is the key following the clear operation (that is, both the R and C bits will have been set to one by the clear operation).

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Special Conditions

A specification exception is recognized and the operation is suppressed for any of the following conditions:

- Bits 32-45, 55, or 63 of general register R_1 are not zero.
- When the nonquiescing key-setting facility is not installed, bit 52 of general register R_1 is not zero.
- The frame-size code specifies a reserved value.
- The CPU is in the 24-bit addressing mode and the frame-size code is 2.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, low-address-protection only, operand 2, when the clear-frame control is one)
- Addressing (operand 2)
- Operation (enhanced-DAT facility not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. When PFMF is issued with the set-key control set to one, the program must ensure that no other CPU or channel subsystem is simultaneously accessing the storage designated by general register R_2. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R_2. See the programming note on page 5-122 for more information.
2. Access exceptions may be recognized for the second operand, even when the clear-frame and set-key controls are both zero.
3. When the move-page-and-set-key facility is installed, some models also implement a performance enhancement for simultaneously clearing a frame and setting its storage key. This is likely to be the fastest way to perform this combined operation. Even though these two functions are combined, another CPU may observe the reference and change bits being set to one, before being set to their final value by the key setting operation. The CPU can invoke this mode of operation for PERFORM FRAME MANAGEMENT FUNCTION when all of the following conditions are met:
   - The set-key control (SK in R_1 bit 46) and the clear-frame control (CF in R_1 bit 47) are both one.
   - The usage indication (UI) is zero. (R_1 bit 48).
   - The reference-bit update mask (MR in R_1 bit 53) and the change-bit update mask (MC in R_1 bit 54) are both zero.

PERFORM TIMING FACILITY FUNCTION

PTFF [E]

'0104'

0 15

A timing facility function specified by the function code in general register 0 is performed. The condition code is set to indicate the outcome of the function. General register 1 contains the address of a parameter block in storage. PTFF query functions place information in the parameter block; PTFF control functions use information obtained from the parameter block.

As observed by other CPUs and channel programs, references to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-54 on page 10-84 shows the assigned function codes. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

Figure 10-53 shows the contents of the general registers just described.

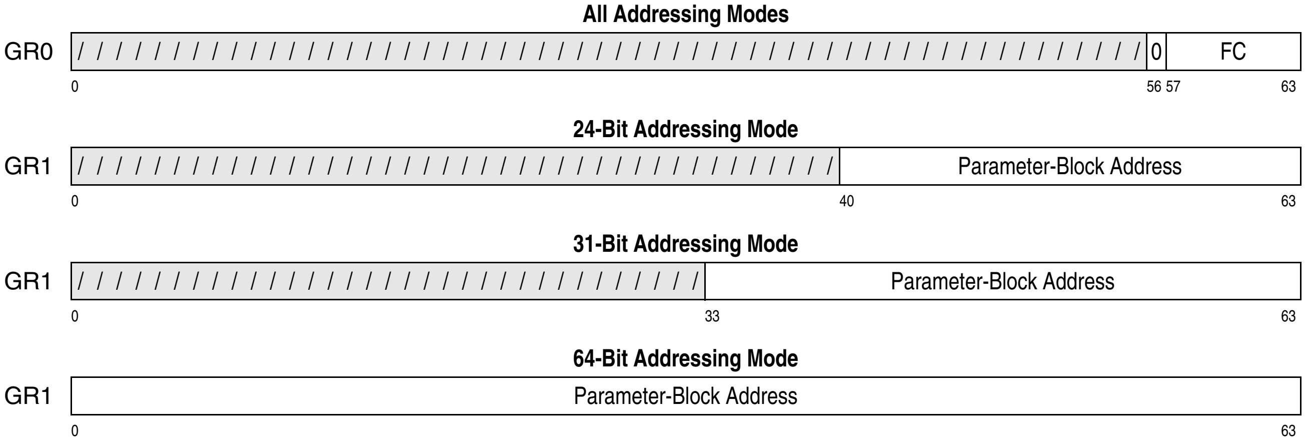


Figure 10-53. General Register Assignment for PERFORM TIMING FACILITY FUNCTION

In the access-register mode, access register 1 specifies the address space containing the parameter block.

The function codes for PERFORM TIMING FACILITY FUNCTION are as follows.

Code		Function	Parm. Block Size (bytes)	Availability
Hex	Dec			
00	0	PTFF-QAF	16	U
01	1	PTFF-QTO	32	U
02	2	PTFF-QSI	56	U
03	3	PTFF-QPT	8	U
04	4	PTFF-QUI	256	U
05	5	PTFF-QTOU	40	U
0A	10	PTFF-QSIE	96	U
0D	13	PTFF-QTOUE	80	U
41	65	PTFF-STO	8	P
45	69	PTFF-STOU	8	P
49	73	PTFF-STOE	16	P
4D	77	PTFF-STOUE	16	P

Explanation:

P Privileged: Available only in the supervisor state.

U Unprivileged: Available in both the problem state and the supervisor state

Figure 10-54. Function Codes for PERFORM TIMING FACILITY FUNCTION

Figure 10-54. Function Codes for PERFORM TIMING FACILITY FUNCTION

All other function codes are unassigned.

The PTFF-QAF (Query Available Functions) function provides the means of indicating the availability of the other functions.

Function 0: PTFF-QAF (Query Available Functions)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Status Bits 0-31	pb.w1
04	4	Status Bits 32-63	pb.w2
08	8	Status Bits 64-95	pb.w3
0C	12	Status Bits 95-127	pb.w4
		0 31	

Figure 10-55. Parameter Block for PTFF-QAF (Query Available Functions)

A 128-bit field is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PTFF instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed. The availability of an installed function is indicated by the condition code returned by the attempted execution of the function.

Function 1: PTFF-QTO (Query TOD Offset)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	TOD Offset (0:31)	pb.d
0C	12	TOD Offset (32:63)	
10	16	Logical TOD Offset (0:31)	pb.dl
14	20	Logical TOD Offset (32:63)	
18	24	TOD Epoch Difference (0:31)	pb.ed
1C	28	TOD Epoch Difference (32:63)	
		0 31	

Figure 10-56. Parameter Block for PTFF-QTO (Query TOD Offset)

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The TOD offset returned is a 64-bit signed binary integer (pb.d) that indicates the value of the TOD-offset (d). This value indicates the amount of steering that has been applied (actually in the case of offset-based TOD-clock steering, or conceptually in the case of hardware-based TOD-clock steering) to the physical clock to form the system TOD clock. The TOD epoch difference is not included in this value.

The 64-bit logical-TOD-offset value returned (pb.dl) indicates the current value of the difference between the TOD clock and the physical clock. The value includes the TOD epoch difference. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

The 64-bit TOD epoch difference value returned (pb.ed) is the TOD epoch difference (includes both the user-specified epoch difference and the sync-check offset). Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

Function 2: PTFF-QSI (Query Steering Information)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Old Episode Start Time (0:31)	pb.old.s
0C	12	Old Episode Start Time (32:63)	
10	16	Old Episode Base Offset (0:31)	pb.old.b
14	20	Old Episode Base Offset (32:63)	
18	24	Old Episode Fine-Steering Rate	pb.old.f
1C	28	Old Episode Gross-Steering Rate	pb.old.g
20	32	New Episode Start Time (0:31)	pb.new.s
24	36	New Episode Start Time (32:63)	
28	40	New Episode Base Offset (0:31)	pb.new.b
2C	44	New Episode Base Offset (32:63)	
30	48	New Episode Fine-Steering Rate	pb.new.f
34	52	New Episode Gross-Steering Rate	pb.new.g
		0 31	

Figure 10-57. Parameter Block for PTFF-QSI (Query Steering Information)

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The remaining fields are the values of the old-episode and new-episode registers.

Function 3: PTFF-QPT (Query Physical Clock)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tr
04	4	Physical Clock (32:63)	
		0 31	

Figure 10-58. Parameter Block for PTFF-QPT (Query Physical Clock)

The 64-bit physical-clock value returned (pb.Tr) is the current value of the physical clock. Zeros are stored for the rightmost bit positions that are not provided by the physical clock. When the clock is running, two executions of PTFF-QPT, either on the same or different CPUs, do not necessarily return different values of the clock.

Function 4: PTFF-QUI (Query UTC Information)

The parameter block used for the function has the following format:

Hex	Dec	
00 ⋮ FC	0 ⋮ 252	UTC Information Block (UIB)
		0 31

Figure 10-59. Parameter Block for PTFF-QUI (Query UTC Information)

The UIB is described in “UTC Information Block (UIB)” on page 4-58.

Function 5: PTFF-QTOU (Query TOD Offset User)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	TOD Offset (0:31)	pb.d
0C	12	TOD Offset (32:63	
10	16	Logical TOD Offset (0:31)	pb.dl
14	20	Logical TOD Offset (32:63)	
18	24	TOD Epoch Difference (0:31)	pb.ed
1C	28	TOD Epoch Difference (32:63)	
20	32	TOD User Specified Epoch Difference (0:31)	pb.edu
24	36	TOD User Specified Epoch Difference (32:63)	
		0 31	

Figure 10-60. Parameter Block for PTFF-QTOU (Query TOD Offset User)

Bytes 0-31 are as defined for the PTFF query-TOD-offset function.

The 64-bit TOD user specified epoch difference value returned is the user-specified portion of the guest epoch difference for the current level of CPU execution. It does not include the sync-check offset portion of the guest epoch difference. When executed at the basic-machine or LPAR hypervisor level, this value is zero. When executed at the guest 1 level, this value is the guest epoch difference excluding the guest 1 sync-check offset portion of the guest 1 epoch difference. When executed at the guest 2 level, this value is the guest epoch difference excluding the guest 2 sync-check offset portion of the guest 2 epoch difference.

Function 10: PTFF-QSIE (Query Steering Information Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Physical Clock (64:95)	
0C	12	Physical Clock (96:127)	
10	16	Old Episode Start Time (0:31)	pb.old.s
14	20	Old Episode Start Time (32:63)	
18	24	Old Episode Start Time (64:95)	
1C	28	Old Episode Start Time (96:127)	
20	32	Old Episode Base Offset (0:31)	pb.old.b
24	36	Old Episode Base Offset (32:63)	
28	40	Old Episode Base Offset (64:95)	
2C	44	Old Episode Base Offset (96:127)	
30	48	Old Episode Fine-Steering Rate	pb.old.f
34	52	Old Episode Gross-Steering Rate	pb.old.g
38	56	New Episode Fine-Steering Rate	pb.new.f
3C	60	New Episode Gross-Steering Rate	pb.new.g
40	64	New Episode Start Time (0:31)	pb.new.s
44	68	New Episode Start Time (32:63)	
48	72	New Episode Start Time (64:95)	
4C	76	New Episode Start Time (96:127)	
50	80	New Episode Base Offset (0:31)	pb.new.b
54	84	New Episode Base Offset (32:63)	
58	88	New Episode Base Offset (64:95)	
5C	92	New Episode Base Offset (96:127)	
		0 31	

Figure 10-61. Parameter Block for PTFF-QSIE (Query Steering Information Extended)

The PTFF-QSIE function is analogous to the PTFF-QSI function, except that the physical-clock, old-episode-start-time, old-episode-base-offset, new-episode-start-time, and new-episode-base-offset fields each contain 128 bits, rather than 64 bits.

The physical-clock, old-episode-start-time, and new-episode-start-time fields each contain a 72-bit unsigned binary integer in the rightmost bits and zeros in the leftmost 56 bits. The old-episode-base-offset and new-episode-base-offset fields each contain a 72-bit signed binary integer in the rightmost bits, and the sign bit in bit 56 is extended to the left 56 bits to form a 128-bit signed binary integer.

Programming Note: The PTFF-QSIE function is available when the multiple-epoch facility is installed in the configuration.

Function 13: PTFF-QTOUE (Query TOD Offset User Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Physical Clock (64:96)	
0C	12	Physical Clock (96:127)	
10	16	TOD Offset (0:31)	pb.d
14	20	TOD Offset (32:63	
18	24	TOD Offset (64:95)	
1C	28	TOD Offset (96:127)	
20	32	Logical TOD Offset (0:31)	pb.dl
24	36	Logical TOD Offset (32:63)	
28	40	Logical TOD Offset (64:95)	
2C	44	Logical TOD Offset (96:127)	
30	48	TOD Epoch Difference (0:31)	pb.ed
34	52	TOD Epoch Difference (32:63)	
38	56	TOD Epoch Difference (64:95)	
3C	60	TOD Epoch Difference (96:127)	
40	64	TOD User Specified Epoch Difference (0:31)	pb.edu
44	68	TOD User Specified Epoch Difference (32:63)	
48	72	TOD User Specified Epoch Difference (64:95)	
4C	76	TOD User Specified Epoch Difference (96:127)	
		0 31	

Figure 10-62. Parameter Block for PTFF-QTOUE (Query TOD Offset User Extended)

The PTFF-QTOUE function is analogous to the PTFF-QTOU function, except each field is 128 bits, rather than 64 bits.

The physical-clock field contains a 72-bit unsigned binary integer in the rightmost bits, and bits 0-55 are stored as zeros. The TOD-offset, logical-TOD-offset, TOD-epoch-difference, and TOD-user-specified-epoch-difference fields each contain a 72-bit signed binary integer in the rightmost bits. The sign bit in bit 56 is extended to the left 56 bits to form a 128-bit signed binary integer.

Programming Note: The PTFF-QTOUE function is available when the multiple-epoch facility is installed in the configuration.

Function 65: PTFF-STO (Set TOD Offset)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New TOD Epoch Difference (0:31)	pb.d
04	4	New TOD Epoch Difference (32:63)	
		0 31	

Figure 10-63. Parameter Block for PTFF-STO (Set TOD Offset)

The function specifies a value that is to replace the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. The function operates only on the TOD epoch difference (D), and the change takes place immediately. The function operates on the combined TOD-epoch difference (D = SCO + Du) and does not modify the sync-check offset. If the sync-check offset is nonzero, a subsequent sync-check-offset correction will modify the TOD epoch difference to reflect the amount of the correction. Depending on the TOD clock resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 32-63 may be ignored by the machine and treated as if they were zeros.

Programming Note: When the multiple-epoch facility is installed, the PTFF-STO function is deprecated, and the PTFF-STOE function should be used.

PTFF-STO provides no means by which an epoch index can be set. When the multiple-epoch facility is installed, the use of PTFF-STO may result in inconsistent values stored by SET CLOCK EXTENDED if the epoch index was previously set to a nonzero value.

At some future date, the PTFF-STO function may be removed from the architecture.

Function 69: PTFF-STOU (Set TOD Offset User)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New TOD User Specified Epoch Difference (0:31)	pb.du
04	4	New TOD User Specified Epoch Difference(32:63)	
		0 31	

Figure 10-64. Parameter Block for PTFF-STOU (Set TOD Offset User)

The function specifies a value that is to replace the user-specified portion of the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be ignored by the machine and treated as if they were zeros.

When the multiple-epoch facility is installed, the PTFF-STOU function is deprecated, and the PTFF-STOUE function should be used.

Programming Note: At some future date, the PTFF-STOU function may be removed from the architecture.

Function 73: PTFF-STOE (Set TOD Offset Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New TOD Epoch Difference (0:31)	pb.ed
04	4	New TOD Epoch Difference (32:63)	
08	8	New TOD Epoch Difference (64:95)	
0C	12	New TOD Epoch Difference (96:127)	
		0 31	

Figure 10-65. Parameter Block for PTFF-STOE (Set TOD Offset Extended)

The PTFF-STOE function is analogous to the PTFF-STO function, except that the new-TOD-epoch-difference field is 128 bits for PTFF-STOE.

The new-TOD-epoch-difference field contains a 72-bit signed binary in the rightmost bits. Bits 0-56 of the field should contain either all zeros or all ones corresponding to the sign of the new TOD epoch difference in bit 56, thus forming a 128-bit signed binary integer in the field. If a mixture of zeros and ones appear in bits 0-56, the results are unpredictable.

The function specifies a value that is to replace the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. The function operates only on the TOD epoch difference (D); no new episode is scheduled, and the change takes place immediately. The function operates on the combined TOD-epoch difference (D = SCO + Du) and does not modify the sync-check offset. If the sync-check offset is nonzero, a subsequent sync-check-offset correction will modify the TOD epoch difference to reflect the amount of the correction.

Bit 127 of the new-TOD-epoch-difference field corresponds to a clock unit. Depending on the TOD-clock-resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 96-127 may be ignored by the machine and treated as if they were zeros.

Programming Note: The PTFF-STOE function is available when the multiple-epoch facility is installed in the configuration.

Function 77: PTFF-STOUE (Set TOD Offset User Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New User-Specified TOD Epoch Diff. (0:31)	pb.ed
04	4	New User-Specified TOD Epoch Diff. (32:63)	
08	8	New User-Specified TOD Epoch Diff. (64:95)	
0C	12	New User-Specified TOD Epoch Diff. (96:127)	
		0 31	

Figure 10-66. Parameter Block for PTFF-STOUE (Set TOD Offset User Extended)

The PTFF-STOUE function is analogous to the PTFF-STOU function, except that the new-TOD-epoch-difference field is 128 bits for PTFF-STOUE.

The new-user-specified-TOD-epoch-difference field contains a 72-bit signed binary in the rightmost bits. Bits 0-56 of the field should contain either all zeros or all ones corresponding to the sign of the new user-specified TOD epoch difference in bit 56, thus forming a 128-bit signed binary integer in the field. If a mixture of zeros and ones appear in bits 0-56, the results are unpredictable.

The function specifies a value that is to replace the user-specified portion of the TOD epoch difference; no new episode is scheduled and the change takes effect immediately.

Bit 127 of the new-user-specified TOD-epoch-difference field corresponds to a clock unit. Depending on the TOD clock resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 96-127 may be ignored by the machine and treated as if they were zeros.

Programming Note: The PTFF-STOUE function is available when the multiple-epoch facility is installed in the configuration.

Special Conditions

A privileged operation exception is recognized if a PTFF control function is issued in the problem state.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.

2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Requested function performed
1 --
2 --
3 Requested function not available

Program Exceptions:

- Access (fetch, parameter block for control functions; store, parameter block for query functions)
- Operation (if the TOD-clock-steering facility instruction is not installed)
- Privileged operation (attempt to execute a PTFF control function in the problem state)
- Specification
- Transaction constraint

The priority of execution for the PTFF instruction is shown in Figure 10-67.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Operation exception.
7.B	Transaction constraint.
8.	Specification exception due to bit 56 of general register 0 being one or bits 57-63 of general register 0 specifying an unassigned or uninstalled function code.
9.	Privileged-operation exception due to attempt to issue PTFF control function in the problem state.
10.	Condition code 3 due to a control function not available in supervisor state.
11.	Access exceptions for an access to the parameter block.
12.	Condition code 0 indicating successful completion.

Figure 10-67. Priority of Execution: PERFORM TIMING FACILITY FUNCTION (PTFF)

Programming Notes:

1. When the STP-hardware-based-TOD-clock-steering facility is not installed, the physical time (pb.Tu) returned in the parameter block for PTFF-QTO, PTFF-QTOU, and PTFF-QSI is the current value of the physical clock, but with zeros in positions to the right of the bit position incremented concurrently with each TOD-offset-update event. This value is not necessarily unique. The same value may be returned if the PTFF instruction is issued multiple times on the same CPU or issued at approximately the same time on different CPUs.

2. When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit value of the physical clock at the most recent TOD-offset-update event (pb.Tu) returned by PTFF-QTO, PTFF-QTOU, and PTFF-QSI may be used by the program to ensure that all events during a short routine occurred with no intervening TOD-offset-update events. This can be accomplished by issuing one of these queries at the beginning of the routine and the other at the end and reiterating if the value of pb.Tu before and the value of pb.Tu after are different.

3. When the STP-hardware-based-TOD-clock-steering facility is installed, there are no TOD-offset-update events, and pb.Tu reports the current value of the physical clock. Steering episode changes are reflected in the old and new episode start times.

4. For Query Steering Information, pb.Tu can be used to determine whether the machine is operating in the old or new episode. When pb.new.s ≤ pb.Tu, the machine is operating in the new episode, and none of the information returned by the query has changed since the most recent TOD-offset-update event. When pb.new.s > Pb.Tr, the machine is operating in the old episode, a new episode has been scheduled and has not yet taken effect. The program should avoid any dependency on the new episode values returned in this case, as it is possible the values may change again before the new episode takes effect.

5. Two or more executions of PTFF-QPT within a short period of time, either on the same or different CPUs, do not appear to step backwards, but are not necessarily unique. Thus, it is not always possible to use the values to determine the sequence of execution.

6. The Network Time Protocol (NTP) is used extensively in the Internet. A description of NTP may be found in Request for Comments (RFC) 1305. Figure 10-69 on page 10-92 shows the value of the TOD clock and NTP timestamp for 00:00:00 (0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 27 leap seconds that will have occurred through January, 2017. Each of these leap seconds is inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed. Also included are values for the beginning of each year since the most recent leap second. Figure 10-68 on page 10-91 shows the values of the TOD clock and NTP timestamp for those instants just after the leftmost bit of one or the other has changed. For instants in the future, the number of leap sec-

onds must be applied and this value is not yet known.

YYYY	MM	DD	hh mm ss	TOD Clock (Hex)	NTP Timestamp (Hex)
1968	01	20	03:14:08.000000	7A12 0000 0000 0000	8000 0000 0000 0000
1971	05	11	11:56:53.685248	8000 0000 0000 0000	8637 BD05 AF6C 69B5*
2036	02	07	06:28:16.000000	F424 0000 0000 0000+	0000 0000 0000 0000
2042	09	17	23:53:47.370496–	0000 0000 0000 0000	0C6F 7A0B 5ED8 D36B*–

Explanation:

*	Value is not exact.
+	Leap seconds must be added to this value.
–	Leap seconds must be subtracted from this value.

Figure 10-68. TOD Clock and NTP Timestamps When a Leftmost Bit Changes

Year	Month	Day	Leap Sec.	TOD Clock (Hex)	NTP Timestamp (Hex)

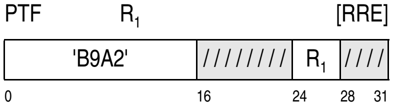
Figure 10-69. TOD Clock and NTP Timestamps

PERFORM TOPOLOGY FUNCTION



The contents of general register R_1 specify a function code in bit positions 56-63, as illustrated in Figure 10-70.

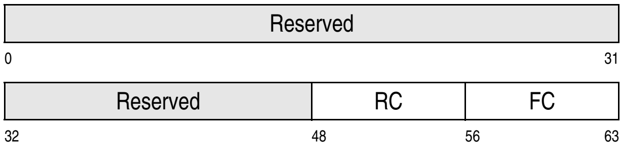


Figure 10-70. General-Register R_1 Format

The defined function codes are as follows:

FC	Meaning
0	Request horizontal polarization.
1	Request vertical polarization.
2	Check topology-change status.

Undefined function codes in the range 0-255 are reserved for future extensions.

Upon completion, if condition code 2 is set, a reason code is stored in bit positions 48-55 of general register R_1.

Bits 16-23 and 28-31 of the instruction are ignored.

Operation of Function Codes 0 and 1

When no exceptional conditions are detected, a process is initiated to place all CPUs in the configuration into the polarization specified by the function code, and condition code 0 is set. Completion of the process is asynchronous with respect to execution of the instruction and may or may not be completed when execution of the instruction completes.

Execution completes with condition code 2, and the reason code is set, for any of the following reasons:

RC	Reason
0	No reason specified.
1	The configuration is already polarized as specified by the function code.
2	A topology change is already in process

Operation of Function Code 2:

The topology-change-report-pending condition is checked. When a topology-change-report is not pending, condition code 0 is set. When a topology-change report is pending, condition code 1 is set.

A topology change is any alteration such that the contents of a SYSIB 15.1.2 would be different from the contents of the SYSIB 15.1.2 prior to the topology change.

A topology-change-report-pending condition is created when a topology-change process completes. A topology-change-report-pending condition is cleared for the configuration when any of the following is performed:

- Execution of PERFORM TOPOLOGY FUNCTION specifies function-code 2 that completes with condition code 1.
- Subsystem reset is performed.

Special Conditions

A specification exception is recognized for either of the following conditions:

- Bit positions 0-55 of general register R_1 are not zeros.
- An undefined function code is specified.

Resulting Condition Code: When the function code is 0 or 1, the condition code is set as follows:

0 Topology-change initiated
1 --
2 Request rejected
3 --

When the function code is 2, the condition code is set as follows:

0 Topology-change-report not pending
1 Topology-change report pending
2 --
3 --

Program Exceptions:

- Operation (configuration-topology facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: Further information on configuration topology may be found in “SYSIB 15.1.2 - 15.1.6 (Configuration Topology)” on page 10-159.

PROGRAM CALL

PC $D_2(B_2)$ [S]

'B218'	B_2	D_2

0 16 20 31

A program-call number specified by the second-operand address is used in a two-level or three-level lookup to locate an entry-table entry (ETE). The program is authorized to use the ETE when the AND of the PSW-key mask in control register 3 and the authorization key mask in the ETE is nonzero or when the CPU is in the supervisor state.

When the PC-type bit, bit 128 of the ETE, is zero, an operation called basic PROGRAM CALL is performed. When the PC-type bit is one, an operation called stacking PROGRAM CALL is performed.

Basic PROGRAM CALL, in the 24-bit or 31-bit addressing mode, loads the basic-addressing-mode bit, bits 33-62 of the updated instruction address, and the problem-state bit from the PSW into bit positions 32-63 of general register 14, and it leaves bits 0-31 of this register unchanged. In the 64-bit addressing mode, bits 0-62 of the updated instruction address and the problem-state bit are placed in bit positions 0-63 of general register 14. In any addressing mode, the PSW-key mask and PASN are placed in bit positions 32-63 of general register 3, and bits 0-31 of this register remain unchanged.

Stacking PROGRAM CALL places the entire PSW contents, except with an unpredictable PER mask, and also the PSW-key mask, PASN, SASN, and EAX in a linkage-stack program-call state entry that it forms. A called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, the numeric part of the program-call number, and the contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. If the ASN-and-LX-reuse facility is installed and enabled, the PASTEIN and SASTEIN also are placed in the state entry.

For basic PROGRAM CALL, the extended-addressing-mode bit, bit 31 of the PSW, must have the same value as the entry-extended-addressing-mode bit, bit 129 of the ETE; otherwise, a special-operation exception is recognized. Basic PROGRAM CALL does not change bit 31 of the PSW and, therefore, does not switch between a basic addressing mode (the 24-bit or 31-bit mode) and the extended addressing mode (the 64-bit mode). In the 24-bit or 31-bit addressing mode, basic PROGRAM CALL sets the basic-addressing-mode bit, bit 32 of the PSW, with the value of the entry-basic-addressing-mode bit, bit 32 of the ETE, and, thus, it may switch between the 24-bit and 31-bit addressing modes. In the 64-bit addressing mode, bit 32 of the PSW remains unchanged.

Stacking PROGRAM CALL, when bit 129 of the ETE is zero, sets bit 31 of the PSW to zero and sets bit 32 of the PSW with the value of bit 32 of the ETE. When bit 129 of the ETE is one, stacking PROGRAM CALL sets bits 31 and 32 of the PSW to one. Thus, stacking PROGRAM CALL can set the 24-bit, 31-bit, or 64-bit addressing mode.

When the resulting addressing mode is the 24-bit or 31-bit mode, both basic and stacking PROGRAM CALL place bits 33-62 of the entry instruction address in the ETE, which are bits 33-62 of the ETE, with 33 leftmost and one rightmost zeros appended, in bit positions 64-127 of the PSW as the new instruction address, and they place the entry-problem-state bit, bit 63 of the ETE, in bit position 15 of the PSW as the new problem-state bit. Bits 32-63 of the entry parameter in the ETE are placed in bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged.

When the resulting addressing mode is the 64-bit mode, both basic and stacking PROGRAM CALL place bits 0-62 of the entry instruction address, bits 0-62 of the ETE, with one rightmost zero appended, in bit positions 64-127 of the PSW, and they place bit 63 of the ETE in bit position 15 of the PSW. Bits 0-63 of the entry parameter in the ETE are placed in general register 4.

Basic PROGRAM CALL ORs the entry key mask from the ETE into the PSW-key mask in control register 3. Stacking PROGRAM CALL does the same, or it replaces the PSW-key mask with the entry key mask, as determined by the PSW-key-mask control in the ETE.

Stacking PROGRAM CALL optionally replaces the PSW key in the PSW and the EAX in control register 8 from the ETE, and it sets the address-space-control bits in the PSW, as determined by control bits in the ETE.

The ETE causes a space-switching operation to occur if it contains a nonzero ASN. When the ETE contains a zero ASN, the operation is called PROGRAM CALL to current primary (PC-cp); when the ETE contains a nonzero ASN, the operation is called PROGRAM CALL with space switching (PC-ss). When space switching is specified, the new PASN is loaded into control register 4 from the ETE, and a new primary-ASTE origin (PASTEO) is loaded into control register 5, also from the ETE. From the PASTE, a new primary ASCE (PASCE) and AX are loaded into control registers 1 and 4, respectively. If ASN-and-LX reuse is enabled, a new primary ASTE instance number (PASTEIN) is loaded into control register 4, also from the PASTE.

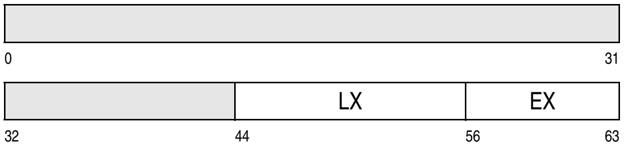
In both PC-cp and PC-ss, the SASN and secondary ASCE (SASCE) are set equal to the original PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the secondary ASTE instance number (SASTEIN) in control register 3 is set equal to the original PASTEIN. However, the space-switching stacking PROGRAM CALL operation may instead set the SASN and SASCE equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, set the SASTEIN equal to the new PASTEIN, as determined by a control bit in the ETE.

In a PC-ss to the base space of the dispatchable unit when the dispatchable unit is subspace active, bits 0-55 and 58-63 of the new PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This occurs before the possible setting of the SASCE equal to the PASCE.

PROGRAM CALL PC-Number Translation

The second-operand address is not used to address data; instead, the rightmost 20 or 32 bits of the address are used as a PC number divided into two fields: a linkage index (LX) and an entry index (EX). The entry index is always the rightmost eight bits of the PC number. When the ASN-and-LX-reuse is not installed or is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the PC number is 20 bits, and the leftmost 12 bits of the number are the linkage index. In this case, the second-operand address has the following format:

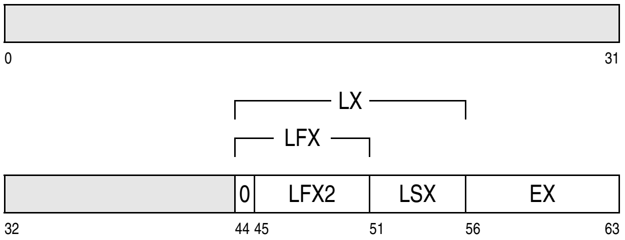
Second-Operand Address when ASN-and-LX Reuse Is Not Enabled



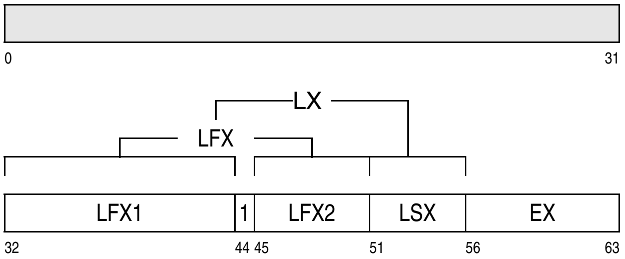
Bit 44 of the effective address has no special meaning and may be zero or one.

When the ASN-and-LX-reuse facility is installed and enabled, referred to simply by saying that ASN-and-LX reuse is enabled, the linkage index is further divided into a linkage first index (LFX) and a linkage second index (LSX). The linkage second index is always the five bits immediately on the left of the entry index. The size and format of the linkage first index depend on whether the PC number is 20 bits or 32 bits, which in turn depends on whether bit 44 of the second-operand address is zero or one, respectively. In these cases, the second-operand address has the following formats:

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is Zero



Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is One



When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, the PC number is 20 bits, and the linkage first index is bits 44-50, or bits 45-50 (LFX2) with a zero appended on the left. Thus, the linkage first index is seven bits of which the leftmost bit is always zero. When bit 44 is one, the PC number is 32 bits, and the linkage first index is bits 45-50 (LFX2) with bits 32-43 (LFX1) appended on the left, or 18 bits, and bit 44 is not a numeric part of the PC number. However, a linkage first table can contain at most 16,384 entries, and, therefore, the leftmost four bits of the linkage first index, bits 32-35 of the second-operand address, must always be zeros; otherwise, an LFX-translation exception is recognized.

Linkage Index (LX): When ASN-and-LX reuse is not enabled, bits 44-55 of the second-operand address are the linkage index and are used to select an entry from the linkage table designated by the linkage-table designation in the primary ASTE.

Linkage First Index (LFX): When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, bits 44-50 of the second-operand address are the linkage first index. When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is one, bits 45-50 with bits 32-43 appended on the left are the linkage first index. In either case, the linkage first index is used to select an entry from the linkage first table designated by the linkage-first-table designation in the primary ASTE.

Linkage Second Index (LSX): When ASN-and-LX reuse is enabled, bits 51-55 of the second-operand address are the linkage second index and are used to select an entry from the linkage second table designated by the linkage-first-table entry.

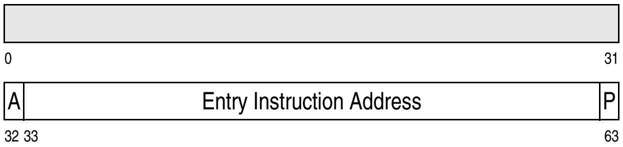
Entry Index (EX): Bits 56-63 of the second-operand address are the entry index and are used to select an entry from the entry table designated by the linkage-table entry or the linkage-second-table entry.

When the PC number is 20 bits, bits 32-43 of the second-operand address are ignored. Bits 0-31 of the second-operand address are always ignored.

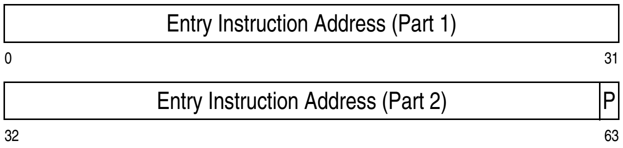
When ASN-and-LX reuse is enabled, the second word of the linkage-second-table entry used contains a linkage-second-table-entry sequence number (LSTESN). When this LSTESN is nonzero, it must be equal to an LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized. When ASN-and-LX reuse is not enabled (including when it is not installed) or the LSTESN in the linkage-second-table entry is zero, bits 0-31 of general register 15 are ignored.

The 32-byte entry-table entry (ETE) has the following format:

When Resulting Addressing Mode Is the 24-Bit or 31-Bit Mode

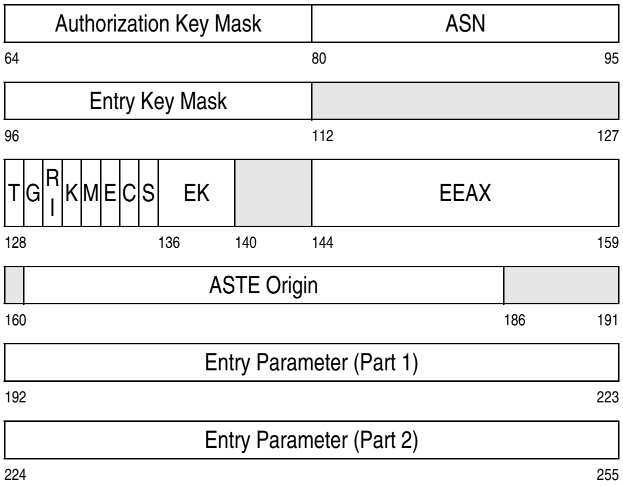


When Resulting Addressing Mode Is the 64-Bit Mode



Entry Instruction Address (Part 1)
0
31
Entry Instruction Address (Part 2)
P
32
63

Remaining fields (independent of addressing mode)



For basic PROGRAM CALL in the 24-bit or 31-bit addressing mode when bit 32 of the ETE (A) is zero (specifying the 24-bit mode), and for stacking PROGRAM CALL when bits 32 (A) and 129 (G) are zeros (specifying the 24-bit mode), bits 33-39 must be zeros; otherwise, a PC-translation-specification exception is recognized.

After the ETE has been fetched, if the current PSW specifies the problem state, the current PSW-key mask in control register 3 is tested against the AKM field in the ETE to determine whether the program is authorized to access this entry. The AKM and PSW-key mask are ANDed, and, if the result is zero, a privileged-operation exception is recognized. The PSW-key mask in control register 3 remains unchanged. When PROGRAM CALL is executed in the supervisor state, the AKM field is ignored.

If the result of the AND of the AKM and the PSW-key mask is not zero, or if the CPU is in the supervisor state, the execution of the instruction continues.

If bit 128 of the ETE (T) is zero, the basic PROGRAM CALL operation is specified. If bit 128 of the ETE is one, the stacking PROGRAM CALL operation is specified.

Basic PROGRAM CALL

The following operations are performed when basic PROGRAM CALL is specified.

Bit 31 of the current PSW (the extended-addressing-mode bit) must equal bit 129 (G) of the ETE; otherwise, a special-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bits 97-126 of the PSW (bits 33-62 of the updated instruction address) are placed in bit positions 33-62 of general register 14, bit 32 of the PSW (the basic-addressing-mode bit) is placed in bit position 32 of the register, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register. Bits 0-31 of the register remain unchanged.

In the 64-bit addressing mode, bits 64-126 of the PSW (bits 0-62 of the updated instruction address) are placed in bit positions 0-62 of general register 14, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register.

In the 24-bit or 31-bit addressing mode, bits 32 and 33-62 of the ETE (A and the EIA), with a zero appended on the right of bits 33-62, are placed in PSW bit positions 32 and 97-127, respectively (the basic-addressing-mode bit and bits 33-63 of the instruction address). In the 64-bit addressing mode, bits 0-62 of the ETE, with a zero appended on the right, are placed in PSW bit positions 64-127 (the instruction address), and PSW bit 32 remains unchanged. In any addressing mode, bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

The PSW-key mask, bits 32-47 of control register 3, is placed in bit positions 32-47 of general register 3, and the current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register 3. Bits 0-31 of general register 3 remain unchanged.

Bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3.

In the 24-bit or 31-bit addressing mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Stacking PROGRAM CALL

The following operations are performed when stacking PROGRAM CALL is specified.

The stacking process is performed to form a linkage-stack program-call state entry and place the following information in the state entry: current PSW (with an unpredictable PER mask), PSW-key mask, PASN, SASN, EAX, called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, numeric part of the program-call number, contents of general registers 0-15, and contents of access registers 0-15, and, if ASN-and-LX reuse is enabled, PASTEIN and SASTEIN. This is described in “Stacking Process” on page 5-84. The entry-type code in the state entry is 0001101 binary.

When bit 129 of the ETE (G) is zero, bit 31 of the PSW (the extended-addressing-mode bit) is set to zero, and bit 32 of the ETE (A) is placed in bit position 32 of the PSW (the basic-addressing-mode bit). (The addressing mode is set to the 24-bit mode if bit 32 is zero or to the 31-bit mode if bit 32 is one.) When bit 129 of the ETE is one, bits 31 and 32 of the PSW are set to one. (The 64-bit addressing mode is set.)

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 33-62 of the ETE (the EIA), with 33 leftmost and one rightmost zeros appended, are placed in PSW bit positions 64-127 (the instruction address). When the resulting addressing mode is the 64-bit mode, bits 0-62 of the ETE (the EIA), with one rightmost zero appended, are placed in PSW bit positions 64-127.

Bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

When bit 131 of the ETE (K) is zero, bits 8-11 of the PSW (the PSW key) remain unchanged. When bit 131 of the ETE is one, bits 136-139 of the ETE (the EK) replace the PSW key in the PSW.

When bit 132 of the ETE (M) is zero, bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3. When bit 132 of the ETE is one, bits 96-111 of the ETE replace the PSW-key mask in control register 3.

When bit 133 of the ETE (E) is zero, the EAX, bits 32-47 of control register 8, remains unchanged. When bit 133 of the ETE is one, bits 144-159 of the ETE (the EEAX) replace the EAX in control register 8.

When bit 134 of the ETE (C) is zero, bits 16 and 17 of the PSW (the address-space-control bits) are set to 00 binary (primary-space mode). When bit 134 of the ETE is one, the address-space-control bits in the PSW are set to 01 binary (access-register mode).

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged. When the resulting addressing mode is the 64-bit mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Key-controlled protection does not apply to references to the linkage stack, but low-address and DAT protection do apply.

PROGRAM CALL to Current Primary (PC-cp)

If bits 80-95 of the ETE (the ASN), are zeros, PROGRAM CALL to current primary (PC-cp) is specified, and the execution of the instruction is completed after the operations described in “PROGRAM CALL PC-Number Translation” and either “Basic PROGRAM CALL” or “Stacking PROGRAM CALL” have been performed and the following operations have been performed.

The current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of control register 3 to become the current SASN.

The current PASCE in control register 1 is placed in control register 7 to become the current SASCE.

If ASN-and-LX reuse is enabled, the current PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of control register 3 to become the current SASTEIN.

The basic PC-cp operation is depicted in parts 1-3 of Figure 10-72 on page 10-102. The stacking PC-cp operation is depicted in parts 1, 4, and 5 of the figure.

PROGRAM CALL with Space Switching (PC-ss)

If the ASN in the ETE is nonzero, PROGRAM CALL with space switching (PC-ss) is specified, and the execution of the instruction is completed after the operations described in “PROGRAM CALL PC-Number Translation” and either “Basic PROGRAM CALL” or “Stacking PROGRAM CALL” have been performed and the following operations have been performed.

Bits 80-95 of the ETE (the ASN) are placed in bit positions 48-63 of control register 4 as the new PASN.

Bits 161-185 of the ETE, with six zeros appended on the right, are used as the real address of the ASTE designated by the new PASN. An ASX-translation exception is recognized if bit 0 of the ASTE is one.

Bits 64-127 of the ASTE (the ASCE) are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE (the AX) are placed in bit positions 32-47 of control register 4 as the new authorization index.

If ASN-and-LX reuse is enabled, bits 352-383 of the ASTE (the ASTEIN) are placed in bit positions 0-31 of control register 4 as the new PASTEIN.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.

In basic PROGRAM CALL, or in stacking PROGRAM CALL when bit 135 of the ETE (S) is zero, the PASN existing before the PASN is replaced from the ETE is placed in bit positions 48-63 of control register 3 to become the current SASN, and the PASCE existing before the PASCE is replaced from the ASTE is placed in control register 7 to become the current SASCE. If ASN-and-LX reuse is enabled, the PASTEIN existing before the PASTEIN is replaced from the ASTE is placed in bit positions 0-31 of control register 3 to become the current SASTEIN. (The SASN and SASCE are set equal to the old PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the old PASTEIN.)

In stacking PROGRAM CALL when bit 135 of the ETE (S) is one, the SASN is replaced by the PASN after the PASN is replaced from the ETE, and the SASCE is replaced by the PASCE after the PASCE is replaced from the ASTE. If ASN-and-LX reuse is enabled, the SASTEIN is replaced by the PASTEIN after the PASTEIN is replaced from the ASTE. (The SASN and SASCE are set equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the new PASTEIN.)

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-70.

The PC-ss operation is depicted in parts 1 and 4-6 of Figure 10-72 on page 10-102.

PROGRAM CALL Serialization

For both the PC-cp and PC-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The basic PROGRAM CALL operation can be performed successfully only when (1) the CPU is in the primary-space mode at the beginning of the operation, (2) the subsystem-linkage control, bit 0 of the linkage-table designation or linkage-first-table designation in the current primary ASN-second-table entry, is one, and (3) the extended-addressing-mode bit, bit 31 of the current PSW, equals the entry-extended-addressing-mode bit, bit 129 of the entry-table entry. Stacking PROGRAM CALL can be performed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation and the subsystem-linkage control is one. In addition, PC-ss can be performed successfully only when the ASN-translation control, bit 44 of control register 14, is one. If any of these rules is violated, a special-operation exception is recognized.

When ASN-and-LX reuse is enabled and the LSTESN in the linkage-second-table entry is nonzero, that LSTESN must be equal to the LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

When, for PC-ss, the primary space-switch-event-control bit, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PC-ss operation if a PER event is reported.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; linkage-table entry; linkage-first-table entry; linkage-second-table entry, entry-table entry; ASN-second-table entry, PC-ss only)
- ASX translation (PC-ss only)
- EX translation
- LFX translation
- LSTE sequence
- LSX translation
- LX translation
- PC-translation specification
- Privileged operation (AND of AKM and PSW-key mask is zero in the problem state)
- Space-switch event (PC-ss only)
- Special operation
- Stack full (stacking PC only)
- Stack specification (stacking PC only)
- Subspace replacement (PC-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-71.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second instruction halfword.

7.B Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.

7.C Transaction constraint.

8.A Trace exceptions.

8.B.1 Addressing exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.

8.B.2 Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero.

Note: The LFX-translation, LSX-translation, and LSTE-sequence exceptions can be recognized only if ASN-and-LX reuse is enabled, and the LX-translation exception cannot be recognized in that case.

8.B.3 LX-translation or LFX-translation exception due to linkage-table or linkage-first-table entry, respectively, being outside table.

8.B.4 Addressing exception for access to linkage-table or linkage-first-table entry.

8.B.5 LX-translation or LFX-translation exception due to I bit (bit 0) in linkage-table or linkage-first-table entry, respectively, being one.

8.B.6 Addressing exception for access to linkage-second-table entry.

8.B.7 LSX-translation exception due to I bit (bit 0) in linkage-second-table entry being one.

8.B.8 LSTE-sequence exception due to LSTE sequence number in linkage-second-table entry being nonzero and not equal to bits 0-31 of general register 15.

8.B.9 EX-translation exception due to entry-table entry being outside table.

8.B.10 Addressing exception for access to entry-table entry.

Figure 10-71. Priority of Execution: PROGRAM CALL (Part 1 of 4)

8.B.11 Special-operation exception due to the CPU being in access-register mode or extended-addressing-mode bit, bit 31 of PSW, not being equal to entry-extended-addressing-mode bit, bit 129 of entry-table entry (basic PC only).

8.B.12 PC-translation-specification exception due to invalid combination (bits 33-39 not zeros when resulting addressing mode is 24 bit) in entry-table entry.

8.B.13 Privileged-operation exception due to zero result from ANDing PSW-key mask and AKM in the problem state.

8.B.14 Special-operation exception due to ASN-translation control, bit 44 of control register 14, being zero (PC-ss only).

8.B.15 Addressing exception for access to ASN-second-table entry (PC-ss only).

8.B.16 ASX-translation exception due to I bit (bit 0) in ASN-second- table entry being one (PC-ss only).

Note: Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.16 and before 9.

8.B.17 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry (stacking PC only).

Note: Exceptions 8.B.18-8.B.23 can occur only if there is not enough remaining free space in the current linkage-stack section.

8.B.18 Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.

8.B.19 Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined (stacking PC only).

8.B.20 Stack-full exception due to forward-section validity bit in the trailer entry being zero (stacking PC only).

8.B.21 Access exceptions (fetch) for entry descriptor of the header entry of the next section (stacking PC only). This entry is presumed to be a header entry; its entry-type field is not examined.

Figure 10-71. Priority of Execution: PROGRAM CALL (Part 2 of 4)

8.B.22 Stack-specification exception due to not enough remaining free space in the next section (stacking PC only).

8.B.23 Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.

8.B.24 Access exceptions (store) for entry descriptor of the current entry and for the new state entry (stacking PC only).

Figure 10-71. Priority of Execution: PROGRAM CALL (Part 3 of 4)

9. Space-switch event (PC-ss only).

Figure 10-71. Priority of Execution: PROGRAM CALL (Part 4 of 4)

Programming Note: The effective address from which a PC number is derived is subject to the addressing mode in the current PSW. Therefore, bits 0-39 of the effective address in the 24-bit addressing mode, and bits 0-32 in the 31-bit addressing mode, are treated as containing zeros.

Basic PC-cp and PC-ss in 24-Bit or 31-Bit Addressing Mode

PROGRAM RETURN

PR	[E]
'0101'	
0	15

The PSW, except for the PER-mask bit, saved in the last linkage-stack state entry is restored as the current PSW. The PER mask in the current PSW remains unchanged. The contents of general registers 2-14 and access registers 2-14 also are restored from the state entry. When the entry-type code in the entry descriptor of the state entry is 0001101 binary, indicating a program-call state entry, (1) the primary ASN (PASN), secondary ASN (SASN), PSW-key mask (PKM), and extended authorization index (EAX) in the control registers also are restored from the state entry and (2) if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the primary ASTE instance number (PASTEIN) and secondary ASTE instance number (SASTEIN) in the control registers also are restored from the state entry. When the entry-type code is 0001100 binary, indicating a branch state entry, the current PASN, SASN, PKM, EAX, PASTEIN, and SASTEIN remain unchanged.

The last state entry is located, and information in it is restored, as described in "Unstacking Process" on page 5-86. The state entry is logically deleted from the linkage stack, and the linkage-stack-entry address in control register 15 is replaced by the address of the next preceding state or header entry. This also is described in “Unstacking Process”.

When the state entry is a program-call state entry, it causes a space-switching operation to occur if it contains a PASN that is not equal to the current PASN. When the state entry contains a PASN that is equal to the current PASN, the operation is called PROGRAM RETURN to current primary (PR-cp); when the state entry contains a PASN that is not equal to the current PASN, the operation is called PROGRAM RETURN with space switching (PR-ss). PASN translation occurs in PR-ss. SASN translation and authorization may occur in either PR-cp or PR-ss. The terms PR-cp and PR-ss do not apply when the state entry is a branch state entry.

When the ASN-and-LX-reuse facility is installed and enabled and PASN or SASN translation occurs, the PASTEIN or SASTEIN, respectively, saved in the state entry is compared to the ASTEIN in the located ASTE.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

The sections “PASN Translation,” “SASN Translation,” “SASN Authorization,” and “PROGRAM RETURN Serialization” apply only when the unstacked state entry is a program-call state entry. The functions described in those sections are not performed when the state entry is a branch state entry.

The actions involving the PASTEIN and SASTEIN occur only when ASN-and-LX reuse is enabled by the ASN-and-LX reuse control in control register 0.

PASN Translation

If the new PASN is equal to the old PASN in bit positions 48-63 of control register 4, PASN translation is not performed, the PASTEIN in control register 4 remain as restored from the state entry, and the PASCE in control register 1 and primary-ASTE origin (PASTEO) in control register 5 are not changed. In this case, there is not a test of whether the new PASTEIN is equal to the old PASTEIN.

If the new PASN is not equal to the old PASN, the new PASN replaces the PASN in bit positions 48-63 of control register 4 and is translated to locate a 64-byte ASTE. The ASN table-lookup process is described in “ASN Translation” on page 3-30. The exceptions associated with ASN translation are collectively called ASN-translation exceptions. These exceptions and their priority are described in Chapter 6, “Interruptions.”

If ASN-and-LX reuse is enabled, the PASTEIN saved in bytes 180-183 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE are placed in bit positions 32-47 of control register 4 as the new AX. The PASN and PASTEIN in control register 4 remain as restored from the state entry.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged.

The description in this paragraph applies to use of the subspace-group facility when PASN translation has occurred. If (1) the subspace-group-control bit, bit 54, in the new PASCE is one, (2) the dispatchable unit is subspace active, and (3) the new primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the new PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs, in the case when the new SASN is equal to the new PASN, before the SASCE is set equal to the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-70.

SASN Translation

If the new SASN is equal to the new PASN, the SASCE in control register 7 is set equal to the new PASCE in control register 1. The SASTEIN, PKM, and SASN in control register 3 remain as restored from the state entry. In this case, there is not a test of whether the new SASTEIN is equal to the new PASTEIN.

If the new SASN is not equal to the new PASN, the new SASN is translated to locate a 64-byte ASTE.

If ASN-and-LX reuse is enabled, the SASTEIN saved in bytes 176-179 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 7 as the new SASCE.

Control register 3 remains as restored from the state entry.

SASN Authorization

If the new SASN is not equal to the new PASN, the authority-table origin (ATO) from the ASTE for the new SASN is used as the base for a third table lookup. The new authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in “ASN Authorization” on page 3-35.

The description in this paragraph applies to use of the subspace-group facility when SASN translation and authorization have occurred. If (1) the subspace-group-control bit, bit 54, in the new SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE origin obtained by SASN translation designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 are replaced by the same bits of the ASCE of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-70.

PROGRAM RETURN Serialization

When the unstacked state entry is a program-call state entry, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The instruction can be executed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation. In addition, if ASN-translation is required for either the PASN or the SASN, it can only be performed when the ASN-translation control, bit 44 of control register 14, is one. If either of these rules is violated, a special-operation exception is recognized.

A stack-empty, stack-operation, stack-specification, or stack-type exception may be recognized during the unstacking process.

If ASN-and-LX reuse is enabled, the restored PASTEIN must equal the ASTEIN in the located ASTE if PASN translation is performed, and the restored SASTEIN must equal the ASTEIN in the located ASTE if SASN translation is performed; otherwise, an ASTE-instance exception is recognized.

When, for PR-ss, the primary space-switch-event control, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PR-ss operation if a PER event is reported.

The PSW which is to be loaded by the instruction is not checked for validity before it is loaded. However, after loading, a specification exception is recognized, and a program interruption occurs, if any of bits 0, 2-4, 12, 24-30, and 33-63 of the PSW is a one, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are both zero and bits 64-103 are not all zeros, or if bits 31 and 32 are one and zero, respectively. In these cases, the operation is completed, and the resulting instruction-length code is 0. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

If a space-switch event is indicated and the PSW that was loaded by the instruction is invalid because of a reason described in the preceding paragraph, it is unpredictable whether the resulting instruction-length code is 0 or 1, or 0 or 2 if EXECUTE was used, or 0 or 3 if EXECUTE RELATIVE LONG was used.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

- Access (fetch and store, except key-controlled protection, linkage-stack entry)
- Addressing (authority-table entry, if SASN translation occurs)
- ASN translation (if PASN or SASN translation occurs)
- ASTE instance (if ASN-and-LX reuse is enabled and PASN or SASN translation occurs)
- Secondary authority (if SASN translation occurs)
- Space-switch event
- Special operation
- Specification
- Stack empty
- Stack operation
- Stack specification
- Stack type
- Subspace replacement (if PASN or SASN translation occurs)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-73.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.

7.B Transaction constraint.

8.A Trace exceptions.

8.B.1 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.

8.B.2 Stack-type exception due to current entry not being a state entry or header entry.

Note: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.

8.B.3 Stack-operation exception due to unstack-suppression bit in the header entry being one.

8.B.4 Access exceptions (fetch) for second word of the header entry.

Figure 10-73. Priority of Execution: PROGRAM RETURN (Part 1 of 3)

8.B.5 Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.

8.B.6 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.

8.B.7 Stack-specification exception due to preceding entry being a header entry.

8.B.8 Stack-type exception due to preceding entry not being a state entry.

8.B.9 Stack-operation exception due to unstack-suppression bit being one in the state entry.

8.B.10 Access exceptions (fetch) for the state entry, and access exceptions (store) for entry descriptor of the entry preceding the state entry.

Note: Exceptions 8.B.11-8.B.15 and the event 9 can occur only if the state entry is a program-call state entry.

8.B.11 Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (if PASN or SASN translation occurs).

8.B.12 ASN-translation exceptions (if PASN translation occurs).

8.B.13 ASTE-instance exception due to new PASTEIN not being equal to ASTEIN in ASN-second-table entry located by PASN translation (if ASN-and-LX reuse enabled).

Note: Subspace-replacement exceptions for replacement of bits in the PASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.13 and before 9.

8.B.14 ASN-translation exceptions (if SASN translation occurs).

8.B.15 ASTE-instance exception due to new SASTEIN not being equal to ASTEIN in ASN-second-table entry located by SASN translation (if ASN-and-LX reuse enabled).

Note: Subspace-replacement exceptions for replacement of bits in the SASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.15 and before 9.

8.B.16 Secondary-authority exception due to authority-table entry being outside table (if SASN translation occurs).

Figure 10-73. Priority of Execution: PROGRAM RETURN (Part 2 of 3)

8.B.17	Addressing exception for access to authority-table entry (if SASN translation occurs).
8.B.18	Secondary-authority exception due to S bit in authority-table entry being zero (if SASN translation occurs).
9.	Space-switch event (PR-ss only).
10.	Specification exception due to any PSW error of the type that causes an immediate interruption.

Figure 10-73. Priority of Execution: PROGRAM RETURN (Part 3 of 3)

Programming Note: Because PROGRAM CALL cannot be executed successfully in the secondary-space or home-space mode, PROGRAM RETURN is not intended to load a PSW specifying one of these translation modes. PROGRAM RETURN, unlike SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST, does not recognize a space-switch event because of loading a PSW that specifies the home-space mode.

PROGRAM TRANSFER

PT R_1,R_2 [RRE]

'B228'	////////	R_1	R_2
0	16	24	28 31

PROGRAM TRANSFER WITH INSTANCE

PTI R_1,R_2 [RRE]

'B99E'	////////	R_1	R_2
0	16	24	28 31

Note: In this instruction definition, the name “PROGRAM TRANSFER (WITH INSTANCE)” refers to the PROGRAM TRANSFER instruction and the PROGRAM TRANSFER WITH INSTANCE instruction.

Bits 32-47 of general register R_1 are used to update the PSW key mask, and bits 48-63 of the register are used as the new SASN and may be used as the new PASN. Bits 32-63 or 0-63 of general register R_2, depending on the current addressing mode, are used as the new values for the problem-state bit, basic-addressing-mode bit, and instruction address in the current PSW. In the PROGRAM TRANSFER WITH INSTANCE operation, bits 0-31 of general register R_1 are an ASTEIN and are compared against the new value of the PASTEIN if the PASN is changed. In the PROGRAM TRANSFER operation, bits 0-31 of general register R_1 are ignored.

The format of general registers R_1 and R_2 are shown in Figure 10-74.

For PROGRAM TRANSFER

R_1	/ /	PSW-Key Mask	ASN
	0	32	48 63

For PROGRAM TRANSFER WITH INSTANCE

R_1	ASTEIN	PSW-Key Mask	ASN
	0	32	48 63

In 24-Bit or 31-Bit Addressing Mode

R_2	/ /	A	Instruction Address	P
	0	32	33	63

In 64-Bit Addressing Mode

R_2	Instruction Address	P
	0	63

Figure 10-74. Register Contents for PROGRAM TRANSFER (WITH INSTANCE)

When the contents of bit positions 48-63 of general register R_1 are equal to the current PASN, the operation is called PROGRAM TRANSFER (WITH INSTANCE) to current primary (PT-cp or PTI-cp); when the fields are not equal, the operation is called PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss).

The contents of general register R_2 are used to update the problem-state bit and the instruction address in the current PSW and, in the 24-bit or

31-bit addressing mode, also the basic-addressing-mode bit in the current PSW. Bit 63 of general register R_2 is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R_2 replaces the basic-addressing-mode bit, bit 32 of the current PSW, and bits 33-62 of the register, with one rightmost zero appended, replace bits 33-63 of the instruction address in the PSW, bits 97-127 of the PSW. In the 64-bit addressing mode, bits 0-62 of general register R_2, with one rightmost zero appended, replace the instruction address, and the basic-addressing-mode bit remains unchanged.

Bits 32-47 of general register R_1 are ANDed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask.

In any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, the ASN specified by bits 48-63 of general register R_1 replaces the SASN in control register 3, and the SASCE in control register 7 is replaced by the final contents of control register 1.

In the PROGRAM TRANSFER operation, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in control register 3 is replaced by the final value of the PASTEIN in control register 4. This replacement occurs in the PROGRAM TRANSFER WITH INSTANCE operation regardless of the value of the ASN-and-LX-reuse control.

PROGRAM TRANSFER (WITH INSTANCE) to Current Primary (PT-cp or PTI-cp)

The PT-cp operation is depicted in part 1 of Figure 10-76 on page 10-115. The PTI-cp operation is depicted in part 1 of Figure 10-77 on page 10-117. The PT-cp or PTI-cp operation is completed when the common portion of the PROGRAM TRANSFER (WITH INSTANCE) operation, described above, is completed. The PASTEIN, authorization index, ASN, primary ASCE, and contents of control register 5 (primary-ASN-second-table-entry origin) are not changed by PT-cp or PTI-cp. In this case in the PTI-cp operation, there is not a test of whether the current PASTEIN equals the ASTEIN specified in bit positions 0-31 of general register R_1; the ASTEIN is ignored.

PROGRAM TRANSFER (WITH INSTANCE) with Space Switching (PT-ss or PTI-ss)

If the ASN in bit positions 48-63 of general register R_1 is not equal to the current PASN, a PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss) operation is specified, and the ASN is translated by means of a two-level table lookup.

The PT-ss operation is depicted in parts 1 and 2 of Figure 10-76 on page 10-115. The PTI-ss operation is depicted in parts 1 and 2 of Figure 10-77 on page 10-117. The PT-ss or PTI-ss operation is completed as follows.

In PT-ss or PTI-ss, the contents of bit positions 48-63 of general register R_1 are used as an ASN, which is translated by means of a two-level table lookup.

Bits 48-57 of general register R_1 are a 10-bit AFX that is used to select an entry from the ASN first table. Bits 58-63 are a six-bit ASX that is used to select an entry from the ASN second table. The ASN table-lookup process is described in “ASN Translation” on page 3-30. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In PT-ss if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero if the CPU is in the problem state at the beginning of the operation; otherwise, a special-operation exception is recognized. Also in PTI-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R_1 must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The authority-table origin from the ASN-second-table entry (ASTE) is used as the base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-35.

The PT-ss or PTI-ss operation is completed by placing bits 64-127 of the ASTE in control register 1 as the new PASCE and in control register 7 as the new SASCE. The contents of bit positions 32-47 of the ASTE replace the authorization index in bit positions 32-47 of control register 4. Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged. The ASN, bits 48-63 of general register R_1, replaces the SASN and PASN in bit positions 48-63 of control registers 3 and 4. In PT-ss if ASN-and-LX reuse is enabled, and in PTI-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN and PASTEIN in bit positions 0-31 of control registers 3 and 4.

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in "Subspace-Replacement Operations" on page 5-70.

PROGRAM TRANSFER (WITH INSTANCE) Serialization

For any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The instruction can be executed only when the CPU is in the primary-space mode and the subsystem-linkage control, bit 0 of the linkage-table designation, or linkage-first-table designation in the current primary ASN-second-table entry, is one. If the CPU is in the real mode, secondary-space mode, access-register mode, or home-space mode, or if the subsystem-linkage control is zero, a special-operation exception is recognized.

In PT-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state at the beginning of the operation, and an ASTE-instance exception is recognized if the ASTEIN in general register R_1 is not equal to the ASTEIN in the ASTE.

Bit 63 of general register R_2 is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, the instruction is completed only if bits 32-39 of general register R_2 specify a valid combination of PSW bits 32 and 97-103. If bit 32 of general register R_2 is zero and bits 33-39 are not all zeros, a specification exception is recognized.

In addition to the above requirements, when a PT-ss or PTI-ss instruction is specified, the ASN-translation control, bit 44 of control register 14, must be one; otherwise, a special-operation exception is recognized.

When, for PT-ss or PTI-ss, the primary space-switch-event-control bit, bit 57 of register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PT-ss or PTI-ss operation if a PER event is reported.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; authority-table entry, PT-ss and PTI-ss only)
- ASN translation (PT-ss and PTI-ss only)
- ASTE instance (PTI-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, PTI only)
- Primary authority (PT-ss and PTI-ss only)
- Privileged operation (attempt to set the supervisor state when in the problem state)
- Space-switch event (PT-ss and PTI-ss only)
- Special operation
- Specification
- Subspace replacement (PT-ss and PTI-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-75.

1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.

7.A Access exceptions for second instruction halfword.

7.B.1 Operation exception (PTI only, if the ASN-and-LX-reuse facility is not installed).

7.B.2 Special-operation exception due to DAT being off or the CPU being in secondary-space mode, access-register mode, or home-space mode.

7.C Transaction constraint.

8.A Trace exceptions.

8.B.1 Addressing exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.

8.B.2 Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero.

8.B.3 Privileged-operation exception due to attempt to set the supervisor state when in the problem state.

8.B.4 Specification exception due to invalid combination (bit 32 is zero and bits 33-39 not zeros) in general register R_2 in 24-bit or 31-bit addressing mode.

Figure 10-75. Priority of Execution: PROGRAM TRANSFER (WITH INSTANCE) (Part 1 of 2)

8.B.5 Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (PT-ss or PTI-ss only).

8.B.6 ASN-translation exceptions (PT-ss and PTI-ss only).

8.B.7 Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (PT-ss only).

8.B.8 Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one and CPU being in problem state at the beginning of the operation (PTI-ss only).

8.B.9 ASTE-instance exception due to ASTEIN in general register R_1 not being equal to ASTEIN in ASN-second-table entry (PTI-ss only).

Note: Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.9 and before 9.

8.B.10 Primary-authority exception due to authority-table entry being outside table (PT-ss and PTI-ss only).

8.B.11 Addressing exception for access to authority-table entry (PT-ss and PTI-ss only).

8.B.12 Primary-authority exception due to P bit in authority-table entry being zero (PT-ss and PTI-ss only).

9. Space-switch event (PT-ss and PTI-ss only).

Figure 10-75. Priority of Execution: PROGRAM TRANSFER (WITH INSTANCE) (Part 2 of 2)

Programming Notes:

1. The operation of PROGRAM TRANSFER (PT) is such that it may be used to restore the CPU to the state saved by a previous basic PROGRAM CALL operation. This restoration is accomplished by issuing PT 3,14. Though general registers 3 and 14 are not restored to their original values, the PASN, PSW-key mask, problem-state bit, and instruction address are restored, and the authorization index, PASCE, and primary-ASN-second-table-entry origin are made consistent with the restored PASN. In the 24-bit or 31-bit addressing mode, the basic-addressing-mode bit also is restored. If ASN-and-LX reuse is enabled, the PASTEIN also is made consistent with the restored PASN. Note that the SASN is not saved by PROGRAM CALL or restored by PROGRAM TRANSFER; PROGRAM TRANSFER sets the

SASN equal to the restored PASN. PROGRAM TRANSFER WITH INSTANCE is the same as PROGRAM TRANSFER except that the PASTEIN is made consistent regardless of ASN-and-LX-reuse enablement.

2. With proper authority, and while being executed in a common area, PROGRAM TRANSFER (WITH INSTANCE) may be used to change the primary address space to any desired space. The secondary address space is also changed to be the same as the new primary address space.

3. Unlike the RR-format branch instructions, a value of zero in the R_2 field for PROGRAM TRANSFER (WITH INSTANCE) designates general register 0, and branching occurs.

4. A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.

Figure 10-77. Execution of PROGRAM TRANSFER WITH INSTANCE (Part 2 of 2).

PURGE ALB

PALB [RRE]

'B248'	////////////////
0	16 31

The ART-lookaside buffer (ALB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The ALB appears cleared of its original contents beginning with the execution of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

PURGE TLB

PTLB [S]

'B20D'	////////////////
0	16 31

The translation-lookaside buffer (TLB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The TLB appears cleared of its original contents beginning with the fetching of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

RESET REFERENCE BIT EXTENDED

RRBE R_1,R_2 [RRE]

'B22A'	////////	R_1	R_2
0	16	24	28 31

The reference bit in the storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is set to zero. The contents of general register R_1 are ignored.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 52-63 of the register are ignored.

Because it is a real address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The remaining bits of the storage key, including the change bit, are not affected.

The condition code is set to reflect the state of the reference and change bits before the reference bit is set to zero.

Resulting Condition Code:

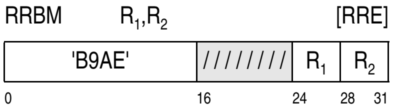
0	Reference bit zero; change bit zero
1	Reference bit zero; change bit one
2	Reference bit one; change bit zero
3	Reference bit one; change bit one

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-30 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

RESET REFERENCE BITS MULTIPLE



Beginning with the block designated by the address in general register R_2, the reference bits in the storage keys of the 64 consecutive 4 K-byte blocks are inspected and reset. For each of the 64 blocks, the reference bit is placed in an ascending bit position of general register R_1, beginning with bit position 0 of the register. Subsequent to the inspection of each reference bit, the reference bit in the storage key is reset to zero.

General register R_2 designates the first of 64 blocks in absolute storage on a 64-block (256 K-byte) boundary. In the 24-bit addressing mode, bits 40-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-39 and 46-63 of the register are ignored. In the 31-bit addressing mode, bits 33-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-32 and 46-63 of the register are ignored. In the 64-bit addressing mode, bits 0-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 46-63 of the register are ignored.

Because it is an absolute address, the address designating the first storage block is not subject to dynamic address translation or prefixing. The references to the storage keys are not subject to protection exceptions.

The remaining bits of the storage keys are not affected.

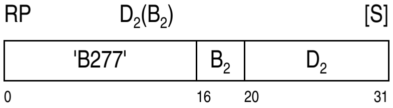
Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Operation (reset-reference-bits-multiple facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-30 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

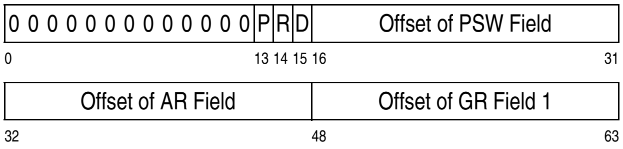
RESUME PROGRAM



Certain contents of the current PSW and of access register and general register B_2 are replaced from three or four corresponding fields in the second operand. The size of the PSW field in the second operand, the size or number of general-register fields in the second operand, and the offsets of the fields in the second operand are specified in a parameter list that immediately follows the instruction in the instruction address space.

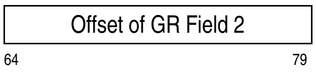
The instruction address space is the address space from which instructions are fetched. It is composed of real addresses if DAT is off.

The first 64 bits of the parameter list have the following format:



In the z/Architecture architectural mode, bits 13-15 of the parameter list further qualify the contents of the second operand, as described below. In the ESA/390-compatibility mode, if any of bits 13-15 of the parameter list is not zero, it is unpredictable whether a specification exception is recognized, or whether these bits operate as in the z/Architecture-architectural-mode definition.

When bits 14 (R) and 15 (D) of the parameter list are both one, the list is an additional 16 bits in length, as follows:



Bit 13 of the parameter list (P) specifies the size of the PSW field in the second operand. The field is eight bytes if bit 13 is zero or 16 bytes if bit 13 is one.

Bits 14 and 15 of the parameter list (R and D) provide specifications about one or two general-register fields in the second operand, as follows:

- When bit 14 is zero, then bit 15 is ignored, the general-register field 1 in the second operand is four bytes, from which bits 32-63 of general register B_2 will be replaced, there is not a general-register field 2 in the second operand, and bits 0-31 of general register B_2 will remain unchanged.
- When bit 14 is one and bit 15 is zero, then the general-register field 1 is eight bytes, from which bits 0-63 of general register B_2 will be replaced, and there is not a general-register field 2.
- When bits 14 and 15 are both one, then the general-register fields 1 and 2 are both four bytes, bits 32-63 of general register B_2 will be replaced from field 1, and bits 0-31 of the register will be replaced from field 2. (The letter “D” stands for disjoint.)

Bits 16-31 of the parameter list are an unsigned binary integer that is the offset in bytes from the beginning of the second operand to a field that has the format of an eight-byte or 16-byte PSW, depending on bit 13, and from which fields in the current PSW will be replaced. Bits 32-47 similarly are an offset to a four-byte field from which the contents of access register B_2 will be replaced. Bits 48-63 similarly are an offset to a four-byte or eight-byte field, depending on bits 14 and 15, from which bits 32-63 or 0-63, respectively, of general register B_2 will be replaced. If bits 64-79 of the parameter list exist, they similarly are an offset to a four-byte field from which bits 0-31 of general register B_2 will be replaced.

Bits 0-12 of the parameter list must be zeros; otherwise, a specification exception is recognized.

Fields in the current PSW are replaced from the corresponding fields in the PSW field in the second operand. The format of a short (eight-byte) PSW is shown in Figure 4-3 on page 4-8, and the format of a 16-byte PSW is shown in Figure 4-2 on page 4-5. The PSW fields that are replaced are shown in Figure 10-78, below.

PSW Bits	Field Name
16 and 17	Address-space control (AS)
18 and 19	Condition code (CC)
20-23	Program mask
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
64-127	Instruction address

Figure 10-78. PSW Bits Replaceable by RESUME PROGRAM

There is no test for whether bit 31 is zero in an eight-byte PSW.

Fields in the current PSW are replaced from the corresponding fields in the PSW field in the second operand. The PSW fields that are replaced are as follows:

PSW Bits	Field Name
16 and 17	Address-space control (AS)
18 and 19	Condition code (CC)
20-23	Program mask
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
64-127	Instruction address

The remaining fields in the PSW field in the second operand are ignored. Specifically, there is no test for whether bit 12 is one in an eight-byte PSW or zero in a 16-byte PSW.

Unassigned fields in the PSW may be assigned in the future and may then be among those restored by RESUME PROGRAM. Therefore, these fields in the PSW field in the second operand should contain zeros; otherwise, the program may not operate compatibly in the future.

When PSW bits 64-127 are replaced from an eight-byte PSW field in the second operand, they are replaced with bits 33-63 of the field, with 33 zeros appended on the left.

The fields in the second operand are fetched before the contents of access register B_2 and general register B_2 are changed.

When RESUME PROGRAM is the target of an execute-type instruction, the parameter list immediately follows the RESUME PROGRAM instruction, not the execute-type instruction.

The references to the parameter list are storage-operand fetches, not instruction fetches.

Special Conditions

The instruction is completed only if the bits 31, 32, and 64-127 that are to be placed in the current PSW are valid for placement in the PSW. If bits 31 and 32 are both zero and bits 64-103 are not all zeros, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are one and zero, respectively, or if bit 127 is one, a specification exception is recognized. A specification exception may or may not result when bit 24 in the second operand is one.

In the ESA/390-compatibility mode, the following applies:

- It is unpredictable whether a specification exception is recognized when any of bits 13-15 of the parameter list is not zero.

- It is unpredictable whether a specification exception is recognized when bit 31 of the PSW in the second operand is one.

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized. When DAT is off, the values of bits 16 and 17 of the PSW field in the second operand are not tested.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified by the new condition code loaded.

Program Exceptions:

- Access (fetch, parameter list and operand 2)
- Privileged operation (attempt to set the home-space mode when in the problem state)
- Space-switch event
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-79.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Access exceptions for bits 0-63 of parameter list.
8.B.2	Specification exception due to bits 0-12 of parameter list not being all zeros.
8.B.3	Access exceptions for bits 64-79 of parameter list, if these bits exist.
8.B.4	Access exceptions for second operand.
8.B.5	Privileged-operation exception due to attempt to set the home-space mode when in the problem state.
8.B.6.a	Specification exception due to invalid values in bit positions 31, 32, and 64-127 of PSW in second operand.
8.B.6.b	Specification exception may or may not occur due to a one in bit position 24 of PSW in second operand.
9.	Space-switch event.

Figure 10-79. Priority of Execution: RESUME PROGRAM

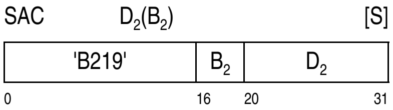
Programming Notes:

1. As described in “Instruction Fetching” on page 5-118, the bytes of an instruction may be fetched piecemeal, and the instruction may be fetched multiple times for a single execution.

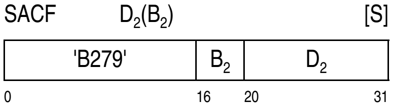
Therefore, the results are unpredictable when instructions are fetched for execution from storage that is being changed by another CPU or a channel program. This warning is particularly applicable when RESUME PROGRAM is the target of an execute-type instruction since the execute-type instruction may be refetched in order to generate, from its second operand, the address of the parameter list used by RESUME PROGRAM. If the execute-type instruction is refetched, there is not necessarily a test for whether storage still contains either the execute-type instruction or the RESUME PROGRAM instruction.

2. The storage-operand references for RESUME PROGRAM may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

SET ADDRESS SPACE CONTROL

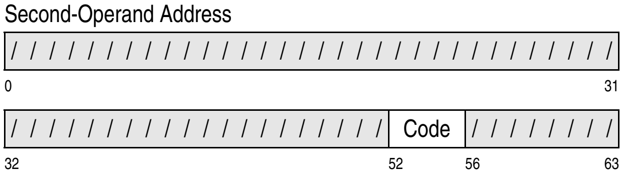


SET ADDRESS SPACE CONTROL FAST



Bits 52-55 of the second-operand address are used as a code to set the address-space-control bits in the PSW. The second-operand address is not used to address data; instead, bits 52-55 form the code. Bits 0-51 and 56-63 of the second-operand address are ignored. Bits 52 and 53 of the second-operand address must be zeros; otherwise, a specification exception is recognized.

The following figure summarizes the operation of SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST:



Code	Name of Mode	Result in PSW Bits 16 and 17
0000	Primary space	00
0001	Secondary space	10
0010	Access register	01
0011	Home space	11
All others	Invalid	

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized.

For SET ADDRESS SPACE CONTROL, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. This function is not performed for SET ADDRESS SPACE CONTROL FAST.

Special Conditions

For SET ADDRESS SPACE CONTROL, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. The same rules apply also to SET ADDRESS SPACE CONTROL FAST, except that whether the secondary-space control is tested is unpredictable.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation (attempt to set the home-space mode in the problem state)
- Space-switch event
- Special operation
- Specification
- Transaction constraint

The priority of recognition of program exceptions for the instructions is shown in Figure 10-80.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero. May be omitted for SET ADDRESS SPACE CONTROL FAST.
7.D	Transaction constraint.
8.	Privileged-operation exception due to attempt to set home-space mode when in problem state.
9.	Specification exception due to nonzero value in bit positions 52 and 53 of second-operand address.
10.	Space-switch event.

Figure 10-80. Priority of Execution: SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST

Programming Notes:

1. SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST are defined in such a way that the mode to be set can be placed directly in the displacement field of the instruction or can be specified from the same bit positions of a general register as those in which the mode is saved by INSERT ADDRESS SPACE CONTROL.

2. SET ADDRESS SPACE CONTROL FAST may provide better performance than SET ADDRESS SPACE CONTROL, depending on the model.

3. Because SET ADDRESS SPACE CONTROL FAST does not perform the serialization function, it does not cause copies of prefetched instructions to be discarded. To ensure predictable results after SET ADDRESS SPACE CONTROL FAST is used to switch to or from the home-space mode, the program must cause prefetched instructions to be discarded before an instruction is executed in a location that does not contain the same instruction in both the primary and home address spaces. The operations that cause prefetched instructions to be discarded are described in “Instruction Fetching” on page 5-118.

4. If a program stores into the instruction stream at a location following a subsequent SET ADDRESS SPACE CONTROL FAST instruction, and the SET ADDRESS SPACE CONTROL FAST instruction changes the translation mode either from or to either the access-register mode or the home-space mode, a copy of a prefetched instruction may be executed instead of the value that was stored. To avoid this situation, either SET ADDRESS SPACE CONTROL must be used instead of SET ADDRESS SPACE CONTROL FAST or some other means must be used to cause prefetched instructions to be discarded after the conceptual store occurs.

SET CLOCK

SCK $D_2(B_2)$ [S]

'B204'	B_2	D_2
0	16	20 31

The current value of the TOD clock is replaced by the contents of the doubleword designated by the second-operand address, and the clock enters the stopped state.

The doubleword operand replaces the contents of the clock, as determined by the resolution of the clock. Only those bits of the operand are set in the clock that correspond to the bit positions which are updated by the clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock. In some models, starting at or to the right of bit position 52, the rightmost bits of the second operand are ignored, and the corresponding positions of the clock which are implemented are set to zeros. Zeros are also placed in positions to the right of bit position 63 of the clock.

After the clock value is set, the clock enters the stopped state. The clock leaves the stopped state to enter the set state and resume incrementing under control of the TOD-clock-sync control, bit 34 of control register 0, of the CPU which most recently caused the clock to enter the stopped state. When the bit is zero, the clock enters the set state at the completion of the instruction. When the bit is one, the clock remains in the stopped state until the bit is set to zero or until another CPU executes a SET CLOCK instruction affecting the clock. If an external time reference (ETR) is installed, a signal from the ETR may be used to set the set state from the stopped state. When the system is not in the interpretive-execution mode, and an external time reference (ETR) is not attached to the configuration, the TOD-clock-sync control is treated as being zero, regardless of its actual value; in this case, the clock enters the set state and resumes incrementing upon completion of the instruction.

The value of the clock is changed and the clock is placed in the stopped state only if the manual TOD-clock control of any CPU in the configuration is set to the enable-set position or the TOD-clock-control-override control, bit 42 of control register 14, is one. If the TOD-clock control of all CPUs is set to the secure position and the TOD-clock-control-override control is zero, the value and state of the clock are not changed. Whether the clock is set or remains unchanged is distinguished by condition codes 0 and 1, respectively.

When the clock is not operational, the value and state of the clock are not changed, regardless of the settings of the TOD-clock control and the TOD-clock-control-override control, and condition code 3 is set.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Clock value set
1 Clock value secure
2 --
3 Clock in not-operational state

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. When the TOD-clock-steering facility is installed, the use of the SET CLOCK instruction is deprecated. In this case, PTFF control functions can be used to provide equivalent function to SET CLOCK.

   The SET CLOCK instruction provides no means by which an epoch index can be set. When the multiple-epoch facility is installed, the use of SET CLOCK may result in inconsistent values stored by STORE CLOCK EXTENDED if the epoch index was previously set to a nonzero value. In this case, the PTFF control function PTFF-STOE (set TOD offset extended) should be used rather than SET CLOCK.

   At some future date, the SET CLOCK instruction may be removed from the architecture.

2. SET CLOCK should be issued only while all other activity on all CPUs in the configuration has been suspended. This activity should not be resumed until after the TOD clock has entered the set state.

SET CLOCK COMPARATOR

SCKC $D_2(B_2)$ [S]

'B206'	B_2	D_2	
0	16	20	31

The current value of the clock comparator is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the clock comparator that correspond to the bit positions to be compared with the TOD clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock comparator.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

SET CLOCK PROGRAMMABLE FIELD

SCKPF [E]

'0107'
0 15

Bits 48-63 of general register 0 are placed in bit positions 16-31 of the TOD programmable register. Zeros are placed in bit positions 0-15 of the TOD programmable register.

Special Conditions

Bits 32-47 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-31 of general register 0 are ignored.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Specification
- Transaction constraint

Programming Note: The values in the TOD programmable registers of a configuration should be the same and should be unique within a multiple-configuration system.

SET CPU TIMER

SPT $D_2(B_2)$ [S]

'B208'	B_2	D_2
0	16	20 31

The current value of the CPU timer is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the CPU timer that correspond to the bit positions to be updated; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the CPU timer.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

SET PREFIX

SPX $D_2(B_2)$ [S]

'B210'	B_2	D_2
0	16	20 31

The word at the second-operand location is fetched, and selected bits of the operand are used to form the address of an area that is tested for accessibility. If accessible, the selected bits of the second operand replace contents of the prefix register, and the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) of this CPU are cleared of entries.

Operation in the z/Architecture Architectural Mode

Bits 1-18 of the operand with 13 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 8 K-byte new prefix area in storage. The contents of bit positions 0 and 19-31 of the second operand are ignored. The two 4 K-byte blocks within the new prefix area are accessed; if either is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The accesses to the blocks are not subject to protection; however, the accesses may cause the reference bits for the blocks to be set to ones.

Assuming no access exception is recognized, the contents of bit positions 33-50 of the prefix register are replaced by the contents of bit positions 1-18 of the word at the location designated by the second-operand address.

Operation in the ESA/390-Compatibility Mode

Bits 1-19 of the operand with 12 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 4 K-byte new prefix area in storage. The contents of bit positions 0 and 20-31 of the second operand are ignored. The 4 K-byte block within the new prefix area is accessed; if it is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The access to the block is not subject to protection; however, the access may cause the reference bit for the block to be set to one.

Assuming no access exception is recognized, the contents of bit positions 33-51 of the prefix register are replaced by the contents of bit positions 1-19 of the word at the location designated by the second-operand address.

Common Operation

The address of the prefix area is treated as a 64-bit address regardless of the addressing mode specified by the current PSW.

If the operation is completed, the new prefix is used for any interruptions following the execution of the instruction and for the execution of subsequent instructions.

The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) are cleared of entries. The ALB and TLB appear cleared of their original contents, beginning with the fetching of the next sequential instruction.

A serialization function is performed before or after the second operand is fetched and again after the operation is completed.

Special Conditions

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

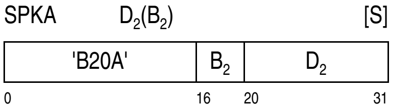
The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Addressing (new prefix area)
- Privileged operation
- Specification
- Transaction constraint

SET PSW KEY FROM ADDRESS



The four-bit PSW key, bits 8-11 of the current PSW, is replaced by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the new PSW key. Bits 0-55 and 60-63 of the second-operand address are ignored.

Special Conditions

In the problem state, the execution of the instruction is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

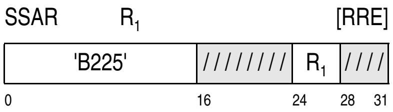
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

Programming Notes:

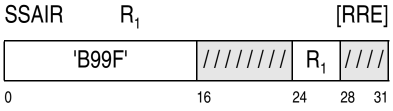
1. The format of SET PSW KEY FROM ADDRESS permits the program to set the PSW key either from the general register designated by the B_2 field or from the D_2 field in the instruction itself.

2. When one program requests another program to access a location designated by the requesting program, SET PSW KEY FROM ADDRESS can be used by the called program to verify that the requesting program is authorized to make this access, provided the storage location of the called program is not protected against fetching. The called program can perform the verification by replacing the PSW key with the requesting-program PSW key before making the access and subsequently restoring the called-program PSW key to its original value. Caution must be exercised, however, in handling any resulting protection exceptions since such exceptions may cause the operation to be terminated. See TEST PROTECTION and the associated programming notes for an alternative approach to the testing of addresses passed by a calling program.

SET SECONDARY ASN



SET SECONDARY ASN WITH INSTANCE



Note: In this instruction definition, the name "SET SECONDARY ASN (WITH INSTANCE)" refers to the SET SECONDARY ASN instruction and the SET SECONDARY ASN WITH INSTANCE instruction.

The ASN specified in bit positions 48-63 of general register R_1 replaces the secondary ASN in control register 3, and the address-space-control element corresponding to that ASN replaces the SASCE in control register 7.

The contents of bit positions 48-63 of general register R_1 are called the new ASN. For SET SECONDARY ASN WITH INSTANCE, bits 0-31 of the register are an STEIN and are compared against the new SASTEIN if the SASTEIN is not set equal to the PASTEIN, and bits 32-47 of the register are ignored. For SET SECONDARY ASN, bits 0-47 of the register are ignored.

When the new ASN is equal to the current PASN, the operation is called SET SECONDARY ASN (WITH INSTANCE) to current primary (SSAR-cp or SSAIR-cp); when the fields are not equal, the operation is called SET SECONDARY ASN (WITH INSTANCE) with space switching (SSAR-ss or SSAIR-ss). The SSAR-cp and SSAR-ss operations are depicted in Figure 10-82 on page 10-131. The SSAIR-cp and SSAIR-ss operations are depicted in Figure 10-83 on page 10-132.

SET SECONDARY ASN (WITH INSTANCE) to Current Primary (SSAR-cp or SSAIR-cp)

In the SSAR-cp or SSAIR-cp operation, the new ASN is equal to the PASN. The new ASN replaces the SASN, bits 48-63 of control register 3; the PASCE in control register 1 replaces the SASCE in control register 7.

In SSAR-cp, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in bit positions 0-31 of control register 3 is replaced by the PASTEIN in bit positions 0-31 of control register 4. This replacement occurs in SSAIR-cp regardless of the value of the ASN-and-LX-reuse control. In SSAIR-cp, there is not a test of whether the current PASTEIN equals the ASTEIN in bit positions 0-31 of general register R_1; the ASTEIN is ignored. The operation is completed.

SET SECONDARY ASN (WITH INSTANCE) with Space Switching (SSAR-ss or SSAIR-ss)

In the SSAR-ss or SSAIR-ss operation, the new ASN is not equal to the PASN, and the new ASN is translated by means of a two-level table lookup. Bits 0-9 of the new ASN (bits 48-57 of the register) are a 10-bit AFX which is used to select an entry from the ASN first table. Bits 10-15 of the new ASN (bits 58-63 of the register) are a six-bit ASX which is used to select an entry from the ASN second table. The two-level lookup is described in "ASN Translation" on page 3-30. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In SSAR-ss, if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero in the problem state; otherwise, a special-operation exception is recognized. Also in SSAIR-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R_1 must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The ASN-second-table entry (ASTE) obtained as a result of the second lookup contains the address-space-control element and the authority-table origin and length associated with the ASN.

The authority-table origin from the ASTE is used as a base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in “ASN Authorization” on page 3-35.

The new ASN, bits 48-63 of general register R_1, replaces the SASN, bits 48-63 of control register 3. The address-space-control element in the ASTE replaces the SASCE in control register 7. In SSAR-ss if ASN-and-LX reuse is enabled, and in SSAIR-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN in bit positions 0-31 of control register 3.

The description in this paragraph applies to use of the subspace-group facility. After the new SASCE has been placed in control register 7, if (1) the subspace-group-control bit, bit 54, in the SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE obtained by ASN translation is the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the SASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-70.

SET SECONDARY ASN (WITH INSTANCE) Serialization

For any of the SSAR-cp, SSAIR-cp, SSAR-ss, and SSAIR-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The operation is performed only when the ASN-translation control, bit 44 of control register 14, is one and DAT is on. When either the ASN-translation-control bit is zero or DAT is off, a special-operation exception is recognized.

In SSAR-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state, and an ASTE-instance exception is recognized if the ASTEIN in general register R_1 is not equal to the ASTEIN in the ASTE.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (authority-table entry, SSAR-ss and SSAIR-ss only)
- ASN translation (SSAR-ss and SSAIR-ss only)
- ASTE instance (SSAIR-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, SSAIR only)
- Secondary authority (SSAR-ss and SSAIR-ss only)
- Special operation
- Subspace replacement (SSAR-ss and SSAIR-ss only)
- Trace
- Transaction constraint

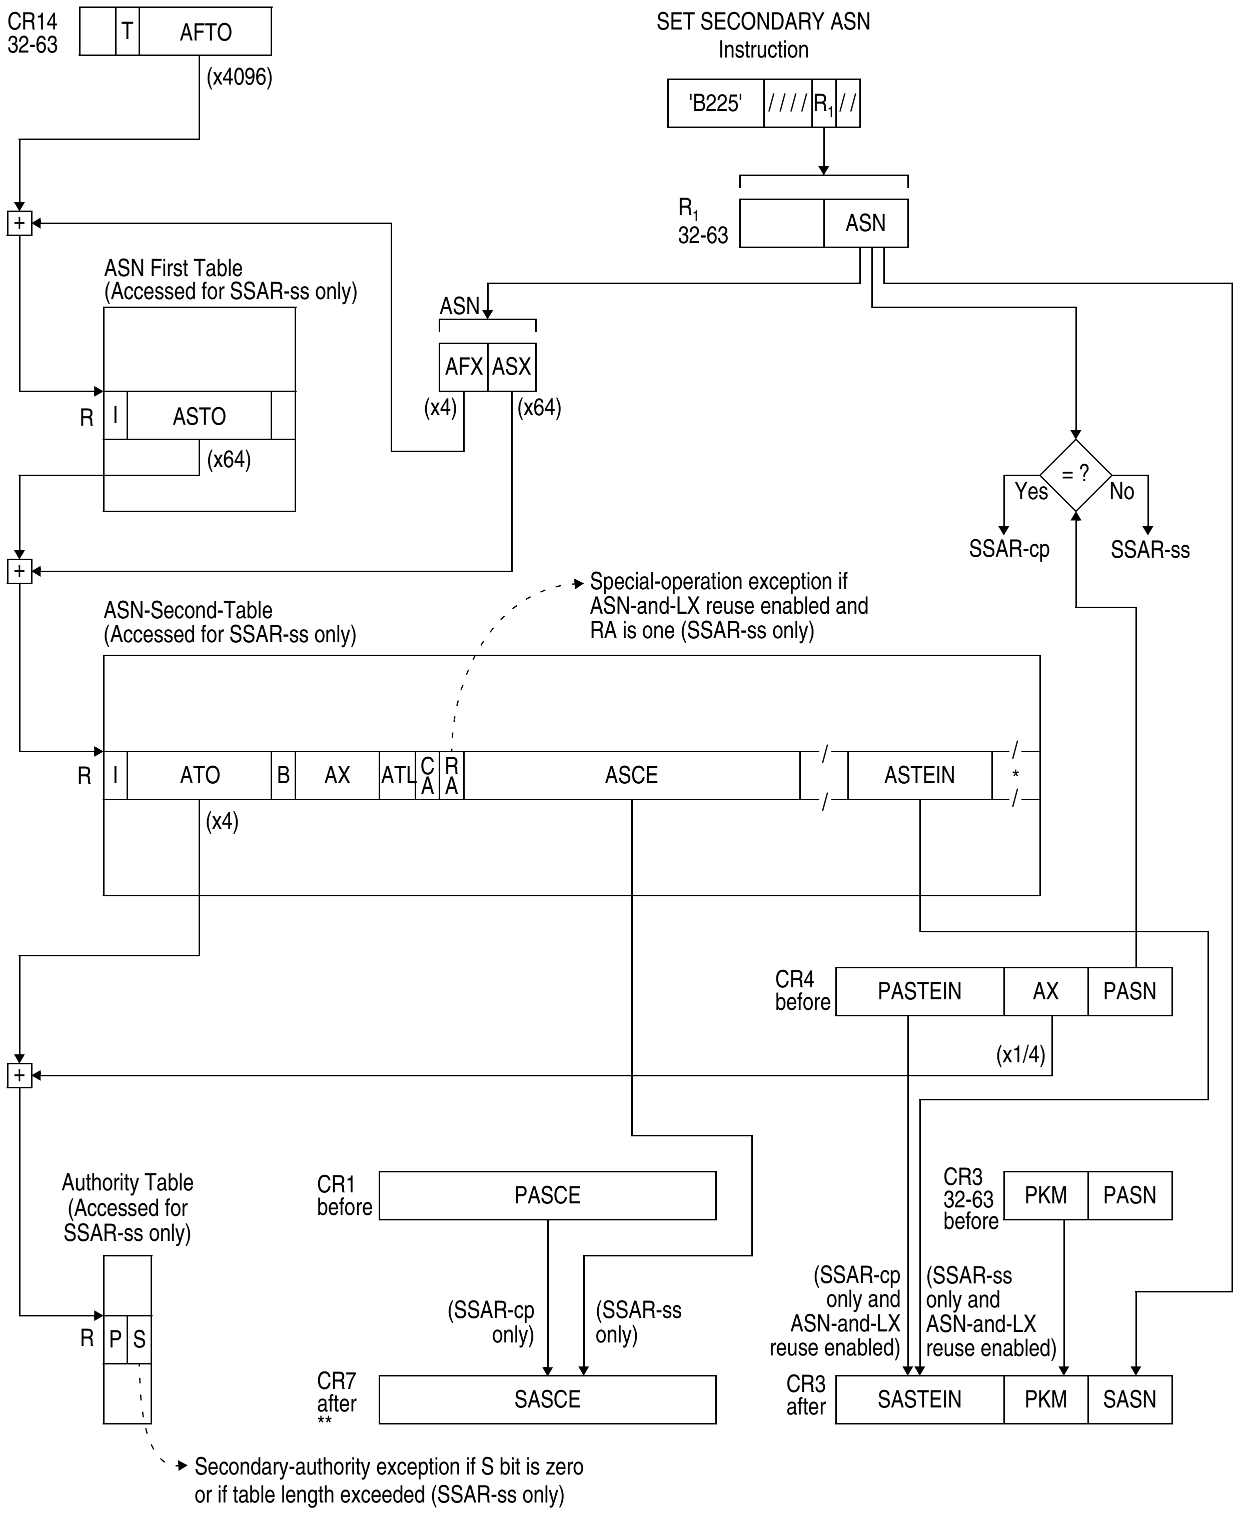
The priority of recognition of program exceptions for the instruction is shown in Figure 10-81 on page 10-130.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception (SSAIR only, if the ASN-and-LX-reuse facility is not installed).
7.B.2	Special-operation exception due to DAT being off, or the ASN-translation control, bit 44 of control register 14, being zero.
7.C	Transaction constraint.
8.A	Trace exceptions.
8.B.1	ASN-translation exceptions (SSAR-ss and SSAIR-ss only).
8.B.2	Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (SSAR-ss only).
8.B.3	Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one in the problem state (SSAIR-ss only).
8.B.4	ASTE-instance exception due to ASTEIN in general register R_1 not being equal to ASTEIN in ASN-second-table entry (SSAIR-ss only).
	Note: Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.4.
8.B.5	Secondary-authority exception due to authority-table entry being outside table (SSAR-ss and SSAIR-ss only).
8.B.6	Addressing exception for access to authority-table entry (SSAR-ss and SSAIR-ss only).
8.B.7	Secondary-authority exception due to S bit in authority-table entry being zero (SSAR-ss and SSAIR-ss only).

Figure 10-81. Priority of Execution: SET SECONDARY ASN (WITH INSTANCE) (Part 1 of 2)

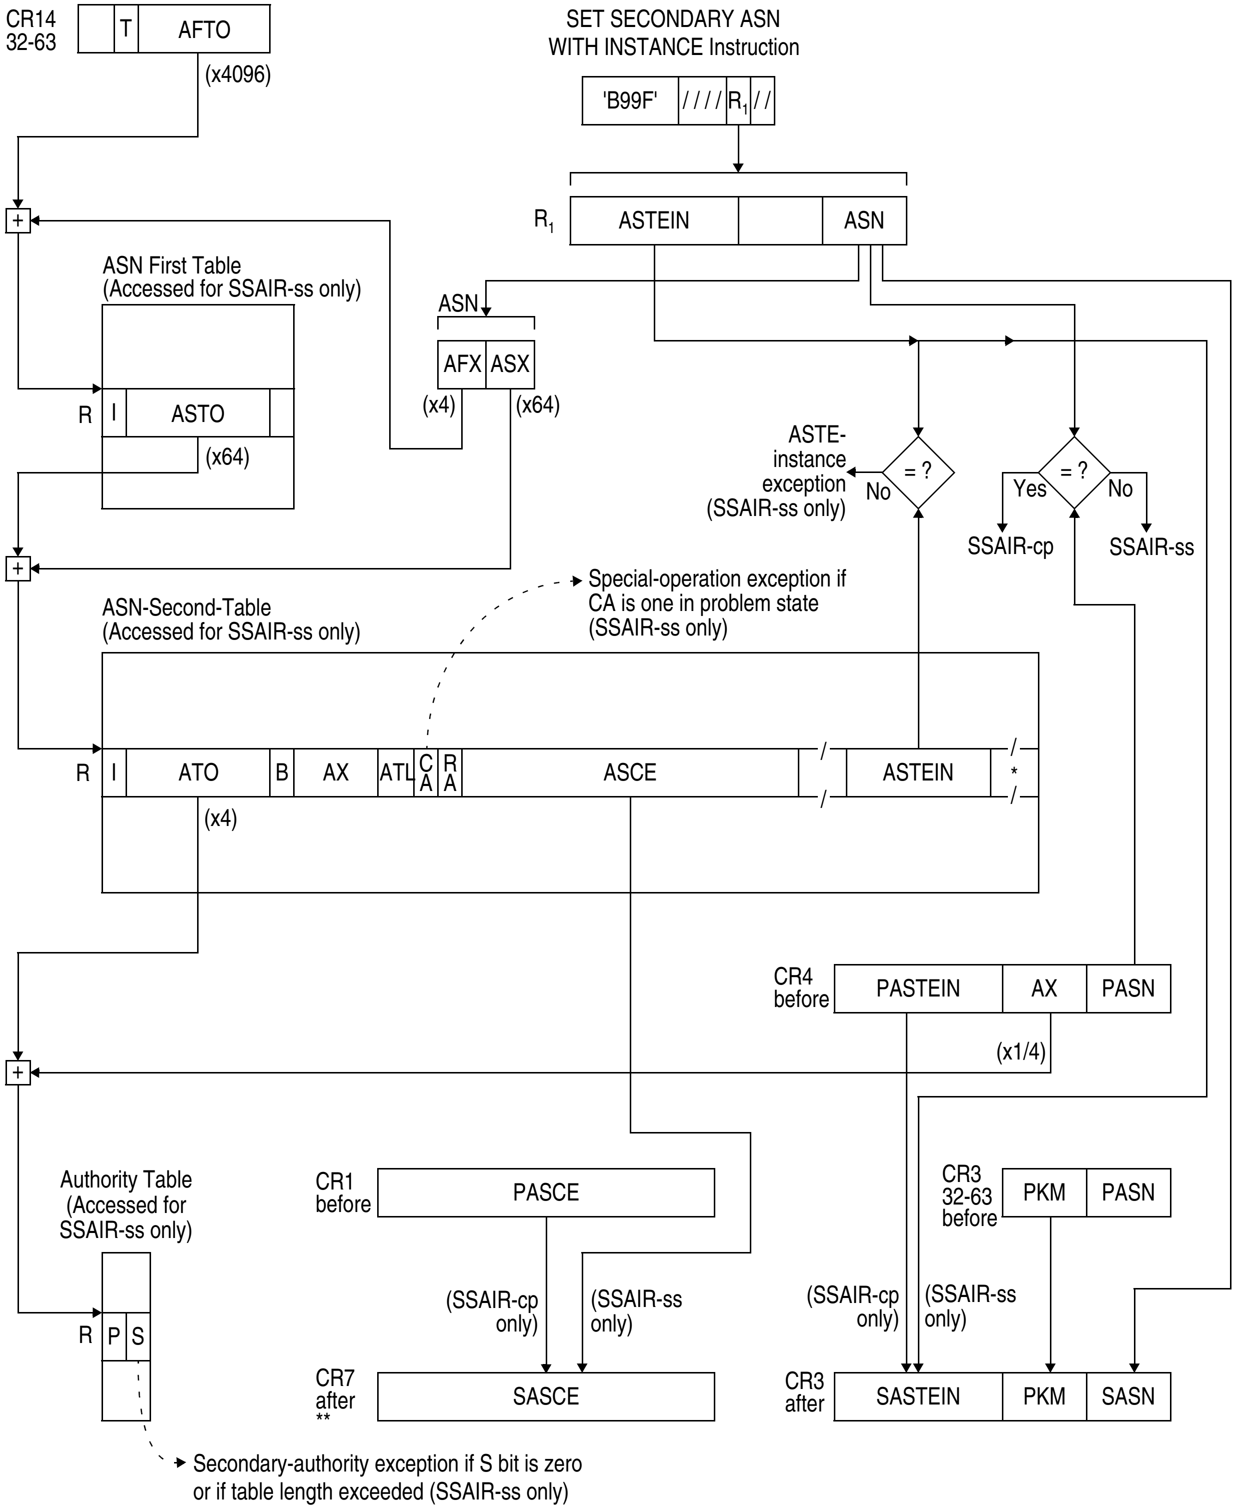
Figure 10-81. Priority of Execution: SET SECONDARY ASN (WITH INSTANCE) (Part 2 of 2)

Programming Note: A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.



R: Address is real
*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.
**: For SSAR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE

Figure 10-82. Execution of SET SECONDARY ASN



R: Address is real
*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.
**: For SSAIR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE

SET STORAGE KEY EXTENDED

SSKE R_1,R_2[,M_3] [RRF-c]

'B22B'	M_3	////	R_1	R_2
0	16	20	24	28 31

The storage key for one or more 4 K-byte blocks is replaced by the value in the first-operand register. When the conditional-SSKE facility is installed, certain functions of the key-setting operation may be bypassed.

When the conditional-SSKE facility is not installed, or when the conditional-SSKE facility is installed and both the MR and MC bits of the M_3 field are zero, the storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is replaced by bits from general register R_1. The instruction completes without changing the condition code.

When the conditional-SSKE facility is installed and either or both of the MR and MC bits are one, the access-control bits, fetch-protection bit, and, optionally, the reference bit and change bit of the storage key that is addressed by the contents of general register R_2 are compared with corresponding bits in general register R_1. If the compared bits are equal, then no change is made to the key; otherwise, selected bits of the key are replaced by the corresponding bits in general register R_1. The storage key prior to any modification is inserted in general register R_1, and the result is indicated by the condition code.

When the enhanced-DAT facility 1 is installed, the above operations may be repeated for the storage keys of multiple 4 K-byte blocks within the same 1MB block, subject to the control of the multiple-block control, described below.

The M_3 field has the following format:

NQ	MR	MC	MB
0	1	2	3

The bits of the M_3 field are defined as follows:

- ***Nonquiescing Control (NQ):*** The NQ bit, bit 0 of the M_3 field, controls whether a quiescing operation is performed, as described below.
- ***Reference-Bit-Update Mask (MR):*** The MR bit, bit 1 of the M_3 field, controls whether updates to the reference bit in the storage key may be bypassed, as described below.
- ***Change-Bit-Update Mask (MC):*** The MC bit, bit 2 of the M_3 field, controls whether updates to the change bit in the storage key may be bypassed, as described below.
- ***Multiple-Block Control (MB):*** The MB bit, bit 3 of the M_3 field, controls whether the storage keys for multiple 4 K-byte blocks of storage may be set, as described in “Setting Storage Keys in Multiple 4 K-byte Blocks” on page 10-135.

When the nonquiescing key-setting facility is not installed, bit 0 of the M_3 field is ignored. When the conditional-SSKE facility is not installed, bit positions 1 and 2 of the M_3 field are ignored. When the enhanced-DAT facility 1 is not installed, bit position 3 of the M_3 field is ignored.

When the conditional-SSKE facility is installed, processing is as follows:

1. When both the MR and MC bits, bits 1 and 2 of the M_3 field, are zero, the instruction completes as though the conditional-SSKE facility was not installed. The storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is replaced by bits from general register R_1, and the instruction completes without changing the condition code.

2. When either or both the MR and MC bits are one, processing is as follows:

   a. Prior to any modification, the contents of the storage key for the 4 K-byte block that is addressed by general register R_2 are placed in bit positions 48-54 of general register R_1, and bit 55 of general register R_1 is set to zero. Bits 0-47 and 56-63 of the register remain unchanged.

      If an invalid checking-block code (CBC) is detected when fetching the storage key, then (a) the entire storage key for the 4 K-byte block is replaced by bits 56-62 of general register R_1, (b) the contents of bit positions 48-55 of general register R_1 are unpredictable, and (c) the instruction completes by setting condition code 3.

b. The access-control bits and fetch-protection bit of the storage key for the designated 4 K-byte block are compared with the corresponding fields in bits 56-60 of general register R_1. If the respective fields are not equal, the entire storage key for the 4 K-byte block is replaced by bits from general register R_1, and the instruction completes by setting condition code 1.

   When the access-control and fetch-protection bits in the storage key are equal to the respective bits in general register R_1, processing continues as described below.

c. When both the MR and MC bits are one, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

d. When the MR bit is zero and the MC bit is one, then the reference bit of the storage key for the designated 4 K-byte block is compared with bit 61 of general register R_1. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

   If the bits are not equal, then either (a) the entire storage key for the designated 4 K-byte block is replaced by the bits in general register R_1, and the instruction completes by setting condition code 1; or (b) the reference bit for the storage key is replaced by bit 61 of general register R_1, the change bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

e. When the MC bit is zero and the MR bit is one, then the change bit of the storage key for the designated 4 K-byte block is compared with bit 62 of general register R_1. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case, except that the reference bit is unpredictable.

   If the bits are not equal, then either (a) the entire storage key for the designated 4 K-byte block is replaced by the bits in general register R_1, and the instruction completes by setting condition code 1; or (b) the change bit for the storage key is replaced by bit 62 of general register R_1, the reference bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

When the enhanced-DAT facility 1 is not installed, or when the facility is installed but the multiple-block control is zero, general register R_2 contains a real address. When the enhanced-DAT facility 1 is installed and the multiple-block control is one, general register R_2 contains an absolute address.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 52-63 of the register are ignored.

Because it is a real or absolute address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The new seven-bit storage-key value, or selected bits thereof, is obtained from bit positions 56-62 of general register R_1. The contents of bit positions 0-55 and 63 of the register are ignored. When the conditional-SSKE facility is installed, and either or both the MR and MC bits are one, bit position 63 should contain a zero; otherwise, the program may not operate compatibly in the future.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the conditional-SSKE facility is installed and the resulting condition code is 0, it is unpredictable whether a serialization and checkpoint-synchronization function is performed after the operation completes.

When the nonquiescing key-setting facility is not installed, or when the facility is installed and the nonquiescing control (NQ) is zero, the following applies:

- A quiescing operation is performed.

- For any store access, by any CPU or channel program, completed to the designated 4 K-byte block either before or after the setting of the key by this instruction, the associated setting of the reference and change bits to one in the storage key for the block also is completed before or after, respectively, the execution of this instruction.

When the nonquiescing key-setting facility is installed and the NQ control is one, a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-120 for a discussion the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-133 for details on the quiescing operation.

Setting Storage Keys in Multiple 4 K-byte Blocks

When the enhanced-DAT facility 1 is not installed, or when the facility is installed, but the multiple-block control is zero, the storage key for a single 4 K-byte block is set, as described above.

When the enhanced-DAT facility 1 is installed, and the multiple-block control is one, the storage keys for multiple 4 K-byte blocks within a 1 M-byte block may be set, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1 M-byte boundary. In this case, SET STORAGE KEY EXTENDED is interruptible, and processing is as follows:

- When an interruption occurs (other than one that follows termination), the leftmost bits of general register R_2 comprising the 4 K-byte block address have been updated so the instruction, when reexecuted, resumes at the point of interruption. If either or both the MR or MC bits are one, the condition code is unpredictable; otherwise, the condition code is unchanged.
- When the instruction completes without interruption, the leftmost bits of general register R_2 comprising the 4 K-byte block address have been updated to the next 1 M-byte boundary. If either or both the MR or MC bits are one, condition code 3 is set; otherwise, the condition code is unchanged.

In either of the above two cases, the following applies:

- Bits 52-63 of general register R_2 remain unchanged.
- When either or both the MR or MC bits are one, bits 48-55 of general register R_1 are unpredictable.

When multiple-block processing occurs and the R_1 and R_2 fields designate the same register, the second-operand address is placed in the register. When multiple-block processing occurs in the 24-bit or 31-bit addressing modes, the leftmost bits which are not part of the address in bit positions 32-63 of general register R_2 are set to zeros; bits 0-31 of the register are unchanged.

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Resulting Condition Code:

When the conditional-SSKE facility is not installed, or when both the MR and MC bits of the M_3 field are zero, the condition code remains unchanged.

When the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one, the condition code is set as follows:

0 Storage key not set
1 Entire storage key set
2 Partial storage key set
3 Entire storage key set; bits 48-55 of general register R_1 are unpredictable.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Transaction constraint

Programming Notes:

1. The M_3 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [] in the assembler syntax.

When the M_3 field is not specified, the assembler places zeros in that field of the instruction.

2. When setting multiple storage keys within the same 1 M-byte block to the same value, use of the multiple-block control (MB, bit 3 of the M_3 field) may yield better performance than executing separate SSKE instructions for each 4 K-byte block in the megabyte.

3. If the program does not rely on the setting of the reference bit, it may set the MR bit of the M_3 field to one, regardless of whether or not the conditional-SSKE facility is installed. Similarly, if the program does not rely on the setting of the change bit, it may set the MC bit of the M_3 field to one, regardless of whether or not the conditional-SSKE facility is installed. In these cases, the program cannot rely on the condition code or the key value returned in general register R_1. Conversely, if the program depends on accurate setting of the reference or change bit, then the MR and MC bits should be set to zero, such that reference and change bit recording are properly maintained when the conditional-SSKE facility is installed.

4. When SSKE is issued, the program must ensure that no channel subsystem is simultaneously altering the storage designated by general register R_2. The program also must ensure that no other CPU or channel subsystem is accessing the storage designated by general register R_2 when the nonquiescing (NQ) control is one. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R_2.

5. Even when the enhanced-DAT facility 2 is installed, the multiple-block control is limited to setting keys in a 1 M-byte block; no provision is made for setting keys in a 2 G-byte block with SSKE. PERFORM FRAME MANAGEMENT FUNCTION with a set-key control of 1 and frame-size code of 2 may be used to set the keys of a 2 G-byte block. See “PERFORM FRAME MANAGEMENT FUNCTION” on page 10-80 for additional details.

6. See the programming note on page 5-122 for restrictions on the use of the nonquiescing control.

SET SYSTEM MASK

SSM $D_2(B_2)$ [SI]

'80'	////////	B_2	D_2
0	8	16	20 31

Bits 0-7 of the current PSW are replaced by the byte at the location designated by the second-operand address.

Bits 8-15 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Special Conditions

When the SSM-suppression-control bit, bit 33 of control register 0, is one and the CPU is in the supervisor state, a special-operation exception is recognized.

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if either (a) the contents of bit positions 0 and 2-4 of the PSW are not all zeros, or (b) in the ESA/390-compatibility mode, bit position 5 of the PSW does not contain zero. In either of these cases, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

SIGNAL PROCESSOR

SIGP $R_1,R_3,D_2(B_2)$ [RS-a]

'AE'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

An eight-bit order code and, if called for, a 64-bit parameter are transmitted to the CPU designated by the CPU address contained in the third operand. The result is indicated by the condition code and may be detailed by status assembled in bit positions 32-63 of the first-operand location.

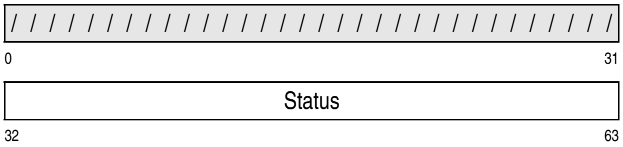
The second-operand address is not used to address data; instead, bits 56-63 of the address contain the eight-bit order code. Bits 0-55 of the second-operand address are ignored. The order code specifies the function to be performed by the addressed CPU. The assignment and definition of order codes appear in “CPU Signaling and Response” on page 4-85.

The 16-bit binary number contained in bit positions 48-63 of general register R_3 forms the CPU address. Bits 0-47 of the register are ignored. When the specified order is the set-architecture or set multithreading order, the CPU address is ignored; all CPUs in the configuration are considered to be addressed. See “CPU-Address Identification” on page 4-84 for details on the CPU address.

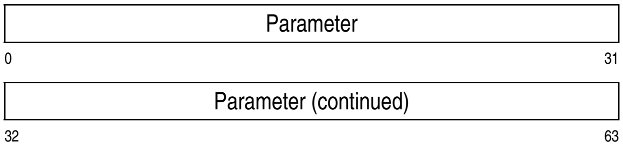
The general register containing the 64-bit parameter in bit positions 0-63 is R_1 or R_1+1, whichever is the odd-numbered register. It depends on the order code whether a parameter is provided and for what purpose it is used.

The operands just described have the following formats:

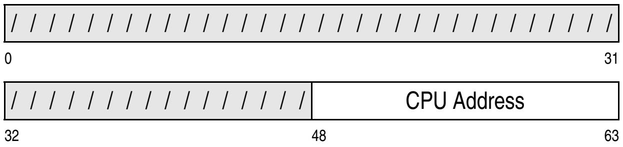
General register designated by R_1:



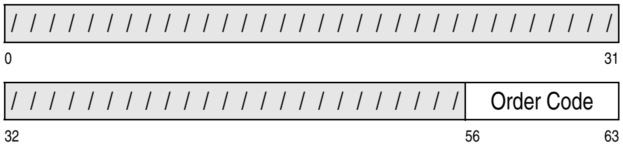
General register designated by R_1 or R_1 + 1, whichever is the odd-numbered register:



General register designated by R_3:



Second-operand address:



A serialization function is performed before the operation begins and again after the operation is completed.

When the order code is accepted and no nonzero status is returned, condition code 0 is set. When status information is generated by this CPU or returned by the addressed CPU, the status is placed in bit positions 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and condition code 1 is set.

When the access path to the addressed CPU is busy, or the addressed CPU is operational but in a state where it cannot respond to the order code, condition code 2 is set.

When the addressed CPU is not operational (that is, it is not provided in the installation, it is not in the configuration, it is in any of certain customer-engineer test modes, or its power is off), condition code 3 is set.

Resulting Condition Code:

0 Order code accepted
1 Status stored
2 Busy
3 Not operational

Program Exceptions:

- Privileged operation
- Transaction constraint

Programming Notes:

1. A more detailed discussion of the condition-code settings for SIGNAL PROCESSOR is contained in “CPU Signaling and Response” on page 4-85.

2. To ensure that presently written programs will be executed properly when new facilities using additional bits are installed, only zeros should appear in the unused bit positions of the second-operand address and in bit positions 32-47 of general register R_3.

3. Certain SIGNAL PROCESSOR orders are provided with the expectation that they will be used primarily in special circumstances. Such orders may be implemented with the aid of an auxiliary maintenance or service processor, and, thus, the execution time may take several seconds. Unless all of the functions provided by the order are required, combinations of other orders, in conjunction with appropriate programming support, can be expected to provide a specific function more rapidly. The following orders are the only orders which are intended for frequent use:

   - Conditional emergency signal
   - Emergency-signal
   - External-call
   - Sense
   - Sense-running-status

   The following orders are intended for infrequent use, and performance therefore may be much slower than for frequently used orders:

   - CPU reset
   - Initial CPU reset
   - Restart
   - Set architecture
   - Set multithreading
   - Set prefix
   - Store additional status at address
   - Store status at address
   - Start
   - Stop
   - Stop and store status

   An alternative to the set-prefix order, for faster performance when the receiving CPU is not already stopped, is the use of the emergency-signal or external-call order, followed by the execution of a SET PREFIX instruction on the addressed CPU. Clearing the TLB of entries is ordinarily accomplished more rapidly through the use of the emergency-signal or external-call order, followed by execution of the PURGE TLB instruction on the addressed CPU, than by use of the set-prefix order.

STORE CLOCK COMPARATOR

STCKC $D_2(B_2)$ [S]

'B207'	B_2	D_2
0	16	20 31

The current value of the clock comparator is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions of the clock comparator that are not compared with the TOD clock.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CONTROL

STCTL $R_1,R_3,D_2(B_2)$ [RS-a]

'B6'	R_1	R_3	B_2	D_2
0	8	12	16	20 31

STCTG $R_1,R_3,D_2(B_2)$ [RSY-a]

'EB'	R_1	R_3	B_2	DL_2	DH_2	'25'
0	8	12	16	20	32	40 47

Bits of the set of control registers starting with control register R_1 and ending with control register R_3 are stored at the locations designated by the second-operand address.

For STORE CONTROL (STCTL), bits 32-63 of the control registers are stored in successive words beginning at the second-operand address, and bits 0-31 of the registers are ignored. For STORE CONTROL (STCTG), bits 0-63 of the control registers are stored in successive doublewords beginning at the second-operand address.

The storage area where the contents of the control registers are placed starts at the location designated by the second-operand address and continues through as many storage words, for STCTL, or doublewords, for STCTG, as the number of control registers specified. The contents of the control registers are stored in ascending order of their register numbers, starting with control register R_1 and continuing up to and including control register R_3, with control register 0 following control register 15. The contents of the control registers remain unchanged.

The displacement for STCTL is treated as a 12-bit unsigned binary integer. The displacement for STCTG is treated as a 20-bit signed binary integer.

Special Conditions

The second operand must be designated on a word boundary for STCTL or on a doubleword boundary for STCTG; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CPU ADDRESS

STAP $D_2(B_2)$ [S]

'B212'	B_2	D_2
0	16	20 31

The CPU address by which this CPU is identified in a multiprocessing configuration is stored at the halfword location designated by the second-operand address.

Special Conditions

The operand must be designated on a halfword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CPU ID

STIDP $D_2(B_2)$ [S]

'B202'	B_2	D_2
0	16	20 31

Information identifying (a) the execution environment, (b) the system serial number, (c) the machine type, and (d) the format of the response is stored at the doubleword location designated by the second-operand address. Depending on the format of the response, the CPU address, logical partition identification, or both may also be stored.

The information stored has the following format:

Environment	Configuration Identification
0	8 31

Machine-Type Number	F	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
32	48	49 63

Environment: Bit positions 0-7 contain an indication of the environment in which the instruction was executed, as follows:

- For a program being executed by an IBM machine in a level-1 configuration (the basic machine), or for a program being executed by a level-2 configuration (in a logical partition), the environment field contains 00 hex.
- For a program being executed natively by the System z Personal-Development Tool (that is, when not executed in a virtual machine running on the zPDT), the environment field contains either C1 hex or D3 hex. (See programming note 6 on page 10-141).

- For a program being executed by a level-3 configuration (a virtual machine), the environment field contains FF hex.

Configuration Identification: Bit positions 8-31 contain six hexadecimal digits. Depending on the environment, the rightmost of these digits may be (a) selected from some or all of the machine's physical serial number, (b) derived from either the zPDT token or the zPDT unique-identification-manager (UIM) server, or (c) assigned by the virtual machine definition.

- When executed by a level-1 configuration, bits 8-31 are stored as follows:

A	n	n	n	n	n
8	12				31

  - When the format bit (bit 48 of the response) is zero, bit positions 8-11 (A) contain the rightmost hexadecimal digit of the physical CPU address. When the format bit is one, bit positions 8-11 contain zeros.
  - Bit positions 12-31 (nnnnn) contain the rightmost five hexadecimal digits of the machine's physical serial number.

- When executed by a level-2 configuration, and the format bit is zero, bits 8-31 are stored as follows:

L	P	n	n	n	n
8	12	16			31

  - Bit positions 8-11 (L) contain the rightmost hexadecimal digit of the logical CPU address.
  - Bit positions 12-15 (P) contain a hexadecimal digit identifying the logical partition.
  - Bit positions 16-31 (nnnn) contain the rightmost four hexadecimal digits of the machine's physical serial number.

- When executed by a level-2 configuration, and the format bit is one, bits 8-31 are stored as follows:

UPID	n	n	n	n
8	16			31

  - Bit positions 8-15 contains a two hexadecimal digit user-partition identifier (UPID) which is bound to the logical partition.
  - Bit positions 16-31 (nnnn) contains the rightmost four hexadecimal digits of the system's serial number.

- When executed by a zPDT configuration, the results are similar to those defined for a level-2 configuration when the format bit is one. See programming note 6 for further details.

- When executed by a level-3 configuration, the results are similar to those defined for a level-2 configuration. However, the hypervisor can supply alternate configuration identification.

Machine-Type Number: Bit positions 32-47 contain an unsigned packed-decimal number identifying the machine type of the CPU.

Format Indication (F): Bit position 48 specifies the format of the first two hexadecimal digits of the configuration-identification field, as described above.

Reserved: Bit positions 49-63 are reserved and stored as zeros.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. The STORE SYSTEM INFORMATION (STSI) instruction provides more comprehensive and complete information identifying the machine, logical partition, and CPU on which the program is executing. In order to ensure world-wide unique identification of the configuration of the issuing CPU, the STSI instruction specifying SYSIB 1.1.1, 1.2.1, 2.2.1, or 3.2.2 should be used.

2. The program should allow for the possibility that the configuration-identification field may contain the hexadecimal digits A-F as well as the digits 0-9.

3. The format bit is stored as one beginning with the IBM eServer zSeries 990 and in newer models.

4. Except when executed in a level-3 configuration (that is, except when executed by a virtual machine), the value of the rightmost four or five hexadecimal digits of the configuration-identification field are equivalent to the value of the corresponding rightmost EBCDIC characters stored in the sequence-code field of the SYSIB 1.1.1 stored by STSI. When executed in a level-3 configuration, the hypervisor may provide a means by which an alternate configuration identification can be specified; however, the sequence code reported in the SYSIB 1.1.1 is that of the real machine, even when executed by a virtual machine.

   Except when executed in a level-3 configuration, the content of the machine-type-number field stored by STIDP is equivalent to the EBCDIC type field of the SYSIB 1.1.1 stored by STSI. When executed in a level-3 configuration, hypervisor features such as live guest relocation may alter machine-type number stored by STIDP to reflect the machine type corresponding to a virtual architecture level. However, the type field reported in the SYSIB 1.1.1 is that of the real machine, even when executed by a virtual machine.

5. In previous versions of the architecture, bit positions 0-7 were called the version code. Prior to z/Architecture, a nonzero version code was usually indicative of the model number and number of CPUs contained in the model.

   In previous versions of the architecture, bit positions 8-31 were called the CPU-identification number. This has been renamed the configuration-identification field to more accurately represent its z/Architecture content.

6. The following applies to execution of STIDP on the System z Personal-Development Tool (zPDT) or Rational Development and Test Environment for System z (RD&T; for brevity the term zPDT also applies to RD&T):

   - The user-partition identifier (UPID) is associated with the Linux zPDT instance number.

     The zPDT instance-number field contains a value from 1-255, derived from either the zPDT token or from the unique-identification-manager (UIM) server.

   - The rightmost four hex digits of the configuration-identification field (called the serial number in zPDT documentation) contain a 16-bit binary value from 1-65,535 that is derived from the UIM server.

STORE CPU TIMER

STPT D$_2$(B$_2$) [S]

'B209'	B$_2$	D$_2$
0	16	20 31

The current value of the CPU timer is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions that are not updated by the CPU timer.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE FACILITY LIST

STFL D$_2$(B$_2$) [S]

'B2B1'	B$_2$	D$_2$
0	16	20 31

A list of bits providing information about facilities is stored in the word at real address 200. The meanings of the bits are identical to the first 32 bits stored by STORE FACILITY LIST EXTENDED. Figure 4-36, “Assigned Facility Bits” on page 4-99 shows the meanings of the assigned facility bits.

The second-operand address is ignored but should be zero to permit possible future extensions.

Key-controlled and low-address protection do not apply.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

Programming Note: STORE FACILITY LIST stores only a 32-bit indication of facilities. STORE FACILITY LIST EXTENDED may be used to store the entire list of installed facilities.

STORE PREFIX

STPX $D_2(B_2)$ [S]

'B211'	B_2	D_2
0	16	20 31

In the z/Architecture architectural mode, the contents of bit positions 33-50 of the prefix register are stored in bit positions 1-18 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 19-31 of the word.

In the ESA/390-compatibility mode, the contents of bit positions 33-51 of the prefix register are stored in bit positions 1-19 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 20-31 of the word.

Special Conditions

The operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE REAL ADDRESS

STRAG $D_1(B_1),D_2(B_2)$ [SSE]

'E502'	B_1	D_1	B_2	D_2
0	16	20	32	36 47

The 64-bit real address corresponding to the second-operand virtual address is stored in the doubleword at the location designated by the first-operand address.

The virtual address specified by the B_2 and D_2 fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in the following table:

PSW Bits 16 and 17	Address-Space-Control Element Used by DAT
00	Contents of control register 1
10	Contents of control register 7
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B_2 field
11	Contents of control register 13

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The resultant 64-bit real address is stored at the first-operand location.

The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

The address computations for the operands are performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Special Conditions

The first operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, an operation exception is recognized.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2, except for an addressing or protection exception for the designated location; store, operand 1)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: STORE REAL ADDRESS is contrasted to LOAD REAL ADDRESS as follows:

- In the 24-bit or 31-bit addressing mode, LOAD REAL ADDRESS (LRA) loads bits 33-63 of the real address if bits 0-32 of the address are all zeros or recognizes a special-operation exception if bits 0-32 are not all zeros. LRA in the 64-bit addressing mode, and LOAD REAL ADDRESS (LRAG) in any addressing mode, loads bits 0-63 of the real address. STORE REAL ADDRESS stores bits 0-63 of the real address in any addressing mode.

- LOAD REAL ADDRESS, for most access-exception conditions, does not recognize the conditions as exceptions but instead sets the condition code to indicate the occurrence of the conditions. STORE REAL ADDRESS recognizes all access-exception conditions as exceptions, resulting in a program interruption.

STORE SYSTEM INFORMATION

STSI $D_2(B_2)$ [S]

'B27D'	B_2	D_2
0	16	20 31

Depending on a function code in general register 0, either an identification of the level of the configuration executing the program is placed in general register 0 or information about a component or components of a configuration is stored in a system-information block (SYSIB). When information about a component or components is requested, the information is specified by further contents of general register 0 and by contents of general register 1. The SYSIB, if any, is designated by the second-operand address.

The machine is considered to provide one, two, or three levels of configuration. The levels are:

1. The basic machine, which is the machine as if it were operating in the basic mode.

2. A logical partition, which is provided if the machine is operating in the logically partitioned (LPAR) mode. A logical partition is provided by the LPAR hypervisor, which is a part of the machine. Basic-machine configuration information is provided even when the machine is operating in the LPAR mode.

3. A virtual machine, which is provided by a virtual-machine (VM) control program that is executed either by the basic machine or in a logical partition. A virtual machine may itself execute a VM control program that provides a higher-level (more removed from the basic machine) virtual machine, which also is considered a level-3 configuration.

The terms basic mode, LPAR mode, logical partition, hypervisor, and virtual machine, and any other terms related specifically to those terms, are not defined in this publication; they are defined in the machine manuals.

A program being executed by a level-1 configuration (the basic machine) can request information about that configuration. A program being executed by a level-2 configuration (in a logical partition) can request information about the logical partition and about the underlying basic machine. A program being executed by a level-3 configuration (a virtual machine) can request information about the virtual machine and about the one or two underlying levels; a basic machine is always underlying, and a logical partition may or may not be between the basic machine and the virtual machine. When information about a virtual machine is requested, information is provided about the configuration executing the program and about any underlying level or levels of virtual machine.

The function code determining the operation is an unsigned binary integer in bit positions 32-35 of general register 0 and is as follows:

Function Code	Information Requested
0	Current-configuration-level number
1	Information about level 1 (the basic machine)
2	Information about level 2 (a logical partition)
3	Information about level 3 (a virtual machine)
4-14	None; codes are reserved
15	Current-configuration-level information

Invalid Function Code

The level of the configuration executing the program is called the current level. The configuration level specified by a nonzero function code (other than 15) is called the specified level. When the specified level is numbered higher than the current level, then the function code is called invalid, the condition code is set to 3, and no other action (including checking) is performed. Function code 15 is invalid when the configuration-topology facility is not installed.

Valid Function Code

When the function code is equal to or less than the number of the current level, or 15, it is called valid. In this case, bits 36-55 of general register 0 and bits 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized. Bits 0-31 of general registers 0 and 1 always are ignored.

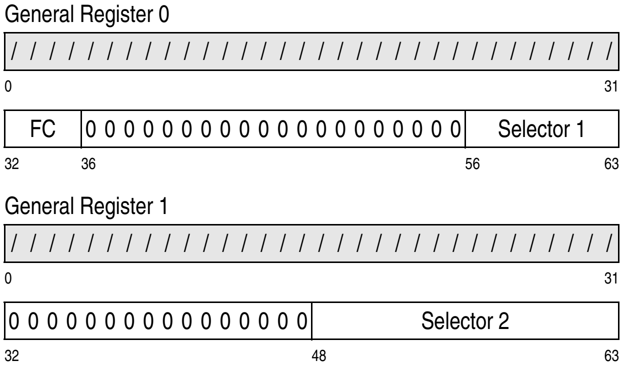
When the function code is 0, an unsigned binary integer identifying the current configuration level (1 for basic machine, 2 for logical partition, or 3 for virtual machine) is placed in bit positions 32-35 of general register 0, the condition code is set to 0, and no further action is performed.

When the function code is valid and nonzero, general registers 0 and 1 contain additional specifications about the information requested, as follows:

- Bit positions 56-63 of general register 0 contain an unsigned binary integer, called *selector 1,* that specifies a component or components of the specified configuration.

- Bit positions 48-63 of general register 1 contain an unsigned binary integer, called *selector 2,* that specifies the type of information requested.

The contents of general registers 0 and 1 are as follows:



When the function code is valid and nonzero, information may be stored in a system-information block (SYSIB) beginning at the second-operand location. The SYSIB is 4K bytes and must begin at a 4 K-byte boundary; otherwise, a specification exception may be recognized, depending on selector 1 and selector 2 and on whether access exceptions are recognized due to references to the SYSIB (see “Special Conditions”).

Selector 1 can have values as follows:

Selector 1	Information Requested
0	None; selector is reserved
1	Information about the configuration level specified by the function code.
2	Information about one or more CPUs in the specified configuration level
3-255	None; selectors are reserved

When selector 1 is 1, selector 2 can have values as follows:

Selector 2 when Selector 1 Is 1	Information Requested
0	None; selector is reserved
1	Information about the specified configuration level

Selector 2 when Selector 1 Is 1	Information Requested
2-6	Topology information about the specified configuration level
7-65,535	None; selectors are reserved

When selector 1 is 2, selector 2 can have values as follows:

Selector 2 when Selector 1 Is 2	Information Requested
0	None; selector is reserved
1	Information about the CPU executing the program in the specified configuration level
2	Information about all CPUs in the specified configuration level
3-65,535	None; selectors are reserved

Only certain combinations of the function code, selector 1, and selector 2 are valid, as shown in Figure 10-84.

Function Code	Selector 1	Selector 2	Information Requested about
0	-	–	Current-configuration-level number
1	1	1	Basic-machine configuration
1	2	1	Basic-machine CPU
1	2	2	Basic-machine CPUs
2	2	1	Logical-partition CPU
2	2	2	Logical-partition CPUs
3	2	2	Virtual-machine CPUs
15	1	2-6	Topology information of current configuration

Explanation:

– Ignored.

Figure 10-84. Valid Function-Code, Selector-1, and Selector-2 Combinations for STORE SYSTEM INFORMATION

When the specified function-code, selector-1, and selector-2 combination is invalid (is other than as shown in Figure 10-84), or if it is valid but the requested information is not available because the specified level does not implement or does not fully implement the instruction or because a necessary part of the level is uninstalled or not initialized, and provided that an exception is not recognized (see "Special Conditions"), the condition code is set to 3. When the function code is nonzero, the combination is valid, the requested information is available, and there is no exception, the requested information is stored in a system-information block (SYSIB) at the second-operand address.

Some or all of the SYSIB may be fetched before it is stored.

A SYSIB may be identified in references by means of "SYSIB fc.s1.s2," where "fc," "s1," and "s2" are the values of a function code, selector 1, and selector 2, respectively.

Following sections describe the defined SYSIBs by means of figures and related text. In the figures, the offsets shown on the left are word values. "The configuration" refers to the configuration level specified by the function code (the configuration level about which information is requested).

Note: In the descriptions of the system-information block (SYSIB) stored by STSI, the term "CPU or core" (or briefly, "CPU/core") indicates the applicability of the text. When the multithreading facility is not installed at the selected configuration level, certain STSI functions store information relevant to logical or physical CPU attributes. When the multithreading facility is installed at the selected configuration level, these STSI functions store information relevant to logical or physical core attributes.

SYSIB 1.1.1 (Basic-Machine Configuration)

SYSIB 1.1.1 is illustrated in Figure 10-85:

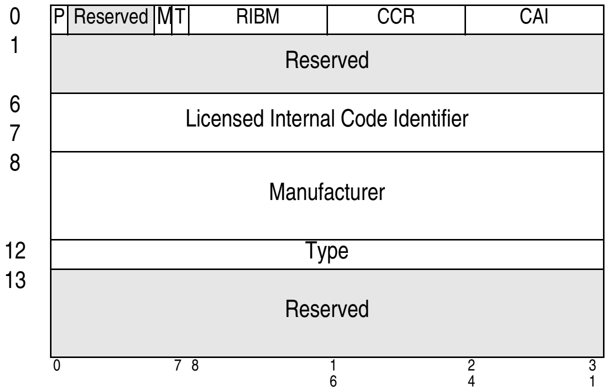


Figure 10-85. Format of the SYSIB 1.1.1 (Part 1 of 2)

16	Model-Capacity Identifier			
20	Sequence Code			
24	Plant of Manufacture			
25	Model			
29	Model-Permanent-Capacity Identifier			
33	Model-Temporary-Capacity Identifier			
37	Model-Capacity Rating			
38	Model-Permanent-Capacity Rating			
39	Model-Temporary-Capacity Rating			
40	Type 1 Perctg.	Type 2 Pctg.	Type 3 Pctg.	Type 4 Pctg.
41	Type 5 Pctg.	Reserved		
42	Nominal Model-Capacity Rating			
43	Nominal Model-Permanent-Capacity Rating			
44	Nominal Model-Temporary-Capacity Rating			
45	Reserved for IBM Use		Reserved	
46 65	Reserved			
66	Reserved for IBM Use		Reserved	
67 1023	Reserved			
	0 7	8	16	24 31

Figure 10-85. Format of the SYSIB 1.1.1 (Part 2 of 2)

Reserved: The contents of bits 1-5 of word 0, words 1-5, words 13-15, bits 8-31 of word 41, bits 16-31 of word 45, and words 46-63 are reserved and are stored as zeros. The contents of words 64-65, bits 16-31 of word 66, and words 67-1023 are reserved and may be stored as zeros or may remain unchanged.

Word 0, Byte 0: Byte 0 of word 0 contains the following bit definitions:

Bit Meaning

0 When bit 0 of byte 0 (P) is one, the type-percentage bytes, located in words 40-41, are valid. When P is zero, the bytes are stored as zeros, but have no meaning.

1-5 Bits 1-5 of byte 0 are reserved and stored as zeros.

6 When bit 6 of byte 0 (M) is zero, the multithreading facility is not installed in the basic machine configuration. When M is one, the multithreading facility is installed in the basic machine configuration.

7 Bit 7 of byte 0 (T), when one, indicates that the condition represented by the CCR and CAI fields is relatively transient.

Reserved for IBM Use (RIBM): Byte 1 of word 0 , bytes 0-1 of word 45, and bytes 0-1 of word 66 are assigned to IBM internal use.

Capacity-Change Reason (CCR): When the CAI byte is nonzero, the content of byte 2 of word 0 is an 8-bit unsigned integer whose value indicates one of the following reasons which is associated with the present values contained in SYSIB 1.1.1.

CCR Capacity-Change Reason

0 Machine is running at nominal capacity.

1 The capacity change is due solely to the setting of a manual control, such as intentional power-save.

2 The capacity change is due to a machine-exception condition, such as detection of overheating.

3 The capacity change is due to a non-exception machine condition, such as concurrent service.

4 The capacity change is due to an exception condition external to the machine, such as detection of supplied power or cooling falling outside required tolerances.

5-255 Reserved.

When the CAI byte is zero, the CCR field is undefined, and stored as zero.

When multiple capacity-change reasons exist, CCR is set according to the following priority:

1a. Machine-exception condition, CCR=2.

1b. External-exception condition, CCR=4.

2. Non-exception machine condition, CCR=3.

3. Manual control, CCR=1.

Capacity-Adjustment Indication (CAI): Byte 3 of word 0, when nonzero, is an 8-bit unsigned integer whose value is in the range 1-100 and represents the aggregate position of model-dependent controls. Temporary capacity changes that affect machine performance are not included; such changes include those caused by capacity-backup (CBU), on/off-capacity-on-demand (OOCoD), and capacity-planned-event (CPE) features. When zero, the indication is not reported. When in the range 1-99, some amount of reduction is indicated. When 100, the machine is operating at its normal capacity.

Primary CPUs and all secondary-type CPUs are similarly affected.

The model-capacity rating is not affected. A change in the CAI may also reflect a change in CPU-capability fields of SYSIB 1.2.2.

Licensed Internal Code (LIC) Identifier: Words 6-7, when nonzero, indicate information about currently installed internal code. The definition of the information conveyed is model dependent. The internal code, to which the information applies, is model dependent.

Manufacturer: Words 8-11 contain the 16-character (0-9 or uppercase A-Z) EBCDIC name of the manufacturer of the configuration. The name is left justified with trailing blanks if necessary.

Type: Word 12 contains the four-character (0-9) EBCDIC type number of the configuration. (This is called the machine-type number in the definition of STORE CPU ID.)

Model-Capacity Identifier (C): Words 16-19 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-capacity identifier of the configuration. The model-capacity identifier is left justified with trailing blanks if necessary.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The sequence code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

Model: When word 25 is not binary zeros, words 25-28 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model identification of the configuration. The model identification is left justified with trailing blanks if necessary. (This is called the model number in programming note 5 on page 10-141 of STORE CPU ID.) When word 25 is binary zeros, the contents of words 16-19 represent both the model-capacity identifier and the model.

Model-Permanent-Capacity Identifier (P): When nonzero, words 29-32 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-permanent-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

Model-Temporary-Capacity Identifier (T): When nonzero, words 33-36 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-temporary-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

Model-Capacity Rating (CR): When nonzero, word 37 contains a 32-bit unsigned integer whose value is associated with the model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Model-Permanent-Capacity Rating (PR): When nonzero, word 38 contains a 32-bit unsigned integer whose value is associated with the model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Model-Temporary-Capacity Rating (TR): When nonzero, word 39 contains a 32-bit unsigned integer whose value is associated with the model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Type N Pctg. Each of the byte fields in words 40-41 that is designated as a type-N percentage contains an 8-bit unsigned binary integer whose value is in the range 0-100 and represents a percentage. When nonzero, the percentage may be used to affect the use and allowed utilization of the secondary-CPUs whose CPU type corresponds to the particular byte. When a byte in this range contains a value of zero, use rules of the corresponding secondary-CPU type are not overridden. The reserved bytes in word 41 are reserved for the potential addition of new secondary CPU types.

Nominal Model-Capacity Rating (NCR): When nonzero, word 42 contains a 32-bit unsigned integer whose value is associated with the nominal model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NCR value equals the CR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the CR value is less than the NCR value.

Nominal Model-Permanent-Capacity Rating (NPR): When nonzero, word 43 contains a 32-bit unsigned integer whose value is associated with the nominal model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NPR value equals the PR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the PR value is less than the NPR value.

Nominal Model-Temporary-Capacity Rating (NTR): When nonzero, word 44 contains a 32-bit unsigned integer whose value is associated with the nominal model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NTR value equals the TR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the TR value is less than the NTR value.

Worldwide Unique Identification: Taken together, the machine type, manufacturer, plant of manufacture, and sequence code allow for worldwide unique identification of the system.

Programming Notes:

1. The fields of the SYSIB 1.1.1 are similar to those of the node descriptor described in the publication *Common I/O-Device Commands and Self Description,* SA22-7204. However, the contents of the SYSIB fields may not be identical to the contents of the corresponding node-descriptor fields because the SYSIB fields:
   - Allow more characters.
   - Are more flexible regarding the type of characters allowed.
   - Provide information that is justified differently within the field.
   - May not use the same method to determine the contents of fields such as the sequence-code field.
2. The model field in a node descriptor corresponds to the content of the STSI model field and not the STSI model-capacity-identifier field.
3. The model field specifies the model of the machine (i.e., the physical model); the model-capacity identifier field specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.
4. Each of the three model-capacity-identifier fields specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.
5. Each of the three model-capacity-rating fields, corresponding one-to-one with the three model-capacity-identifier fields, specifies a numeric value that may or may not represent the actual capacity of the machine
6. The term *capacity backup* (CBU) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, normally for a relatively limited period of time. Typically CBU is used when another CPC of the enterprise has failed, and the CPC operating under CBU rules is making up for the missing CPC’s capacity. However, CBU can also indicate a capacity that reflects a net reduction such that the current capacity would be less than the permanent capacity.
7. The term *On/Off Capacity on Demand* (On/Off CoD) represents a methodology by which spare capacity in a CPC can be made available to increase the total capacity within an enterprise, normally for a limited period of time. For example, On/Off CoD may be used to acquire additional capacity in order to handle a workload peak.
8. The content of the model-capacity identifier (C) field corresponds to the current capacity at which the central-processing complex (CPC) is operating.

9. The content of the model-permanent-capacity identifier (P) corresponds to the capacity of the CPC exclusive of temporarily-available increased capacity and temporarily-available replacement capacity.

10. The content of the model-temporary-capacity identifier (T) corresponds to the total of permanent capacity and temporarily-available increased capacity but exclusive of any temporarily-available replacement capacity.

11. When the T bit in byte 0 is one, the current capacity values and indicators are in a relatively-short period of transition and should be permitted to stabilize, that is, a result where T is zero, before any resultant action proceeds.

12. There is no facility indication defined to distinguish whether a model stores zeros, or information pertaining to installed internal code, in the licensed internal code identifier field. A program may test the licensed internal code identifier field stored, for a nonzero value, to recognize whether or not a specific machine provides the information requested.

SYSIB 1.2.1 (Basic-Machine CPU/Core)

SYSIB 1.2.1 is illustrated in Figure 10-86:

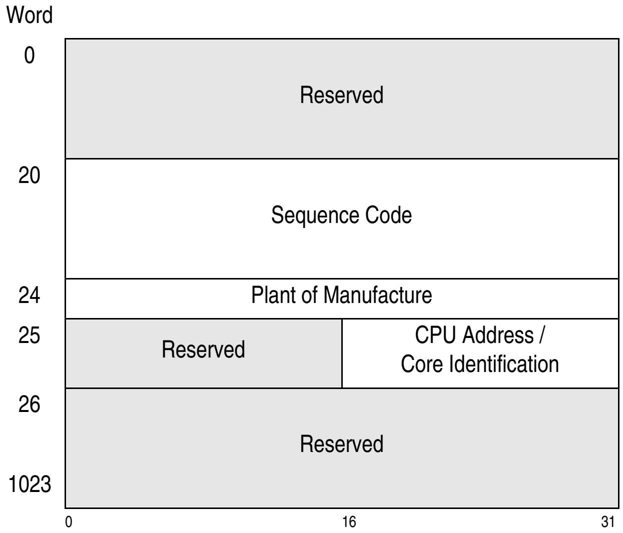

Figure 10-86. Format of the SYSIB 1.2.1

Reserved: The contents of words 0-19, bytes 0 and 1 of word 25, and words 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

CPU Address: When the multithreading facility is not installed in the machine, bytes 2 and 3 of word 25 contain the CPU address by which this CPU is identified in a multiprocessing configuration. The CPU address is a 16-bit unsigned binary integer. The CPU address is the same as is stored by STORE CPU ADDRESS when the program is executed by a machine operating in the basic mode.

Core Identification: When multithreading is installed in the machine, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification, right justified in the field. The core ID field contains the core-ID portion of the value that would be stored by STORE CPU ADDRESS when executed by a machine operating in the basic mode; no thread ID is included.

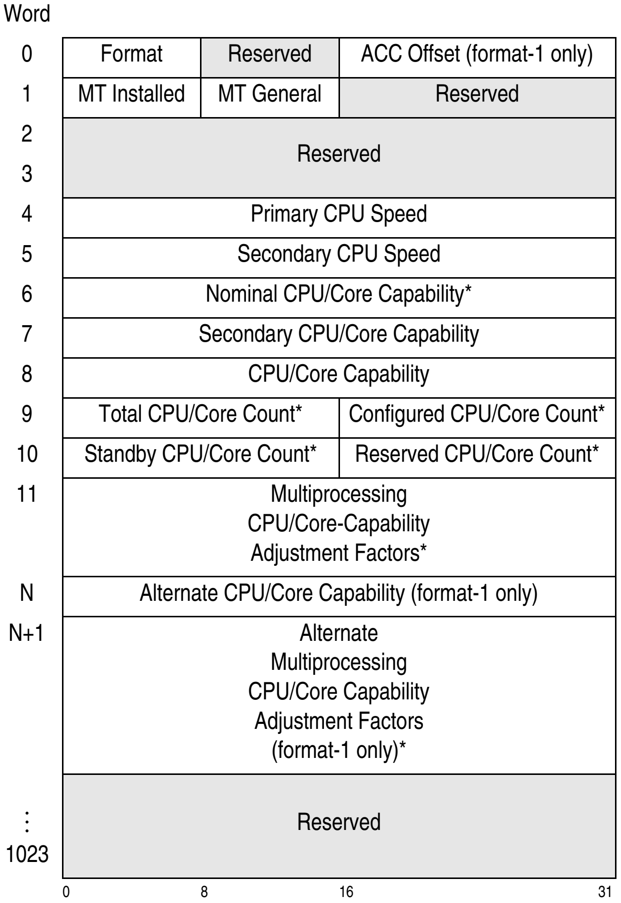
Worldwide Unique Identification: Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

Programming Note: Multiple CPUs in the same configuration have the same sequence code, and it is necessary to use other information, such as the CPU address, to establish a unique CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

SYSIB 1.2.2 (Basic-Machine CPUs)

The general format of the SYSIB 1.2.2 is illustrated in Figure 10-87. Some fields may or may not be valid, as indicated by the contents of the format field in byte 0 of word zero.

When the multithreading facility is not installed (as indicated by bit 0 of word 1), fields labelled “CPU/Core” apply to a CPU. When the multithreading facility is installed, fields labelled “CPU/Core” apply to a core.



Word	0	8	16 31
0	Format	Reserved	ACC Offset (format-1 only)
1	MT Installed	MT General	Reserved
2 3	Reserved		
4	Primary CPU Speed		
5	Secondary CPU Speed		
6	Nominal CPU/Core Capability*		
7	Secondary CPU/Core Capability		
8	CPU/Core Capability		
9	Total CPU/Core Count*		Configured CPU/Core Count*
10	Standby CPU/Core Count*		Reserved CPU/Core Count*
11	Multiprocessing CPU/Core-Capability Adjustment Factors*		
N	Alternate CPU/Core Capability (format-1 only)		
N+1	Alternate Multiprocessing CPU/Core Capability Adjustment Factors (format-1 only)*		
⋮ 1023	Reserved		

Explanation:

* Field applies to general CPUs or to cores comprising general CPUs.

Figure 10-87. Format of the SYSIB 1.2.2

Reserved: The contents of byte 1 of word 0, bytes 2-3 of word 1, and words 2-3 are reserved and stored as zeros. When the format field contains a value of zero, bytes 2-3 of word 0 are reserved and stored as zeros.

When fewer than 64 words are needed to contain the information for all the CPUs or cores, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB, or the alternate-adjustment-factor list in a format-1 SYSIB, up to and including word 63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

When 64 or more words are needed to contain the information for all the CPUs, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB or the alternate-adjustment-factor list in a format-1 SYSIB, up to and including word 1023 are reserved and may be stored as zeros or may remain unchanged.

Format: Byte 0 of word 0 contains an 8-bit unsigned binary integer that specifies the format of SYSIB 1.2.2.

Alternate-CPU/Core-Capability Offset: When the format field has a value of one, bytes 2-3 of word 0 contain a 16-bit unsigned binary integer that specifies the offset in bytes of the alternate-CPU-capability field in the SYSIB. Zeros are stored in the rightmost two bits of the ACC offset field, thus the ACC offset is a multiple of four and designates word N in Figure 10-87.

MT Installed: When bit 0 of the MT-installed field (byte 0 of word 1) is zero, the remainder of the field and the MT-general field are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general field are meaningful, as described below.

Bits	**Meaning**
0	When zero, the multithreading facility is not installed in the machine. When one, the multithreading facility is installed in the machine.
1-2	Reserved (stored as zeros).
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core in the machine. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count .

MT General: The contents of byte 1 of word 1 are meaningful only when bit 0 of word 1 is one.

Bit	**Meaning**
0-2	Reserved.
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core.

The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

Primary CPU/Core Speed: When not zero, word 4 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a primary CPU, encoded as the approximate number of CPU cycles per microsecond.

Secondary CPU/Core Speed: When not zero, word 5 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a secondary CPU, encoded as the approximate number of CPU cycles per microsecond.

Nominal CPU/Core Capability: Word 6, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability.

When the CAI byte of SYSIB 1.1.1 is zero, the nominal CPU capability (word 6) is stored as zero. The nonzero value equals the word-8 value when the CAI byte of SYSIB 1.1.1 contains a value of 100. When the CAI byte of SYSIB 1.1.1 is nonzero and less than 100, the word-6 value indicates a CPU speed greater than the CPU speed indicated by the word-8 value.

Secondary CPU/Core Capability: Word 7, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability, and specifies a secondary capability that may be applied to certain types of CPUs in the configuration.

There is no formal description of the algorithm used to generate this value, except that it is the same as the algorithm used to generate the CPU capability. The value is used as an indication of the capability of a CPU relative to the capability of other CPU models, and also relative to the capability of other CPU types within a model.

The capability value applies to each of the specialty CPUs/cores of one or more applicable CPU/core types in the configuration. That is, all CPUs in the configuration of an applicable type or types have the same capability. When the value is zero, all CPUs of any CPU type in the configuration have the same capability, as specified by the CPU capability.

The secondary CPU capability may or may not be the same value as the CPU-capability value.

The multiprocessing-CPU-capability-adjustment factors are also applicable to CPUs whose capability is specified by the secondary CPU capability.

CPU/Core Capability: Word 8 specifies the capability of one of the CPUs in the configuration.

If bits 0-8 of word 8 are zero, the word contains a 32-bit unsigned binary integer (I) in the range $1 \leq I < 2^{23}$. If bits 0-8 of word 8 are nonzero, the word contains a 32-bit binary floating point short-format number instead of an unsigned binary integer.

Regardless of encoding, the value represents the capability of one of the CPUs in the configuration, and a lower value indicates a proportionally higher CPU capability. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the capability of the CPU relative to the capability of other CPU models.

The capability value applies to each of the general CPUs in the configuration. That is, all non-secondary CPUs in the configuration have the same capability.

Total CPU/Core Count: Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of general CPUs or cores comprising general CPUs in the configuration. This number includes all general CPUs/cores in the configured state, the standby state, or the reserved state.

Configured CPU/Core Count: Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the configured state. A CPU/core is in the configured state when it is in the configuration and available to be used to execute programs.

Standby CPU/Core Count: Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the standby state. A CPU/core is in the standby state when it is in the configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the reserved state. A CPU/core is in the reserved state when it is in the configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place a reserved CPU in the standby or configured state by means of manual actions.)

Multiprocessing CPU/Core-Capability Adjustment Factors: Beginning with bytes 0 and 1 of word 11, the SYSIB contains a series of contiguous two-byte fields, each containing a nonzero 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range of 1 through 100, inclusive, a denominator of 100 is indicated which produces a fraction of V/100.

- If V is in the range of 101 through 255, inclusive, a denominator of 255 is indicated which produces a fraction of V/255.

- If V is in the range of 256 through 65,535, inclusive, a denominator of 65,535 is indicated which produces a fraction of V/65,535.

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

Programming Note: The applicable MP adjustment factor is an approximation that is sensitive to the particular workload.

Alternate CPU/Core Capability: When the format field has a value of one, the location of word N is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field. If bits 0-8 of word N are zero, the word contains a 32-bit unsigned binary integer (I) in the range $0 \leq I < 2^{23}$ that specifies the announced capability of one of the CPUs in the configuration. If bits 0-8 of word N are nonzero, the word contains a 32-bit binary floating point short-format number instead of a 32-bit unsigned binary integer.

Regardless of encoding, a lower value indicates a proportionally higher CPU capacity. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the announced capability of the CPU relative to the announced capability of other CPU models.

The alternate-capability value applies to each of the general CPUs or cores comprising general CPUs in the configuration. That is, all general CPUs/cores in the configuration have the same alternate capability.

Alternate Multiprocessing CPU/Core-Capability Adjustment Factors: When the format field has a value of one, the location of word N + 1 is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field plus four. Beginning with bytes 0 and 1 of word N + 1, the SYSIB contains a series of contiguous two-byte fields, each containing a nonzero 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the alternate-CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range of 1 through 100, inclusive, a denominator of 100 is indicated which produces a fraction of V/100.

- If V is in the range of 101 through 255, inclusive, a denominator of 255 is indicated which produces a fraction of V/255.

- If V is in the range of 256 through 65,535, inclusive, a denominator of 65,535 is indicated which produces a fraction of V/65,535.

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of alternate-adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The alternate-adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first alternate-adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive alternate-adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

SYSIB 2.2.1 (Logical-Partition CPU/Core)

SYSIB 2.2.1 is illustrated in Figure 10-88.

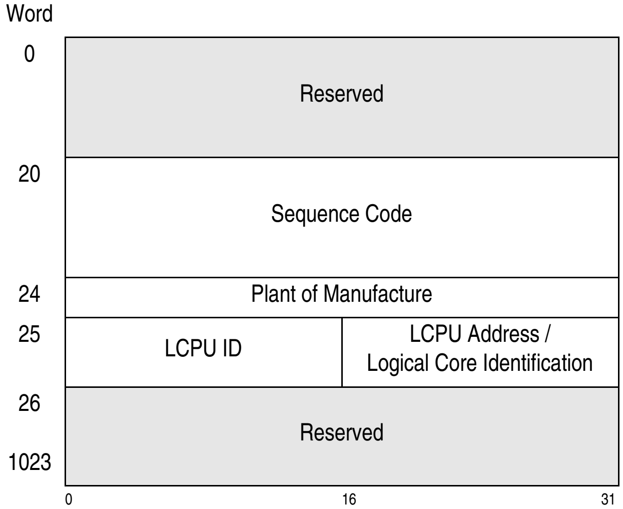


Figure 10-88. Format of the SYSIB 2.2.1

Reserved: The contents of words 0-19 and 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

Logical-CPU ID: Bytes 0 and 1 of word 25 contain a 16-bit unsigned binary integer that can be used in conjunction with the logical-CPU address to distinguish the logical CPU from the other logical CPUs provided by the same LPAR hypervisor.

Logical-CPU Address: When the multithreading facility is not enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain the logical-CPU address by which this logical CPU is identified within the level-2 configuration. The logical-CPU address is a 16-bit unsigned binary integer. The logical-CPU-address field contains the same information as is stored by STORE CPU ADDRESS when the machine is operating in the LPAR mode.

Logical-Core Identification: When the multithreading facility is enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification by which the core is identified within the configuration, right justified in the field.

Worldwide Unique Identification: Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

Programming Note: Multiple logical CPUs in the same level-2 configuration have the same logical-CPU sequence code, and it is necessary to use other information, such as the logical-CPU address, to establish a unique logical-CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

SYSIB 2.2.2 (Logical-Partition CPUs / Cores)

SYSIB 2.2.2 is illustrated in Figure 10-89.

When the multithreading facility is not enabled (as indicated by the PSMTID field), fields labeled with an asterisk (*) apply to a primary CPU. When the multithreading facility is enabled, fields labeled with an asterisk apply to a core comprising primary CPUs.

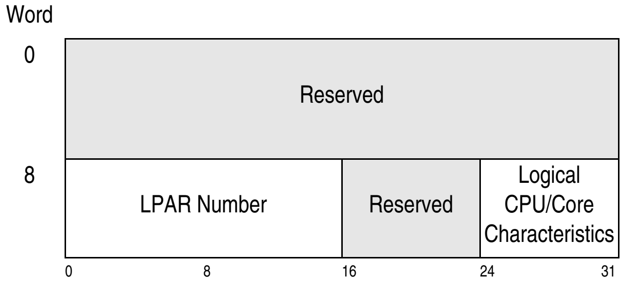

Figure 10-89. Format of the SYSIB 2.2.2 (Part 1 of 2)

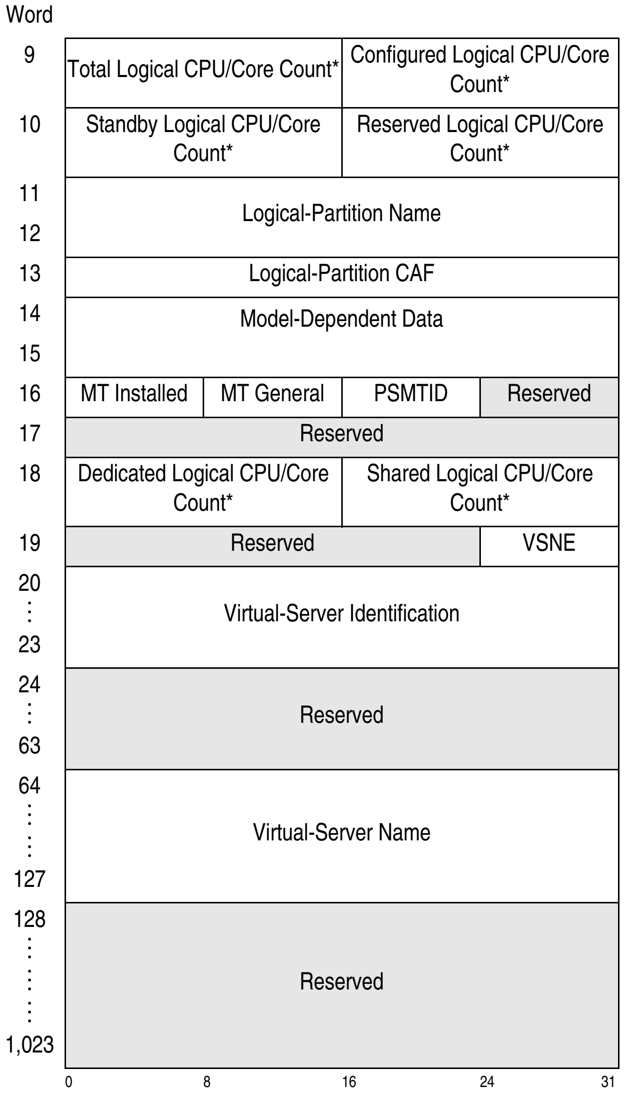

Word	0	8	16	24
9	Total Logical CPU/Core Count*		Configured Logical CPU/Core Count*

16	MT Installed	MT General	PSMTID	Reserved
17	Reserved			
18	Dedicated Logical CPU/Core Count*		Shared Logical CPU/Core Count*	
19	Reserved			VSNE
20 ⋮ 23	Virtual-Server Identification			
24 ⋮ 63	Reserved			
64 ⋮ 127	Virtual-Server Name			
128 ⋮ 1,023	Reserved			

Figure 10-89. Format of the SYSIB 2.2.2 (Part 2 of 2)

Reserved: The contents of words 0-7, byte 2 of word 8, byte 3 of word 16, word 17, bytes 0-2 of word 19, and words 24-63 are reserved and are stored as zeros. When virtual-server information is not provided, the contents of byte 3 of word 19 and words 20-23 are reserved and stored as zeros, and the contents of words 64-127 are reserved and may be stored as zeros or may remain unchanged. The contents of words 128-1023 are reserved and may be stored as zeros or may remain unchanged.

Logical-Partition Number: Bytes 0 and 1 of word 8 contain a 16-bit unsigned binary integer which is the number of the level-2 configuration. This number distinguishes the configuration from all other level-2 configurations provided by the same LPAR hypervisor.

Logical-CPU/Core Characteristics: The contents of byte 3 of word 8 describe the characteristics of the logical CPUs/cores that are provided for the level-2 configuration. The bits and their meanings are as follows:

Bit Meaning

0 Dedicated: When one, bit 0 indicates that one or more of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that are dedicated to this level-2 configuration and are not used to provide logical CPUs/cores for any other level-2 configuration. The number of logical CPUs/cores that are provided using dedicated level-1 CPUs/cores is specified by the dedicated-LCPU-count value in bytes 0 and 1 of word 18.

When zero, bit 0 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that are dedicated to this level-2 configuration.

1 Shared: When one, bit 1 indicates that one or more of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that can be used to provide logical CPUs/cores for other level-2 configurations. The number of logical CPUs/cores that are provided using shared level-1 CPUs/cores is specified by the shared-LCPU-count value in bytes 2 and 3 of word 18.

When zero, bit 1 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using shared level-1 CPUs/cores.

2 Utilization Limit: When one, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is limited.

When zero, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is unlimited.

3-7 Reserved.

Total Logical-CPU/Core Count: Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-2 configuration. This number includes all of the logical

CPUs/cores that are in the configured state, the standby state, or the reserved state.

Configured Logical-CPU/Core Count: Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-2 configuration and is available to be used to execute programs.

Standby Logical-CPU/Core Count: Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-2 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved Logical-CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-2 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the reserved CPU/core in the standby or configured state through manual actions.)

Logical-Partition Name: Words 11-12 contain the 8-character EBCDIC name of this level-2 configuration. The name is left justified with trailing blanks if necessary.

Logical-Partition Capability Adjustment Factor (CAF): Word 13 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-configuration capability that is allowed to be used for this level-2 configuration by the LPAR hypervisor. The fraction of level-1-configuration capability is determined by dividing the CAF value by 1000.

MT Installed: When bit 0 of the MT-installed field (byte 0 of word 16) is zero, the remainder of the field and the MT-general and PSMTID fields are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general and PSMTID fields are meaningful, as described below.

Bits **Meaning**

0 When zero, the multithreading facility is not installed in the level-2 configuration. When one, the multithreading facility is installed in the level-2 configuration.

1-2 Reserved (stored as zeros).

3-7 A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core of the level-2 configuration. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count .

MT General: The contents of byte 1 of word 16 are meaningful only when bit 0 the MT-installed field is one.

Bit **Meaning**

0-2 Reserved.

3-7 A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core. The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

Program-Specified Maximum TID (PSMTID): The contents of byte 2 of word 16 are meaningful only when bit 0 of word 16 is one.

Bits **Meaning**

0-2 Reserved (stored as zeros).

3-7 When the multithreading facility is enabled in the level-2 configuration, bit positions 3-7 contain the program-specified maximum thread identification as set by the SIGNAL

PROCESSOR set-multithreading order; the value is copied from bit positions 59-63 of the SIGP parameter register. When the multithreading facility is not enabled in the level-2 configuration, bit positions 3-7 contain zeros.

Dedicated Logical-CPU Count/Core: Bytes 0 and 1 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using dedicated level-1 CPUs/cores. (See the description of bit 0 of the logical-CPU-characteristics field.)

Shared Logical-CPU/Core Count: Bytes 2 and 3 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using shared level-1 CPUs/cores. (See the description of bit 1 of the logical-CPU-characteristics field.)

Virtual-Server-Name Encoding (VSNE): Byte 3 of word 19 contains an 8-bit unsigned integer indicating whether virtual-server information is provided, and if so, the encoding of the virtual-server-name field in words 64-127, as follows:

Value	Meaning
0	Virtual-server information is not provided.
1	EBCDIC
2	UTF-8
3-255	Reserved.

Virtual-Server Identification: When virtual-server information is provided, words 20-23 contain a 128-bit binary universally-unique identification (UUID, also known as a *handle*) of the virtual server for this configuration. When virtual-server information is not provided, words 20-23 are stored as zeros.

Virtual-Server Name: When virtual-server information is provided, words 64-127 contain a 256-byte name of the virtual server for this configuration. The virtual-server name is left justified in the field; if the name is less than 256 bytes, the field is padded on the right with zeros. The VSNE field, byte 3 of word 19, indicates the encoding of the virtual-server-name field.

When virtual-server information is not provided, words 64-127 are reserved and may be stored as zeros or may remain unchanged.

SYSIB 3.2.2 (Virtual-Machine CPUs / Cores)

SYSIB 3.2.2 is illustrated in Figure 10-90:

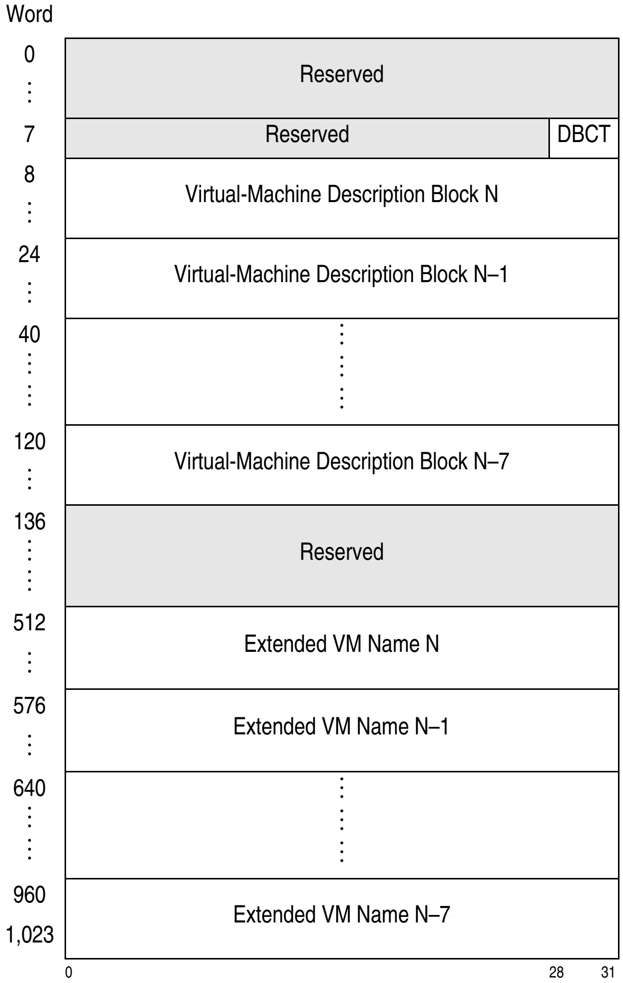

Figure 10-90. Format of the SYSIB 3.2.2

Reserved: The contents of words 0-6, bits 0-27 of word 7, and all portions of SYSIB words 8–1,023 that do not contain virtual-machine description blocks or extended virtual-machine-name blocks are reserved and are stored as zeros.

Description-Block Count (DBCT): Bits 28-31 of word 7 contain a four-bit unsigned binary integer that specifies the number (up to eight) of virtual-machine description blocks and extended-virtual-machine-name blocks that are stored in the SYSIB beginning at words 8 and 512, respectively.

Virtual-Machine Description Blocks: Depending on the number of nested level-3 configurations (if any) and their processing characteristics, from one to eight 64-byte virtual-machine description blocks are stored, beginning at word 8. The contents of the VMDB are described in the section "Virtual-Machine Description Block" on page 10-158.

When a level-3 configuration is provided by a virtual-machine control program and the control program is being executed by a level-3 configuration provided by another virtual-machine control program, the level-3 configurations are said to be "nested." Level-3 configurations can be nested in this way for several levels.

The collection of nested level-3 configurations that is in the path between a program being executed by a level-3 configuration and the basic machine is called a "level-3-configuration stack." The level-3 configurations in a stack are consecutively numbered. The level-3 configuration provided by a virtual-machine control program being executed by either a level-2 configuration or a level-1 configuration is the lowest-numbered (0) level-3 configuration in the stack. The level-3 configuration that is executing the program containing this instruction is the highest numbered (N) level-3 configuration in the stack.

If more than one virtual-machine description block is stored in words 8-135 of the SYSIB, the blocks are stored according to the following rules:

- The collection of level-3 configurations described is a contiguous subset of the total collection of level-3 configurations in the level-3-configuration stack. The subset always includes the highest-numbered level-3 configuration in the stack. One or more level-3 configurations at the bottom of the stack may not be described because the limit of eight description blocks would be exceeded.
- The highest-numbered level-3 configuration in the level-3-configuration stack is always described by the first description block in the SYSIB. The lowest-numbered level-3 configuration in the stack, of those that are included in the subset that is described, is described by the last description block in the SYSIB.

Extended VM Name(s): For each VMDB, there is a corresponding extended-VM-name field in the SYSIB 3.2.2, as shown below:

	SYSIB 3.2.2 Word Offset	
Nesting Level	VMDB	Extended VM Name
N	8	512
N–1	24	576
N–2	40	640
N–3	56	704
N–4	72	768
N–5	88	832
N–6	104	896
N–7	120	960

Figure 10-91. SYSIB 3.2.2 Offset of VMDB and Corresponding Extended-VM Name

The extended-VM-name-encoding (EVMNE) field of a VMDB indicates the encoding of the corresponding extended VM name. When the EVMNE field of a VMDB is zero, the corresponding extended-VM-name field is stored as zeros.

The extended VM name is left justified in the field; if the name is less than 256 bytes, the field is padded on the right with zeros. If the leftmost byte of the extended-VM-name field contains zeros, no extended VM name is provided for that nesting level, regardless of whether the corresponding EVMNE is nonzero.

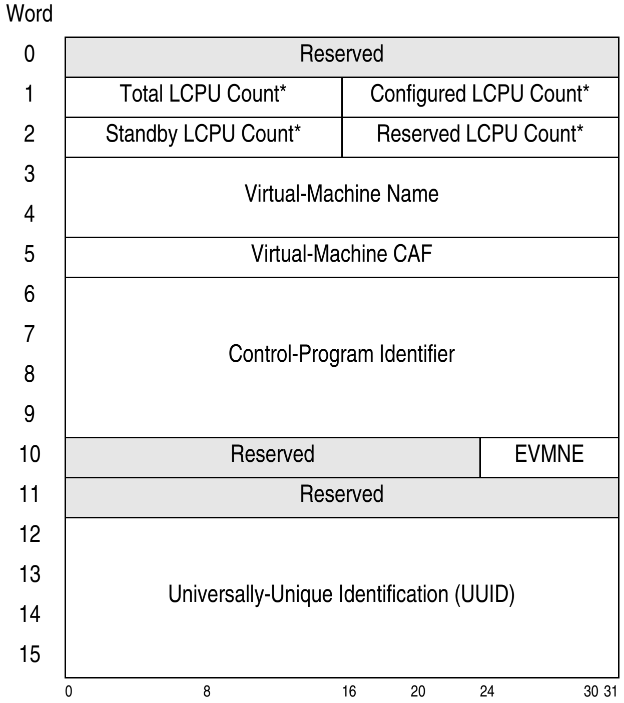
Programming Note: The highest-numbered configuration in the level-3-configuration stack that does not provide an extended VM name effectively delimits the array of extended VM names.

For example, if VMDBs for nested levels 3, 2, 1, and 0 are stored in the SYSIB, but only levels 3, 2, and 0 provide extended VM names, then extended VM names will be stored only for levels 3 and 2 (beginning at words 512 and 576, respectively). Even though the EVMNE field of the VMDB at nesting level 0 may designate a valid nonzero encoding, the extended-VM-name field for nesting-level 0 (beginning at word 704) will contain zeros.

If the configuration is not capable of providing an extended VM name, then it is assumed that the configuration is also not capable of managing extended VM names for lower-numbered nesting levels.

Virtual-Machine Description Block

The virtual-machine description block is illustrated in Figure 10-92 .



Explanation:

* Field applies to a primary CPU. The CPUs may either be general or specialty CPUs.

Figure 10-92. Virtual-Machine Descriptor Block

Reserved: The contents of word 0, bytes 0-2 of word 10, and word 11 are reserved and are stored as zeros.

Total Logical-CPU/Core Count: Bytes 0 and 1 of word 1 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-3 configuration. This number includes all of the primary logical CPUs/cores that are in the configured state, the standby state, and the reserved state.

Configured Logical-CPU/Core Count: Bytes 2 and 3 of word 1 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-3 configuration and is available to be used to execute programs.

Standby Logical-CPU/Core Count: Bytes 0 and 1 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-3 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved Logical-CPU/Core Count: Bytes 2 and 3 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-3 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the logical CPU/core in the standby or configured state through manual actions.)

Virtual-Machine Name: Words 3-4 contain the eight-character EBCDIC name of this level-3 configuration. The name is left justified with trailing blanks if necessary.

Virtual-Machine Capability Adjustment Factor (CAF): Word 5 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-, level-2-, or level-3-configuration capability that is allowed to be used for this level-3 configuration by the virtual-machine control program. The fraction of the underlying capability is determined by dividing the CAF value by 1000.

Control-Program Identifier: Words 6-9 contain the 16-character EBCDIC identifier of the virtual-machine control program that provides this level-3 configuration. This identifier may include qualifiers such as version number and release level. The identifier is left justified with trailing blanks if necessary.

Extended VM-Name Encoding (EVMNE): Byte 3 of word 10 contains an 8-bit unsigned integer indicating whether a corresponding extended virtual-machine name is provided, and if so, the encoding of the extended-virtual-machine-name field, as follows:

Value	Meaning
0	Extended virtual-machine name is not provided
1	EBCDIC
2	UTF-8
3-255	Reserved.

When byte 3 of word 10 is zero, an extended virtual-machine name is not provided for this configuration.

Programming Note: Even if the EVMNE field is nonzero, an extended-VM name is not provided when the leftmost byte of the corresponding extended-VM-name field is zero.

Universally-Unique Identification (UUID): When the 128-bit binary value formed by words 12-15 is nonzero, the value comprises a universally-unique identification (UUID, also known as a handle) of the configuration. When words 12-15 contain all zeros, no UUID is provided.

SYSIB 15.1.2 - 15.1.6 (Configuration Topology)

SYSIBs 15.1.2 through 15.1.6 are illustrated in each have the following format:

Word	0	8	16	24 31
0	Reserved		Length	
1	Mag6	Mag5	Mag4	Mag3
2	Mag2	Mag1	Reserved	MNest
3	Reserved			
4 ⋮ N-1	Topology List			
N ⋮ 1023	Reserved			

Figure 10-93. Format of the SYSIB 15.1.2 - 15.1.6

Selector 2 specifies the MNest value to which the response is limited. STSI completes with condition code 3 for the following cases:

1. If the maximum-MNest facility is installed and selector 2 exceeds the nonzero model-dependent maximum-selector-2 value.
2. If the maximum-MNest facility is not installed and selector 2 is not specified as two.

Reserved: The contents of bytes 0-1 of word 0, byte 2 of word 2, and word 3 are reserved and are stored as zeros. The contents of words N-1023 are reserved and may be stored as zeros or may remain unchanged.

Length: Bytes 2-3 of word 0 contain a 16-bit unsigned binary integer whose value is the count of bytes of the entire SYSIB 15.1.2. The length of just the topology list is determined by subtracting 16 from the length value in bytes 2-3 of word 0. N in Figure 10-94 is determined by evaluating the formula N=Length/4.

Mag1-6: Word 1 and bytes 0-1 of word 2 constitute six one-byte fields where the content of each byte indicates the maximum number of container-type topology-list entries (TLE) or CPU-type TLEs at the corresponding nesting level. CPU-type TLEs are always found only at the Mag1 level. Additionally, the Mag1 value also specifies the maximum number of CPUs that may be represented by a container-type TLE of the Mag2 level. When the value of the nesting level is greater than one, containing nesting levels above the Mag1 level are occupied only by container-type TLEs. A dynamic change to the topology may alter the number of TLEs and the number of CPUs at the Mag1 level, but the limits represented by the values of the Mag1-6 fields do not change within a model family of machines.

The topology is a structured list of entries where an entry defines one or more CPUs or else is involved with the nesting structure. The following illustrates the meaning of the magnitude fields:

- When all CPUs of the machine are peers and no containment organization exists, other than the entirety of the central-processing complex itself, the value of the nesting level is 1, Mag1 is the only nonzero magnitude field, and the number of CPU-type TLEs stored does not exceed the Mag1 value.
- When all CPUs of the machine are subdivided into peer groups such that one level of containment exists, the value of the nesting level is 2,

Mag1 and Mag2 are the only nonzero magnitude fields, the number of container-type TLEs stored does not exceed the Mag2 value, and the number of CPU-type TLEs stored within each container does not exceed the Mag1 value.

- The Mag3-6 bytes similarly become used (proceeding in a right-to-left direction) when the value of the nesting level falls in the range 3-6.

MNest: When the maximum-MNest facility is not installed, byte 3 of word 2 specifies the nesting level of the topology to which the configuration may be extended without requiring a re-IPL. The maximum MNest value is model dependent in the range 2-6; the minimum is one. If MNest is one, there is no actual TLE nesting structure, Mag1 is the only nonzero field in the Mag1-6 range, and only CPU-type TLEs are represented in the topology list. The MNest value indicates the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1), proceeding left when MNest is greater than one, and with the remaining magnitude fields stored as zeros.

The value of MNest is the maximum possible nesting. No dynamic configuration change exceeds this limit.

When the maximum-MNest facility is installed, the maximum possible nesting is indicated by other means and the MNest value in byte 3 of word 2 reflects both the requested selector-2 value and the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1).

Topology List: Words of Figure 10-94 in the range 4 through N-1 specify a list of one or more topology-list entries (TLE). Each TLE is an eight-byte or sixteen-byte field; thus N is an even number of words, and a corollary is that a TLE always starts on a doubleword boundary.

Topology-List Entries: The first TLE in the topology list begins at a nesting level equal to MNest-1. The entire topology list represents the configuration of the issuer of the STSI instruction specifying SYSIB 15.1.x; no outermost container TLE entry is used as it would be redundant with the entire list, and the entire configuration. Therefore, the highest nesting level may have more than a single peer container.

Figure 10-94 illustrates the container type of TLE, and Figure 10-95 illustrates the CPU type of TLC.

Word			
0	NL>0	Reserved	
1	0 0 0 0 0 0 0 0	Reserved	Container ID
	0	8	16 31

Figure 10-94. Container-Type Topology-List Entry

Word					
0	NL=0			Reserved	
1	0 0 0 0 0	D	P P	CPU Type	CPU Address Origin
2 3	CPU Mask				
	0	5	6	8	16 31

Figure 10-95. CPU-Type Topology-List Entry

Nesting Level (NL): Byte 0 of word 0 specifies the TLE nesting level.

NL	Meaning
00	The TLE is a CPU-type TLE.
01-05	The TLE is a container-type TLE. The first container-type TLE stored in a topology list or a parent container has a container-ID in the range 1-255. If sibling containers exist within the same parent, they proceed in an ascending order of container IDs, that may or may not be consecutive, to a maximum value of 255.
06-FF	Reserved

Sibling TLEs have the same value of nesting level which is equivalent to either the value of the nesting level minus one of the immediate parent TLE, or the value of MNest minus one, because the immediate parent is the topology list rather than a TLE.

Reserved, 0: For a container-type TLE, bytes 1-3 of word 0 and bytes 0-2 of word 1 are reserved and stored as zeros. For a CPU-type TLE, bytes 1-3 of word 0 and bits 0-4 of word 1 are reserved and stored as zeros.

Container ID: Byte 3 of word 1 of a container-type TLE specifies an 8-bit unsigned nonzero binary integer whose value is the identifier of the container. The container ID for a TLE is unique within the same parent container.

Fields Specific to a CPU-type TLE

The remaining fields described below are specific to a CPU-type TLE. When the multithreading facility is not installed, or when it the facility is installed but not enabled, these fields describe one or more CPUs in the configuration having common topology attributes. When the multithreading facility is installed and enabled, these fields describe one or more cores in the configuration having common topology attributes; each core comprises a set of CPUs that have the same topology attributes.

Dedicated (D): Bit 5 of word 1 of a CPU-type TLE, when one, indicates that the one or more CPUs represented by the TLE are dedicated. When D is zero, the one or more CPUs of the TLE are not dedicated.

Polarization (PP): Bits 6-7 of word 1 of a CPU-type TLE specify the polarization value and, when polarization is vertical, the degree of vertical polarization also called entitlement (high, medium, low) of the corresponding CPU(s) represented by the TLE. The following values are used:

PP	Meaning
0	The one or more CPUs represented by the TLE are horizontally polarized.
1	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is low.
2	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is medium.
3	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is high.

Polarization is only significant in a logical and virtual multiprocessing configuration that uses shared host processors and addresses how the resource assigned to a configuration is applied across the CPUs of the configuration. When horizontal polarization is in effect, each CPU of a configuration is guaranteed approximately the same amount of resource. When vertical polarization is in effect, CPUs of a configuration are classified into three levels of resource entitlement: high, medium, and low.

Both subsystem reset and successful execution of the SIGP set-architecture order specifying ESA/390 mode place a configuration and all of its CPUs into horizontal polarization. The CPUs immediately affected are those that are in the configured state. When a CPU in the standby state is configured, it acquires the current polarization of the configuration and causes a topology change of that configuration to be recognized.

A dedicated CPU is either horizontally or vertically polarized. When a dedicated CPU is vertically polarized, entitlement is always high. Thus, when D is one, PP is either 00 binary or 11 binary.

CPU Type: Byte 1 of word 1 of a CPU-type TLE specifies an 8-bit unsigned binary integer whose value is the CPU type of the one or more CPUs represented by the TLE. The CPU-type value specifies either a primary-CPU type or any one of the possible secondary-CPU types.

When the multithreading facility is installed and enabled, the TLE represents one or more cores, each CPU of which has the same CPU type.

CPU-Address Origin: When the multithreading facility is not installed, or when the facility is installed but not enabled, bytes 2-3 of word 1 of a CPU-type TLE specify a 16-bit unsigned binary integer whose value is the CPU address of the first CPU in the range of CPUs represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask. The value of a CPU-address origin is the same as that stored by the STORE CPU ADDRESS (STAP) instruction when executed on the CPU represented by bit position 0 in the CPU mask.

When the multithreading facility is installed and enabled. bytes 2-3 of word 1 specify a right-justified 16-bit unsigned binary integer whose value is the first core identification in the range of cores represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask.

The CPU-address origin is evenly divisible by 64.

CPU Mask: Words 2-3 of a CPU-type TLE specify a 64-bit mask where each bit position represents a CPU or core. When the multithreading facility is not installed, or when the facility is installed but not enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the CPU address for the corresponding CPU.
- When a CPU-mask bit is zero, the corresponding CPU is not represented by the TLE. Either the CPU is not in the configuration, or else it must be represented by another CPU-type TLE.

- When a CPU mask bit is one, the corresponding CPU has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

When the multithreading facility is installed and enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the core ID for the corresponding core.
- When a CPU-mask bit is zero, the corresponding core is not represented by the TLE. Either the core is not in the configuration or else must be represented by another CPU-type TLE.
- When a CPU-mask bit is one, the corresponding core and each of its CPUs has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

Programming Notes:

1. The following example applies when the multithreading facility is not installed, or when the facility is installed but disabled: If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, CPU 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.
2. The following examples apply when the multithreading facility is installed and enabled:

   A CPU-address-origin value of 0000 hex represents a set of core IDs in the range 0 to 63, 0040 hex represents a set of core IDs in the range 64 to 127, as so forth.

   If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, core ID 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.

   In this example, if multithreading had been enabled with a program-specified maximum thread identification of three (that is, with four threads per core, thus a TID width of 2 bits), the CPU addresses of any CPU in the core can be determined by multiplying the core ID by four (that is, shifting it left TID-width bit positions), and adding the thread ID. Thus, the CPU addresses for core 79 are 316 - 319 (013C-013F hex).

TLE Ordering: The modifier attributes that apply to a CPU-type TLE are CPU type, polarization, entitlement, and dedication. Polarization and entitlement (for vertical polarization) are taken as a single attribute, albeit with four possible values (horizontal, vertical-high, vertical-medium, and vertical-low).

A single CPU TLE is sufficient to represent as many as 64 CPUs or cores that all have the same modifier-attribute values.

When more than 64 CPUs or cores exist, or the entire range of CPU addresses are not covered by a single CPU-address origin, and the modifier attributes are constant, a separate sibling CPU TLE is stored for each CPU-address origin, as necessary, in ascending order of CPU-address origin. Each such TLE stored has at least one CPU or core represented. The collection of one or more such CPU TLEs is called a CPU-TLE set.

When multiple CPU types exist, a separate CPU-TLE set is stored for each, in ascending order of CPU type.

When multiple polarization-and-entitlement values exist, a separate CPU-TLE set is stored for each, in descending order of polarization value and degree (vertical high, medium, low, then horizontal). When present, all polarization CPU-TLE sets of a given CPU type are stored before the first CPU-TLE set of the next CPU type.

When both dedicated and not-dedicated CPUs exist, a separate CPU-TLE set is stored for each, dedicated appearing before not-dedicated.

All TLEs are ordered assuming a depth-first traversal where the sort order from major to minor is as follows:

1. CPU type
   a. Lowest CPU-type value
   b. Highest CPU-type value
2. Polarization-Entitlement
   a. Vertical high
   b. Vertical medium

c. Vertical low

d. Horizontal

3. Dedication (when applicable)

a. Dedicated

b. Not dedicated

The ordering by CPU-address origin and modifier attributes of sibling CPU TLEs within a parent container is done according to the following list, which proceeds from highest to lowest.

1. CPU-TLE set of lowest CPU-type value, vertical high, dedicated
2. CPU-TLE set of lowest CPU-type value, vertical high, not-dedicated
3. CPU-TLE set of lowest CPU-type value, vertical medium, not-dedicated
4. CPU-TLE set of lowest CPU-type value, vertical low, not-dedicated
5. CPU-TLE set of lowest CPU-type value, horizontal, dedicated
6. CPU-TLE set of lowest CPU-type value, horizontal, not-dedicated
7. CPU-TLE set of highest CPU-type value, vertical high, dedicated
8. CPU-TLE set of highest CPU-type value, vertical high, not-dedicated
9. CPU-TLE set of highest CPU-type value, vertical medium, not-dedicated
10. CPU-TLE set of highest CPU-type value, vertical low, not-dedicated
11. CPU-TLE set of highest CPU-type value, horizontal, dedicated
12. CPU-TLE set of highest CPU-type value, horizontal, not-dedicated

Other TLE Rules :

1. A container-type TLE is located at nesting levels in the range 1-5.
2. A CPU-type TLE is located at nesting level 0.
3. The number of sibling container-type TLEs in a topology list or a given parent container does not exceed the value of the magnitude byte (Mag2-6) of the nesting level corresponding to the siblings.
4. The number of CPUs represented by the one or more CPU-type TLEs of the parent container does not exceed the value of the Mag1 magnitude byte.
5. The content of a TLE is defined as follows:
   - If a TLE is a container-type TLE, the content is a list that immediately follows the parent TLE, comprised of one or more child TLEs, and each child TLE has a nesting level of one less than the nesting level of the parent TLE or topology-list end.
   - If a TLE is a CPU-type TLE, the content is one or more CPUs, as identified by the other fields of a CPU TLE.
6. When the first TLE at a nesting level is a CPU entry, the maximum nesting level 0 has been reached.

CPU Topology Overview

With the advent of the IBM System z9 Enterprise Class and subsequent models, and even previously, machine organization into nodal structures has resulted in a non-uniform memory access (NUMA) behavior, sometimes also called “lumpiness”. The purpose of the SYSIB 15.1.2 and the PERFORM TOPOLOGY FUNCTION (PTF) instruction is to provide additional machine topology awareness to the program so that certain optimizations can be performed to improve cache-hit ratios and thereby improve overall performance.

The amount of host-CPU resource assigned to a multiprocessing (MP) guest configuration has generally been spread evenly across the number of configured guest CPUs. Such an even spread implies that no particular guest CPU or CPUs are entitled to any extra host-CPU provisioning than any other, arbitrarily-determined guest CPUs. This condition of the guest configuration, affecting all CPUs of the configuration, is called *horizontal polarization*.

Under horizontal polarization, assignment of a host CPU to a guest CPU is approximately the same amount of provisioning for each guest CPU. When the provisioning is not dedicated, the same host CPUs provisioning the guest CPUs also may be used to provision guest CPUs of another guest, or even other guest CPUs of the same guest configuration. When the other guest configuration is a different logical partition, a host CPU, when active in each partition, typically must access main storage more because the cache-hit ratio is reduced by having to share the caches across multiple relocation zones. If host-CPU provisioning can alter the balance such that some host CPUs are mostly, or even exclusively, assigned to a given guest configuration, and that becomes the normal behavior, then cache-hit ratios improve, as does performance. Such an uneven spread implies that one or more guest CPUs are entitled to extra host-CPU provisioning versus other, arbitrarily-determined guest CPUs that are entitled to less host-CPU provisioning. This condition of the guest configuration, affecting all CPUs of the configuration, is called *vertical polarization*.

The architecture categorizes vertical polarization into three levels of entitlement of provisioning, high, medium, and low:

- High entitlement guarantees approximately 100% of a host CPU being assigned to a logical/virtual CPU, and the affinity is maintained as a strong correspondence between the two. With respect to provisioning of a logical partition, when vertical polarization is in effect, the entitlement of a dedicated CPU is defined to be high.

- Medium entitlement guarantees an unspecified amount of host CPU resource (one or more host CPUs) being assigned to a logical/virtual CPU, and any remaining capacity of the host CPU is considered to be slack that may be assigned elsewhere. The best case for the available slack would be to assign it as local slack if that is possible. A less-beneficial result occurs if that available slack is assigned as remote slack. (See “CPU Slack” on page 10-164 for descriptions of the two slack terms.) It is also the case that the resource percentage assigned to a logical CPU of medium entitlement is a much softer approximation as compared to the 100% approximation of a high-entitlement setting.

- Low entitlement guarantees approximately 0% of a host CPU being assigned to a logical/virtual CPU. However, if slack is available, such a logical/virtual CPU may still receive some CPU resource.

A model of nested containers using polarization is intended to provide a level of intelligence about the machine's nodal structure as it applies to the requesting configuration, so that, generally, clusters of host CPUs can be assigned to clusters of guest CPUs, thereby improving as much as possible the sharing of storage and the minimizing of different configurations essentially colliding on the same host CPUs.

Polarization and entitlement indicate the relationship of physical CPUs to logical CPUs or logical CPUs to virtual CPUs in a guest configuration, and how the capacity assigned to the guest configuration is apportioned across the CPUs that comprise the configuration. Historically, a guest configuration has been horizontally polarized. For however many guest CPUs were defined to the configuration, the host-CPU resource assigned was spread evenly across all of the guest CPUs in an equitable, non-entitled manner. It can be said that the weight of a single logical CPU in a logical partition when horizontal polarization is in effect is approximately equal to the total configuration weight divided by the number of CPUs. However, with the introduction of the 2097 and family models, it becomes imperative to be able to spread the host-CPU resource in a different manner, which is called vertical polarization of a configuration, and then the degree of provisioning of guest CPUs with host CPUs being indicated as high, medium, or low entitlement. High entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is entirely backed by the same host CPU. Medium entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is partially backed by a host CPU. Low entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is not guaranteed any host-CPU resource, other than what might become available due to slack resource becoming available.

CPU Slack

Regarding slack CPU resource, there are two kinds:

- Local slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used within the configuration of that CPU. Local slack is preferred over remote slack as better hit ratios on caches are expected when the slack is used within the configuration.

- Remote slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used outside the configuration of that CPU. Remote slack is expected to exhibit lower hit ratios on caches, but it is still better than not running a logical/virtual CPU at all.

The goal is to maximize the CPU cache hit ratios.

For a logical partition, the amount of physical-CPU resource is determined by the overall system weightings that determine the CPU resource assigned to each logical partition. For example, in a logical 3-way MP that is assigned physical-CPU resource equivalent to a single CPU, and is horizontally polarized, each logical CPU would be dispatched independently and thus receive approximately 33% physical-CPU resource. If the same configuration were to be vertically polarized, only a single logical CPU would be run and would receive approximately 100% of the assigned physical-CPU resource (high entitlement) while the remaining two logical CPUs would not normally be dispatched (low entitlement). Such resource assignment is normally an approximation. Even a low-entitlement CPU may receive some amount of resource if only to help ensure that a program does not get stuck on such a CPU.

By providing a means for a control program to indicate that it understands polarization, and to receive an indication for each CPU of its polarization and, if vertical polarization, the degree of entitlement, the control program can make more-intelligent use of data structures that are generally thought to be local to a CPU vs. available to all CPUs of a configuration. Also, such a control program can avoid directing work to any low-entitlement CPU.

The actual physical-CPU resource assigned might not constitute an integral number of CPUs, so there is also the possibility of one or more CPUs in an MP vertically-polarized configuration being entitled but not to a high degree, thereby resulting in such CPUs having either medium or low vertical entitlement.

It is possible for any remaining low-entitlement CPUs to receive some amount of host-CPU resource. For example, this may occur when such a CPU is targeted, such as via a SIGP order and slack host-CPU resource is available. Otherwise, such a logical/virtual CPU might remain in an undispatched state, even if it is otherwise capable of being dispatched.

A 2-bit polarization field is defined for the CPU-type topology-list entry (TLE) of the STORE SYSTEM INFORMATION (STSI) instruction. The degree of vertical-polarization entitlement for each CPU is indicated as high, medium, or low. The assignment is not a precise percentage but rather is somewhat fuzzy and heuristic.

In addition to vertical polarization as a means of reassigning weighting to guest CPUs, another concept exists, which is the creation and management of slack capacity (also called “white space”). Slack capacity is created under the following circumstances:

- A high-vertical CPU contributes to slack when its average utilization (AU) falls below 100 percent (100-AU).
- A medium-vertical CPU that has an assigned provisioning of M percent of a host CPU contributes to slack when its average utilization (AU) falls below M percent (M-AU > 0).
- A low-vertical CPU does not contribute to slack.
- A high-vertical CPU is not a consumer of slack.
- A medium-vertical CPU may or may not be a consumer of slack.
- A low-vertical CPU is only a consumer of slack.

Depending upon its utilization and pattern of being dispatched, a horizontally-polarized CPU can be either a contributor to slack or a consumer of it.

Programming Note: A possible examination process of a topology list is described. Before an examination of a topology list is begun, the current-TLE pointer is initialized to reference the first or top TLE in the topology list, the prior-TLE pointer is initialized to null, and then TLEs are examined in a top-to-bottom order.

As a topology-list examination proceeds, the current-TLE pointer is advanced by incrementing the current-TLE pointer by the size of the current TLE to which it points. A container-type TLE is advanced by adding eight to the current-TLE pointer. A CPU-type TLE is advanced by adding sixteen to the current-TLE pointer. The process of advancing the current-TLE pointer includes saving its value as the prior-TLE pointer just before it is incremented. TLE examination is not performed if the topology list has no TLEs.

The examination process is outlined in the following steps:

1. If the current-TLE nesting level is zero, and the prior-TLE nesting level is null or one, the current TLE represents the first CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when a new group of one or more CPUs is first observed. Go to step 5.

2. If the current-TLE nesting level is zero, and the prior-TLE nesting level is zero, the current TLE represents a subsequent CPU-type TLE of a group of CPU-type TLEs that represent siblings of the CPUs previously observed in steps 1 or 2. The program should perform whatever action is appropriate for when the size of an existing sibling group of one or more CPUs is increased. Go to step 5.

3. If the current-TLE nesting level is not zero, and the prior-TLE nesting level is zero, the prior TLE represents a last or only CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed. Go to step 5.

4. Go to step 5.

   By elimination, this would be the case where the current-TLE nesting level is not zero, and the prior-TLE nesting level is not zero. If the current-TLE nesting level is less than the prior-TLE nesting level, the direction of topology-list traversal is toward a CPU-type TLE. If the current-TLE nesting level is greater than the prior-TLE nesting level, the direction of topology-list traversal is away from a CPU-type TLE. Container-type TLEs are being traversed leading to either (1) another group of CPU-type TLEs that are a separate group in the overall topology, or (2) the end of the topology list. In either case, no particular processing is required beyond advancing to the next TLE.

5. Advance to the next TLE position based upon the type of the current TLE. If the advanced current-TLE pointer is equivalent to the end of the topology list:

   a. No more TLEs of any type exist.

   b. If the prior-TLE nesting level is zero, the program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed.

   c. The examination is complete.

   Otherwise go to step 1.

Special Conditions

The condition code is set to 3 if the function code in bit positions 32-35 of general register 0 is greater than the current-level number.

Bits 36-55 of general register 0 and 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized.

When the function code is valid and nonzero, the following special conditions apply in an unpredictable order:

- The second operand must be designated on a 4 K-byte boundary; otherwise, a specification exception is recognized.
- If the function-code, selector-1, and selector-2 combination is invalid, or if it is valid but the requested information is not available, the condition code is set to 3.

Resulting Condition Code:

0 Requested configuration-level number placed in general register 0 or requested SYSIB information stored
1 --
2 --
3 Requested SYSIB information not available

Program Exceptions:

- Access (store, operand 2, only if function code nonzero)
- Privileged operation
- Specification
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-96.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Privileged-operation exception for privileged instruction.
7.C	Transaction constraint.
8.	Condition code 3 due to function code greater than current-level number.
9.	Specification exception due to bits 36-55 of general register 0 or bits 32-47 of general register 1 not zero.
10.	Condition code 0 due to function code 0.
11.A	Specification exception due to second-operand address not designating a 4 K-byte boundary.
11.B	Condition code 3 due to invalid function-code, selector-1, and selector-2 combination or requested information not available.
12.	Access exceptions (store) for system-information block.
13.	Condition code 0 due to information stored in system-information block.

Figure 10-96. Priority of Execution: STORE SYSTEM INFORMATION

Programming Note: The storage-operand references for STORE SYSTEM INFORMATION may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

STORE THEN AND SYSTEM MASK

STNSM $D_1(B_1),I_2$ [SI]

'AC'	I_2	B_1	D_1
0	8	16	20 31

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical AND of their original contents and the second operand.

Special Conditions

The operation is suppressed on addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 1)
- Privileged operation
- Transaction constraint

Programming Note: STORE THEN AND SYSTEM MASK permits the program to set selected bits in the system mask to zeros while retaining the original contents for later restoration. For example, it may be necessary that a program, which has no record of the present status, disable program-event recording for a few instructions.

STORE THEN OR SYSTEM MASK

STOSM $D_1(B_1),I_2$ [SI]

'AD'	I_2	B_1	D_1
0	8	16	20 31

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical OR of their original contents and the second operand.

Special Conditions

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if either (a) the contents of bit positions 0 and 2-4 of the PSW are not all zeros, or (b) in the ESA/390-compatibility mode, bit position 5 of the PSW does not contain zero. In either of these cases, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on addressing and protection exceptions.

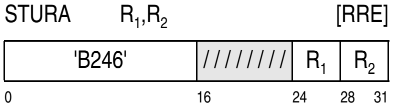
Condition Code: The code remains unchanged.

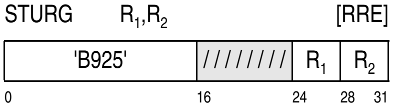
Program Exceptions:

- Access (store, operand 1)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: STORE THEN OR SYSTEM MASK permits the program to set selected bits in the system mask to ones while retaining the original contents for later restoration. For example, the program may enable the CPU for I/O interruptions without having available the current status of the external-mask bit.

STORE USING REAL ADDRESS





For STORE USING REAL ADDRESS (STURA), bits 32-63 of general register R_1 are stored in the word at the real-storage location addressed by the contents of general register R_2. For STORE USING REAL ADDRESS (STURG), bits 0-63 of general register R_1 are stored in the doubleword at that real-storage location.

In the 24-bit addressing mode, bits 40-63 of general register R_2 designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R_2 designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R_2 designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

Special Conditions

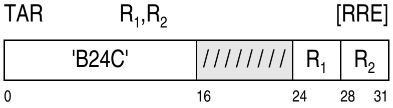
The contents of general register R_2 must designate a location on a word boundary for STURA or on a doubleword boundary for STURG; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Protection (store, operand 2, key-controlled protection and low-address protection)
- Specification
- Transaction constraint

TEST ACCESS



Note: In the ESA/390-compatibility mode when ESA extended-configuration (ESA/XC) applies, the behavior of TEST ACCESS is described in Reference [12.] on page xxx, except that it is unpredictable whether a special-operation exception is recognized when bit position 47 of control register 0 contains zero.

The access-list-entry token (ALET) in access register R_1 is tested for exceptions recognized during access-register translation (ART). The extended authorization index (EAX) used is bits 32-47 of general register R_2. The ALET is also tested for whether it designates the dispatchable-unit access list or the primary-space access list and for whether it is 00000000 or 00000001 hex.

When R_1 is 0, the actual contents of access register 0 are used in ART, instead of the 00000000 hex that is usually used.

Bits 0-31 and 48-63 of general register R_2 are ignored.

The operation does not depend on the translation mode — bits 5, 16, and 17 of the PSW are ignored.

When the ALET specified by means of the R_1 field is other than 00000000 or 00000001 hex, the ART process is applied to the ALET. The EAX specified by means of the R_2 field is called the effective EAX, and it is the EAX which is used by ART. When a condition exists that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	ALET bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to effective EAX, and secondary bit selected by effective EAX either outside authority table or zero

When ART is completed without one of the above conditions being present, the instruction is completed by setting condition code 1 or 2, depending on whether the effective access list is the dispatchable-unit access list or the primary-space access list, respectively. The effective access list is the dispatchable-unit access list if bit 7 of the ALET is zero, or it is the primary-space access list if bit 7 is one. ART, including the obtaining of the effective access-list designation, is described in “Access-Register-Translation Process” on page 5-59.

When the ALET is 00000000 hex, the instruction is completed by setting condition code 0. When the ALET is 00000001 hex, the instruction is completed by setting condition code 3.

Special Conditions

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

In the ESA/390-compatibility mode, it is unpredictable whether a special-operation exception is recognized when bit position 47 of control register 0 contains zero.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Access-list-entry token (ALET) is 00000000 hex
1 ALET designates the dispatchable-unit access list and does not cause exceptions in access-register translation (ART)
2 ALET designates the primary-space access list and does not cause exceptions in ART
3 ALET is 00000001 hex or causes exceptions in ART

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, or authority-table entry)
- Special operation (in the ESA/390-compatibility mode)
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-97.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
8.	Condition code 0 due to access-list-entry-token (ALET) being 00000000 hex.
9.	Condition code 3 due to ALET being 00000001 hex or ALET bits 0-6 not being all zeros.
10.	Addressing exception for access to effective access-list designation.
11.	Condition code 3 due to access-list entry (ALE) being outside the list.
12.	Addressing exception for access to ALE.
13.	Condition code 3 due to ALE being invalid (bit 0 is 1) or access-list-entry sequence number (ALESN) in the ALET not being equal to the ALESN in the ALE.
14.	Addressing exception for access to ASN-second-table entry (ASTE).

Figure 10-97. Priority of Execution: TEST ACCESS (Part 1 of 2)

15. Condition code 3 due to ASTE being invalid (bit 0 is one) or ASTE sequence number (ASTESN) in the ALE not being equal to the ASTESN in the ASTE.

16. Condition code 3 due to authority-table entry being outside table.

17. Addressing exception for access to authority-table entry.

18. Condition code 3 due to ALE private bit not being zero, ALE authorization index (ALEAX) not being equal to effective extended authorization index (EAX), and secondary bit selected by effective EAX being zero.

19. Condition code 1 if ALET bit 7 is zero; otherwise, condition code 2.

Figure 10-97. Priority of Execution: TEST ACCESS (Part 2 of 2)

Programming Notes:

1. TEST ACCESS permits a called program to check whether an ALET passed from the calling program is authorized for use by means of the calling program's EAX. The calling program's EAX can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE. The called program can thus avoid performing an operation for the calling program, through the use of the called program's EAX, which the calling program is not authorized to perform by means of its own EAX.

2. When an ALET equal to 00000000 hex is passed during a program linkage performed by PROGRAM CALL with space switching (PC-ss), and the ALET conceptually designates the calling program's primary address space and the called program's secondary address space, the ALET must be changed to 00000001 hex before it is used by the called program. Condition code 0 of TEST ACCESS indicates a 00000000 hex ALET so that the ALET can be changed to 00000001 hex by the called program.

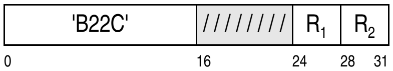
3. PROGRAM CALL to current primary (PC-cp) sets the secondary address space equal to the primary address space. PC-ss sets the secondary address space equal to the calling program's primary address space, except that stacking PC-ss sets it equal to the called program's primary address space when the secondary-ASN control in the entry-table entry used is one. In all these cases, a passed 00000001 hex ALET that conceptually designates the calling program's secondary address space is not usable by the called program, even after any transformation (unless the operation was PC-cp and the calling program's PASN and SASN are equal). This is why TEST ACCESS sets condition code 3 when the tested ALET is 00000001 hex.

4. After a PC-ss, a passed ALET that conceptually designates an entry in the primary-space access list of the calling program is not usable by the called program. This is why TEST ACCESS sets condition code 2, instead of condition code 1, when the tested ALET designates the primary-space access list.

5. The control program may manage the ASN-second-table entry in a way that causes a correctable ASTE-validity or ASTE-sequence exception situation to exist; that is, a situation which, if it were to cause a program interruption during access-register translation, would be corrected by the control program so that access-register translation could be completed successfully. In this case, the program should not use TEST ACCESS directly but should instead use a control-program service that uses TEST ACCESS and that corrects the situation, if possible, when condition code 3 is set. MVS/ESA provides the TESTART macro instruction for use instead of the direct use of TEST ACCESS.

TEST BLOCK

TB R_1,R_2 [RRE]



The storage locations and storage key of a 4 K-byte block are tested for usability, and the result of the test is indicated in the condition code. The test for usability is based on the susceptibility of the block to the occurrence of invalid checking-block code.

The block tested is addressed by the contents of general register R_2. The contents of general register R_1 are ignored.

A complete testing operation is necessarily performed only when the initial contents of bit positions 32-63 of general register 0 are zero in the 24-bit or 31-bit addressing mode, or the initial contents of bit positions 0-63 of that register are zero in the 64-bit addressing mode. In the 24-bit or 31-bit addressing mode, the contents of bit positions 32-63 of general register 0 are set to zero at the completion of the operation, and bits 0-31 of the register always are ignored and remain unchanged. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register are set to zero at the completion of the operation.

If the block is found to be usable, the 4K bytes of the block are cleared to zeros, the contents of the storage key are unpredictable, and condition code 0 is set. If the block is found to be unusable, the data and the storage key are set, as far as is possible by the model, to a value such that subsequent fetches to the area do not cause a machine-check condition, and condition code 1 is set.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of the register designate the block, and bits 0-32 and 52-63 are ignored. In the 64-bit addressing mode, bits 0-51 of the register designate the block, and bits 52-63 are ignored.

The address of the block is a real address, and the accesses to the block designated by the second-operand address are not subject to access-list-controlled, DAT, instruction-execution, or key-controlled protection. Low-address protection does apply. The operation is terminated on addressing and protection exceptions. If termination occurs, the condition code and the contents of bit positions 32-63 of general register 0 are unpredictable in the 24-bit or 31-bit addressing mode, or the condition code and bits 0-63 of the register are unpredictable in the 64-bit addressing mode. The contents of the storage block and its associated storage key are not changed when these exceptions occur.

Depending on the model, the test for usability may be performed (1) by alternately storing and reading out test patterns to the data and storage key in the block or (2) by reference to an internal record of the usability of the blocks which are available in the configuration, or (3) by using a combination of both mechanisms.

In models in which an internal record is used, the block is indicated as unusable if a solid failure has been previously detected, or if intermittent failures in the block have exceeded the threshold implemented by the model. In such models, depending on the criteria, attempts to store may or may not occur. Thus, if block 0 is not usable, and no store occurs, low-address protection may or may not be indicated.

In models in which test patterns are used, TEST BLOCK may be interruptible. When an interruption occurs after a unit of operation, other than the last one, the condition code is unpredictable, and the contents of bit positions 32-63 of general register 0 may contain a record of the state of intermediate steps in the 24-bit or 31-bit addressing mode, or the contents of bit positions 0-63 may contain that record in the 64-bit addressing mode. When execution is resumed after an interruption, the condition code is ignored, but the record in general register 0 may be used to determine the resumption point.

If (1) TEST BLOCK is executed with an initial value other than zero in bit positions 32-63 of general register 0 in the 24-bit or 31-bit addressing mode or bit positions 0-63 in the 64-bit addressing mode, or (2) the interrupted instruction is resumed after an interruption with a value in bit positions 32-63 or 0-63 (depending on the addressing mode) of general register 0 or a value in the storage block or its associated storage key other than the corresponding value which was present at the time of the interruption, or (3) the block or its associated storage key is accessed by another CPU or by the channel subsystem during the execution of the instruction, then the contents of the storage block, its associated storage key, and bit positions 32-63 or 0-63 of general register 0 are unpredictable, along with the resultant condition-code setting.

Invalid checking-block-code errors initially found in the block or encountered during the test do not normally result in machine-check conditions. The test-block function is implemented in such a way that the frequency of machine-check interruptions due to the instruction execution is not significant. However, if, during the execution of TEST BLOCK for an unusable block, that block is accessed by another CPU (or by the channel subsystem), error conditions may be reported both to this CPU and to the other CPU (or to the channel subsystem).

A serialization function is performed before the block is accessed and again after the operation is completed (or partially completed).

Resulting Condition Code:

0 Block usable
1 Block not usable
2 --
3 --

Program Exceptions:

- Addressing (fetch and store, operand 2)
- Privileged operation
- Protection (store, operand 2, low-address protection only)
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-98.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Privileged-operation exception.
7.C	Transaction constraint.
8.	Addressing exception due to block not being available in the configuration.*
9.A	Condition code 1, block not usable.
9.B	Protection exception due to low-address protection.*
10.	Condition code 0, block usable and set to zeros.
Explanation:	
*	The operation is terminated on addressing and protection exceptions, and the condition code may be unpredictable.

Figure 10-98. Priority of Execution: TEST BLOCK

Programming Notes:

1. The execution of TEST BLOCK on most models is significantly slower than that of the MOVE LONG instruction with padding; therefore, the instruction should not be used for the normal case of clearing storage.

2. The program should use TEST BLOCK at initial program loading and as part of the vary-storage-online procedure to determine if blocks of storage exist which should not be used.

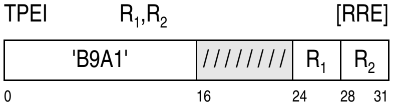
3. The program should use TEST BLOCK when an uncorrected error is reported in either the data or storage key of a block. This is because in the execution of TEST BLOCK the attempt is made, as far as is possible on the model, to leave the contents of a block in a state such that subsequent prefetches or unintended references to the block do not cause machine-check conditions. The program may use the resulting condition code in this case to determine if the block can be reused. (The block could be indicated as usable if, for example, the error were an externally generated error or an indirect storage error.) This procedure should be followed regardless of whether the indirect-storage-error indication is reported.

4. The model may or may not be successful in removing the errors from a block when TEST BLOCK is executed. The program therefore should take every reasonable precaution to avoid referencing an unusable block. For example, the program should not place the page-frame real address of an unusable block in an attached and valid page-table entry.

5. On some models, machine checks may be reported for a block even though the block is not referenced by the program. When a machine check is reported for a storage-key error in a block which has been marked as unusable by the program, it is possible that SET STORAGE KEY EXTENDED may be more effective than TEST BLOCK in validating the storage key.

6. The storage-operand references for TEST BLOCK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

TEST PENDING EXTERNAL INTERRUPTION



General register R_2 contains a mask representing one or more external-interruption subclasses to be tested for pending interruptions. The bit positions representing tested subclasses are shown in Figure 10-99. All other bits in general register R_2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit	External Interruption Subclass
30	Warning track
48	Malfunction alert
49	Emergency signal
50	External call

Figure 10-99. External-Interruption Subclasses and Corresponding Bit Positions in General Registers R_1 and R_2.

For the purposes of this instruction, an interruption is considered to be pending for a subclass regardless of whether the subclass is enabled in control register 0 and regardless of PSW bit 7. If an external interruption is pending for a designated subclass, the corresponding bit in general register R_1 is set to one; otherwise, the corresponding bit in general register R_1 is set to zero. All other bit positions in general register R_1 are set to zeros.

When any resulting bit position in general register R_1 contains a one, the instruction completes by setting condition code 1; otherwise, the instruction completes by setting condition code 0.

Resulting Condition Code:

0 None of the tested subclasses of external interruptions are pending, or no subclasses were tested.
1 One or more of the tested subclasses of external interruptions are pending
2 --
3 --

Program Exceptions:

- Operation (test-pending-external-interruption facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: Unlike the TEST PENDING INTERRUTION (TPI) instruction which is subject to the I/O-interruption subclass-mask bits in control register 6, TEST PENDING EXTERNAL INTERRUPTION does not take subclass enablement into consideration.

TEST PROTECTION

TPROT $D_1(B_1),D_2(B_2)$ [SSE]

'E501'	B_1	D_1	B_2	D_2
0	16	20	32	36 47

The location designated by the first-operand address is tested for protection exceptions by using the access key specified by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the access key to be used in testing. Bits 0-55 and 60-63 of the second-operand address are ignored.

The first-operand address is a logical address. When the CPU is in the access-register mode (when DAT is on and PSW bits 16 and 17 are 01 binary), the first-operand address is subject to translation by means of both the access-register-translation (ART) and the dynamic-address-translation (DAT) processes. ART applies to the access register designated by the B_1 field, and it obtains the address-space-control element to be used by DAT. When DAT is on but the CPU is not in the access-register mode, the first-operand address is subject to translation by DAT. In this case, DAT uses the address-space-control element contained in control register 1, 7, or 13 when the CPU is in the primary-space, secondary-space, or home-space mode, respectively. When DAT is off, the first-operand address is a real address not subject to translation by either ART or DAT.

When the CPU is in the access-register mode and an address-space-control element cannot be obtained by ART because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero

When the access register contains 00000000 hex or 00000001 hex, ART obtains the address-space-control element from control register 1 or 7, respectively, without accessing the access list. When the B_1 field designates access register 0, ART treats the access register as containing 00000000 hex and does not examine the actual contents of the access register.

When ART is completed successfully, the operation is continued through the performance of DAT.

When DAT is on and the first-operand address cannot be translated because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of first-operand address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of first-operand address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of first-operand address not all zeros.
Region first translation	Region-first-table entry outside table or invalid.
Region second translation	Region-second-table entry outside table or invalid.
Region third translation	Region-third-table entry outside table or invalid.
Segment translation	Segment-table entry outside table or invalid
Page translation	Page-table entry invalid

When translation of the first-operand address can be completed, or when DAT is off, the storage key for the block designated by the first-operand address is tested against the access key specified in bit positions 56-59 of the second-operand address, and the condition code is set to indicate whether store and fetch accesses are permitted, taking into consideration all applicable protection mechanisms except for instruction-execution protection. Thus, for example, if low-address protection is active and the first-operand effective address is in the range 0-511 or 4096-4607, then a store access is not permitted. Access-list-controlled protection, DAT protection, storage-protection override, and fetch-protection override also are taken into account; instruction-execution protection is not considered.

When EDAT-1 does not apply, when EDAT-1 applies but the STE-format control is zero, or when EDAT-2 applies but the RTTE-format control is zero, bits 0-4 of the storage key for the 4 K-byte block corresponding to the virtual address in the first operand are examined to determine the condition code. When EDAT-1 applies and both the STE-format and AV controls in the STE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the segment-table entry used in the translation of the first operand are examined to determine the condition code. When EDAT-2 applies and both the RTTE-format and AV controls in the RTTE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the region-third-table entry used in the translation of the first operand are examined to determine the condition code.

The contents of storage, including the change bit, are not affected. Depending on the model, the reference bit for the first-operand address may be set to one, even for the case in which the location is protected against fetching.

Special Conditions

When the CPU is in the access-register mode, an addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

When DAT is on, an addressing exception is recognized when the address of the region-table entry or entries, segment-table entry, or page-table entry or the operand real address after translation designates a location which is not available in the configuration. Also, a translation-specification exception is recognized when a region-table entry or the segment-table entry or page-table entry has a format error, that is, when any of the reasons 1-5 listed in “Translation-Specification Exception” on page 6-46 applies. When DAT is off, only the addressing exception due to the operand real address applies.

For all of the above cases, the operation is suppressed.

Resulting Condition Code:

0 Fetching permitted; storing permitted
1 Fetching permitted; storing not permitted
2 Fetching not permitted; storing not permitted
3 Translation not available

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, page-table entry, or operand 1)
- Privileged operation
- Translation specification
- Transaction constraint

Programming Notes:

1. TEST PROTECTION permits a program to determine the protection attributes of an address passed from a calling program without incurring program exceptions. The instruction sets a condition code to indicate whether fetching or storing is permitted at the location designated by the first-operand address of the instruction. The instruction takes into consideration all of the protection mechanisms in the machine: access-list controlled, DAT, key-controlled, and low-address protection, storage-protection override, and fetch-protection override. Additionally, since ASCE-type, region-translation, segment-translation, and page-translation-exception conditions may be a program substitute for a protection violation, these conditions are used to set the condition code rather than cause a program exception.

   When the CPU is in the access-register mode, TEST PROTECTION additionally permits the program to check the usability of an access-list-entry token (ALET) in an access register without incurring program exceptions. The ALET is checked for validity (absence of an ALET-specification, ALEN-translation, and ALE-sequence-exception condition) and for being authorized for use by the program (absence of an ASTE-validity, ASTE-sequence, and extended-authority-exception condition).

2. See the programming notes under SET PSW KEY FROM ADDRESS for more details and for an alternative approach to testing the key-controlled protection attributes of addresses passed by a calling program. The approach using TEST PROTECTION has the advantage of a test which does not result in interruptions; however, the test and use are separated in time and may not be accurate if the possibility exists that the storage key of the location in question can change between the time it is tested and the time it is used.

3. In the handling of dynamic address translation, TEST PROTECTION is similar to LOAD REAL ADDRESS in that the instructions do not cause ASCE-type, region-translation, segment-translation, and page-translation exceptions. Instead, these exception conditions are indicated by means of a condition-code setting. Similarly, access-register translation sets a condition code

for certain exception conditions when performed during either of the two instructions. Conditions which result in condition codes 1, 2, and 3 for LOAD REAL ADDRESS result in condition code 3 for TEST PROTECTION. The instructions also differ in several other respects. The first-operand address of TEST PROTECTION is a logical address and thus is not subject to dynamic address translation when DAT is off. The second-operand address of LOAD REAL ADDRESS is a virtual address which is always translated.

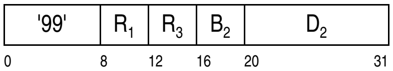
Access-register translation applies to TEST PROTECTION only when the CPU is in the access-register mode (DAT is on), whereas it applies to LOAD REAL ADDRESS when PSW bits 16 and 17 are 01 binary regardless of whether DAT is on or off. When condition code 3 is set because of an exception condition in access-register translation, LOAD REAL ADDRESS, but not TEST PROTECTION, returns in a general register the program-interruption code assigned to the exception.

4. Condition code 3 does not necessarily indicate that the first-operand location will always be inaccessible to the program; rather it merely indicates that the current conditions prevent the instruction from determining the protection attributes of the operand. For example, in a virtual storage environment, condition code 3 may be set if the storage location has been paged out by the operating system. If the program attempts to access the location, the operating system may resolve the page-translation exception and subsequently make the location accessible to the program.

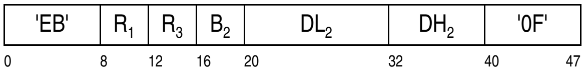
   Similarly, condition code 1 does not necessarily indicate that the address cannot ever be stored into. In an operating system that implements a Posix fork function, DAT protection is used to alert the operating system of a copy-on-write event (as described in Programming Note 1 on page 3-19). Following the operating-system resolution of the copy-on-write event, the program may be given store access to the location.

TRACE

TRACE $R_1,R_3,D_2(B_2)$ [RS-a]



TRACG $R_1,R_3,D_2(B_2)$ [RSY-a]



When explicit tracing is on (bit 63 of control register 12 is one), the second operand, which is a 32-bit word in storage, is fetched, and bit 0 of the word is examined. If bit 0 of the second operand is zero, a trace entry is formed at the real-storage location designated by control register 12.

If explicit tracing is off (bit 63 of control register 12 is zero), or if bit 0 of the second operand is one, no trace entry is formed, and no trace exceptions are recognized.

The displacement for TRACE is treated as a 12-bit unsigned binary integer. The displacement for TRACG is treated as a 20-bit signed binary integer.

The trace entry is composed of an entry-type identifier, a count of the number of general registers whose partial or entire contents are placed in the entry, a field whose contents indicate whether the entry was formed by TRACE (TRACE) or TRACE (TRACG), selected bits of the TOD clock, the second operand, and the partial or entire contents of a range of general registers. For TRACE (TRACE), bits 16-63 of the TOD clock and bits 32-63 of the general registers are placed in the trace entry. For TRACE (TRACG), bits 1-7 of the epoch index, bits 0-79 of the clock, and bits 0-63 of the registers are placed in the entry. See “Trace Entries” on page 4-15 for further details.

The general registers are stored in ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15. The trace table and the trace-entry formats are described in “Tracing” on page 4-12.

When a trace entry is made, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store. Additionally, when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, it is unpredictable whether explicit tracing causes serialization to be performed.

Special Conditions

A privileged-operation exception is recognized in the problem state, even when explicit tracing is off or bit 0 of the second operand is one.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized. It is unpredictable whether the specification exception is recognized when explicit tracing is off.

It is unpredictable whether access exceptions or PER zero-address-detection events are recognized for the second operand when explicit tracing is off.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Trace
- Transaction constraint

Programming Notes:

1. Bits 1-15 of the second operand are reserved for model-dependent functions and should therefore be set to zeros.

2. When the store-clock-fast facility is not installed, or when the TOD-clock-control in bit 32 of control register 0 is zero, the entire 32-bit TRACE operand is stored in bits 64-95 of the trace entry for TRACE (TRACE) and in bits 96-127 of the trace entry for TRACE (TRACG).

3. When the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, the following conditions apply:

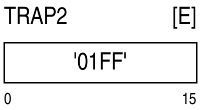
   - Two executions of the instruction do not necessarily store different values in the TOD-clock bits of the trace entry.

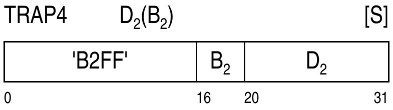
   - The value of the TOD clock bits stored in the trace entry does not necessarily indicate the order of operations among multiple CPUs.

   - The contents of bit positions 16-31 of the TRACE operand are stored in bits 80-95 of the trace entry for TRACE (TRACE) and in bits 112-127 of the trace entry for TRACE (TRACG).

   - Bits 64-79 of the trace entry for TRACE (TRACE) and bits 96-111 of the trace entry for TRACE (TRACG) are set to a model-dependent value.

TRAP





A trap operation is performed if the CPU is in the primary-space or access-register mode and the TRAP-enabled bit in byte 47 of the dispatchable-unit control table (DUCT) is one. Otherwise, a special-operation exception is recognized.

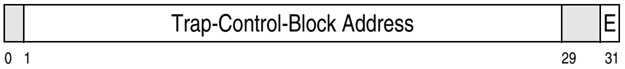
The trap operation obtains a trap-control-block address from the DUCT and then a trap-save-area address and a trap-program address from the trap control block. State information is stored in the trap save area. Then the trap-control-block address is loaded into general register 15. Finally, the current PSW is updated by setting the basic-addressing-mode bit to one (which will leave the addressing mode as either the 31-bit mode or the 64-bit mode or will change the addressing mode from the 24-bit mode to the 31-bit mode) and the address-space-control bits to zeros (primary-space mode) and by replacing the instruction address with the trap-program address. Compatibility with the ESA/390 operation of TRAP optionally is provided.

For TRAP4, the second-operand address is not used to address data; instead, bits 33-63 of the address are stored in the trap save area.

Dispatchable-Unit Control Table

Bytes 44-47 (word 10) of the dispatchable-unit-control table (DUCT) are used by this instruction. The contents of those bytes are as follows:

DUCT Bytes 44-47



The fields in bytes 44-47 of the DUCT are allocated as follows:

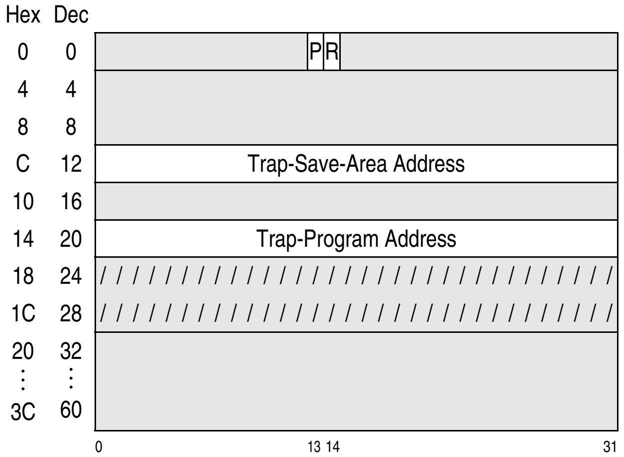
Trap-Control-Block Address: Bits 1-28, with three zeros appended on the right, form the 31-bit home virtual address of the trap control block. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. This address, with a zero appended on the left, is placed in bit positions 32-63 of general register 15 after the contents of that register have been saved in the trap save area. If the current addressing mode is the 64-bit mode, bits 0-31 of general register 15 are set to zeros.

TRAP-Enabled Bit (E): Bit 31 specifies, when one, that the trap operation is to be performed. TRAP recognizes a special-operation exception if bit 31 is zero.

Bits 0, 29, and 30 of bytes 44-47 are ignored, but they should be zeros to permit possible future extensions.

Trap Control Block

The trap control block is 64 bytes aligned on a doubleword boundary. The format of the trap control block is:



The fields in the trap control block are allocated as follows:

PSW Control (P): Bit 13 of bytes 0-3 controls the allowed value of bit 31 of the current PSW and how bits 12 and 33-127 of the current PSW are stored in the PSW-values field in the trap save area. When bit 13 is zero:

- Bit 31 of the current PSW, the extended-addressing-mode bit, must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of the PSW-values field even though bit 12 of the current PSW is zero.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of the PSW-values field, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of the PSW-values field.

When bit 13 is one:

- Bit 31 of the current PSW may be zero or one.
- Bit 12 of the current PSW is stored in bit position 12 of the PSW-values field.
- Bits 64-127 of the current PSW are stored in bit positions 64-127 of the PSW-values field.

General-Registers Control (R): Bit 14 of bytes 0-3 controls how the contents of the general registers are stored in the general-registers 0-15 field in the trap save area. When R is zero, bits 32-63 of the general registers are stored in consecutive four-byte locations beginning at the beginning of the general-registers 0-15 field, bits 0-31 of the registers are not stored, and the last 64 bytes of the general-registers 0-15 field remain unchanged. When R is one, bits 0-63 of the general registers are stored in consecutive eight-byte locations in the general-registers 0-15 field.

Trap-Save-Area Address: Bits 1-28 of bytes 12-15, with three zeros appended on the right, form the 31-bit home virtual address of the trap save area. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. Bits 0 and 29-31 of bytes 12-15 are ignored.

Trap-Program Address: Bits 1-31 of bytes 20-23 form the 31-bit primary virtual address of the trap program. This address is treated as a 31-bit primary virtual address regardless of the current addressing mode.

Bit positions 0-12 and 15-31 of bytes 0-3 and bytes 4-11, 16-19, and 32-63 of the trap control block are reserved and should contain zeros. Bytes 24-31 are available for use by programming.

Trap Save Area

The trap save area is 256 bytes aligned on a doubleword boundary.

The trap operation stores information into the trap save area as follows:

Hex	Dec	
0	0	Trap Flags
4	4	Reserved (Zeros Stored)
8	8	Bits 33-63 of Second-Op Address of TRAP4
C	12	Access Register 15
10	16	PSW Values
20	32	General Registers 0-15
A0	160	/ /
A4	164	/ /
A8	168	Reserved (Unchanged)
⋮	⋮	
FC	252	
		0 ... 31

The fields in the trap save area are allocated as follows:

Trap Flags: Information identifying the instruction(s) causing the trap operation is stored in byte positions 0-3. The detailed format of bytes 0-3 is as follows:

Flag Bits	**Meaning**
0	TRAP was target of an execute-type instruction
1	TRAP is TRAP4 (not TRAP2)
2-12	Reserved, zeros stored
13-14	Instruction-length code (ILC)
15-31	Reserved, zeros stored

Bit 0 of bytes 0-3 is set to one if TRAP was the target of an execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG).

Bit 1 of bytes 0-3 is set to one if TRAP is TRAP4 (not TRAP2).

Bits 13 and 14 are the instruction-length code (ILC) that specifies the length of the TRAP instruction, or the length of the execute-type instruction if TRAP was the target of an execute-type instruction.

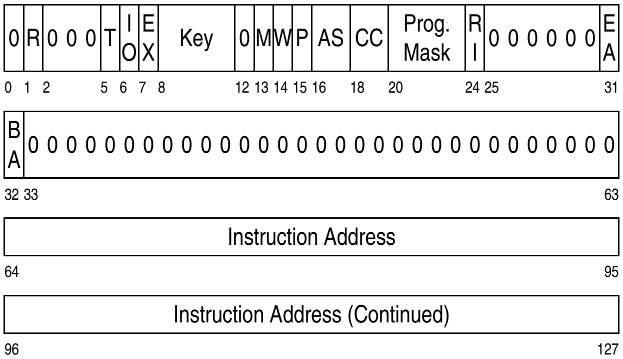
Bits 2-12 and 15-31 are reserved and are stored as zeros.

Bits 33-63 of Second-Operand Address of TRAP4: For TRAP4, bits 33-63 of the second-operand address, generated under the control of the current addressing mode and with a zero appended on the left, are stored in byte positions 8-11. Only bits 33-63 of the second-operand address are stored even when the current addressing mode is the 64-bit mode. For TRAP2, all zeros are stored in byte positions 8-11.

Access Register 15: The contents of access register 15 are stored in byte positions 12-15.

PSW Values: The following description applies when the PSW control, bit 13 of bytes 0-3 of the trap control block, is one.

Certain information from the current PSW is stored in byte positions 16-31. The PSW has the following format:



Bits 0-127 of bytes 16-31 correspond one-to-one with bits 0-127 of the PSW. For some bit positions of bytes 16-31, the corresponding PSW bits are stored. For the other bit positions of bytes 16-31, unpredictable values are stored. Information is stored in bytes 16-31 as follows:

Bits	**Value**
0	Zero
1	Unpredictable
2-4	Zero
5-11	Unpredictable
12	Zero
13	Unpredictable
14	Wait state (W)
15	Problem state (P)
16-17	Address-space control (AS)
18-19	Condition code (CC)
20-23	Program mask
25-30	Zero
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
33-63	Zero
64-127	Instruction address

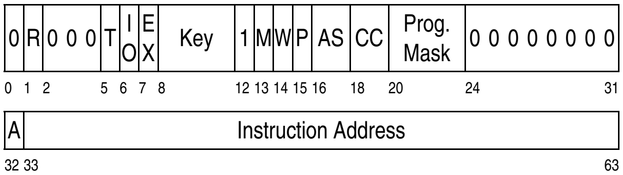
In summary, bits 0, 2-4, 12, 24-30, and 33-63 are zero, bits 1, 5-11, and 13 are unpredictable, and the other bits are set with variable information from the PSW.

The wait-state, problem-state, address-space-control, condition-code, program-mask, extended-addressing-mode, and basic-addressing-mode values specify the state of the CPU before the TRAP instruction was executed. The instruction-address value is the updated instruction address, which is the address of the instruction following TRAP, or the address of the instruction following the execute-type instruction if TRAP was the target of an execute-type instruction.

When the PSW control in the trap control block is zero, the operation is as described above except as follows:

- Bit 31 of the current PSW must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of bytes 16-31.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of bytes 16-31, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of bytes 16-31 (bytes 24-31).

In this case, bytes 16-23 have the format of an ESA/390 PSW, which is as follows:



General Registers 0-15: Contents of general registers 0-15 are stored in byte positions 32-159 as described in “General-Registers Control (R)” on page 10-178. When bits 32-63 or 0-63 of the general registers are stored, they are stored in ascending order of register numbers, starting with register 0 and continuing up to and including register 15.

Bytes 160-255 always remain unchanged. Bytes 168-255 are reserved. Bytes 160-167 are available for use by programming.

Special Conditions

The CPU must be in the primary-space mode or access-register mode, and bit 31 in bytes 44-47 of the dispatchable-unit control table must be one; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the PSW control, bit 13 of bytes 0-3 of the trap control block is zero and bit 31 of the current PSW, the extended-addressing-mode bit, is one.

All protection mechanisms apply in the usual way to the accesses to the trap control block and trap save area. Access exceptions may or may not be recognized for sections of the trap control block and trap save area that are not referenced by the TRAP instruction.

The trap-program address in the trap control block is not tested before it replaces the instruction address in the PSW. An odd address will cause a specification exception to be recognized as part of the execution of the next instruction.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, trap control block; store, trap save area)
- Addressing (dispatchable-unit control table)
- Special operation
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-100.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword (TRAP4 only).
7.B	Special-operation exception due to the CPU not being in the primary-space mode or access-register mode.
7.C.1	Addressing exception for access to dispatchable-unit control table.
7.C.2	Special-operation exception due to bit 31 in bytes 44-47 of dispatchable-unit control table being zero.
7.D	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Access exceptions (fetch) for trap control block.
8.B.2	Special-operation exception due to PSW control in trap control block being zero and PSW bit 31 being one.
8.B.3	Access exceptions (store) for trap save area.

Figure 10-100. Priority of Execution: TRAP

Programming Notes:

1. It is intended that TRAP instructions will overlay instructions in an application program in order to give control to a trap program, which might be a program for performing fix-ups of data used by the application program, such as dates that may be a “Year-2000” problem. TRAP2 can overlay a two-byte instruction, and TRAP4 can overlay a four-byte instructions or the first four bytes of a six-byte instruction. The trap program is to simulate the overlaid instruction and perform fix-ups as appropriate, and it is then to return control to the application program.

2. The trap program can use the RESUME PROGRAM instruction to return control to the application program. For example, the trap program can restore the contents of all registers except access and general registers 15, and then, using those registers (or at least the general register) to address the trap save area, can restore the contents of those registers and also PSW fields from the trap save area. RESUME PROGRAM

has control bits in its parameter list that allow it to restore PSW fields from a field having either the short format (as shown in Figure 4-3 on page 4-8) or the 16-byte format (as shown in Figure 4-2 on page 4-5) and to restore either bits 32-63 or 0-63 of a general register.

3. The trap control block and trap save area are in the home address space, and the trap program is in the primary address space. The trap-control-block address placed in general register 15 by TRAP can be useful to the trap program if (1) the primary address space and home address space are the same address space, (2) the trap control block and trap save area are at the same locations in the primary address space as in the home address space, or (3) the trap program can use access registers to access the home address space.

4. The storage-operand references for TRAP may be multiple-access references. (See “Storage-Operand Consistency” on page 5-125.)

Summary of Machine-Check Masking 11-28

The machine-check-handling mechanism provides extensive equipment-malfunction detection to ensure the integrity of system operation and to permit automatic recovery from some malfunctions. Equipment malfunctions and certain external disturbances are reported by means of a machine-check interruption to assist in program-damage assessment and recovery. The interruption supplies the program with information about the extent of the damage and the location and nature of the cause. Equipment malfunctions, errors, and other situations which can cause machine-check interruptions are referred to as machine checks.

Machine-Check Detection

Machine-check-detection mechanisms may take many forms, especially in control functions for arithmetic and logical processing, addressing, sequencing, and execution. For program-addressable information, detection is normally accomplished by encoding redundancy into the information in such a manner that most failures in the retention or transmission of the information result in an invalid code. The encoding normally takes the form of one or more redundant bits, called check bits, appended to a group of data bits. Such a group of data bits and the associated check bits are called a checking block. The size of the checking block depends on the model.

The inclusion of a single check bit in the checking block allows the detection of any single-bit failure within the checking block. In this arrangement, the check bit is sometimes referred to as a “parity bit.” In other arrangements, a group of check bits is included to permit detection of multiple errors, to permit error correction, or both.

For checking purposes, the contents of the entire checking block, including the redundancy, are called the checking-block code (CBC). When a CBC completely meets the checking requirements (that is, no failure is detected), it is said to be valid. When both detection and correction are provided and a CBC is not valid but satisfies the checking requirements for correction (the failure is correctable), it is said to be near-valid. When a CBC does not satisfy the checking requirements (the failure is uncorrectable), it is said to be invalid.

Correction of Machine Malfunctions

Four mechanisms may be used to provide recovery from machine-detected malfunctions: error checking and correction, CPU retry, channel-subsystem recovery, and unit deletion.

Machine failures which are corrected successfully may or may not be reported as machine-check interruptions. If reported, they are system-recovery conditions, which permit the program to note the cause of CPU delay and to keep a log of such incidents.

Error Checking and Correction

When sufficient redundancy is included in circuitry or in a checking block, failures can be corrected. For example, circuitry can be triplicated, with a voting circuit to determine the correct value by selecting two matching results out of three, thus correcting a single failure. An arrangement for correction of failures of one order and for detection of failures of a higher order is called error checking and correction (ECC). Commonly, ECC allows correction of single-bit failures and detection of double-bit failures.

Depending on the model and the portion of the machine in which ECC is applied, correction may be reported as system recovery, or no report may be given.

Uncorrected errors in storage and in the storage key may be reported, along with a failing-storage address, to indicate where the error occurred. Depending on the situation, these errors may be reported along with system recovery or with the damage or backup condition resulting from the error.

CPU Retry

In some models, information about some portion of the state of the machine is saved periodically. The point in the processing at which this information is saved is called a checkpoint. The information saved is referred to as the checkpoint information. The action of saving the information is referred to as establishing a checkpoint. The action of discarding previously saved information is called invalidation of the checkpoint information. The length of the interval between establishing checkpoints is model-dependent. Checkpoints may be established at the beginning of each instruction or several times within a single instruction, or checkpoints may be established less frequently.

Subsequently, this saved information may be used to restore the machine to the state that existed at the time when the checkpoint was established. After restoring the appropriate portion of the machine state, processing continues from the checkpoint. The process of restoring to a checkpoint and then continuing is called CPU retry.

CPU retry may be used for machine-check recovery, to effect nullification and suppression of instruction execution when certain program interruptions occur, and in other model-dependent situations.

Effects of CPU Retry

CPU retry is, in general, performed so that there is no effect on the program. However, change bits which have been changed from zeros to ones are not necessarily set back to zeros. As a result, change bits may appear to be set to ones for blocks which would have been accessed if restoring to the checkpoint had not occurred. If the path taken by the program is dependent on information that may be changed by another CPU or by a channel program or if an interruption occurs, then the final path taken by the program may be different from the earlier path; therefore, change bits may be ones because of stores along a path apparently never taken.

During the execution of the following instructions, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the right of the location designated by the final address in general register R_1.

- COMPRESSION CALL
- CONVERT UTF-16 TO UTF-32
- CONVERT UTF-16 TO UTF-8
- CONVERT UTF-32 TO UTF-16
- CONVERT UTF-32 TO UTF-8
- CONVERT UTF-8 TO UTF-16
- CONVERT UTF-8 TO UTF-32
- CIPHER MESSAGE
- CIPHER MESSAGE WITH AUTHENTICATION
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- DEFLATE CONVERSION CALL (see below for additional information)
- TRANSLATE ONE TO ONE
- TRANSLATE ONE TO TWO
- TRANSLATE TWO TO ONE
- TRANSLATE TWO TO TWO

During the execution of the PERFORM RANDOM NUMBER OPERATION instruction's generate operation, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the left of the rightmost byte of the first operand (that is, to the left of the location designated by the combination of general registers R_1 and $R_1 + 1$).

During the execution of DEFLATE CONVERSION CALL when the specified function is DFLTCC-CMPR or DFLTCC-XPND and the history-buffer type is circular, CPU retry may result with possibly incorrect data stored to the third-operand location.

The amount of data stored depends on the operation and the point in time at which CPU retry occurred. The amount of incorrect data stored will not exceed the minimum of (a) the length of the first operand, (b) the length of the second operand (for instructions having a second operand), and (c) the data processed in a single unit of operation of the instruction. In all cases, the storing will occur again, with correct data stored, if the instruction is executed again to continue processing the same operands.

Checkpoint Synchronization

Checkpoint synchronization consists in the following steps.

1. The CPU operation is delayed until all conceptually previous accesses by this CPU to storage have been completed, both for purposes of machine-check detection and as observed by other CPUs and by channel programs.

2. All previous checkpoints, if any, are invalidated.

3. Optionally, a new checkpoint is established.

The CPU operation is delayed until all of these actions appear to be completed, as observed by other CPUs and by channel programs.

Handling of Machine Checks during Checkpoint Synchronization

When, in the process of completing all previous stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully but can successfully restore the machine to a previous checkpoint, processing backup is reported.

When, in the process of completing all stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully and cannot successfully restore the machine to a previous checkpoint, the type of machine-check-interruption condition reported depends on the origin of the store. Failure to successfully complete stores associated with instruction execution may be reported as instruction-processing damage, or some less critical machine-check-interruption condition may be reported with the storage-logical-validity bit set to zero. A failure to successfully complete stores associated with the execution of an interruption, other than program or supervisor call, is reported as system damage.

When the machine check occurs as part of a checkpoint-synchronization action before the execution of an instruction, the execution of the instruction is nullified. When it occurs before the execution of an interruption, the interruption condition, if the interruption is external, I/O, or restart, is held pending. If the checkpoint-synchronization operation was a machine-check interruption, then along with the originating condition, either the storage-logical-validity bit is set to zero or instruction-processing damage is also reported. Program interruptions, if any, are lost.

Checkpoint-Synchronization Operations

All interruptions and the execution of certain instructions cause a checkpoint-synchronization action to be performed. The operations which cause a checkpoint-synchronization action are called checkpoint-synchronization operations and include:

- CPU reset
- All interruptions: external, I/O, machine check, program, restart, and supervisor call
- The BRANCH ON CONDITION (BCR) instruction with the M_1 and R_2 fields containing all ones and all zeros, respectively
- The instructions LOAD PSW, LOAD PSW EXTENDED, SET STORAGE KEY EXTENDED, and SUPERVISOR CALL
- All I/O instructions
- The instructions MOVE TO PRIMARY, MOVE TO SECONDARY, PROGRAM CALL, PROGRAM TRANSFER, SET ADDRESS SPACE CONTROL, and SET SECONDARY ASN, and PROGRAM RETURN when the state entry to be unstacked is a program-call state entry
- The four trace functions: branch tracing, ASN tracing, mode tracing, and explicit tracing, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether explicit tracing causes a checkpoint-synchronization action.
- PAGE IN and PAGE OUT

Programming Note: The instructions which are defined to cause the checkpoint-synchronization action invalidate checkpoint information but do not necessarily establish a new checkpoint. Additionally, the CPU may establish a checkpoint between any two instructions or units of operation, or within a single unit of operation. Thus, the point of interruption for the machine check is not necessarily at an instruction defined to cause a checkpoint-synchronization action.

Checkpoint-Synchronization Action

For all interruptions except I/O interruptions, a checkpoint-synchronization action is performed at the completion of the interruption. For I/O interruptions, a checkpoint-synchronization action may or may not be performed at the completion of the interruption. For all interruptions except program, supervisor-call, and exigent machine-check interruptions, a checkpoint-synchronization action is also performed before the interruption. The fetch access to the new PSW may be performed either before or after the first checkpoint-synchronization action. The store accesses and the changing of the current PSW associated with the interruption are performed after the first checkpoint-synchronization action and before the second.

For all checkpoint-synchronization instructions except BRANCH ON CONDITION (BCR), I/O instructions, and SUPERVISOR CALL, checkpoint-synchronization actions are performed before and after the execution of the instruction. For BCR, only one checkpoint-synchronization action is necessarily performed, and it may be performed either before or after the instruction address is updated. For SUPERVISOR CALL, a checkpoint-synchronization action is performed before the instruction is executed, including the updating of the instruction address in the PSW. The checkpoint-synchronization action taken after the supervisor-call interruption is considered to be part of the interruption action and not part of the instruction execution. For I/O instructions, a checkpoint-synchronization action is always performed before the instruction is executed and may or may not be performed after the instruction is executed.

The four trace functions — branch tracing, ASN tracing, mode tracing, and explicit tracing — cause checkpoint-synchronization actions to be performed before the trace action and after completion of the trace action, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether checkpoint-synchronization actions are performed for explicit tracing.

Channel-Subsystem Recovery

When errors are detected in the channel subsystem, the channel subsystem attempts to analyze and recover the internal state associated with the various channel-subsystem functions and the state of the channel subsystem and various subchannels. This process, which is called channel-subsystem recovery, may result in a complete recovery or may result in the termination of one or more I/O operations and the clearing of the affected subchannels. Special channel-report-pending machine-check-interruption conditions may be generated to indicate to the program the status of the channel-subsystem recovery.

Malfunctions associated with the I/O operations, depending on the severity of the malfunction, may be reported by means of the I/O-interruption mechanism or by means of the channel-report-pending and channel-subsystem-damage machine-check-interruption conditions.

Unit Deletion

In some models, malfunctions in certain units of the system can be circumvented by discontinuing the use of the unit. Examples of cases where unit deletion may occur include the disabling of all or a portion of a cache or of a translation-lookaside buffer (TLB). Unit deletion may be reported as a degradation machine-check-interruption condition.

Handling of Machine Checks

A machine check is caused by a machine malfunction and not by data or instructions. This is ensured during the power-on sequence by initializing the machine controls to a valid state and by placing valid CBC in the CPU registers, in the storage keys, and in main storage.

Designation of an unavailable component, such as a storage location, subchannel, or I/O device, does not cause a machine-check indication. Instead, such a condition is indicated by the appropriate program or I/O interruption or condition-code setting. In particular, an attempt to access a storage location which is not in the configuration, or which has power off at the storage unit, results in an addressing exception when detected by the CPU and does not generate a machine-check condition, even though the storage location or its associated storage key has invalid CBC. Similarly, if the channel subsystem attempts to access such a location, an I/O-interruption condition indicating program check is generated rather than a machine-check condition.

A machine check is indicated whenever the result of an operation could be affected by information with invalid CBC or when any other malfunction makes it impossible to establish reliably that an operation can be, or has been, performed correctly. When information with invalid CBC is fetched but not used, the condition may or may not be indicated, and the invalid CBC is preserved.

When a machine malfunction is detected, the action taken depends on the model, the nature of the malfunction, and the situation in which the malfunction occurs. Malfunctions affecting operator-facility actions may result in machine checks or may be indicated to the operator. Malfunctions affecting certain other operations such as SIGNAL PROCESSOR may be indicated by means of a condition code or may result in a machine-check-interruption condition.

A malfunction detected as part of an I/O operation may cause a machine-check-interruption condition, an I/O-error condition, or both. I/O-error conditions are indicated by an I/O interruption or by the appropriate condition-code setting during the execution of an I/O instruction. When the machine reports a failing-storage location detected during an I/O operation, both I/O-error and machine-check conditions may be indicated. The I/O-error condition is the primary indication to the program. The machine-check condition is a secondary indication, which is presented as system recovery together with a failing-storage address.

Certain malfunctions detected as part of I/O instructions and I/O operations are reported by means of special machine-check conditions called I/O machine-check conditions. Thus, malfunctions detected as part of an operation which is I/O related may be reported, depending on the error, in any of three ways: I/O-error condition, I/O machine-check condition, or non-I/O machine-check condition. In some cases, the definition requires the error to be reported by only one of these mechanisms; in other cases, any one, or in some cases, more than one, may be indicated.

Programming Note: Although the definition for machine-check conditions is that they are caused by machine malfunctions and not by data and instructions, there are certain unusual situations in which machine-check conditions are caused by events which are not machine malfunctions. Two examples follow:

1. In some cases, the channel-report-pending machine-check-interruption condition indicates a non-error situation. For example, this condition is generated at the completion of the function specified by RESET CHANNEL PATH.

2. Improper use of DIAGNOSE may result in machine-check conditions.

Validation

Machine errors can be generally classified as solid or intermittent, according to the persistence of the malfunction. A persistent machine error is said to be solid, and one that is not persistent is said to be intermittent. In the case of a register or storage location, a third type of error must be considered, called externally generated. An externally generated error is one where no failure exists in the register or storage location but invalid CBC has been introduced into the location by actions external to the location. For example, the value could be affected by a power transient, or an incorrect value may have been introduced when the information was placed at the location.

Invalid CBC is preserved as invalid when information with invalid CBC is fetched or when an attempt is made to update only a portion of the checking block. When an attempt is made to replace the contents of the entire checking block and the block contains invalid CBC, it depends on the operation and the model whether the block remains with invalid CBC or is replaced. An operation which replaces the contents of a checking block with valid CBC, while ignoring the current contents, is called a validation operation. Validation is used to place a valid CBC in a register or at a location which has an intermittent or externally generated error.

Validating a checking block does not ensure that a valid CBC will be observed the next time the checking block is accessed. If the failure is solid, validation is effective only if the information placed in the checking block is such that the failing bits are set to the value to which they fail. If an attempt is made to set the bits to the state opposite to that in which they fail, then the validation will not be effective. Thus, for a solid failure, validation is only useful to eliminate the error condition, even though the underlying failure remains, thereby reducing the exposure to additional reports. The locations, however, cannot be used, since invalid CBC will result from attempts to store other values at the location. For an intermittent failure, however, validation is useful to restore a valid CBC such that a subsequent partial store into the checking block will be permitted. (A partial store is a store into a checking block without replacing the entire checking block.)

When a checking block consists of multiple bytes in storage, or multiple bits in CPU registers, the invalid CBC can be made valid only when all of the bytes or bits are replaced simultaneously.

A register is automatically validated as part of the machine-check-interruption sequence after the original contents of the register are placed in the appropriate save area.

When an error occurs in a checking block, the original information contained in the checking block should be considered lost even after validation. Automatic register validation leaves the contents unpredictable.

Invalid CBC in Storage

The size of the checking block in storage depends on the model but is never more than 4K bytes.

When invalid CBC is detected in storage, a machine-check condition may occur; depending on the circumstances, the machine-check condition may be system damage, instruction-processing damage, or system recovery. If the invalid CBC is detected as part of the execution of a channel program, the error is reported as an I/O-error condition. When a CCW, indirect-data-address word, modified-indirect-data-address word, or data is prefetched from storage, is found to have invalid CBC, but is not used in the channel program, the condition is normally not reported as an I/O-error condition. The condition may or may not be reported as a machine-check-interruption condition. Invalid CBC detected during accesses to storage for other than CPU-related accesses may be reported as system recovery with storage error uncorrected indicated, since the primary error indication is reported by some other means.

When the storage checking block consists of multiple bytes and contains invalid CBC, special storage-validation procedures are generally necessary to restore or place new information in the checking block. Validation of storage is provided with the manual load-clear and system-reset-clear operations and is also provided as a program function. Programmed storage validation is done a block at a time, by executing the privileged instruction TEST BLOCK. Manual storage validation by clear reset validates all blocks which are available in the configuration.

A checking block with invalid CBC is never validated unless the entire contents of the checking block are replaced. An attempt to store into a checking block having invalid CBC, without replacing the entire checking block, leaves the data in the checking block (including the check bits) unchanged. Even when an instruction or a channel-program-input operation specifies that the entire contents of a checking block are to be replaced, validation may or may not occur, depending on the operation and the model.

Programming Note: Machine-check conditions may be reported for prefetched and unused data. Depending on the model, such situations may or may not be successfully retried. For example, a BRANCH AND LINK (BALR) instruction which specifies an R_2 field of zero will never branch, but on some models a prefetch of the location designated by register 0 may occur. Access exceptions associated with this prefetch will not be reported. However, if an invalid checking-block code is detected, CPU retry may be attempted. Depending on the model, the prefetch may recur as part of the retry, and thus the retry will not be successful. Even when the CPU retry is successful, the performance degradation of such a retry is significant, and system recovery may be presented, normally with a failing-storage address. To avoid continued degradation, the program should initiate proceedings to eliminate use of the location and to validate the location.

Programmed Validation of Storage

Provided that an invalid CBC does not exist in the storage key associated with a 4 K-byte block, the instruction TEST BLOCK causes the entire 4 K-byte block to be set to zeros with a valid CBC, regardless of the current contents of the storage. TEST BLOCK thus removes an invalid CBC from a location in storage which has an intermittent, or one-time, failure. However, if a permanent failure exists in a portion of the storage, a subsequent fetch may find an invalid CBC.

Invalid CBC in Storage Keys

Depending on the model, each storage key may be contained in a single checking block, or the access-control and fetch-protection bits and the reference and change bits may be in separate checking blocks.

Figure 11-1 on page 11-8 describes the action taken when the storage key has invalid CBC. The figure indicates the action taken for the case when the access-control and fetch-protection bits are in one checking block and the reference and change bits are in a separate checking block. In machines where both fields are included in a single checking block, the action taken is the combination of the actions for each field in error, except that completion is permitted only if an error in all affected fields permits completion. References to main storage to which key-controlled protection does not apply are treated as if an access key of zero is used for the reference. This includes such references as channel-program references during initial program loading and implicit references, such as interruption action and DAT-table accesses.

	Action Taken on Invalid CBC	
Type of Reference	For Access-Control and Fetch-Protection Bits	For Reference and Change Bits
SET STORAGE KEY EXTENDED	Complete; validate.	Complete; validate.
INSERT STORAGE KEY EXTENDED	PD; preserve.	PD; preserve.
RESET REFERENCE BIT EXTENDED	PD or complete; preserve.	PD; preserve.
INSERT VIRTUAL STORAGE KEY or TEST PROTECTION	PD; preserve.	CPF; preserve.
CPU prefetch (information not used)	CPF; preserve.	CPF; preserve.
Channel-program prefetch (information not used)	IPF; preserve.	IPF; preserve.
Fetch, nonzero access key	MC; preserve.	MC or complete; preserve.
Store[1], nonzero access key	MC[2]; preserve.	MC and preserve; or complete[3] and correct.
Fetch, zero access key[4]	MC or complete; preserve.	MC or complete; preserve.
Store[1], zero access key[2]	MC or complete; preserve.	MC and preserve; or complete[3] and correct.

Explanation:

[1] CPU virtual- and logical-address store accesses are subject to DAT protection. When the DAT-protection bit is one, the location will not be changed; however, the machine may indicate a machine-check condition if the storage key or the data itself has invalid CBC.

[2] The contents of the main-storage location are not changed.

[3] The contents of the reference and change bits are set to ones if the “complete” action is taken.

[4] The action shown for an access key of zero is also applicable to references to which key-controlled protection does not apply.

Complete The condition does not cause termination of the execution of the instruction, and, unless an unrelated condition prohibits it, the execution of the instruction is completed, ignoring the error condition. No machine- check-damage conditions are reported, but system recovery may be reported.

Correct The reference and change bits are set to ones with valid CBC.

Preserve The contents of the entire checking block having invalid CBC are left unchanged.

Validate The entire key is set to the new value with valid CBC. When the conditional-SSKE facility is installed and either or both the MR and MC bits of the M_3 field are one, condition code 3 is set when the instruction completes.

CPF Invalid CBC in the storage key for a CPU prefetch which is unused, or for instructions which do not examine the reference and change bits, may result in any of the following situations:

- The operation is completed; no machine-check condition is reported.
- The operation is completed; system recovery, with storage-key error uncorrected, is reported.
- Instruction-processing damage, with or without backup and with storage-key error uncorrected, is reported.

IPF Invalid CBC in the storage key for a channel-program prefetch which is unused may result in any of the following:

- The I/O operation is completed; no machine-check condition is reported.
- The I/O operation is completed; system recovery, with storage-key error uncorrected, is reported.

MC Same as PD for CPU references, but a channel-subsystem reference may result in the following combinations of I/O-error conditions and machine-check conditions:

- An I/O-error condition is reported; no machine-check condition is reported.
- An I/O-error condition is reported; system recovery, with or without storage-key error uncorrected, is reported.

PD Instruction-processing damage, with or without backup and with or without storage-key error uncorrected, is reported.

Note: When storage-key error uncorrected is reported, a failing storage address may or may not also be reported.

Figure 11-1. Invalid CBC in Storage Keys

Invalid CBC in Registers

When invalid CBC is detected in a CPU register, a machine-check condition may be recognized. CPU registers include the general, floating-point, floating-point-control, access, control, vector, and TOD programmable registers, the current PSW, the prefix register, the TOD clock, the CPU timer, and the clock comparator.

When a machine-check interruption occurs, whether or not it is due to invalid CBC in a CPU register, the following actions affecting the CPU registers, other than the prefix register and the TOD clock, are taken as part of the interruption.

1. The contents of the registers are saved in assigned storage locations. Any register which is in error is identified by a corresponding validity bit of zero in the machine-check-interruption code. Malfunctions detected during register saving do not result in additional machine-check-interruption conditions; instead, the correctness of all the information stored is indicated by the appropriate setting of the validity bits.
2. Registers with invalid CBC are then changed to have valid CBC, their actual contents being unpredictable, except that in the ESA/390-compatibility mode, bits 0-31 of all control registers are predictably set to zeros.

The prefix register and the TOD clock are not stored during a machine-check interruption, have no corresponding validity bit, and are not validated. Invalid CBC associated with the prefix register cannot safely be reported by the machine-check interruption, since the interruption itself requires that the prefix value be applied to convert real addresses to the corresponding absolute addresses. Invalid CBC in the prefix register causes the CPU to enter the check-stop state immediately.

Programming Note: Prior to the advent of z/Architecture, certain older models did not perform validation of registers during a machine-check interruption. On such models, programmed validation of the registers during machine-check interruption handling was necessary.

All z/Architecture-capable processors automatically validate registers prior to presenting a machine-check interruption to the program. Therefore, any programmed validation of registers during machine-check interruption handling is superfluous.

However, regardless of the automatic register validation that occurs as a result of a machine-check interruption, the contents of the access registers, clock-comparator register, control registers, CPU-timer register, floating-point registers, floating-point-control register, general registers, guarded-storage-control registers, TOD-programmable register, and vector registers are unpredictable following a machine-check interruption. Prior to using any of these registers or features that they control following a machine-check interruption, the program should load the with register with predictable contents.

Check-Stop State

In certain situations, it is impossible or undesirable to continue operation when a machine error occurs. In these cases, the CPU may enter the check-stop state, which is indicated by the check-stop indicator.

In general, the CPU may enter the check-stop state whenever an uncorrectable error or other malfunction occurs and the machine is unable to recognize a specific machine-check-interruption condition.

The CPU always enters the check-stop state if any of the following conditions exists:

- PSW bit 13 is zero, and an exigent machine-check condition is generated.
- During the execution of an interruption due to one exigent machine-check condition, another exigent machine-check condition is detected.
- During a machine-check interruption, the machine-check-interruption code cannot be stored successfully, or the new PSW cannot be fetched successfully.
- Invalid CBC is detected in the prefix register.
- A malfunction in the receiving CPU, which is detected after accepting the order, prevents the successful completion of a SIGNAL PROCESSOR order and the order was a reset, or the receiving CPU cannot determine what the order was. The receiving CPU enters the check-stop state.

There may be many other conditions for particular models when an error may cause check stop.

When the CPU is in the check-stop state, instructions and interruptions are not executed. The TOD clock is normally not affected by the check-stop state. The CPU timer may or may not run in the check-stop state, depending on the error and the model. The start key and stop key are not effective in this state.

The CPU may be removed from the check-stop state by CPU reset.

In a multiprocessing configuration, a CPU entering the check-stop state generates a request for a malfunction-alert external interruption to all CPUs in the configuration. Except for the reception of a malfunction alert, other CPUs and the I/O system are normally unaffected by the check-stop state in a CPU. However, depending on the nature of the condition causing the check stop, other CPUs may also be delayed or stopped, and channel subsystem and I/O activity may be affected.

System Check Stop

In a multiprocessing configuration, some errors, malfunctions, and damage conditions are of such severity that the condition causes all CPUs in the configuration to enter the check-stop state. This condition is called a system check stop. The state of the channel subsystem and I/O activity is unpredictable.

Machine-Check Interruption

A request for a machine-check interruption, which is made pending as the result of a machine check, is called a machine-check-interruption condition. There are two types of machine-check-interruption conditions: exigent conditions and repressible conditions.

Exigent Conditions

Exigent machine-check-interruption conditions are those in which damage has or would have occurred such that execution of the current instruction or interruption sequence cannot safely continue. Exigent conditions include two subclasses: instruction-processing damage and system damage. In addition to indicating specific exigent conditions, system damage is used to report any malfunction or error which cannot be isolated to a less severe report.

Exigent conditions for instruction sequences can be either nullifying exigent conditions or terminating exigent conditions, according to whether the instructions affected are nullified or terminated. Exigent conditions for interruption sequences are terminating exigent conditions. The terms “nullification” and “termination” have the same meanings as those used in Chapter 5, “Program Execution”, except that more than one instruction may be involved. Thus, a nullifying exigent condition indicates that the CPU has returned to the beginning of a unit of operation prior to the error. A terminating exigent condition means that the results of one or more instructions may have unpredictable values.

Repressible Conditions

Repressible machine-check-interruption conditions are those in which the results of the instruction-processing sequence have not been affected. Repressible conditions can be delayed, until the completion of the current instruction or even longer, without affecting the integrity of CPU operation. Repressible conditions are of three groups: recovery, alert, and repressible damage. Each group includes one or more subclasses.

A malfunction in the CPU, storage, or operator facilities which has been successfully corrected or circumvented internally without logical damage is called a recovery condition. Depending on the model and the type of malfunction, some or all recovery conditions may be discarded and not reported. Recovery conditions that are reported are grouped in one subclass, system recovery.

A machine-check-interruption condition not directly related to a machine malfunction is called an alert condition. The alert conditions are grouped in two subclasses: degradation and warning.

A malfunction resulting in an incorrect state of a portion of the system not directly affecting sequential CPU operation is called a repressible-damage condition. Repressible-damage conditions are grouped in five subclasses, according to the function affected: timing-facility damage, external damage, channel report pending, channel-subsystem damage, and service-processor damage.

Programming Notes:

1. Even though repressible conditions are usually reported only at normal points of interruption, they may also be reported with exigent machine-check conditions. Thus, if an exigent machine-check condition causes an instruction to be abnormally terminated and a machine-check interruption occurs to report the exigent condition, any pending repressible conditions may also be reported. The meaningfulness of the validity bits depends on what exigent condition is reported.

2. Classification of damage as either exigent or repressible does not imply the severity of the damage. The distinction is whether action must be taken as soon as the damage is detected (exigent) or whether the CPU can continue processing (repressible). For a repressible condition, the current instruction can be completed before taking the machine-check interruption if the CPU is enabled for machine checks; if the CPU is disabled for machine checks, the condition can safely be kept pending until the CPU is again enabled for machine checks.

   For example, the CPU may be disabled for machine-check interruptions because it is handling an earlier instruction-processing-damage interruption. If, during that time, an I/O operation encounters a storage error, that condition can be kept pending because it is not expected to interfere with the current machine-check processing. If, however, the CPU also makes a reference to the area of storage containing the error before re-enabling machine-check interruptions, another instruction-processing-damage condition is created, which is treated as an exigent condition and causes the CPU to enter the check-stop state.

3. A repressible condition may be a floating condition. A floating repressible condition is eligible to cause an interruption on any CPU in the configuration. At the point when a CPU performs an interruption for a floating repressible condition, the condition is no longer eligible to cause an interruption on the remaining CPUs in the configuration.

Interruption Action

A machine-check interruption causes the following actions to be taken, depending on the architectural mode of the configuration.

Interruption Action in the z/Architecture Architectural Mode

An architectural-mode identification with the value 01 hex is stored at real location 163. The PSW reflecting the point of interruption is stored as the machine-check old PSW in the quadword at real location 352. The contents of other registers are stored in register-save areas at real locations 4608-4863, 4892-4895, 4900-4911, 4913-4919, 4928-5119, and in a machine-check extended save area designated by the contents of real locations 4528-4535. After the contents of the registers are stored in register-save areas and extended save area, depending on the model, the registers may be validated with the contents being unpredictable. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. An external-damage code may be stored at real locations 244-247, and a failing-storage address may be stored at real locations 248-255. The new PSW is fetched from real locations 480-495. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, and the fixed-logout area are all real addresses.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-2.

Information Stored (Fetched)	Starting Location*	Length in Bytes
Architectural-mode identification	163	1
Old PSW	352	16
New PSW (fetched)	480	16
Machine-check-interruption code	232	8
Register-save areas		
Floating-point registers 0-15	4608	128
General registers 0-15	4736	128
Floating-point control register	4892	4
TOD programmable register	4900	4
CPU timer	4904	8

Figure 11-2. Machine-Check-Interruption Locationsin the z/Architecture Architectural Mode

Information Stored (Fetched)	Starting Location*	Length in Bytes
Clock comparator	4913	7
Access registers 0-15	4928	64
Control registers 0-15	4992	128
Extended interruption information		
External-damage code	244	4
Failing-storage address	248	8
Fixed-logout area	4864	16

Explanation:

* All locations are in real storage.

Figure 11-2. Machine-Check-Interruption Locationsin the z/Architecture Architectural Mode

When certain facilities are installed, and the machine-check-extended-save-area origin (beginning at real location 4528) is nonzero, the contents of the respective facilities' registers may be stored in the machine-check extended save area. See "Machine-Check-Extended-Save-Area Designation (MCESAD): During a machine check interruption, additional information may be stored at the absolute storage location designated by the doubleword at locations 4528-4535. The leftmost bits of the doubleword, called the machine-check-extended-save-area origin (MCESAO), appended on the right with binary zeros, forms the address of the area." on page 3-81 for a description of the contents of real locations 4528-4535.

The section "Machine-Check Extended Save Area (MCESA)" on page 11-24 provides a description of the contents of the area. Depending on the facilities installed and the length of the extended save area, the following additional registers may be stored:

- Vector registers
- Guarded-storage registers

Interruption Action in the ESA/390-Compatibility Mode

An architectural-mode identification with an all zeros value is stored at real location 163. The PSW reflecting the point of interruption is stored as the short-format machine-check old PSW at real locations 48-55. The contents of other registers are stored in register save areas at real locations 216-231 and 288-511, and in a machine-check extended save area designated by the contents of real locations 212-215. After the contents of the registers are stored in register save areas and the extended save area, depending on the model, the registers may be validated with the contents being unpredictable. A failing-storage address may be stored at real locations 248-251, and an external-damage code may be stored at real locations 244-247. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. The new short-format PSW is fetched from real locations 112-119. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, the locations containing the extended-save-area address, and the fixed-logout area are all real addresses. The extended-save-area address is an absolute address.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-3.

Information Stored (Fetched)	Starting Location*	Length in Bytes
Old PSW	48	8
Architectural-mode identification	163	1
New PSW (fetched)	112	8
Extended-save-area address (fetched)	212	4
Machine-check-interruption code	232	8
Register-save areas		
CPU timer	216	8
Clock comparator	224	8
Access registers 0-15	288	64
Floating-point registers 0, 2, 4, and 6	352	32
General registers 0-15 (bits 32-63)	384	64
Control registers 0-15 (bits 32-63)	448	64
Extended interruption information		
External-damage code	244	4
Failing-storage address	248	8
Fixed-logout area	256	16

Explanation:

* All locations are in real storage.

Figure 11-3. Machine-Check-Interruption Locations in the ESA/390-compatibility Mode

When the extended-save-area control, bit 34 of control register 14, is one, and bits 1-19 of the word at real locations 212-215 are not all zeros, then other fields are stored in the machine-check extended save area. Figure 11-4 lists the fields that are stored, their offsets within the area, and their lengths. Bytes 144-4095 of the extended save area remain unchanged.

Field	Byte Offset	Length in Bytes
Floating-point registers 0-15	0	128
Floating-point control register	128	4
Reserved (zeros stored)	132	12

Figure 11-4. Machine-Check Extended-Save-Area Locations in the ESA/390-compatibility Mode

The address of the machine-check extended save area is formed by appending 33 zeros to the left and 12 zeros to the right of bits 1-19 of the word at real locations 212-215. This address is treated as a 64-bit absolute address. If the 4096-byte block of storage at the address is not available in the configuration, storing into the extended save area is not performed.

Interruption Action: Common Actions

If the machine-check-interruption code cannot be stored successfully or the new PSW cannot be fetched successfully, the CPU enters the check-stop state.

A repressible machine-check condition can initiate a machine-check interruption only if both PSW bit 13 is one and the associated subclass mask bit, if any, in control register 14 is also one. When it occurs, the interruption does not terminate the execution of the current instruction; the interruption is taken at a normal point of interruption, and no program or supervisor-call interruptions are eliminated. If the machine check occurs during the execution of a machine function, such as a CPU-timer update, the machine-check interruption takes place after the machine function has been completed.

When the CPU is disabled for a particular repressible machine-check condition, the condition remains pending. Depending on the model and the condition, multiple repressible conditions may be held pending for a particular subclass, or only one condition may be held pending for a particular subclass, regardless of the number of conditions that may have been detected for that subclass.

When a repressible machine-check interruption occurs because the interruption condition is in a subclass for which the CPU is enabled, pending conditions in other subclasses may also be indicated by the same interruption code, even though the CPU is disabled for those subclasses. All indicated conditions are then cleared.

If a machine check which is to be reported as a system-recovery condition is detected during the execution of the interruption procedure due to a previous machine-check condition, the system-recovery condition may be combined with the other conditions, discarded, or held pending.

An exigent machine-check condition can cause a machine-check interruption only when PSW bit 13 is one. When a nullifying exigent condition causes a machine-check interruption, the interruption is taken at a normal point of interruption. When a terminating exigent condition causes a machine-check interruption, the interruption terminates the execution of the current instruction and may eliminate the program and supervisor-call interruptions, if any, that would have occurred if execution had continued. Proper execution of the interruption sequence, including the storing of the old PSW and other information, depends on the nature of the malfunction. When an exigent machine-check condition occurs during the execution of a machine function, such as a CPU-timer update, the sequence is not necessarily completed.

If, during the execution of an interruption due to one exigent machine-check condition, another exigent machine check is detected, the CPU enters the check-stop state. If an exigent machine check is detected during an interruption due to a repressible machine-check condition, system damage is reported.

When PSW bit 13 is zero, an exigent machine-check condition causes the CPU to enter the check-stop state.

Machine-check-interruption conditions are handled in the same manner regardless of whether the wait-state bit in the PSW is one or zero: a machine-check condition causes an interruption if the CPU is enabled for that condition.

Machine checks which occur while the rate control is set to the instruction-step position are handled in the same manner as when the control is set to the process position; that is, recovery mechanisms are active, and machine-check interruptions occur when allowed. Machine checks occurring during a manual operation may be indicated to the operator, may generate a system-recovery condition, may result in system damage, or may cause a check stop, depending on the model.

Every reasonable attempt is made to limit the side effects of any machine check and the associated interruption. Normally, interruptions, as well as the progress of I/O operations, remain unaffected. The malfunction, however, may affect these activities, and, if the currently active PSW has bit 13 set to one, the machine-check interruption will indicate the total extent of the damage caused, and not just the damage which originated the condition.

Architecture Notes:

Point of Interruption

The point in the processing which is indicated by the interruption and used as a reference point by the machine to determine and indicate the validity of the status stored is referred to as the point of interruption.

Because of the checkpoint capability in models with CPU retry, the interruption resulting from an exigent machine-check-interruption condition may indicate a point in the CPU processing sequence which is logically prior to the error. Additionally, the model may have some choice as to which point in the CPU processing sequence the interruption is indicated, and, in some cases, the status which can be indicated as valid depends on the point chosen.

Only certain points in the processing may be used as a point of interruption. For repressible machine-check interruptions, the point of interruption must be after one unit of operation is completed and any associated program or supervisor-call interruption is taken, and before the next unit of operation is begun.

Exigent machine-check conditions for instruction sequences are those in which damage has or would have occurred to the instruction stream. Thus, the damage can normally be associated with a point part way through an instruction, and this point is called the point of damage. In some cases, there may be one or more instructions separating the point of damage and the point of interruption, and the processing associated with one or more instructions may be damaged. When the point of interruption is a point prior to the point of damage due to a nullifiable exigent machine-check condition, the point of interruption can be only at the same points as for repressible machine-check conditions.

In addition to the point of interruption permitted for repressible machine-check conditions, the point of interruption for a terminating exigent machine-check condition may also be after the unit of operation is completed but before any associated program or supervisor-call interruption occurs. In this case, a valid PSW instruction address is defined as that which would have been stored in the old PSW for the program or supervisor-call interruption. Since the operation has been terminated, the values in the result fields, other than the instruction address, are unpredictable. Thus, the validity bits associated with fields which are due to be changed by the instruction stream are meaningless when a terminating exigent machine-check condition is reported.

When the point of interruption and the point of damage due to an exigent machine-check condition are separated by a checkpoint-synchronization function, the damage has not been isolated to a particular program, and system damage is indicated.

When an exigent machine-check-interruption condition occurs, the point of interruption which is chosen affects the amount of damage which must be indicated. An attempt is made, when possible, to choose a point of interruption which permits the minimum indication of damage. In general, the preference is the interruption point immediately preceding the error.

When all the status information stored as a result of an exigent machine-check-interruption condition does not reflect the same point, an attempt is made, when possible, to choose the point of interruption so that the instruction address which is stored in the machine-check old PSW is valid.

Machine-Check-Interruption Code

On all machine-check interruptions, a machine-check-interruption code (MCIC) is stored in the doubleword starting at real location 232. The code has the format shown in Figure 11-5.

Bits in the MCIC which are not assigned or not implemented by a particular model are stored as zeros.

SD	PD	SR	0	CD	ED	0	DG	W	CP	SP	CK	0	0	B	0	SE	SC	KE	DS	WP	MS	PM	IA	FA	VR	EC	FP	GR	CR	RI	ST	IE	AR	DA	0	GS	0	0	0	0	0	PR	FC	AP	0	CT	CC	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

21	PSW mask and key validity (MS)
22	PSW program-mask and condition-code validity (PM)
23	PSW-instruction-address validity (IA)
24	Failing-storage-address validity (FA)
25	Vector-register validity (VR)
26	External-damage-code validity (EC)
27	Floating-point-register validity (FP)
28	General-register validity (GR)
29	Control-register validity (CR)
30	Reserved for IBM use
31	Storage logical validity (ST)
32	Indirect storage error (IE)
33	Access-register validity (AR)
34	Delayed-access exception (DA)
36	Guarded-storage-registers validity (GS)
42	TOD-programmable-register validity (PR)
43	Floating-point-control-register validity (FC)
44	Ancillary report (AP)
46	CPU-timer validity (CT)
47	Clock-comparator validity (CC)

Note: All other bits of the MCIC are unassigned and stored as zeros.

Figure 11-5. Machine-Check Interruption-Code Format

Subclass

Bits 0-2 and 4-11 are the subclass bits which identify the type of machine-check condition causing the interruption. At least one of the subclass bits is stored as a one. When multiple errors have occurred, several subclass bits may be set to ones.

System Damage

Bit 0 (SD), when one, indicates that damage has occurred which cannot be isolated to one or more of the less severe machine-check subclasses. When system damage is indicated, the ancillary-report bit, bit 44, is meaningful, the remaining bits in the machine-check-interruption code are not meaningful, and information stored in the register-save areas and machine-check extended-interruption fields is not meaningful.

System damage is a terminating exigent condition and has no subclass-mask bit.

Instruction-Processing Damage

Bit 1 (PD), when one, indicates that damage has occurred to the instruction processing of the CPU.

The exact meaning of bit 1 depends on the setting of the backed-up bit, bit 14. When the backed-up bit is one, the condition is called processing backup. When the backed-up bit is zero, the condition is called processing damage. These two conditions are described in “Synchronous Machine-Check-Interruption Conditions” on page 11-18.

Instruction-processing damage can be a nullifying or a terminating exigent condition and has no subclass-mask bit.

System Recovery

Bit 2 (SR), when one, indicates that malfunctions were detected but did not result in damage or have been successfully corrected. Some malfunctions detected as part of an I/O operation may result in a system-recovery condition in addition to an I/O-error condition. The presence and extent of the system-recovery capability depend on the model.

System recovery is a repressible condition. It is masked by the recovery subclass-mask bit, which is in bit position 36 of control register 14.

Programming Notes:

1. System recovery may be used to report a failing-storage address detected by a CPU prefetch or by an I/O operation.

2. Unless the corresponding validity bits are ones, the indication of system recovery does not imply storage logical validity or that the fields stored as a result of the machine-check interruption are valid.

Timing-Facility Damage

Bit 4 (CD), when one, indicates that damage has occurred to the TOD clock, CPU timer, clock comparator, or TOD programmable register, or to the CPU-timer or clock-comparator external-interruption conditions. The timing-facility-damage machine-check condition is set whenever any of the following occurs:

1. The TOD clock enters the error or not-operational state.

2. The CPU timer is damaged, and the CPU is enabled for CPU-timer external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for CPU-timer interruptions. Depending on the model, the machine-check condition may be generated only as the CPU timer enters an error state. Or, the machine-check condition may be continuously generated whenever the CPU is enabled for CPU-timer interruptions, until the CPU timer is validated.

3. The clock comparator is damaged, and the CPU is enabled for clock-comparator external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for clock-comparator interruptions.

Timing-facility damage may also be set along with instruction-processing damage when an instruction which accesses the TOD clock, CPU timer, or clock comparator produces incorrect results. Depending on the model, the TOD programmable register, CPU timer, or clock comparator may be validated by the interruption which reports the TOD programmable register, CPU timer, or clock comparator as invalid.

Timing-facility damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Timing-facility-damage conditions for the CPU timer and the clock comparator are not recognized on most models when these facilities are not in use. The facilities are considered not in use when the CPU is disabled for the corresponding external interruptions (PSW bit 7, or the subclass-mask bits, bits 52 and 53 of control register 0, are zeros), and when the corresponding set and store instructions are not executed. Timing-facility-damage conditions that are already pending remain pending, however, when the CPU is disabled for the corresponding external interruption.

Timing-facility-damage conditions due to damage to the TOD clock are always recognized.

With TOD-clock steering, damage to the TOD clock is considered to be of such severity that it is undesirable to continue operation. When the TOD-clock-steering facility is installed, and damage has occurred to the TOD-clock-steering registers or the TOD clock and the damage is limited to a single CPU, then that CPU enters the check-stop state. If the TOD clock is in the not-operational state or error state, or when damage has occurred to the TOD-clock-steering registers or the TOD clock, and the damage affects all CPUs, then a system check stop occurs.

External Damage

Bit 5 (ED), when one, indicates that damage has occurred during operations not directly associated with processing the current instruction.

When bit 5, external damage, is one and bit 26, external-damage-code validity, is also one, the external-damage code has been stored to indicate, in more detail, the cause of the external-damage machine-check interruption. When the external damage cannot be isolated to one or more of the conditions as defined in the external-damage code, or when the detailed indication for the condition is not implemented by the model, external damage is indicated with bit 26 set to zero. The presence and extent of reporting external damage depend on the model.

External damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Degradation

Bit 7 (DG), when one, indicates that continuous degradation of system performance, more serious than that indicated by system recovery, has occurred. Degradation may be reported when system-recovery conditions exceed a machine-preestablished threshold or when unit deletion has occurred. The presence and extent of the degradation-report capability depend on the model.

Degradation is a repressible condition. It is masked by the degradation subclass-mask bit, which is in bit position 37 of control register 14.

Warning

Bit 8 (W), when one, indicates that damage is imminent in some part of the system (for example, that power is about to fail, or that a loss of cooling is occurring). Whether warning conditions are recognized depends on the model.

If the condition responsible for the imminent damage is removed before the interruption request is honored (for example, if power is restored), the request does not remain pending, and no interruption occurs. Conversely, the request is not cleared by the interruption, and, if the condition persists, more than one interruption may result from the same condition.

Warning is a repressible condition. It is masked by the warning subclass-mask bit, which is in bit position 39 of control register 14.

Channel Report Pending

Bit 9 (CP), when one, indicates that a channel report, consisting of one or more channel-report words, has been made pending, and the contents of the channel-report words describe, in further detail, the effect of the malfunction and the results of analysis or the action performed. A channel report becomes pending when one of the following conditions has occurred:

1. Channel-subsystem recovery has been completed. The channel-subsystem recovery may have been initiated with no prior notice to the program or may have been a result of a condition previously reported to the program.

2. The function specified by RESET CHANNEL PATH has been completed.

A channel report may also become pending under other conditions.

The channel-report words which make up the channel report may be cleared, one at a time, by execution of the instruction STORE CHANNEL REPORT WORD, which is described in "I/O Instructions" on page 14-1.

Bit 9 is meaningless when channel-subsystem damage is reported.

Channel report pending is a floating repressible condition. It is masked by the channel-report-pending subclass-mask bit, which is in bit position 35 of control register 14.

Service-Processor Damage

Bit 10 (SP), when one, indicates that damage has occurred to the service processor. Service-processor damage may be made pending at all CPUs in the configuration, or it may be detected independently by each CPU. The presence and extent of reporting service-processor damage depend on the model.

Service-processor damage is a repressible condition and has no subclass-mask bit.

Channel-Subsystem Damage

Bit 11 (CK), when one, indicates that an error or malfunction has occurred in the channel subsystem, or that the channel subsystem is in the check-stop state. The channel subsystem enters the check-stop state when a malfunction occurs which is so severe that the channel subsystem cannot continue, or if power is lost in the channel subsystem.

Channel-subsystem damage is a floating repressible condition and has no subclass-mask bit.

Subclass Modifiers

Bits 14 (B), 34 (DA), and 44 (AP) of the machine-check-interruption code act as modifiers to the subclass bits.

Backed Up

Bit 14 (B), when one, indicates that the point of interruption is at a checkpoint before the point of error. This bit is meaningful only when the instruction-processing-damage bit, bit 1, is also set to one. The presence and extent of the capability to indicate a backed-up condition depend on the model.

Delayed Access Exception

Bit 34 (DA), when one, indicates that an access exception was detected during a storage access using DAT when no such exception was detected by an earlier test for access exceptions.

Bit 34 is a modifier to instruction-processing damage (bit 1) and is meaningful only when bit 1 of the machine-check-interruption code is one. When bit 1 is zero, bit 34 has no meaning. The presence and extent of reporting delayed access exception depend on the model.

Programming Note: The occurrence of a delayed access exception normally indicates that the program is using an improper procedure to update the DAT tables.

Ancillary Report

Bit 44 (AP), when one, indicates that a malfunction of a system component has occurred which has been recognized previously or which has affected the activities of multiple system elements such as CPUs and subchannels. When the malfunction affects the activities of multiple elements, an ancillary-report condition is recognized for all of the affected elements except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful for all conditions indicated by either the machine-check-interruption code or the external-damage code.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions. When ancillary-report recognition is not provided, bit 44 is set to zero.

Synchronous Machine-Check-Interruption Conditions

The instruction-processing damage and backed-up bits, bits 1 and 14 of the machine-check-interruption code, identify, in combination, two conditions.

Bit 1	Bit 14	Name of Condition
1	0	Processing damage
1	1	Processing backup

Processing Backup

The processing-backup condition indicates that the point of interruption is prior to the point, or points, of error. This is a nullifying exigent condition. When all of the other CPU-related-damage subclasses and modifiers of the machine-check-interruption code are zero, and certain validity bits associated with CPU status are indicated as valid, then the machine has successfully returned to a checkpoint prior to the malfunction, and no damage has yet occurred to the CPU.

The subclass bits which must be zero for no damage to have occurred are as follows:

MCIC Bit	Name
0	System damage
4	Timing-facility damage

The delayed-access-exception subclass-modifier bit, MCIC bit 34, must be zero for no damage to have occurred.

The validity bits in the machine-check-interruption code which must be one for no damage to have occurred are as follows:

MCIC Bit	Name
20	PSW MWP bits
21	PSW mask and key
22	PSW program mask and condition code
23	PSW instruction address
25	Vector registers
27	Floating-point registers
28	General registers
29	Control registers
31	Storage logical validity (result fields within current checkpoint interval)
33	Access registers
42	TOD programmable register
43	Floating-point-control register
46	CPU timer
47	Clock comparator

Programming Note: The processing-backup condition is reported rather than system recovery to indicate that a malfunction or failure stands in the way of continued operation of the CPU. The malfunction has not been circumvented, and damage would have occurred if instruction processing had continued.

Processing Damage

The processing-damage condition indicates that damage has occurred to the instruction processing of the CPU. The point of interruption is a point beyond some or all of the points of damage. Processing damage is a terminating exigent condition; therefore, the contents of result fields may be unpredictable and still indicated as valid.

Processing damage may include malfunctions in program-event recording, monitor call, tracing, access-register translation, and dynamic address translation. Processing damage causes any supervisor-call-interruption condition and program-interruption condition to be discarded. However, the contents of the old PSW and interruption-code locations for these interruptions may be set to unpredictable values.

Storage Errors

Bits 16-18 of the machine-check-interruption code are used to indicate an invalid CBC or a near-valid CBC detected in main storage or an invalid CBC in a storage key. Bit 19, storage degradation, may be indicated concurrently with bit 17. The failing-storage-address field, when indicated as valid, identifies a location within the storage checking block containing the error, or, for storage-key error uncorrected, within the block associated with the storage key. Bit 32, indirect storage error, may be set to one to indicate that the location designated by the failing-storage address is not the original source of the error.

The storage-error-uncorrected and storage-key-error-uncorrected bits do not in themselves indicate the occurrence of damage because the error detected may not have affected a result. The portion of the configuration affected by an invalid CBC is indicated in the subclass field of the machine-check-interruption code.

Storage errors detected for a channel program, when indicated as I/O-error conditions, may also be reported as system recovery. CBC errors that occur in storage or in the storage key and that are detected on prefetched or unused data for a CPU program may or may not be reported, depending on the model.

Storage Error Uncorrected

Bit 16 (SE), when one, indicates that a checking block in main storage contained invalid CBC and that the information could not be corrected. The contents of the checking block in main storage have not been changed. The location reported may have been accessed or prefetched for this CPU or another CPU or a channel program, or it may have been accessed as the result of a model-dependent storage access.

Storage Error Corrected

Bit 17 (SC), when one, indicates that a checking block in main storage contained near-valid CBC and that the information has been corrected before being used. Depending on the model, the contents of the checking block in main storage may or may not have been restored to valid CBC. The location reported may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access. The presence and extent of the storage-error-correction capability depend on the model. This indication may or may not be accompanied by an indication of storage degradation, bit 19 (DS).

Storage-Key Error Uncorrected

Bit 18 (KE), when one, indicates that a storage key contained invalid CBC and that the information could not be corrected. The contents of the checking block in the storage key have not been changed. The storage key may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access.

Storage Degradation

Bit 19 (DS), when one, indicates that degradation of the recovery characteristics has occurred for the 4 K-byte block reported by the failing-storage address.

Storage degradation indicates that although the associated storage error has been corrected, there are solid failures associated with the storage block (or with its associated key) that cause the correction process to take a substantial amount of time, and that if an additional error occurs in the block, the error may not be correctable or may go undetected. Thus, this bit indicates that use of the indicated block of storage should be avoided, if possible.

The indication of storage degradation has meaning only when failing-storage-address validity, MCIC bit 24, is also one. The presence and extent of reporting storage degradation depend on the model.

Because storage degradation is normally reported with system recovery, the recovery subclass mask, bit 36 of control register 14, should be set to one in order for storage degradation to be indicated.

Indirect Storage Error

Bit 32 (IE), when one, indicates that the physical main-storage location identified by the failing-storage address is not the original source of the error. Instead, the error originated in another level of the storage hierarchy and has been propagated to the current physical-storage portion of the storage hierarchy. Bit 32 is meaningful only when bit 16 or 18 (storage error uncorrected or storage-key error uncorrected) of the machine-check-interruption code is one. When bits 16 and 18 are both zeros, bit 32 has no meaning.

For errors originating outside the storage hierarchy, the attempt to store is rejected, and the appropriate error indication is presented. When an error is detected during implicit movement of information inside the storage hierarchy, the action is not rejected and reported in this manner because the movement may be asynchronous and may be initiated as the result of an attempt to access completely unrelated information. Instead, errors in the contents of the source during implicit moving of information from one portion of the storage hierarchy to another may be preserved in the target area by placing a special invalid CBC in the checking block associated with the target location. These propagated errors, when detected later, are reported as indirect storage errors. The original source of such an error may have been in a cache associated with an I/O processor or a CPU, or the error may have been the result of a data-path failure in transmitting data from one portion of the storage hierarchy to another. Additionally, a propagated error may be generated during the movement of data from one physical portion of storage to another as the result of a storage-reconfiguration action.

The presence and extent of reporting indirect storage error depend on the model.

Programming Note: See the programming notes under TEST BLOCK in Chapter 10, “Control Instructions” for the action which should be taken after storage errors are reported.

Machine-Check Interruption-Code Validity Bits

Bits 20-29, 31 33, 42, 43, 46, and 47 of the machine-check-interruption code are validity bits. Each bit indicates the validity of a particular field in storage. With the exception of the storage-logical-validity bit (bit 31), each bit is associated with a field stored during the machine-check interruption. When a validity bit is one, it indicates that the saved value placed in the corresponding storage field is valid with respect to the indicated point of interruption and that no error was detected when the data was stored.

When a validity bit is zero, one or more of the following conditions may have occurred: the original information was incorrect, the original information had invalid CBC, additional malfunctions were detected while storing the information, or none or only part of the information was stored. Even though the information is unpredictable, the machine attempts, when possible, to place valid CBC in the storage field and thus reduce the possibility of additional machine checks being caused.

The validity bits for the floating-point registers, general registers, control registers, access registers, vector registers, TOD programmable register, floating-point control register, CPU timer, and clock comparator indicate the validity of the saved value placed in the corresponding save area. The information in these registers after the machine-check interruption is not necessarily correct even when the correct value has been placed in the save area and the validity bit set to one. The use of the registers and the operation of the facility associated with the control registers, floating-point control register, TOD programmable register, CPU timer, and clock comparator are unpredictable until these registers are validated. (See “Invalid CBC in Registers” on page 9.)

PSW-MWP Validity

Bit 20 (WP), when one, indicates that bits 12-15 of the machine-check old PSW are correct.

PSW Mask and Key Validity

Bit 21 (MS), when one, indicates that the system mask, PSW key, and miscellaneous bits of the machine-check old PSW are correct. specifically, this bit covers bits 0-11, 16, 17, 24-30, and 33-63 of the PSW.

PSW Program-Mask and Condition-Code Validity

Bit 22 (PM), when one, indicates that the program mask and condition code of the machine-check old PSW are correct.

PSW-Instruction-Address Validity

Bit 23 (IA), when one, indicates that the addressing-mode and instruction-address bits, bits 31, 32, and 64-127, of the machine-check old PSW are correct.

Failing-Storage-Address Validity

Bit 24 (FA), when one, indicates that a correct failing-storage address has been stored at real location 248-255 (in the z/Architecture architectural mode) or real location 248-251 (in the ESA/390-compatibility mode) after a storage-error-uncorrected, storage-key-error-uncorrected, or storage-error-corrected condition has occurred. The presence and extent of the capability to identify the failing-storage location depend on the model. When no such errors are reported, that is, bits 16-18 of the machine-check-interruption code are zeros, the failing-storage address is meaningless, even though it may be indicated as valid.

Vector Register Validity

Bit 25 (VR), when one, indicates that the contents of locations 0-1023 of the machine-check extended save area reflect the correct state of the vector registers 0-31 at the point of the interruption.

Bit 25 is zero when the vector facility for z/Architecture is not installed or the machine-check extended save area address formed from the contents of real locations 4528-4535 is either invalid or all zeros.

External-Damage-Code Validity

Bit 26 (EC), when one, and provided that bit 5, external damage, is also one, indicates that a valid external-damage code has been stored in the word at real location 244. When bit 5 is zero, bit 26 has no meaning.

Floating-Point-Register Validity

In the z/Architecture architectural mode, bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 4608-4735 reflect the correct state of the floating-point registers at the point of interruption. In the ESA/390-compatibility mode, bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 352-383 reflect the correct state of floating-point registers 0, 2, 4, and 6 at the point of interruption.

General-Register Validity

In the z/Architecture architectural mode, bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 4736-4863 reflect the correct state of the general registers at the point of interruption. In the ESA/390-compatibility mode, bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 384-447 reflect the correct state of bits 32-63 of the general registers at the point of interruption. `

Control-Register Validity

In the z/Architecture architectural mode, bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 4992-5119 reflect the correct state of the control registers at the point of interruption. In the ESA/390-compatibility mode, bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 448-511 reflect the correct state of bits 32-63 of the control registers at the point of interruption.

Storage Logical Validity

Bit 31 (ST), when one, indicates that the storage locations, the contents of which are modified by the instructions being executed, contain the correct information relative to the point of interruption. That is, all stores before the point of interruption are completed, and all stores, if any, after the point of interruption are suppressed. When a store before the point of interruption is suppressed because of an invalid CBC, the storage-logical-validity bit may be indicated as one, provided that the invalid CBC has been preserved as invalid.

When instruction-processing damage is indicated but processing backup is not indicated, the storage-logical-validity bit has no meaning.

Storage logical validity reflects only the instruction-processing activity and does not reflect errors in the state of storage as the result of either I/O operations or the storing of the old PSW and other interruption information.

Access-Register Validity

In the z/Architecture architectural mode, bit 33 (AR), when one, indicates that the contents of the access-register save area at real locations 4928-4991 reflect the correct state of the access registers at the point of interruption. In the ESA/390-compatibility mode, bit 33 (AR), when one, indicates that the contents of the access-register save area at real locations 288-351 reflect the correct state of the access registers at the point of interruption.

Guarded-Storage-Registers Validity

Bit 36 (GS), when one, indicates that the contents of locations 1024-1055 of the machine-check extended save area reflect the correct state of the guarded-storage registers at the point of the interruption. The guarded-storage registers are stored in the same format as that of the guarded-storage control block as shown in Figure 4-19 on page 4-67.

Bit 36 is zero when any of the following is true:

- The guarded-storage facility is not installed.
- The machine-check extended save area address formed from the contents of real locations 4528-4535 is either invalid or all zeros.
- The length characteristic (LC) in bits 60-63 of real locations 4528-4535 specifies a reserved value or a value less than 11.

TOD-Programmable-Register Validity

Bit 42 (PR), when one, indicates that the contents of the TOD-programmable-register save area at real locations 4900-4903 reflect the correct state of the TOD programmable register at the point of interruption.

Floating-Point-Control-Register Validity

In the z/Architecture architectural mode, bit 43 (FC), when one, indicates that the contents of the floating-point-control-register save area at real locations 4892-4895 reflect the correct state of the floating-point-control register at the point of interruption.

In the ESA/390-compatibility mode, bit 43 (XF), when one, indicates that the contents of locations 0-143 of the machine-check extended save area reflect the correct state of floating-point registers 0-15 and the floating-point-control register at the point of interruption. Bit 43 is zero when the extended-save-area control, bit 34 of control register 14, is zero, or the machine-check extended-save-area address formed from the contents of real locations 212-215 is either invalid or all zeros.

CPU-Timer Validity

In the z/Architecture architectural mode, bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real locations 4904-4911 reflect the correct state of the CPU timer at the time the interruption occurred. In the ESA/390-compatibility mode, bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real location 216-223 reflect the correct state of the CPU timer at the time the interruption occurred.

Clock-Comparator Validity

In the z/Architecture architectural mode, bit 47 (CC), when one, indicates that the clock comparator is not in error, that the contents of the clock-comparator save area at real locations 4913-4919 reflect the correct state of the clock comparator at the time the interruption occurred, and that zeros have been stored at real location 4912. In the ESA/390-compatibility mode, bit 47 (CC), when one, indicates that the clock comparator is not in error and that the contents of the clock-comparator save area at real locations 224-231 reflect the correct state of the clock comparator at the time the interruption occurred.

Programming Note: The validity bits must be used in conjunction with the subclass bits and the backed-up bit in order to determine the extent of the damage caused by a machine-check condition. No damage has occurred to the system when all of the following are true:

- The four PSW-validity bits, the seven register-validity bits, the two timing-facility-validity bits, and the storage-logical-validity bit are all ones.
- Subclass bits 0, 4, 5, 10, and 11 are zeros.
- The instruction-processing-damage bit is zero or, if one, the backed-up bit is also one.
- The delayed-access-exception bit is zero.

Machine-Check Extended Interruption Information

As part of the machine-check interruption, in some cases, extended interruption information is placed in fixed areas assigned in storage. The contents of registers associated with the CPU are placed in register-save areas. For external damage, additional information is provided for some models by storing an external-damage code. When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated, the failing-storage address is saved.

Each of these fields has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

Register-Save Areas

As part of the machine-check interruption, the current contents of the CPU registers, except for the prefix register and the TOD clock, are stored in register-save areas assigned in storage. Each of these areas has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

Figure 11-6 lists the eight sets of registers and the real locations in storage where their contents are saved during a machine-check interruption in the z/Architecture architectural mode.

Locations	Registers
4608-4735	Floating-point registers 0-15
4736-4863	General registers 0-15
4892-4895	Floating-point-control register
4900-4903	TOD programmable register
4904-4911	CPU timer
4913-4919	Clock comparator
4928-4991	Access registers 0-15
4992-5119	Control registers 0-15

Figure 11-6. Register Save Areas in the z/Architecture Architectural Mode.

Figure 11-7 lists the six sets of registers and the real locations in storage where their contents are saved during a machine-check interruption in the ESA/390-compatibility mode.

Locations	Registers
216-223	CPU timer
224-231	Clock comparator
288-351	Access registers 0-15
352-383	Floating-point registers 0, 2, 4, and 6
384-447	General registers 0-15 (bits 32-63)
448-511	Control registers 0-15 (bits 32-63)

Figure 11-7. Register Save Areas in the ESA/390-compatibility Mode.

Figure 11-7. Register Save Areas in the ESA/390-compatibility Mode.

External-Damage Code

The word at real location 244 is the external-damage code. This field, when implemented and indicated as valid, describes the cause of external damage. The field is valid only when the external-damage bit and the external-damage-code-validity bit (bits 5 and 26 in the machine-check-interruption code) are both ones. The presence and extent of reporting an external-damage code depend on the model.

The external-damage code has the following format:

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	SC	0 0 0 0	SS	IC	CC	CS	0 0 0 0
0	19		24				28 31

ETR Sync Check (SC): Bit 19, when one, indicates that bits 32 through the rightmost incremented bit of a running clock are not in synchronism with the same bits of the ETR.

If the condition happens more than once before the interruption occurs, the condition is generated only once. The condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

STP Sync Check (SS): Bit 24, when one, indicates that an STP-sync-check has occurred. The STP-sync-check condition is generated when the configuration is in the STP-timing mode and the timing state changes from the synchronized state to the unsynchronized or stopped state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

Island Condition (IC): Bit 25, when one, indicates that an island condition has been detected. The island condition is generated when an attached server attempts to communicate over an STP link and both of the following conditions are detected:

- The servers have matching CTN IDs, and

- Both servers have valid stratum-1-configurations and the configurations do not match.

The island condition indicates that two separate CTNs may be operating with the same CTN ID.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

CTN Configuration Change (CC): Bit 26, when one, indicates that a CTN-configuration-change has occurred in the CTN. The conditions that cause the CTN-configuration-change condition to be generated include the following:

- A new node with a matching CTN ID has attached to this node.
- An attached node that had a matching CTN ID is no longer attached to this node
- The CTN ID for this node has changed.
- The stratum level of this node has changed, or a change in the stratum-1 or alternate-stratum-1 for the network has changed.
- STP active or maximum version number has changed.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

STP Clock Source Error (CS): Bit 27, when one, indicates that an STP-clock-source error has occurred. The STP-clock-source condition is generated when the configuration is in the STP-timing mode and the STP-clock-source state changes from the usable state to the not-usable state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

Reserved: Bits 0-7, 10-16, 21-23, and 28-31 are reserved for future expansion and are always set to zero.

Failing-Storage Address

When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated in the machine-check-interruption code, the associated address, called the failing-storage address, is stored at real locations 248-255(in the z/Architecture architectural mode) or 248-251 (in the ESA/390-compatibility mode). The field is valid only if the failing-storage-address validity bit, bit 24 of the machine-check-interruption code, is one.

In the case of storage errors, the failing-storage address may designate any byte within the checking block. For storage-key error uncorrected, the failing-storage address may designate any address within the block of storage associated with the storage key that is in error. When an error is detected in more than one location before the interruption, the failing-storage address may designate any of the failing locations. The address stored is an absolute address; that is, the value stored is the address that is used to reference storage after dynamic address translation and prefixing have been applied.

Machine-Check Extended Save Area (MCESA)

Machine-Check Extended Save Area in the z/Architecture Architectural Mode

In the z/Architecture architectural mode, the machine-check-extended-save-area designation (MCESAD) at real locations 4528-4535 specifies the location and size of the machine-check extended save area (MCESA). See “Machine-Check-Extended-Save-Area Designation (MCESAD): During a machine check interruption, additional information may be stored at the absolute storage location designated by the doubleword at locations 4528-4535. The leftmost bits of the doubleword, called the machine-check-extended-save-area origin (MCESAO), appended on the right with binary zeros, forms the address of the area.” on page 3-81 for a description of the contents of the MCESAD field. When the machine-check-extended-save-area origin (MCESAO) is nonzero, the designated area is accessible, and the length characteristic (LC) provides sufficient length, the contents of various facilities’ registers are stored in the save area. A facility’s registers are only stored in the MCESA when the facility is installed. The facilities accommodated by the MCESA include the following:

- Vector facility for z/Architecture
- Guarded-storage facility

When the guarded-storage facility is not installed, the length and alignment of the MCESA is 1024 bytes. When the guarded-storage facility is installed, the length characteristic (LC) in bits 60-63 of the MCESAD specifies the length and alignment of the MCESA as a power of two; an LC value of zero is treated as 10. Figure 11-8 shows the contents of the MCESA; reserved fields remain unmodified.

Offset		Content	Minimum LC
Hex	Dec		
000-1FF	0-511	Vector Registers 0-31	10
200-3FF	512-1023	Reserved	
400-407	1024-1031	Zeros	11
408-40F	1032-1039	GSD Register	
410-417	1040-1047	GSSM Register	
418-41F	1048-1055	GSEPLA Register	
420-7FF	1056-2047	Reserved	
800-FFF	2048-4095	Reserved	12

Figure 11-8. Contents of the Machine-Check Extended Save Area, Associated MCIC-Validity Bit, and Minimum Length Characteristic Required

If the minimum length required to store a facility's registers is not specified in the length code, then those registers are not stored in the MCESA.

The parameter register and additional-status-area used by the SIGNAL PROCESSOR store-additional-status-at-address order have formats identical to those of the MCESAD and MCESA, respectively. See "Store Additional Status at Address" on page 4-93 for further details.

Machine-Check Extended Save Area in the ESA/390 Compatibility Mode

In the ESA/390-compatibility mode, when the extended-save-area control, bit 34 of control register 14, is one, and bits 1-19 of real locations 212-215 are not all zeros, then, as part of a machine-check interruption, the current contents of floating-point registers 0-15 and the floating-point-control register are stored in a machine-check extended save area. The absolute address of the extended save area is obtained by appending 33 bits of zeros to the left and 12 bits of zeros to the right of bits 1-19 of real locations 212-215. Storing does not occur if the address is invalid.

The extended save area has associated with it a validity bit, bit 43, in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the area, the associated validity bit is set to zero.

Figure 11-9 lists the fields that are stored, their offsets within the area, and their lengths. Bytes 144-4095 of the extended save area remain unchanged.

Field	Byte Offset	Length in Bytes
Floating-point registers 0-15	0	128
Floating-point control register	128	4
Reserved (zeros stored)	132	12

Figure 11-9. Machine-Check Extended-Save-Area Locations in the ESA/390-compatibility Mode

Handling of Machine-Check Conditions

Floating Interruption Conditions

An interruption condition which is made available to any CPU in a multiprocessing configuration is called a floating interruption condition. The first CPU that accepts the interruption clears the interruption condition, and it is no longer available to any other CPU in the configuration.

Floating interruption conditions include service-signal external-interruption and I/O-interruption conditions. Two machine-check-interruption conditions, channel report pending and channel-subsystem damage, are floating interruption conditions. Additionally, floating interruption conditions include STP external-damage machine-check conditions (STP Sync Check, STP Island Condition, STP CTN Configuration Error, and STP Clock Source Error) when STP machine-check floating interruptions are enabled.

Depending on the model, some machine-check-interruption conditions associated with system recovery and warning may also be floating interruption conditions.

A floating interruption is presented to the first CPU in the configuration which is enabled for the interruption condition and can accept the interruption. A CPU cannot accept the interruption when the CPU is in the check-stop state, has an invalid prefix, is performing an unending string of interruptions due to a PSW-format error of the type that is recognized early, or is in the stopped state. However, a CPU with the rate control set to instruction step can accept the interruption when the start key is activated.

Programming Note: When a CPU enters the check-stop state in a multiprocessing configuration, the program on another CPU can determine whether a floating interruption may have been reported to the failing CPU and then lost. This can be accomplished if the interruption program places zeros in the real storage locations containing old PSWs and interruption codes after the interruption has been handled (or has been moved into another area for later processing). After a CPU enters the check-stop state, the program on another CPU can inspect the old-PSW and interruption-code locations of the failing CPU. A nonzero value in an old PSW or interruption code indicates that the CPU has been interrupted but the program did not complete the handling of the interruption.

Floating Machine-Check-Interruption Conditions

Floating machine-check-interruption conditions are reset only by the manually initiated resets through the operator facilities. When a machine check occurs which prohibits completion of a floating machine-check interruption, the interruption condition is no longer considered a floating interruption condition, and system damage is indicated.

Floating I/O Interruptions

The detection of a machine malfunction by the channel subsystem, while in the process of presenting an I/O-interruption request for a floating I/O interruption, may be reported as channel report pending or as channel-subsystem damage. Detection of a machine malfunction by a CPU, while in the process of accepting a floating I/O interruption, is reported as system damage.

Machine-Check Masking

All machine-check interruptions are under control of the machine-check mask, PSW bit 13. In addition, some machine-check conditions are controlled by subclass masks in control register 14.

The exigent machine-check conditions (system damage and instruction-processing damage) are controlled only by the machine-check mask, PSW bit 13. When PSW bit 13 is one, an exigent condition causes a machine-check interruption. When PSW bit 13 is zero, the occurrence of an exigent machine-check condition causes the CPU to enter the check-stop state.

The repressible machine-check conditions, except channel-subsystem damage and service-processor damage, are controlled both by the machine-check mask, PSW bit 13, and by five subclass-mask bits in control register 14. If PSW bit 13 is one and one of the subclass-mask bits is one, the associated condition initiates a machine-check interruption. If a subclass-mask bit is zero, the associated condition does not initiate an interruption but is held pending. However, when a machine-check interruption is initiated because of a condition for which the CPU is enabled, those conditions for which the CPU is not enabled may be presented along with the condition which initiates the interruption. All conditions presented are then cleared.

Control register 14 contains mask bits that specify whether certain conditions can cause machine-check interruptions. It has the following format:

...		CR	RM	DM	EM	WM	...
	32	35	36	37	38	39	40

Bits 35-39 of control register 14 are the subclass masks for repressible machine-check conditions. In addition, bit 32 of control register 14 is initialized to one but is otherwise ignored by the machine.

Programming Note: The program should avoid, whenever possible, operating with PSW bit 13, the machine-check mask, set to zero, since any exigent machine-check condition which is recognized during this situation will cause the CPU to enter the check-stop state. In particular, the program should avoid executing I/O instructions or allowing I/O interruptions with PSW bit 13 zero.

Channel-Report-Pending Subclass Mask
