Bit 35 (CM) of control register 14 controls channel-report-pending interruption conditions. This bit is initialized to zero.

Recovery Subclass Mask

Bit 36 (RM) of control register 14 controls system-recovery interruption conditions. This bit is initialized to zero.

Degradation Subclass Mask

Bit 37 (DM) of control register 14 controls degradation interruption conditions. This bit is initialized to zero.

External-Damage Subclass Mask

Bit 38 (EM) of control register 14 controls timing-facility-damage and external-damage interruption conditions. This bit is initialized to one.

Warning Subclass Mask

Bit 39 (WM) of control register 14 controls warning interruption conditions. This bit is initialized to zero.

Machine-Check Logout

As part of the machine-check interruption, some models may place model-dependent information in the fixed-logout area. In the z/Architecture architectural mode, this area is 16 bytes in length and starts at real location 4864. In the ESA/390-compatibility mode, this area is 16 bytes in length and starts at real location 256.

Summary of Machine-Check Masking

A summary of machine-check masking is given in Figure 11-10 and Figure 11-11.

Machine-Check Condition			
MCIC Bit	**Subclass**	**Sub-Class Mask**	**Action when CPU Disabled for Subclass**
0	System damage	-	Check stop
1	Instruction-processing damage	-	Check stop
2	System recovery	RM	Y
4	Timing-facility damage	EM	P
5	External damage	EM	P
7	Degradation	DM	P
8	Warning	WM	P
9	Channel report pending	CM	P
10	Service-processor damage	-	P
11	Channel-subsystem damage	-	P

Explanation:

-	The condition does not have a subclass mask.
P	Indication is held pending.
Y	Indication may be held pending or may be discarded.
CM	Channel-report-pending subclass mask (bit 35 of CR14).
DM	Degradation subclass mask (bit 37 of CR14).
EM	External-damage subclass mask (bit 38 of CR14).
RM	Recovery subclass mask (bit 36 of CR14).
WM	Warning subclass mask (bit 39 of CR14).

Figure 11-10. Machine-Check-Condition Masking

Bit Description	Control Register 14 Bit Position	State of Bit on Initial CPU Reset
Channel-report-pending subclass mask	35	0
Recovery subclass mask	36	0
Degradation subclass mask	37	0

Figure 11-11. Machine-Check Control-Register Bits

External-damage subclass mask	38	1
Warning subclass mask	39	0

Manual Operation

The operator facilities provide functions for the manual operation and control of the machine. The functions include operator-to-machine communication, indication of machine status, control over the setting of the TOD clock, initial program loading, resets, and other manual controls for operator intervention in normal machine operation. A model may not implement all of the operator facilities described in this chapter.

A model may provide additional operator facilities which are not described in this chapter. Examples are the means to indicate specific error conditions in the equipment, to change equipment configurations, and to facilitate maintenance. Furthermore, controls covered in this chapter may have additional settings which are not described here. Such additional facilities and settings may be described in the appropriate System Library publication.

Most models provide, in association with the operator facilities, a console device which may be used as an I/O device for operator communication with the program; this console device may also be used to implement some or all of the facilities described in this chapter.

The operator facilities may be implemented on different models in various technologies and configurations. On some models, more than one set of physical representations of some keys, controls, and indicators may be provided, such as on multiple local or remote operating stations, which may be effective concurrently.

A machine malfunction that prevents a manual operation from being performed correctly, as defined for that operation, may cause the CPU to enter the check-stop state or give some other indication to the operator that the operation has failed. Alternatively, a machine malfunction may cause a machine-check-interruption condition to be recognized

Basic Operator Facilities

Address-Compare Controls

The address-compare controls provide a way to stop the CPU when a preset address matches the address used in a specified type of main-storage reference.

One of the address-compare controls is used to set up the address to be compared with the storage address.

Another control provides at least two positions to specify the action, if any, to be taken when the address match occurs:

1. The normal position disables the address-compare operation.

2. The stop position causes the CPU to enter the stopped state on an address match. When the control is in this setting, the test indicator is on. Depending on the model and the type of reference, pending I/O, external, and machine-check interruptions may or may not be taken before entering the stopped state.

A third control may specify the type of storage reference for which the address comparison is to be made. A model may provide one or more of the following positions, as well as others:

1. The any position causes the address comparison to be performed on all storage references.

2. The data-store position causes address comparison to be performed when storage is addressed to store data.

3. The I/O position causes address comparison to be performed when storage is addressed by the channel subsystem to transfer data or to fetch a channel-command or indirect-data-address word. Whether references to the measurement block, interruption-response block, channel-path-status word, channel-report word, subchannel-status word, subchannel-information block, and operation-request block cause a match to be indicated depends on the model.

4. The instruction-address position causes address comparison to be performed when storage is addressed to fetch an instruction. The rightmost bit of the address setting may or may not be ignored. The match is indicated only when the first byte of the instruction is fetched from the selected location (which includes fetching the target instruction of an execute-type instruction).

Depending on the model and the type of reference, address comparison may be performed on virtual, real, or absolute addresses, and it may be possible to specify the type of address.

In a multiprocessing configuration, it depends on the model whether the address setting applies to one or all CPUs in the configuration and whether an address match causes one or all CPUs in the configuration to stop.

Depending on the model, the availability of address-compare controls may be limited by the use of program-event-recording (PER) controls; PER controls include bit 1 of the PSW and all bits of control registers 9, 10, and 11. The address-compare-control limitations are as follows:

- The setting of address-compare controls may be inhibited when any PER control is nonzero. In a multi-processing configuration, the setting of address-compare controls may be inhibited on all CPUs in the configuration when any PER control is nonzero on any CPU in the configuration.

- If address-compare controls have been set on a CPU, and any PER control is set to a nonzero value, the address-compare controls may be disabled; the address-compare controls may remain disabled even if the respective PER controls are all subsequently reset to zero. In a multi-processing configuration, the address-compare controls may be disabled on all CPUs in the configuration if any PER control is set to a nonzero value in any CPU in the configuration.

Alter-and-Display Controls

The operator facilities provide controls and procedures to permit the operator to alter and display the contents of locations in storage, the storage keys, the general, floating-point, floating-point-control, vector, access, and control registers, the prefix, and the PSW.

Before alter-and-display operations may be performed, the CPU must first be placed in the stopped state. During alter-and-display operations, the manual indicator may be turned off temporarily, and the start and restart keys may be inoperative.

Addresses used to select storage locations for alter-and-display operations are real addresses. The capability of specifying logical, virtual, or absolute addresses may also be provided.

Architectural-Mode Indicator

Depending on the model, the configuration may be activated in the ESA/390 architectural mode, the ESA/390 compatibility mode, or the z/Architecture architectural mode.

The architectural-mode indicator shows the architectural mode of operation (the ESA/390 mode, ESA/390 compatibility mode, z/Architecture mode, or some other mode) selected by the last architectural-mode-selection operation and by the last SIGNAL PROCESSOR set-architecture order or the last reset that determined the mode.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is installed, the z/Architecture architectural mode is indicated.

Architectural-Mode-Selection Controls

The architectural-mode-selection controls provide for the selection of the ESA/390 architectural mode of operation, the ESA/390 compatibility mode of operation, the z/Architecture architectural mode of operation, or, possibly, some other architectural mode of operation. (When a configuration is activated in either the ESA/390 or ESA/390-compatibility mode, the z/Architecture mode is selected from the ESA/390 mode by the SIGNAL PROCESSOR set-architecture order.) Depending on the model, the architectural-mode selection may be provided as part of the IML operation or may be a separate operation.

As part of the architectural-mode-selection process, all CPUs and the associated channel-subsystem components in a particular configuration are placed in the same architectural mode.

Check-Stop Indicator

The check-stop indicator is on when the CPU is in the check-stop state. Reset operations normally cause the CPU to leave the check-stop state and thus turn off the indicator. The manual indicator may also be on in the check-stop state.

CPUs-per-Core Indicator

When the multithreading facility is installed, the CPUs-per-core indicator is provided. When the multithreading facility is not enabled, the value of this indicator is one. When the multithreading facility is enabled, the value of this indicator is one more than value of the program-specified maximum thread identification last set by the SIGNAL PROCESSOR set-multithreading order.

Operation Note: Certain operator functions are addressed to a specific CPU, designated by a CPU address. When multithreading is enabled, the CPU address includes a core identification and a thread identification as described in “CPU-Address Identification” on page 4-84. The CPUs-per-core indicator can be used to determine which format of CPU address is needed when selecting a CPU to which operator functions are addressed.

IML Controls

The IML controls provided with some models perform initial machine loading (IML), which is the loading of licensed internal code into the machine.

When the IML operation is completed, the state of the affected CPUs, channel subsystem, main storage, and operator facilities is the same as if a power-on reset had been performed, except that the value and state of the TOD clock are not changed. The contents of expanded storage may have been cleared to zeros with valid checking-block code or may have remained unchanged, depending on the model.

The IML controls are effective while the power is on.

Interrupt Key

When the interrupt key is activated, an external-interruption condition indicating the interrupt key is generated. (See “Interrupt Key” on page 6-13.)

The interrupt key is effective when the CPU is in the operating or stopped state. It depends on the model whether the interrupt key is effective when the CPU is in the load state.

Load Indicator

The load indicator is on during CCW-type initial program loading, indicating that the CPU is in the load state. The indicator goes on for a particular CPU when the load-clear, load-clear-list-directed, load-normal or load-with-dump key is activated for that CPU and the corresponding operation is started. It goes off after the new PSW is loaded successfully. For details, see “Initial Program Loading” on page 4-81 and “Initial Program Loading” on page 17-16.

Load-Clear Key

Activating the load-clear key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Clear reset is performed on the configuration. For details, see "Resets" on page 4-74 and "Initial Program Loading" on page 4-81.

The load-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Clear-List-Directed Key

Activating the load-clear-list-directed key causes a reset operation to be performed and list-directed initial program loading to be started using the I/O device designated by the list-directed IPL parameters. Clear reset is performed on the configuration. For details, see "Resets" on page 4-74 and "List-Directed IPL" on page 17-19.

The load-clear-list-directed key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Normal Key

Activating the load-normal key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Initial CPU reset is performed on the CPU for which the load-normal key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see "Resets" on page 4-74 and "Initial Program Loading" on page 4-81.

The load-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-with-Dump Key

Activating the load-with-dump key causes a reset operation to be performed and list-directed initial program loading to be started by using the I/O devices designated by the list-directed IPL parameters. A store-status operation followed by an initial CPU reset is performed on the CPU for which the load-with-dump key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see "Resets" on page 4-74 and "List-Directed IPL" on page 17-19.

The load-with-dump key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Unit-Address Controls

The load-unit-address controls specify four hexadecimal digits that provide the device number used for CCW-type initial program loading. When the alternate-subchannel-set-IPL-device facility is installed the load-unit-address controls may specify an additional hexadecimal digit that provides the subchannel-set ID for CCW-type initial program loading. For details, see "Initial Program Loading" on page 4-81.

Manual Indicator

The manual indicator is on when the CPU is in the stopped state. Some functions and several manual controls are effective only when the CPU is in the stopped state.

Power Controls

The power controls are used to turn the power on and off.

The CPUs, storage, channel subsystem, operator facilities, and I/O devices may all have their power turned on and off by common controls, or they may have separate power controls. When a particular unit has its power turned on, that unit is reset. The sequence is performed so that no instructions or I/O operations are performed until explicitly specified. The controls may also permit power to be turned on in stages, but the machine does not become operational until power on is complete.

When the power is completely turned on, an IML operation is performed on models which have an IML function. A power-on reset is then initiated (see "Resets" on page 4-74). It depends on the model whether the architectural mode of operation can be selected when the power is turned on, or whether the mode-selection controls have to be used to change the mode after the power is on.

Rate Control

A model may provide the rate control, the setting of which determines the effect of the start function and the manner in which instructions are executed.

When the rate control is provided, it has at least two positions. The normal position is the process position. Another position is the instruction-step position. When the rate control is set to the process position and the start function is performed, the CPU starts operating at normal speed. When the rate control is set to the instruction-step position and the wait-state bit is zero, one instruction or, for interruptible instructions, one unit of operation is executed, and all pending allowed interruptions are taken before the CPU returns to the stopped state. When the rate control is set to the instruction-step position and the wait-state bit is one, no instruction is executed, but all pending allowed interruptions are taken before the CPU returns to the stopped state. For details, see “CPU States” on page 4-2.

The test indicator is on while the rate control is not set to the process position.

If the setting of the rate control is changed while the CPU is in the operating or load state, the results are unpredictable.

When the rate control is not provided, the CPU operates as though the rate control was in the process position, and instruction stepping is not available.

Restart Key

Activating the restart key initiates a restart interruption. (See “Restart Interruption” on page 6-56.)

The restart key is effective when the CPU is in the operating or stopped state. The key is not effective when the CPU is in the check-stop state. It depends on the model whether the restart key is effective when any CPU in the configuration is in the load state.

The effect is unpredictable when the restart key is activated while any CPU in the configuration is in the load state. In particular, if the CPU performs a restart interruption and enters the operating state while another CPU is in the load state, operations such as I/O instructions, the SIGNAL PROCESSOR instruction, and the INVALIDATE PAGE TABLE ENTRY instruction may not operate according to the definitions given in this publication

Start Key

Activating the start key causes the CPU to perform the start function. (See “CPU States” on page 4-2.)

The start key is effective only when the CPU is in the stopped state. The effect is unpredictable when the stopped state has been entered by a reset.

Stop Key

Activating the stop key causes the CPU to perform the stop function. (See “CPU States” on page 4-2.)

The stop key is effective only when the CPU is in the operating state.

Operation Note: Activating the stop key has no effect when:

- An unending string of certain program or external interruptions occurs.
- The prefix register contains an invalid address.
- The CPU is in the load or check-stop state.

Store-Status Key

Activating the store-status key initiates a store-status operation. (See “Store Status” on page 4-82.)

The store-status key is effective only when the CPU is in the stopped state.

Operation Note: The store-status operation may be used in conjunction with a standalone dump program for the analysis of major program malfunctions. For such an operation, the following sequence would be called for:

1. Activation of the stop or system-reset-normal key

2. Activation of the store-status key (this step is unnecessary if the standalone dump program is loaded by activating the load-with-dump key)

3. Activation of the load-normal key to enter a stand-alone dump program

The system-reset-normal key must be activated in step 1 when (1) the stop key is not effective because a continuous string of interruptions is occurring, (2) the prefix register contains an invalid address, or (3) the CPU is in the check-stop state.

System-Reset-Clear Key

Activating the system-reset-clear key causes a clear-reset operation to be performed on the configuration. For details, see "Resets" on page 4-74.

The system-reset-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

System-Reset-Normal Key

Activating the system-reset-normal key causes a CPU-reset operation and a subsystem-reset operation to be performed. In a multiprocessing configuration, a CPU reset is propagated to all CPUs in the configuration. For details, see "Resets" on page 4-74.

The system-reset-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Test Indicator

The test indicator is on when a manual control for operation or maintenance is in an abnormal position that can affect the normal operation of a program.

Setting the address-compare controls to the stop position or setting the rate control to the instruction-step position turns on the test indicator.

The test indicator may be on when one or more diagnostic functions under the control of DIAGNOSE are activated, or when other abnormal conditions occur.

The abnormal setting of a manual control causes the test indicator of the affected CPU to be turned on; however, in a multiprocessing configuration, the operation of other CPUs may be affected even though their test indicators are not turned on.

Depending on the model, if address-compare controls have been disabled due to bit position 1 of the PSW being set to one or any or all of control registers 9, 10, and 11 containing nonzero values, the test indicator may remain on even though the address-compare controls have been disabled.

Operation Note: If a manual control is left in a setting intended for maintenance purposes, such an abnormal setting may, among other things, result in false machine-check indications or cause actual machine malfunctions to be ignored. It may also alter other aspects of machine operation, including instruction execution, channel-subsystem operation, and the functioning of operator controls and indicators, to the extent that operation of the machine does not comply with that described in this publication.

TOD-Clock Control

When the TOD-clock control is not activated, that is, the control is set to the secure position, the state and value of the TOD clock are protected against unauthorized or inadvertent change by not permitting the instructions SET CLOCK or DIAGNOSE to change the state or value.

When the TOD-clock control is activated, that is, the control is set to the enable-set position, alteration of the clock state or value by means of SET CLOCK or DIAGNOSE is permitted. This setting is momentary, and the control automatically returns to the secure position.

If there is more than one physical representation of the TOD-clock control, the TOD clock is secure only if all TOD-clock controls in the configuration are set to the secure position.

Wait Indicator

The wait indicator is on when the wait-state bit in the current PSW is one. Instead of a wait indicator, a model may have a means of indicating a time-averaged value of the wait-state bit.

Multiprocessing Configurations

In a multiprocessing configuration, one of each of the following keys and controls is provided for each CPU:

- Alter and display
- Interrupt

- Restart
- Start
- Stop
- Store status.

On some models, a rate control may also be provided.

On some models, the load-clear, load-clear-list-directed, load-normal, load-with-dump, and load-unit-address keys are provided for each primary CPU in the configuration. On other models, a single load-clear, load-clear-list-directed, load-normal, and load-with-dump key are provided for the entire configuration and apply to the lowest-numbered primary online CPU that is not in the check-stop state.

There need not be more than one of each of the following keys and controls in a multiprocessing configuration: address compare, IML, power, system reset clear, system reset normal, and TOD clock.

One check-stop, manual, test, and wait indicator may be provided for each CPU. A load indicator is provided only on a primary CPU. Alternatively, a single set of indicators may be switched to more than one CPU.

There need not be more than one architectural-mode and CPUs-per-core indicator in a multiprocessing configuration.

In a system capable of reconfiguration, there must be a separate set of keys, controls, and indicators in each configuration.

Multithreading Considerations

A CPU address is used to identify the CPU to which CPU-specific operator functions are directed. These CPU-specific operator functions are enumerated in the section “Multiprocessing Configurations”, above. When multithreading is enabled (that is, when the CPUs-per-core indicator is greater than one), the CPU address comprises a core identification and a thread identification, as described in “CPU-Address Identification” on page 4-84.

Some models provide a control to select the primary CPU to be started following a load operation. On such a model, when the multithreading facility is enabled prior to the load operation, the operator designates an expanded-format CPU address as described in “CPU-Address Identification” on page 4-84. However, only the core-identification portion of the designated CPU address is meaningful; the operation is always targeted to the CPU having thread identification zero of the designated core.

On models that do not provide a control to select the primary CPU to be started following a load operation, the operation is targeted to the CPU having thread identification zero in the lowest-numbered operational core.

In either case, the targeted CPU is (a) the one upon which the initial-CPU reset is performed, and (b) the CPU that is started after the load operation is completed

Input/Output (I/O)

The terms “input” and “output” are used to describe the transfer of data between I/O devices and main storage. An operation involving this kind of transfer is referred to as an I/O operation. The facilities used to control I/O operations are collectively called the channel subsystem. (I/O devices and their control units attach to the channel subsystem.) This chapter provides a brief description of the basic components and operation of the channel subsystem.

The Channel Subsystem

The channel subsystem directs the flow of information between I/O devices and main storage. It relieves CPUs of the task of communicating directly with I/O devices and permits data processing to proceed concurrently with I/O processing. The channel subsystem uses one or more channel paths as the communication link in managing the flow of information to or from I/O devices. As part of I/O processing, the channel subsystem also performs a path-management operation by testing for channel-path availability, chooses an available channel path, and initiates the performance of the I/O operation by the device.

Within the channel subsystem are subchannels. One subchannel is provided for and dedicated to each I/O device accessible to the program through the channel subsystem.

The multiple-subchannel-set facility is an optional facility. When it is installed, subchannels are partitioned into multiple subchannel sets, and each subchannel set may provide one dedicated subchannel to an I/O device. Depending on the model and the interface used, some I/O devices may only be allowed to be accessed via certain subchannel sets.

Each subchannel provides information concerning the associated I/O device and its attachment to the channel subsystem. The subchannel also provides information concerning I/O operations and other functions involving the associated I/O device. The subchannel is the means by which the channel subsystem provides information about associated I/O devices to CPUs, which obtain this information by executing I/O instructions. The actual number of subchannels provided depends on the model and the configuration; the maximum addressability is 0-65,535 in each subchannel set.

I/O devices are attached through control units to the channel subsystem by means of channel paths. Control units may be attached to the channel subsystem by more than one channel path, and an I/O device may be attached to more than one control unit. In all, an individual I/O device may be accessible to the channel subsystem by as many as eight different channel paths via a subchannel, depending on the model and the configuration. The total number of channel paths provided by a channel subsystem depends on the model and the configuration; the maximum addressability is 0-255.

The performance of a channel subsystem depends on its use and on the system model in which it is implemented. Channel paths are provided with different data-transfer capabilities, and an I/O device designed to transfer data only at a specific rate (a magnetic-tape unit or a disk storage, for example) can operate only on a channel path that can accommodate at least this data rate.

The channel subsystem contains common facilities for the control of I/O operations. When these facilities are provided in the form of separate, autonomous equipment designed specifically to control I/O devices, I/O operations are completely overlapped with the activity in CPUs. The only main-storage cycles required by the channel subsystem during I/O operations are those needed to transfer data and control information to or from the final locations in main storage, along with those cycles that may be required for the channel subsystem to access the subchannels when they are implemented as part of non-addressable main storage. These cycles do not delay CPU programs, except when both the CPU and the channel subsystem concurrently attempt to reference the same main-storage area.

Subchannel Sets

When the multiple-subchannel-set facility is installed, subchannels are partitioned into multiple subchannel sets. There may be up to four subchannel sets, each identified by a subchannel-set identifier (SSID). When the multiple-subchannel-set facility is not installed, there is only one subchannel set with an SSID of zero. When the multiple-subchannel-set facility is not enabled, only subchannel set zero is visible to the program. See “Multiple-Subchannel-Set Facility” on page 17-33 for more information on the multiple-subchannel-set facility.

Subchannels

A subchannel provides the logical appearance of a device to the program and contains the information required for sustaining a single I/O operation. The subchannel consists of internal storage that contains information in the form of a channel-program designation, channel-path identifier, device number, count, status indications, and I/O-interruption-subclass code, as well as information on path availability and functions pending or being performed. I/O operations are initiated with a device by the execution of I/O instructions that designate the subchannel associated with the device.

Each device is accessible by means of one subchannel in each channel subsystem to which it is assigned during configuration at installation time. The device may be a physically identifiable unit or may be housed internal to a control unit. For example, in certain disk-storage devices, each actuator used in retrieving data is considered to be a device. In all cases, a device, from the point of view of the channel subsystem, is an entity that is uniquely associated with one subchannel and that responds to selection by the channel subsystem by using the communication protocols defined for the type of channel path by which it is accessible.

On some models, subchannels are provided in blocks. On these models, more subchannels may be provided than there are attached devices. Subchannels that are provided but do not have devices assigned to them are not used by the channel subsystem to perform any function and are indicated by storing the associated device-number-valid bit as zero in the subchannel-information block of the subchannel.

The number of subchannels provided by the channel subsystem is independent of the number of channel paths to the associated devices. For example, a device accessible through alternate channel paths still is represented by a single subchannel. Each subchannel is addressed by using the following:

- a 16-bit binary subchannel number
- a two-bit SSID when the subchannel-set facility is installed

After I/O processing at the subchannel has been requested by the execution of START SUBCHANNEL, the CPU is released for other work, and the channel subsystem assembles or disassembles data and synchronizes the transfer of data bytes between the I/O device and main storage. To accomplish this, the channel subsystem maintains and updates an address and a count that describe the destination or source of data in main storage. Similarly, when an I/O device provides signals that should be brought to the attention of the program, the channel subsystem transforms the signals into status information and stores the information in the subchannel, where it can be retrieved by the program.

Attachment of Input/Output Devices

Channel Paths

The channel subsystem communicates with I/O devices by means of channel paths between the channel subsystem and control units. A control unit may be accessible by the channel subsystem by more than one channel path. Similarly, an I/O device may be accessible by the channel subsystem through more than one control unit, each having one or more channel paths to the channel subsystem.

Devices that are attached to the channel subsystem by multiple channel paths configured to a subchannel, may be accessed by the channel subsystem using any of the available channel paths. Similarly, a device having the dynamic-reconnection feature and operating in the multipath mode can be initialized to operate such that the device may choose any of the available channel paths configured to the subchannel, when logically reconnecting to the channel subsystem to continue a chain of I/O operations.

The channel subsystem may contain more than one type of channel path. Examples of channel-path types used by the channel subsystem are the ESCON I/O interface, FICON I/O interface, FICON-converted I/O interface, and IBM System/360 and System/370 I/O interface. The term “serial-I/O interface” is used to refer the ESCON I/O interface, the FICON I/O interface, and the FICON-converted I/O interface. The term “parallel-I/O interface” is used to refer to the IBM System/360 and System/370 I/O interface.

The ESCON I/O interface is described in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

The FICON I/O interface is described in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*

The IBM System/360 and System/370 I/O interface is described in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

Depending on the type of channel path, the facilities provided by the channel path, and the I/O device, an I/O operation may occur in one of three modes, frame-multiplex mode, burst mode, or byte-multiplex mode.

In the frame-multiplex mode, the I/O device may stay logically connected to the channel path for the duration of the execution of a channel program. The facilities of a channel path capable of operating in the frame-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode the information required to complete an I/O operation is divided into frames that may be interleaved with frames from I/O operations for other I/O devices. During this period, multiple I/O devices are considered to be logically connected to the channel path.

In the burst mode, the I/O device monopolizes a channel path and stays logically connected to the channel path for the transfer of a burst of information. No other device can communicate over the channel path during the time a burst is transferred. The burst can consist of a few bytes, a whole block of data, a sequence of blocks with associated control and status information (the block lengths may be zero), or status information that monopolizes the channel path. The facilities of the channel path capable of operating in the burst mode may be shared by a number of concurrently operating I/O devices.

Some channel paths can tolerate an absence of data transfer for about a half minute during a burst-mode operation, such as occurs when a long gap on magnetic tape is read. An equipment malfunction may be indicated when an absence of data transfer exceeds the prescribed limit.

In the byte-multiplex mode, the I/O device stays logically connected to the channel path only for a short interval of time. The facilities of a channel path capable of operating in the byte-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode, all I/O operations are split into short intervals of time during which only a segment of information is transferred over the channel path. During such an interval, only one device and its associated subchannel are logically connected to the channel path. The intervals associated with the concurrent operation of multiple I/O devices are sequenced in response to demands from the devices. The channel-subsystem facility associated with a subchannel exercises its controls for any one operation only for the time required to transfer a segment of information. The segment can consist of a single byte of data, a few bytes of data, a status report from the device, or a control sequence used for the initiation of a new operation.

Ordinarily, devices with high data-transfer-rate requirements operate with the channel path in the frame-multiplex mode, slower devices operate in the burst mode, and the slowest devices operate in the byte-multiplex mode. Some control units have a manual switch for setting the desired mode of operation.

An I/O operation that occurs on a parallel-I/O-interface type of channel path may occur in either the burst mode or the byte-multiplex mode depending on the facilities provided by the channel path and the I/O device. For improved performance, some channel paths and control units are provided with facilities for high-speed transfer and data streaming. See the *System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, for a description of those two facilities.

An I/O operation that occurs on a serial-I/O-interface-type of channel path may occur in either the frame-multiplex mode or the burst mode. For improved performance, some control units attaching to the serial-I/O interface provide the capability to provide sense data to the program concurrent with the presentation of unit-check status, if permitted to do so by the program. (See“Concurrent Sense” on page 17-27.)

Depending on the control unit or channel subsystem, access to a device through a subchannel may be restricted to a single channel-path type.

The modes and features described above affect only the protocol used to transfer information over the channel path and the speed of transmission. No effects are observable by CPU or channel programs with respect to the way these programs are executed.

Control Units

A control unit provides the logical capabilities necessary to operate and control an I/O device and adapts the characteristics of each device so that it can respond to the standard form of control provided by the channel subsystem.

Communication between the control unit and the channel subsystem takes place over a channel path. The control unit accepts control signals from the channel subsystem, controls the timing of data transfer over the channel path, and provides indications concerning the status of the device.

The I/O device attached to the control unit may be designed to perform only certain limited operations, or it may perform many different operations. A typical operation is moving a recording medium and recording data. To accomplish its operations, the device needs detailed signal sequences peculiar to its type of device. The control unit decodes the commands received from the channel subsystem, interprets them for the particular type of device, and provides the signal sequence required for the performance of the operation.

A control unit may be housed separately, or it may be physically and logically integrated with the I/O device, the channel subsystem, or a CPU. In the case of most electromechanical devices, a well-defined interface exists between the device and the control unit because of the difference in the type of equipment the control unit and the device require. These electromechanical devices often are of a type where only one device of a group attached to a control unit is required to transfer data at a time (magnetic-tape units or disk-access mechanisms, for example), and the control unit is shared among a number of I/O devices. On the other hand, in some electronic I/O devices, such as the channel-to-channel adapter, the control unit does not have an identity of its own.

From the programmer's point of view, most functions performed by the control unit can be merged with those performed by the I/O device. Therefore, this publication normally makes no specific mention of the control-unit function; the performance of I/O operations is described as if the I/O devices communicated directly with the channel subsystem. Reference is made to the control unit only when emphasizing a function performed by it or when describing how the sharing of the control unit among a number of devices affects the performance of I/O operations.

I/O Devices

An input/output (I/O) device provides external storage, a means of communication between data-processing systems, or a means of communication between a system and its environment. I/O devices include such equipment as magnetic-tape units, direct-access-storage devices (for example, disks), display units, typewriter-keyboard devices, printers, teleprocessing devices, and sensor-based equipment. An I/O device may be physically distinct equipment, or it may share equipment with other I/O devices.

Most types of I/O devices, such as printers, or tape devices, use external media, and these devices are physically distinguishable and identifiable. Other types are solely electronic and do not directly handle physical recording media. The channel-to-channel adapter, for example, provides for data transfer between two channel paths, and the data never reaches a physical recording medium outside main storage. Similarly, communication controllers may handle the transmission of information between the data-processing system and a remote station, and its input and output are signals on a transmission line.

In the simplest case, an I/O device is attached to one control unit and is accessible from one channel path. Switching equipment is available to make some devices accessible from two or more channel paths by switching devices among control units and by switching control units among channel paths. Such switching equipment provides multiple paths by which an I/O device may be accessed. Multiple channel paths to an I/O device are provided to improve performance or I/O availability, or both, within the system. The management of multiple channel paths to devices is under the control of the channel subsystem and the device, but the channel paths may indirectly be controlled by the program.

I/O Addressing

Four different types of I/O addressing are provided by the channel subsystem for the necessary addressing of the various components: channel-path identifiers, subchannel numbers, device numbers, and, though not visible to programs, addresses dependent on the channel-path type. When the multiple-subchannel-set facility is installed, the subchannel-set identifier (SSID) is also used in I/O addressing.

Subchannel-Set Identifier

The subchannel-set identifier (SSID) is a two-bit value assigned to each provided subchannel set.

Channel-Path Identifier

The channel-path identifier (CHPID) is a system-unique eight-bit value assigned to each installed channel path of the system. A CHPID is used to address a channel path. A CHPID is specified by the second-operand address of RESET CHANNEL PATH and used to designate the channel path that is to be reset. The channel paths by which a device is accessible are identified in the subchannel-information block (SCHIB), each by its associated CHPID, when STORE SUBCHANNEL is executed. The CHPID can also be used in operator messages when it is necessary to identify a particular channel path. A system model may provide as many as 256 channel paths. The maximum number of channel paths and the assignment of CHPIDs to channel paths depends on the system model.

Subchannel Number

A subchannel number is a 16-bit value used to address a subchannel. This value is unique within a subchannel set of a channel subsystem. The subchannel is addressed by eight I/O instructions: CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, START SUBCHANNEL, STORE SUBCHANNEL, and TEST SUBCHANNEL. All I/O functions relative to a specific I/O device are specified by the program by designating a subchannel assigned to the I/O device. Subchannels in each subchannel set are always assigned subchannel numbers within a single range of contiguous numbers. The lowest-numbered subchannel is subchannel 0. The highest-numbered subchannel of the channel subsystem has a subchannel number equal to one less than the number of subchannels provided. A maximum of 65,536 subchannels can be provided in each subchannel set. Normally, subchannel numbers are only used in communication between the CPU program and the channel subsystem.

Device Number

Each subchannel that has an I/O device assigned to it also contains a parameter called the device number. The device number is a 16-bit value that is assigned as one of the parameters of the subchannel at the time the device is assigned to the subchannel. The device number identifies a device to the program and is unique within a subchannel set of a channel subsystem.

The device number provides a means to identify a device, independent of any limitations imposed by the system model, the configuration, or channel-path protocols. The device number is used in communications concerning the device that take place between the system and the system operator. For example, the device number is entered by the system operator to designate the input device to be used for initial program loading.

Programming Note: The device number is assigned at device-installation time and may have any value. However, the user must observe any restrictions on device-number assignment that may be required by the control program, support programs, or the particular control unit or I/O device.

Device Identifier

A device identifier is an address, not apparent to the program, that is used by the channel subsystem to communicate with I/O devices. The type of device identifier used depends on the specific channel-path type and the protocols provided. Each subchannel contains one or more device identifiers.

For a channel path of the parallel-I/O-interface type, the device identifier is called a device address and consists of an eight-bit value. For the ESCON I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address. For the FICON I/O interface, the device identifier consists of an eight-bit control-unit-image ID and an eight-bit device address. For the FICON-converted I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address.

The device address identifies the particular I/O device (and, on the parallel-I/O interface, the control unit) associated with a subchannel. The device address may identify, for example, a particular magnetic-tape drive, disk-access mechanism, or transmission line. Any number in the range 0-255 can be assigned as a device address.

For further information about the device identifier used with a particular channel-path type, see the appropriate publication for the channel-path type.

Fibre-Channel Extensions

The fibre-channel-extensions (FCX) facility is an optional facility that provides for the formation of a channel program that is composed of a transport-control word (TCW) that designates a transport-command-control block (TCCB) and a transport-status block (TSB). The TCCB includes a transport-command area (TCA) which contains a list of up to 30 I/O commands that are in the form of device-command words (DCWs).

The FCX-bidirectional-data-transfer facility is an additional and optional facility that provides support for TCW channel programs that specify both read and write operations. Whether a device recognizes bidirectional data transfers is determined by device-dependent means.

When a device does not recognize bidirectional data transfers, a TCW and its TCCB may specify either read or a write data transfers. When a device recognizes bidirectional data transfers, a TCW and its TCCB may, depending on the device, specify both read and write data transfers. For interruptions, the TSB contains the completion status and other information related to the TCW channel program in addition to the information in the IRB.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as output data. Whether a device supports TCA extensions is determined by device-dependent means.

In addition to the IRB, the TSB contains the completion status and other information related to the TCW channel program.

The FCX facility provides the ability to directly or indirectly designate any or all of the TCCB, the input data storage area, and the output data storage area.

When a storage area is designated directly, the TCW specifies the location of a single, contiguous block of storage. When a storage area is designated indirectly, the TCW designates the location of a list of one or more transport-indirect-data-address words (TIDAWs). TIDAW lists and the storage area designated by each TIDAW in a list are restricted from crossing 4 K-byte boundaries

The FCX facility also provides an interrogate operation that may be initiated by the CANCEL SUBCHANNEL instruction to determine the state of an I/O operation.

I/O-Command Words

An I/O-command word specifies a command and contains information associated with the command. When the FCX facility is installed, there are two elemental forms of I/O command words which are the channel-command word (CCW) and the device-command word (DCW).

A CCW is 8-bytes in length and specifies the command to be executed. For commands that initiate certain operations the CCW also designates the storage area associated with the operation, the count of data bytes, the action to be taken when the command completes, and other options. All I/O devices recognize CCWs.

A DCW is 8-bytes in length and specifies the command to be executed. the count of data bytes, and other options. I/O devices that support FCX recognize DCWs.

Transport Command Word (TCW)

A TCW designates a transport-command-control block (TCCB) which contains a list of commands to be transported to and executed by an I/O device. The TCW also designates the storage areas for the commands in the TCCB as well as a transport-status block (TSB) to contain the status of the I/O operation.

Channel Program Organization

When the FCX facility is not installed, there is a single form of channel program which is the CCW channel program. When the FCX facility is installed, there is an additional form of channel program which is the TCW channel program. Both forms of channel programs are described below.

CCW Channel Program

A channel program that is composed of one or more CCWs is called a CCW channel program (CCP). Such a channel program contains one or more CCWs that are logically linked and arranged for sequential execution by the channel subsystem.

Figure 13-1 shows a conceptual example of a simple CCW channel program in program storage. This channel program contains 4 CCWs and specifies the transfer of data to or from contiguous areas of storage. The first CCW designates a control command and the remaining CCWs designate the transfer of data.

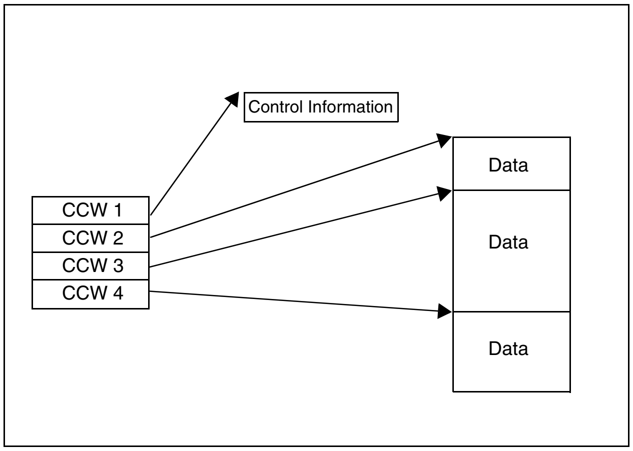

Figure 13-1. CCW Channel Program Example

TCW Channel Program

A channel program that is composed of a single TCW is called a TCW channel program. A TCW designates a transport-command-control block (TCCB) that contains from 1 to 30 DCWs.

When DCWs within the TCCB are logically linked and arranged for sequential execution. For DCWs that specify control information, the TCCB also contains the control information for those commands. The TCW also designates the storage area or areas for the DCWs that specify the transfer of data from or to the device and the location of a transport-status block (TSB) for completion status. The TCCB and the storage areas for the transfer of data may be specified as either contiguous or noncontiguous storage.

Figure 13-2 shows a conceptual example of a TCW channel programin program storage. This channel program is similar to the CCW channel program in Figure 13-1. This channel program is composed of a TCW that designates a TCCB containing 4 DCWs, all of which specify the transfer of data either to or from contiguous areas of storage. The first DCW designates a control command and the remaining DCWs designate the transfer of data. The TCW also designates a TSB for completion status.

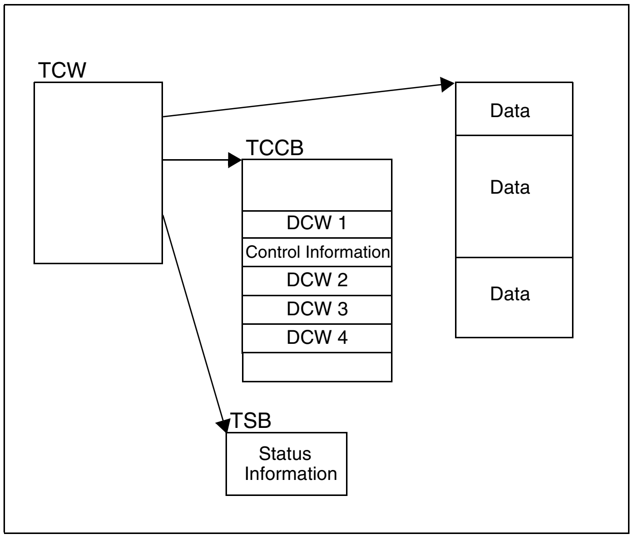

Figure 13-2. Example of TCW Channel Program Example Designating I/O

Execution of I/O Operations

I/O operations are initiated and controlled by information with four types of formats: the instruction START SUBCHANNEL, transport-command words, I/O-command words, and orders. The START SUBCHANNEL instruction is executed by a CPU and is part of the CPU program that supervises the flow of requests for I/O operations from other programs that manage or process the I/O data.

When START SUBCHANNEL is executed, parameters are passed to the target subchannel requesting that the channel subsystem perform a start function with the I/O device associated with the subchannel. The channel subsystem performs the start function by using information at the subchannel, including the information passed during the execution of the START SUBCHANNEL instruction, to find an accessible channel path to the device. Once the device has been selected, the execution of an I/O operation is accomplished by the decoding and execution of a CCW by the channel subsystem and the I/O device, for CCW channel programs, or for TCW channel programs, by transporting the TCCB to the I/O device by the channel subsystem and the decoding and execution of a DCW by the device. I/O-command words, and transport-command words.are fetched from main storage, although the modifier bits in the command code of a CCW DCW may specify device-dependent conditions for the execution of an operation at the device.

Operations peculiar to a device, such as rewinding tape or positioning the access mechanism on a disk drive, are specified by orders that are decoded and executed by I/O devices. Orders may be transferred to the device as modifier bits in the command code of a control command, may be transferred to the device as data during a control or write operation, or may be made available to the device by other means.

Start-Function Initiation

CPU programs initiate I/O operations with the instruction START SUBCHANNEL. This instruction passes the contents of an operation-request block (ORB) to the subchannel.

If the ORB specifies a CCW channel program, the contents of the ORB include the subchannel key, the address of the first CCW to be executed, and a specification of the format of the CCWs. The CCW specifies the command to be executed and the storage area, if any, to be used. If the ORB specifies a TCW channel program, the contents of the ORB include the subchannel key and the address of the TCW to be executed. The TCW designates the TCCB which contains the commands to be transported to the device for execution,the storage area or areas, if any, to be used for data transfer, and the TSB to contain the status of the I/O operation.

When the ORB contents have been passed to the subchannel, the execution of START SUBCHANNEL is complete. The results of the execution of the instruction are indicated by the condition code set in the program-status word.

When facilities become available and the ORB specifies a CCW channel program, the channel subsystem fetches the first CCW and decodes it according to the format bit specified in the ORB. If the format bit is zero, format-0 CCWs are specified. If the format bit is one, format-1 CCWs are specified. Format-0 and format-1 CCWs contain the same information, but the fields are arranged differently in the format-1 CCW so that 31-bit addresses can be specified directly in the CCW. When facilities become available and the ORB specifies a TCW channel program, the channel subsystem fetches the designated TCW and transports the designated TCCB to the device. Storage areas designated by the TCW for the transfer of data to or from the device are 64-bit addresses.

Subchannel Operation Modes

There are two modes of subchannel operation. A subchannel enters transport mode when the FCX facility is installed and the start function is set at the subchannel as the result of the execution of a START SUBCHANNEL instruction that specifies a TCW channel program. The subchannel remains in transport mode until the start function is reset at the subchannel. At all other times, the subchannel is in command mode.

Path Management

If ORB specifies a CCW channel program and the first CCW passes certain validity tests and does not have the suspend flag specified as one or if the ORB specifies a TCW channel program and the designated TCW passes certain validity tests, the channel subsystem attempts device selection by choosing a channel path from the group of channel paths that are available for selection. A control unit that recognizes the device identifier connects itself logically to the channel path and responds to its selection.

If the ORB specifies a CCW channel program, the channel subsystem sends the command-code part of the CCW over the channel path, and the device responds with a status byte indicating whether the command can be executed. The control unit may logically disconnect from the channel path at this time, or it may remain connected to initiate data transfer.

If the ORB specifies a TCW channel program, the channel subsystem uses information in the designated TCW to transfer the TCCB to the control unit. The contents of the TCCB are ignored by the channel subsystem and only have meaning to the control unit and I/O device.

If the attempted selection does not occur as a result of either a busy indication or a path-not-operational condition, the channel subsystem attempts to select the device by an alternate channel path if one is available. When selection has been attempted on all paths available for selection and the busy condition persists, the operation remains pending until a path becomes free. If a path-not-operational condition is detected on one or more of the channel paths on which device selection was attempted, the program is alerted by a subsequent I/O interruption. The I/O interruption occurs either upon execution of the channel program (assuming the device was selected on an alternate channel path) or as a result of the execution being abandoned because path-not-operational conditions were detected on all of the channel paths on which device selection was attempted.

Channel-Program Execution

If the command is initiated at the device and command execution does not require any data to be transferred to or from the device, the device may signal the end of the operation immediately on receipt of the command code. In operations that involve the transfer of data, the subchannel is set up so that the channel subsystem will respond to service requests from the device and assume further control of the operation.

An I/O operation may involve the transfer of data to or from one storage area, designated by a single CCW or TCW or to or from a number of noncontiguous storage areas. In the latter case, generally a list of CCWs is used for the execution of the I/O operation, with each CCW designating a contiguous storage area and the CCWs are coupled by data chaining. Data chaining is specified by a flag in the CCW and causes the channel subsystem to fetch another CCW upon the exhaustion or filling of the storage area designated by the current CCW. The storage area designated by a CCW fetched on data chaining pertains to the I/O operation already in progress at the I/O device, and the I/O device is not notified when a new CCW is fetched.

Provision is made in the CCW format for the programmer to specify that, when the CCW is decoded, the channel subsystem request an I/O interruption as soon as possible, thereby notifying a CPU program that chaining has progressed at least as far as that CCW in the channel program.

To complement dynamic address translation in CPUs, CCW indirect data addressing and modified CCW indirect data addressing are provided.

When the ORB specifies a CCW channel program and CCW-indirect-data addressing is used, a flag in the CCW specifies that an indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the boundary of a block of storage is reached, the list is referenced to determine the next block of storage to be used. The ORB specifies whether the size of each block of storage is 2K bytes or 4K bytes.

When the ORB specifies a CCW channel program and modified-CCW-indirect-data addressing is used, a flag in the ORB and a flag in the CCW specify that a modified-indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the count of bytes specified for a block of storage is reached, the list is referenced to determine the next block of storage to be used. Unlike when indirect data addressing is used, the block may be specified on any boundary and length up to 4K, provided a data transfer across a 4 K-byte boundary is not specified.

When the ORB specifies a TCW channel programand transport-indirect-data addressing is used, flags in the TCW specify whether a transport-indirect-data-address list is to be used to designate the storage areas containing the TCCB and whether a transport-indirect-data-address list is used to designate the data storage areas associated with the DCWs in the TCCB. Each time the count of bytes specified for a block of storage is reached, the corresponding transport-indirect-data-address list is referenced to determine the next storage block to be used.

CCW indirect data addressing and modified CCW indirect data addressing permit essentially the same CCW sequences to be used for a program running with dynamic address translation active in the CPU as would be used if the CPU were operating with equivalent contiguous real storage. CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to 2^{64}-1independent of whether format-0 or format-1 CCWs have been specified in the ORB. Modified CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to 2^{64}-1, independent of whether format-0 or format-1 CCWs have been specified in the ORB.

In general, the execution of an I/O operation or chain of operations involves as many as three levels of participation:

1. Except for effects due to the integration of CPU and channel-subsystem equipment, a CPU is busy for the duration of the execution of START SUBCHANNEL, which lasts until the addressed subchannel has been passed the ORB contents.

2. The subchannel is busy for a new START SUBCHANNEL from the receipt of the ORB contents until the primary interruption condition is cleared at the subchannel.

3. The I/O device is busy from the initiation of the first operation at the device until either the subchannel becomes suspended or the secondary interruption condition is placed at the subchannel. In the case of a suspended subchannel, the device again becomes busy when the execution of the suspended channel program is resumed.

Conclusion of I/O Operations

The conclusion of an I/O operation normally is indicated by two status conditions: channel end and device end. The channel-end condition indicates that the I/O device has received or provided all data associated with the operation and no longer needs channel-subsystem facilities. This condition is called the primary interruption condition, and the channel end in this case is the primary status. Generally, the primary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the subchannel of the I/O operation or chain of I/O operations.

The device-end signal indicates that the I/O device has concluded execution and is ready to perform another operation. This condition is called the secondary interruption condition, and the device end in this case is the secondary status. Generally, the secondary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the device of the I/O operation or chain of operations. The secondary interruption condition can occur concurrently with, or later than, the primary interruption condition.

Concurrent with the primary or secondary interruption conditions, both the channel subsystem and the I/O device can provide indications of unusual situations.

The conditions signaling the conclusion of an I/O operation can be brought to the attention of the program by I/O interruptions or, when the CPUs are disabled for I/O interruptions, by programmed interrogation of the channel subsystem. In the former case, these conditions cause storing of the I/O-interruption code, which contains information concerning the interrupting source. In the latter case, the interruption code is stored as a result of the execution of TEST PENDING INTERRUPTION.

When the primary interruption condition is recognized, the channel subsystem attempts to notify the program, by means of an interruption request, that a subchannel contains information describing the conclusion of an I/O operation at the subchannel. For command-mode interruptions, the information identifies the last CCW used and may provide its residual byte count, thus describing the extent of main storage used. For transport-mode interruptions, the information identifies the current TCW and the TSB associated with the channel program that contains additional status about the I/O operation, such as residual byte count. In addition to information about the channel program, both the channel subsystem and the I/O device may provide additional indications of unusual conditions as part of either the primary or the secondary interruption condition. The information contained at the subchannel may be stored by the execution of TEST SUBCHANNEL or the execution of STORE SUBCHANNEL. This information, when stored, is called a subchannel-status word (SCSW).

Chaining When Using a CCW Channel Program

When the ORB specifies a CCW channel program, facilities are provided for the program to initiate the execution of a chain of I/O operations with a single START SUBCHANNEL instruction. When the current CCW specifies command chaining and no unusual conditions have been detected during the operation, the receipt of the device-end signal causes the channel subsystem to fetch a new CCW. If the CCW passes certain validity tests and the suspend flag is not specified as a one in the new CCW, execution of a new command is initiated at the device. If the CCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, and the status associated with the new CCW causes an interruption condition to be generated. If the suspend flag is specified as a one and this value is valid because of a one value in the suspend control, bit 4 of word 1 of the associated ORB, execution of the new command is not initiated, and command chaining is concluded.

Execution of the new command is initiated by the channel subsystem in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a CCW specifying command chaining are not made available to the program. When another I/O operation is initiated by command chaining, the channel subsystem continues execution of the channel program. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and the ending signals causing the termination are made available to the program.

The suspend-and-resume function provides the program with control over the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend-control bit in the ORB. The suspend function is signaled to the channel subsystem during channel-program execution when the suspend-control bit in the ORB is one and the suspend flag in the first CCW or in a CCW fetched during command chaining is one.

Suspension occurs when the channel subsystem fetches a CCW with the suspend flag validly (because of a one value of the suspend-control bit in the ORB) specified as one. The command in this CCW is not sent to the I/O device, and the device is signaled that the chain of commands is concluded. A subsequent RESUME SUBCHANNEL instruction informs the channel subsystem that the CCW that caused suspension may have been modified and that the channel subsystem must refetch the CCW and examine the current setting of the suspend flag. If the suspend flag is found to be zero in the CCW, the channel subsystem resumes execution of the chain of commands with the I/O device.

Chaining When Using a TCW Channel Program

When the ORB specifies a TCW channel program, facilities are also provided for the program to initiate the execution of a chain of device operations with a single START SUBCHANNEL instruction. Command chaining may be specified for those DCWs designated by a single TCW. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, recognition of the successful execution of the DCW causes the next DCW in the current TCCB to be processed.

If the next DCW passes certain validity tests, execution of a new command is initiated at the device and the DCW becomes the current DCW. If the DCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, the channel program is terminated, and the status associated with the new DCW causes an interruption condition to be generated.

Execution of the new command is initiated in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a DCW that is not the last specified DCW are not made available to the program. When another I/O operation is initiated by command chaining, execution of the channel program continues. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and status is made available to the program that identifies the unusual condition.

Premature Conclusion of I/O Operations

Channel-program execution may be terminated prematurely by CANCEL SUBCHANNEL, HALT SUBCHANNEL or CLEAR SUBCHANNEL. The execution of CANCEL SUBCHANNEL causes the channel subsystem to terminate the start function at the subchannel if the channel program has not been initiated at the device. When the start function is terminated by the execution of CANCEL SUBCHANNEL, the channel subsystem sets condition code 0 in response to the CANCEL SUBCHANNEL instruction. The execution of HALT SUBCHANNEL causes the channel subsystem to issue the halt signal to the I/O device and terminate channel-program execution at the subchannel. When channel-program execution is terminated by the execution of HALT SUBCHANNEL, the program is notified of the termination by means of an I/O-interruption request. When the subchannel is in command mode, the interruption request is generated when the device presents status for the terminated operation. When the subchannel is in transport mode, the interruption request is generated immediately.If, however, the halt signal was issued to the device during command chaining after the receipt of device end but before the next command was transferred to the device, the interruption request is generated after the device has been signaled. In the latter case, the device-status field of the SCSW will contain zeros. The execution of CLEAR SUBCHANNEL clears the subchannel of indications of the channel program in execution, causes the channel subsystem to issue the clear signal to the I/O device, and causes the channel subsystem to generate an I/O-interruption request to notify the program of the completion of the clear function.

I/O Interruptions

Conditions causing I/O-interruption requests are asynchronous to activity in CPUs, and more than one condition can occur at the same time. For I/O interruptions associated with subchannels, the conditions are preserved at the subchannels until cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL, or reset by an I/O-system reset.

When an I/O-interruption condition has been recognized by the channel subsystem and indicated at the subchannel, an I/O-interruption request is made pending for the I/O-interruption subclass specified at the subchannel. The I/O-interruption subclass for which the interruption is made pending is under programmed control through the use of MODIFY SUBCHANNEL. A pending I/O interruption may be accepted by any CPU that is enabled for interruptions from its I/O-interruption subclass. Each CPU has eight mask bits, in control register 6, that control the enablement of that CPU for each of the eight I/O-interruption subclasses, with the I/O mask, bit 6 in the PSW, being the master I/O-interruption mask for the CPU.

When an I/O interruption occurs at a CPU, the I/O-interruption code is stored in real locations 184-195, and the I/O-interruption request is cleared. For I/O interruptions associated with subchannels, the I/O-interruption code identifies the subchannel for which the interruption was pending. The conditions causing the generation of the interruption request associated with the subchannel may then be retrieved from the subchannel explicitly by TEST SUBCHANNEL or by STORE SUBCHANNEL.

A pending I/O-interruption request may also be cleared by TEST PENDING INTERRUPTION when the corresponding I/O-interruption subclass is enabled but the PSW has I/O interruptions disabled. For I/O interruptions associated with subchannels, a pending I/O interruption may also be cleared by TEST SUBCHANNEL when the CPU is disabled for I/O interruptions from the corresponding I/O-interruption subclass. A pending I/O-interruption request associated with a subchannel may also be cleared by CLEAR SUBCHANNEL. Both CLEAR SUBCHAN-

NEL and TEST SUBCHANNEL clear the preserved interruption condition at the subchannel as well.

Normally, unless the interruption request is cleared by CLEAR SUBCHANNEL, the program issues TEST SUBCHANNEL to obtain subchannel information concerning the execution of the operation.

Chapter 14. I/O Instructions

I/O-Interruption Code 14-20
TEST SUBCHANNEL 14-21

All the I/O instructions described here are provided for the control of channel-subsystem operations. The I/O instructions are listed in Figure 14-1 on page 14-3. All of the I/O instructions are privileged instructions.

Several I/O instructions result in the channel subsystem being signaled to perform functions asynchronous to the execution of the instructions. The description of each instruction of this type contains a section, “Associated Functions,” that summarizes the asynchronous functions.

I/O-Instruction Formats

I/O instructions use the S format:

Op Code	B_2	D_2
0	16	20 31

The use of the second-operand address and general registers 1 and 2 (as implied operands) depends on the I/O instruction. Figure 14-1 on page 14-3 defines which operands are used to execute each I/O instruction. In addition, detailed information regarding operand usage appears in the description of each I/O instruction.

All I/O instructions that reference a subchannel use the contents of general register 1 as an implied operand. For these I/O instructions, general register 1 contains the subsystem-identification word (SID).

When the multiple-subchannel set (MSS) facility is installed, the format of the subsystem-identification word is as follows:

/ /
0 31

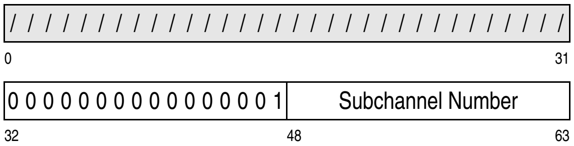
0 0 0 0 0 0 0 0 0 0 0 0 0	SSID	1	Subchannel Number
32	45	47	48 63

Bit positions 0-31 are ignored. Bit positions 32-44must contain zeros and bit 47 must contain 1. (Exception conditions are listed later in the section.)

Bit positions 45-46 of general register 1 contain the subchannel-set identifier (SSID) uniquely identifying a subchannel set (SS). When the multiple-subchannel-set facility is not installed, the SSID must be equal to zero. Bit positions 48-63 of general register 1 contain the binary number of the subchannel within the specified subchannel set to be used for the function specified by the instruction.

(See “Multiple-Subchannel-Set Facility” on page 17-33 for more information on SSID.)

The format of the subsystem-identification word when the MSS facility is not installed is as follows:



Bit positions 48-63 of general register 1 contain the binary number of the subchannel to be used for the function specified by the instruction. Bit positions 0-31 of general register 1 are ignored and bits 32-47 specify the binary number one.

I/O-Instruction Execution

Serialization

The execution of any I/O instruction causes a serialization and checkpoint synchronization function to occur. For a definition of the serialization of CPU operations,see “CPU Serialization” on page 5-130 and “Channel-Program Serialization” on page 5-133.

Operand Access

During the execution of an I/O instruction, the order in which fields of the operand and fields of the subchannel, if applicable, are accessed is unpredictable. It is also unpredictable whether fetch accesses are made to fields of an operand or the subchannel, as applicable, when those fields are not needed to complete the execution of the I/O instruction. (See “Relation between Operand Accesses” on page 5-129.)

Condition Code

During the execution of some I/O instructions, the results of certain tests are used to set one of four condition codes in the PSW. The I/O instructions for which execution can result in the setting of the condition code are listed in Figure 14-1 on page 14-3. The condition code indicates the result of the execution of the I/O instruction. The general meaning of the condition code for I/O instructions is given below; the meaning of the condition code for a specific instruction appears in the description of that instruction.

Condition Code 0: Instruction execution produced the expected or most probable result. (See “Deferred Condition Code (CC)” on page 16-9 for a description of conditions that can be encountered subsequent to the presentation of condition code 0 that result in a nonzero deferred condition code.)

Condition Code 1: Instruction execution produced the alternate or second-most-probable result, or status conditions were present that may or may not have prevented the expected result.

Condition Code 2: Instruction execution was ineffective because the designated subchannel or channel-subsystem facility was busy with a previously initiated function.

Condition Code 3: Instruction execution was ineffective because the designated element was not operational or because some condition precluded initiation of the normal function.

In situations where conditions exist that could cause more than one nonzero condition code to be set, the priority of the condition codes is as follows:

Condition code 3 has precedence over condition codes 1 and 2.

Condition code 1 has precedence over condition code 2.

Program Exceptions

The program exceptions that the I/O instructions can encounter are access, operand, privileged-operation, and specification exceptions. Figure 14-1 on page 14-3 shows the exceptions that are applicable to each of the I/O instructions. The execution of the instruction is suppressed for privileged-operation, operand, and specification exceptions. Except as indicated otherwise in the section “Special Conditions” for each instruction, the instruction ending for access exceptions is as described in “Recognition of Access Exceptions” on page 6-47).

Instructions

The mnemonics, format, and operation codes of the I/O instructions are given in Figure 14-1 on page 14-3. The figure also indicates the conditions that can cause a program interruption and whether the condition code is set.

In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For START SUBCHANNEL, for example, SSCH is the mnemonic and $D_2(B_2)$ the operand designation.

Name	Mnemonic	Characteristics											Op-code	Page
CANCEL SUBCHANNEL	XSCH	S	C	P			OP	¢	GS				B276	14-3
CLEAR SUBCHANNEL	CSCH	S	C	P			OP	¢	GS				B230	14-5

TEST SUBCHANNEL	TSCH	S	C	P	A	SP	OP	¢	GS		ST	B_2	B235	14-21

Explanation:

*	PER zero-address-detection not recognized
¢	Causes a serialization and checkpoint synchronization function.
A	Access exceptions for logical addresses.
A^1	When the effective address is zero, it is not used to access storage, and no access exceptions can occur, except that access exceptions may occur during access-register translation.
B_2	B_2 field designates an access register in the access-register mode.
C	Condition code is set.
G1	Instruction execution includes implied use of general register 1 as a parameter.
GM	Instruction execution includes the implied use of multiple general registers: • General registers 0 and 1 for SET CHANNEL MONITOR.
GS	Instruction execution includes the implied use of general register 1 as the subsystem-identification word.
OP	Operand exception.
P	Privileged-operation exception; also, restricted from transactional execution.
S	S instruction format.
SP	Specification exception.
ST	PER storage-alteration event.

Figure 14-1. Summary of I/O Instructions

CANCEL SUBCHANNEL

XSCH [S]

'B276'	////////////////
0	16 31

The current start function, if any, is terminated at the designated subchannel if CANCEL SUBCHANNEL is applicable.

General register 1 contains a subsystem-identification word that designates the subchannel for which the current START FUNCTION, if any, is to be terminated.

If the subchannel (1) is not subchannel active, (2) is start pending, resume pending, or suspended, and (3) is performing only the start function, then the start function at the subchannel is terminated, and the subchannel is made no longer start pending, resume pending, or suspended, as appropriate. In addition, internal indications of busy are reset for the subchannel.

Condition code 0 is set to indicate that the actions described above have been taken.

If an invalid ORB field or a no-path-available condition is present for a previously initiated start function and the condition was not reported during the execution of START SUBCHANNEL, condition code 0 may be indicated for CANCEL SUBCHANNEL provided that the subchannel is not yet status pending to report the error condition; if condition code 0 is presented, no subsequent status is generated to indicate the error condition.

During the execution of CANCEL SUBCHANNEL for a transport-mode operation, the channel subsystem may be signaled to asynchronously perform the interrogate function.

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending with any status.

Condition code 2 is set, and no other action is taken, when CANCEL SUBCHANNEL is not applicable and the subchannel is not status pending, or when conditions exist that prevent immediate determination of internal conditions for the subchannel and the CPU has determined to end the instruction. CANCEL SUBCHANNEL is not applicable when the subchannel (1) has no function specified, (2) has a function other than the start function alone specified, (3) is not resume pending, is not start pending, and is not suspended, or (4) is subchannel active.

When the subchannel is operating in transport mode and condition code 2 is set, the CPU may signal the channel subsystem to asynchronously perform the interrogate function, and end the instruction.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for CANCEL SUBCHANNEL. A subchannel is not operational for CANCEL SUBCHANNEL when the subchannel is not provided by the channel subsystem, has no valid device number assigned to it, or is not enabled.

CANCEL SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0 Start function canceled
1 Status pending
2 CANCEL SUBCHANNEL not applicable
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. The actions taken by CANCEL SUBCHANNEL are completed during the execution of the instruction.

   If condition code 0 is presented, there is no subsequent I/O interruption resulting from the terminated I/O operation. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device.

   Condition code 2 may be presented to indicate that the CPU has determined to end the instruction because the internal conditions of the specified subchannel cannot be immediately determined. Subsequent execution of STORE SUBCHANNEL may store an SCSW indicating that CANCEL SUBCHANNEL is applicable (i.e., the subchannel is performing the start function alone, is start pending, resume pending, or suspended, and is not subchannel-active). In such a case, the program can either recognize that the I/O operation has not been terminated and allow the operation to start or the program can retry CANCEL SUBCHANNEL in an attempt to terminate the start function. However, retrying CANCEL SUBCHANNEL does not guarantee that the instruction will end with condition code 0.

   In transport mode, condition code 2 may be presented to indicate that the CPU has determined to asynchronously signal the channel subsystem to perform the interrogate function, and end the instruction. The LPUM must contain a nonzero value for the interrogate to be initiated.

2. Upon the completion of CANCEL SUBCHANNEL with condition code 0, the subchannel is ready to accept a new start function initiated by START SUBCHANNEL.

CLEAR SUBCHANNEL

CSCH [S]

'B230'	////////////////
0	16 31

The designated subchannel is cleared, the current start or halt function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the clear function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel to be cleared.

If a start or halt function is in progress, it is terminated at the subchannel.

The subchannel is made no longer status pending. All activity, as indicated in the activity-control field of the SCSW, is cleared at the subchannel, except that the subchannel is made clear pending. Any functions in progress, as indicated in the function-control field of the SCSW, are cleared at the subchannel, except for the clear function that is to be performed because of the execution of this instruction.

The channel subsystem is signaled to asynchronously perform the clear function. The clear function is summarized below in the section “Associated Functions” and is described in detail in “Clear Function” on page 15-14.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem asynchronously performs the clear function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the clear signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending. Conditions encountered by the channel subsystem that preclude issuing the clear signal to the device do not prevent the subchannel from becoming status pending (see “Clear Function” on page 15-14).

When the subchannel becomes status pending as a result of performing the clear function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the clear-function bit stored as one. If the channel subsystem can determine that the clear signal was issued to the device, the clear-pending bit is stored as zero in the SCSW. Otherwise, the clear-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 16-6.)

Measurement data is not accumulated, and device-connect time is not stored in the extended-status word for the subchannel, for a start function that is terminated by CLEAR SUBCHANNEL.

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for CLEAR SUBCHANNEL. A subchannel is not operational for CLEAR SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

CLEAR SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

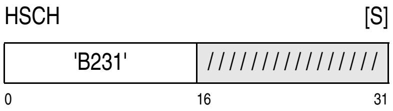
Resulting Condition Code:

0 Function initiated
1 —
2 —
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

HALT SUBCHANNEL



The current start function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the halt function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word that designates the subchannel to be halted.

If a start function is in progress, it is terminated at the subchannel.

The subchannel is made halt pending, and the halt function is indicated at the subchannel.

When HALT SUBCHANNEL is executed and the designated subchannel is subchannel-and-device active and status pending with intermediate status, the status-pending indication is eliminated (see the discussion of bits 24, 25, and 28 in “Activity Control (AC)” on page 16-14). The status-pending condition is reestablished as part of the halt function (see the section “Associated Functions” below).

The channel subsystem is signaled to asynchronously perform the halt function. The halt function is summarized below in the section “Associated Functions” and is described in detail in “Halt Function” on page 15-16.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem asynchronously performs the halt function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the halt signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending.

When the subchannel becomes status pending as a result of performing the halt function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the halt-function bit stored as one. If the halt signal was issued to the device, the halt-pending bit is stored as zero. Otherwise, the halt-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 16-6. and “Halt Function” on page 15-16.)

On some models, path availability is tested as part of the halt function instead of as part of the execution of the instruction. In these models, when no channel path is available for selection, the halt signal is not issued, and the subchannel is made status pending. When the status-pending condition is subsequently cleared by TEST SUBCHANNEL, the halt-pending bit is stored as one in the SCSW.

If a status-pending condition is eliminated during the execution of HALT SUBCHANNEL, then this condition is reestablished along with the other status conditions when the completion of the halt function is indicated to the program.

The halt-pending condition may not be recognized by the channel subsystem if a status-pending condition has been generated. This situation could occur, for example, when alert status is presented or generated while the subchannel is already start pending or resume pending, or when primary status is presented during the attempt to initiate the I/O operation for the first command as specified by the start function or implied by the resume function. If recognition of the status-pending condition by the channel subsystem has occurred logically prior to recognition of the halt-pending condition, the SCSW, when cleared by TEST SUBCHANNEL, has the halt-pending bit stored as one.

If measurement data is being accumulated when a start function is terminated by HALT SUBCHANNEL, the measurement data continues to be accumulated for the subchannel and reflects the extent of subchannel and device usage required, if any, while performing the currently terminated start function. The measurement data, if any, is accumulated in the measurement block for the subchannel or placed in the extended-status word, as appropriate, when the subchannel becomes status-pending with primary or secondary status. (See “Channel-Subsystem Monitoring” on page 17-1.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending alone or is status pending with any combination of alert, primary, or secondary status.

Condition code 2 is set, and no other action is taken, when the subchannel is busy for HALT SUBCHANNEL. The subchannel is busy for HALT SUBCHANNEL when a halt function or clear function is already in progress at the subchannel.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for HALT SUBCHANNEL. A subchannel is not operational for HALT SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled. On some models, a subchannel is also not operational for HALT SUBCHANNEL when no channel path is available for selection by the device. (See “Channel-Path Availability” on page 15-13 for a description of channel paths that are available for selection.)

HALT SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0 Function initiated
1 Status pending with other than intermediate status
2 Busy
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Note: After the execution of HALT SUBCHANNEL, the status-pending condition indicating the completion of the halt function may be delayed for an extended period of time, for example, when the device is a magnetic-tape unit executing a rewind command.

MODIFY SUBCHANNEL

MSCH $D_2(B_2)$ [S]

'B232'	B_2	D_2
0	16	20 31

The information contained in the subchannel-information block (SCHIB) is placed in the program-modifiable fields at the subchannel. As a result, the program influences, for that subchannel, certain aspects of I/O processing relative to the clear, halt, resume, and start functions and certain I/O support functions.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel that is to be modified as specified by certain fields of the SCHIB. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The channel-subsystem operations that may be influenced due to placement of SCHIB information in the subchannel are:

- I/O processing (E field)
- Interruption processing (interruption parameter and ISC field)
- Path management (D, LPM, and POM fields)

- Monitoring and address-limit checking (measurement-block index, LM, and MM fields)
- Measurement-block-format control (F field)
- Extended-measurement-word-mode enable (X field)
- Concurrent-sense facility (S field)
- Measurement-block address (MBA)

Bits 0, 1, 6, and 7 of word 1, and bits 0-28 of word 6 of the SCHIB operand must be zeros, and bits 9 and 10 of word 1 must not both be ones. When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized. The remaining fields of the SCHIB are ignored and do not affect the processing of MODIFY SUBCHANNEL. (For further details, see “Subchannel-Information Block” on page 15-2.)

Condition code 0 is set to indicate that the information from the SCHIB has been placed in the program-modifiable fields at the subchannel, except that, when the device-number-valid bit (V) at the designated subchannel is zero, then condition code 0 is set, and the information from the SCHIB is not placed in the program-modifiable fields.

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending. (See “Status Control (SC)” on page 16-17.)

Condition code 2 is set, and no other action is taken, when a clear, halt, or start function is in progress at the subchannel. (See “Function Control (FC)” on page 16-13.)

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for MODIFY SUBCHANNEL. A subchannel is not operational for MODIFY SUBCHANNEL when the subchannel is not provided in the channel subsystem.

MODIFY SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the SCHIB, bits 0, 1, 6, and 7 must be zeros and, when the address-limit-checking facility is installed, bits 9 and 10 must not both be ones. In word 6 of the SCHIB, bits 0-28 must be zeros. Otherwise an operand exception is recognized.

When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros; otherwise, an operand exception is recognized. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of MODIFY SUBCHANNEL is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Function completed
1 Status pending
2 Busy
3 Not operational

Program Exceptions:

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. If a device signals I/O-error alert while the associated subchannel is disabled, the channel subsystem issues the clear signal to the device and discards the I/O-error-alert indication without generating an I/O-interruption condition.

2. If a device presents unsolicited status while the associated subchannel is disabled, that status is discarded by the channel subsystem without generating an I/O-interruption condition. However, if the status presented contains unit check, the channel subsystem issues the clear signal for the associated subchannel and does not generate an I/O-interruption condition. This should be taken into account when the program uses MODIFY SUBCHANNEL to enable a subchannel. For example, the medium on the associated device that was present when the subchannel became disabled may have been replaced, and, therefore, the program should verify the integrity of that medium.

3. It is recommended that the program inspect the contents of the subchannel by subsequently issuing STORE SUBCHANNEL when MODIFY SUBCHANNEL sets condition code 0. Use of STORE SUBCHANNEL is a method for determining if the designated subchannel was changed or not. Failure to inspect the subchannel following the setting of condition code 0 by MODIFY SUBCHANNEL may result in conditions that the program does not expect to occur.

RESET CHANNEL PATH

RCHP [S]

'B23B'	////////////////
0	16 31

The channel-path-reset facility is signaled to perform the channel-path-reset function on the channel path designated by the contents of general register 1.

The format of general register 1 is as follows:

/////////////////////////////////
0   31

000000000000000000000000	CHPID
32	56 63

Channel-Path Identifier (CHPID): Bit positions 56-63 of general register 1 contain an unsigned binary integer that designates the channel path on which the channel-path-reset function is to be performed.

Bit positions in general register 1 that are shown as zeros, are reserved and must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

If conditions allow, the channel-path-reset facility is signaled to asynchronously perform the channel-path-reset function on the designated channel path. The channel-path-reset function is summarized below in the section “Associated Functions” and is described in detail in “Channel-Path Reset” on page 17-13.

Condition code 0 is set to indicate that the channel-path-reset facility has been signaled.

Associated Functions

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset facility asynchronously performs the channel-path-reset function. Certain indications are reset at all subchannels that have access to the designated channel path, and the reset signal is issued on that channel path. Any I/O functions in progress at the devices are reset, but only for the channel path on which the reset signal is received. An I/O operation or chain of I/O operations taking place in the multipath mode may be able to continue to be executed on other channel paths in the multipath group, if any. (See “Channel-Path-Reset Function” on page 15-80.)

The result of performing the channel-path-reset function on the designated channel path is communicated to the program by means of a channel report (see “Channel Report” on page 17-28).

Special Conditions

Condition code 2 is set, and no other action is taken, when, on some models, the channel-path-reset facility is busy performing the channel-path-reset function for a previous execution of the RESET CHANNEL PATH instruction.

Condition code 3 is set, and no other action is taken, when, on some models, the designated channel path is not operational for the execution of RESET CHANNEL PATH. On these models, the channel path is not operational for the execution of RESET CHANNEL PATH when the designated channel path is not physically available.

If the channel-path-reset facility is busy and the designated channel path is not physically available, it depends on the model whether condition code 2 or 3 is set.

RESET CHANNEL PATH can encounter the program exceptions described or listed below.

Bit positions 32-55 of general register 1 must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

Resulting Condition Code:

0 Function initiated
1 —
2 Busy
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. To eliminate the possibility of a data-integrity exposure for devices that have the capability of generating unsolicited device-end status, I/O operations in progress with such devices on the channel path for which RESET CHANNEL PATH is to be executed must be terminated by the execution of either HALT SUBCHANNEL or CLEAR SUBCHANNEL. Otherwise, subsequent to receiving the reset signal, the device may present an unsolicited device end that may be interpreted by the channel subsystem as a solicited device end and cause command chaining to occur.
2. If the status-verification facility is being used and RESET CHANNEL PATH is executed without first stopping all ongoing operations associated with the channel path being reset, erroneous device-status-check conditions may be detected

RESUME SUBCHANNEL

RSCH [S]

'B238'	////////////////

0 16 31

The channel subsystem is signaled to perform the resume function at the designated subchannel.

General register 1 contains a subsystem-identification word that designates the subchannel at which the resume function is to be performed.

The subchannel is made resume pending.

Logically prior to the setting of condition code 0 and only if the subchannel is currently in the suspended state, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the resume function. The resume function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 15-20

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of RESUME SUBCHANNEL, the channel subsystem asynchronously performs the resume function. Except when the subchannel is subchannel active, if the execution of RESUME SUBCHANNEL results in the setting of condition code 0, performance of the resume function causes execution of a currently suspended channel program to be resumed with the associated device, provided that the suspend flag for the current CCW has been set to zero by the program. If the suspend flag remains one, execution of the channel program remains suspended. But, if the subchannel is subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0, then it is unpredictable whether execution of the current program is resumed or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status when the resume-pending condition is recognized by the channel subsystem. (See “Start Function and Resume Function” on page 15-20.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending.

Condition code 2 is set, and no other action is taken, when the resume function is not applicable. The resume function is not applicable when the subchannel (1) has any function other than the start function alone specified, (2) has no function specified, (3) is resume pending, or (4) does not have suspend control specified for the start function in progress.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for the resume function. A subchannel is not operational for the resume function if the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

RESUME SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0	Function initiated
1	Status pending
2	Function not applicable
3	Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. When channel-program execution is resumed from the suspended state, the device views the resumption as the beginning of a new chain of commands. When the suspension of channel-program execution occurs and the device requires that certain commands be first or appear only once in a chain of commands (for example, direct-access-storage devices), the program must ensure that the appropriate commands in the proper sequence are fetched by the channel subsystem after channel-program execution is resumed. One way the program can ensure proper sequencing of commands at the device is by allowing the I/O interruption to occur for an intermediate interruption condition due to suspension.

   It is not reliable to notify the program that the subchannel is suspended by using the PCI flag in the CCW that contains the S flag because the PCI I/O interruption may occur before the subchannel is suspended. The SCSW would indicate that an I/O operation is in progress at the subchannel and device in this case.

   The suspend flag of the target CCW should be set to zero before RESUME SUBCHANNEL is executed; otherwise, it is possible that the resume-pending condition may be recognized and the CCW refetched while the suspend flag is still one, in which case the resume-pending condition would be reset, and the execution of the channel program would be suspended. If the suspend flag of the target CCW is set to zero before the execution of RESUME SUBCHANNEL, the channel program is not suspended, provided that the subchannel is not subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0. If condition code 0 is set while the subchannel is still subchannel active, it is unpredictable whether the resume-pending condition is recognized by the channel subsystem or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status at the time the resume-pending condition is recognized. When the subchannel is suspended, the execution of TEST SUBCHANNEL, which clears the intermediate interruption condition, also clears the indication of resume pending.

2. Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched having an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

3. Path availability is not tested during the execution of RESUME SUBCHANNEL. Instead, path availability is tested when the channel subsystem begins performance of the resume function.

4. The contents of the CCW fetched during performance of the resume function may be different from the contents of the same CCW when it was previously fetched and contained an S flag validly set to one.

SET ADDRESS LIMIT

SAL [S]

'B237'	////////////////	
0	16	31

The address-limit-checking facility is signaled to use the specified address as the address-limit value, and the specified address is passed to the facility. Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for operand exception and privileged-operation exception, and then is suppressed.

When the address-limit-checking facility is installed, the SET ADDRESS LIMIT instruction is available for use. When the address-limit-checking facility is not installed, or the FCX facility is installed, the SET ADDRESS LIMIT instruction is not provided.

General register 1 contains the absolute address to be used as the address-limit value. The specified address must be on a 64 K-byte boundary and may designate a maximum absolute storage address of 2,147,418,112 (7FFF0000 hex) regardless of whether the CPU is operating in the 24-bit, 31-bit, or 64-bit addressing mode. Bits 0-31 of general register 1 are ignored, and bit 32 must be zero.

General register 1 has the following format:

/////////////////////////////////		
0		31
0	Address-Limit Value	
32		63

Associated Functions

The value that is used by the address-limit-checking facility when determining whether to permit or prohibit a data access is called the address-limit value. The initial address-limit value is zero. The initial address-limit value is used by the address-limit-checking facility until the facility recognizes a signal, caused by the execution of SET ADDRESS LIMIT, to use a specified address. The recognition of this specified address as the new address-limit value occurs asynchronously with respect to the execution of SET ADDRESS LIMIT.

If address-limit checking is specified for a subchannel, then whether the specified address is used by the address-limit-checking facility, when determining whether to permit or prohibit a data access, depends on whether SET ADDRESS LIMIT was executed before, during, or after the execution of START SUBCHANNEL for that subchannel. If SET ADDRESS LIMIT is executed before START SUBCHANNEL, the specified address is used by the address-limit-checking facility. If SET ADDRESS LIMIT is executed during or after the execution of START SUBCHANNEL, it is unpredictable whether the specified address is used by the address-limit-checking facility for that particular start function. For a description of the manner in which address-limit checking is performed, see “Address-Limit Checking” on page 17-26.

Special Conditions

SET ADDRESS LIMIT can encounter the program exceptions described or listed below.

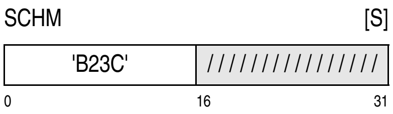
The address in general register 1 must be designated on a 64K byte boundary, and bit 32 of general register 1 must be zero; otherwise, an operand exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

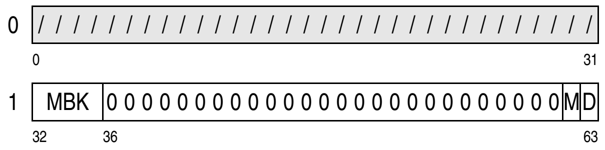
- Operand
- Privileged operation
- Transaction constraint

SET CHANNEL MONITOR



Each of the measurement-block-update mode and device-connect-time-measurement mode of the channel subsystem is made either active or inactive, depending on the values of the measurement-mode-control bits in general register 1. If the measurement-mode-control bit for measurement-block update is one, the measurement-block origin and measurement-block key are passed to the channel subsystem.

General register 1 has the following format:



Ignored: Bit positions 0-31 of general register 1 are ignored.

Measurement-Block Key (MBK): Bit positions 32-35 of general register 1 contain the measurement-block key. When bit 62 is one, MBK specifies the access key that is to be used by the channel subsystem when it accesses the measurement-block area and, when the extended-I/O-measurement-block facility is installed, to access format-1 measurement blocks. Otherwise, MBK is ignored.

Measurement-Block-Update Control (M): Bit 62 of general register 1 is the measurement-mode-control bit that controls the measurement-block-update mode. When bit 62 of general register 1 is one and conditions allow, the measurement-block-update facility is signaled to asynchronously make the measurement-block-update mode active. In addition, the measurement-block-origin (MBO) address in general register 2 and the measurement-block key (MBK) in general register 1 are passed to the measurement-block-update facility.

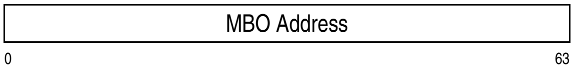
The measurement-block origin is used to determine the location of format-0 measurement blocks; the address of format-1 measurement blocks is stored at the subchannel using MODIFY SUBCHANNEL. The measurement-block key is used to access both format-0 and format-1 measurement blocks. The asynchronous functions that are performed by the measurement-block-update facility are summarized below in the section “Associated Functions” and are described in detail in “Channel-Subsystem Monitoring” on page 17-1.

When bit 62 of general register 1 is zero and conditions allow, the measurement-block-update mode is made inactive if it is active or remains inactive if it is inactive. The contents of bit positions 32-35 (MBK) of general register 1 and the contents of general register 2 are ignored.

Device-Connect-Time-Measurement Control (D): Bit 63 of general register 1 is the measurement-mode-control bit (D). When bit 63 is one and conditions allow, the device-connect-time-measurement mode is made active if it is inactive or remains active if it is active. When bit 63 is zero and conditions allow, the device-connect-time-measurement mode is made inactive if it is active or remains inactive if it is inactive.

Bit positions 36-61of general register 1 are reserved and must contain zeros; otherwise, an operand exception is recognized.

General register 2 has the following format:



Measurement-Block-Origin (MBO) Address: When bit 62 (M) of general register 1 is one, bit positions 0-63 of general register 2 contain the absolute address of the measurement-block origin (MBO), which is the beginning of the measurement-block area. The MBO address is used by the channel subsystem to locate format-0 measurement blocks. The origin of the measurement-block area must be designated on a 32-byte boundary otherwise, an operand exception is recognized. When bit 62 of general register 1 is zero, the contents of general register 2 are ignored.

If the channel-subsystem timer that is used by the channel-subsystem-monitoring facilities is in the error state, the state is reset. This happens independent of the setting of the two measurement-mode-control bits. (See “Channel-Subsystem Timing” on page 17-2 for a description of the timing facilities.)

Associated Functions

When the measurement-block-update facility is signaled (by means of SET CHANNEL MONITOR) to make the measurement-block-update mode active, the functions that are performed by the facility depend on whether or not the mode is already active when the signal is generated.

If the measurement-block-update mode is inactive when the signal is generated, the mode remains inactive until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the measurement-block-update mode is made active, and the MBK that was passed when the signal was generated is used to access all measurement blocks, and the MBO that was passed when the signal was generated is used to determine the address of format-0 measurement blocks.

If the measurement-block-update mode is active when the signal is generated, the mode remains active, and the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction continue to be used to control the storing of measurement data until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the MBK and MBO associated with that signal are used instead of the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction. The SET CHANNEL MONITOR instruction does not affect the measurement-block address used for format-1 measurement blocks, but the MBK associated with the signal becomes the key used to access the measurement block.

In all above cases, the measurement-block-update facility recognizes the signal during, or subsequent to, the execution of the SET CHANNEL MONITOR instruction that caused the signal to be generated and logically prior to the performance of any start function that is initiated by the subsequent execution of START SUBCHANNEL for a subchannel that is enabled for measurement by this facility. If a subchannel that is enabled for measurement by this facility already has a start function in progress when the signal is generated, it is unpredictable when measurement data for that subchannel is stored by using the MBK and MBO associated with that signal.

While the measurement-block-update mode is active, performance measurements are accumulated for subchannels that are enabled for measurement-block update. Measurements for a subchannel are either accumulated in a single 32-byte format-0 measurement block within the measurement-block area, or a 64-byte format-1 measurement block pointed to by the measurement-block address at the subchannel. A subchannel is enabled for the measurement-block-update mode by setting the measurement-block-update-enable bit to one in the SCHIB and then executing the MODIFY SUBCHANNEL instruction for that subchannel. The measurement-block-format-control bit (F) at the subchannel specifies whether a format-0 or format-1 measurement block is stored for a subchannel when the measurement-block-update mode is active and the subchannel is enabled for measurement-block updates. When the F bit is zero, the MBO and MBI are used to determine the address of the measurement block for the subchannel, and a format-0 measurement block is stored. When the F bit is one, the measurement-block-address field at the subchannel contains the address of the measurement block for the subchannel, and a format-1 measurement block is stored. The F bit and measurement-block-address field are modified using the MODIFY SUBCHANNEL instruction.

When the device-connect-time-measurement mode is active, measurements of the length of time that the device is actively communicating with the channel subsystem during the execution of a channel program are accumulated for subchannels that are enabled for device-connect-time measurement. Measurements for a subchannel are provided in the extended-status word ESW of the IRB. A subchannel is enabled for device-connect-time-measurement mode by setting the device-connect-time-measurement-enable bit to one in the SCHIB and then executing MODIFY SUBCHANNEL for that subchannel.

For a more detailed description of the measurement-block-update mode, the format and contents of the measurement block, and the device-connect-time-measurement mode, see “Channel-Subsystem Monitoring” on page 17-1.

Special Conditions

SET CHANNEL MONITOR can encounter the program exceptions described or listed below.

Bits 36-61 of general register 1 must be zeros. When bit 62 (M) of general register 1 is one, the MBO address in general register 2 must be designated on a 32-byte boundary. Otherwise, an operand exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Note: When the channel subsystem is initialized, the measurement-block-update and device-connect-time-measurement modes are made inactive.

START SUBCHANNEL

SSCH $D_2(B_2)$ [S]

'B233'	B_2	D_2
0	16	20 31

The channel subsystem is signaled to asynchronously perform the start function for the associated device, and the execution parameters that are contained in the designated ORB are placed at the designated subchannel. (See “Operation-Request Block” on page 15-24.)

General register 1 contains a subsystem-identification word that designates the subchannel to be started. The second-operand address is the logical address of the ORB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution parameters contained in the ORB are placed at the subchannel.

When START SUBCHANNEL is executed, the subchannel is status pending with only secondary status, and the extended-status-word-format bit (L) is zero, the status-pending condition is discarded at the subchannel.

The subchannel is made start pending, and the start function is indicated at the subchannel. If the second operand designates a command-mode ORB, the subchannel remains in command mode. If the second operand designates a transport-mode ORB, the subchannel enters transport mode. When the subchannel enters transport mode, the LPUM is set to zero if no previous dedicated allegiance exists; otherwise the LPUM is not changed.

Logically prior to the setting of condition code 0, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the start function. The start function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 15-20.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of START SUBCHANNEL, the channel subsystem asynchronously performs the start function.

The contents of the ORB, other than the fields that must contain all zeros, are checked for validity. On some models, the fields of the ORB that must contain zeros are checked asynchronously, instead of during the execution of the instruction. When invalid fields are detected asynchronously, the subchannel becomes status pending with primary, secondary, and alert status and with deferred condition code 1 and program check indicated. (See “Program Check” on page 16-25.) In this situation, the I/O operation or chain of I/O operations is not initiated at the device, and the condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL. (See “Subchannel-Status Word” on page 16-7).

On some models, path availability is tested asynchronously, instead of during the execution of the instruction. When no channel path is available for selection, the subchannel becomes status pending with primary and secondary status and with deferred condition code 3 indicated. The I/O operation or chain of I/O operations is not initiated at the device, and this condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL.

If conditions allow, a channel path is chosen, and execution of the channel program that is designated in the ORB is initiated. (See“Start Function and Resume Function” on page 15-20.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending when START SUBCHANNEL is executed. On some models, condition code 1 is not set when the subchannel is status pending with only secondary status; instead, the status-pending condition is discarded.

Condition code 2 is set, and no other action is taken, when a start, halt, or clear function is currently in progress at the subchannel (see “Function Control (FC)” on page 16-13).

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for START SUBCHANNEL. A subchannel is not operational for START SUBCHANNEL if the subchannel is not provided in the channel subsystem, has no valid device number associated with it, or is not enabled.

A subchannel is also not operational for START SUBCHANNEL, on some models, when no channel path is available for selection. On these models, the lack of an available channel path is detected as part of the START SUBCHANNEL execution. On other models, channel-path availability is only tested as part of the asynchronous start function.

START SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the command-mode ORB, bits 26-30 must be zeros, and, in word 2 of the command-mode ORB, bit 0 must be zero. Otherwise, on some models, an operand exception is recognized. On other models, an I/O-interruption condition is generated, indicating program check, as part of the asynchronous start function.

START SUBCHANNEL can also encounter the program exceptions listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of START SUBCHANNEL is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Function initiated
1 Status pending
2 Busy
3 Not operational

Program Exceptions:

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

STORE CHANNEL PATH STATUS

STCPS $D_2(B_2)$ [S]

'B23A'	B_2	D_2
0	16	20 31

Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for privileged operation exception and the instruction is suppressed by the machine

A channel-path-status word of up to 256 bits is stored at the designated location.

The second-operand address is the logical address of the location where the channel-path-status word is to be stored and must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The channel-path-status word indicates which channel paths are actively communicating with a device at the time STORE CHANNEL PATH STATUS is executed. Bit positions 0-255 correspond, respectively, to the channel paths having the channel-path identifiers 0-255. Each of the 256 bits at the designated location is set to one, set to zero, or left unchanged, as follows:

- For all channel paths in the configuration that are actively communicating with devices at the time STORE CHANNEL PATH STATUS is executed, the corresponding bits are stored as ones.
- For all channel paths that are (1) provided in the system (PIM bit in the PMCW is one) and (2) in the configuration but not currently being used by the channel subsystem in actively communicating with devices, the corresponding bits are stored as zeros.
- For all channel paths that are not provided in the system (PIM bit in the PMCW is zero), the corresponding bits either are not stored or are stored as zeros.
- For all channel paths in the configuration that are in the channel-path-terminal state or are not physically available (the corresponding PAM bit in the PMCW is zero), the corresponding bits are stored as zeros.

Special Conditions

STORE CHANNEL PATH STATUS can encounter the program exceptions described or listed below.

The second operand must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL PATH STATUS is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. To ensure a consistent interpretation of channel-path-status-word bits, the program should, prior to the initial use of the area, store zeros at the location where the channel-path-status word is to be stored.

STORE CHANNEL REPORT WORD

STCRW $D_2(B_2)$ [S]

'B239'	B_2	D_2
0	16	20 31

A CRW containing information affecting the channel subsystem is stored at the designated location.

The second-operand address is the logical address of the location where the CRW is to be stored and must be designated on a word boundary; otherwise, a specification exception is recognized.

When a malfunction or other condition affecting channel-subsystem operation is recognized, a channel report (consisting of one or more CRWs) describing the condition is made pending for retrieval and analysis by the program. The channel report contains information concerning the identity and state of a facility following the detection of the malfunction or other condition. For a description of the channel report, the CRW, and program-recovery actions related to the channel subsystem, see “Channel-Subsystem Recovery” on page 17-27.

When one or more channel reports are pending, the instruction causes a CRW to be stored at the designated location and condition code 0 to be set. A pending CRW can only be stored by the execution of STORE CHANNEL REPORT WORD and, once stored, is no longer pending. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.

Special Conditions

STORE CHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 CRW stored
1 Zeros stored
2 —
3 —

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. If the overflow condition is encountered, one or more channel-report words have been lost. (See “Channel-Subsystem Recovery” on page 17-27 for details.)

2. A pending CRW can be cleared by any CPU in the configuration executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU.

STORE SUBCHANNEL

STSCH $D_2(B_2)$ [S]

'B234'	B_2	D_2
0	16	20 31

Control and status information for the designated subchannel is stored in the designated SCHIB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

When the extended-I/O-measurement-block facility is not installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, and three words of model-dependent information. When the extended-I/O-measurement-block facility is installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, the measurement-block-address field, and one word of model-dependent information. (See “Subchannel-Information Block” on page 15-2.)

The execution of STORE SUBCHANNEL does not change any information at the subchannel.

Condition code 0 is set to indicate that control and status information for the designated subchannel has been stored in the SCHIB. When the execution of STORE SUBCHANNEL results in the setting of condition code 0, the information in the SCHIB indicates a consistent state of the subchannel.

Special Conditions

Condition code 3 is set, and no other action is taken, when the designated subchannel is not operational for STORE SUBCHANNEL. A subchannel is not operational for STORE SUBCHANNEL if the subchannel is not provided in the channel subsystem.

STORE SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 SCHIB stored
1 —
2 —
3 Not operational

Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

2. The information that is stored in the SCHIB is obtained from the subchannel. The STORE SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. STORE SUBCHANNEL may be executed at any time to sample conditions existing at the subchannel, without causing any pending status conditions to be cleared.

4. Repeated execution of STORE SUBCHANNEL without an intervening delay (for example, to determine when a subchannel changes state) should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit access of the subchannel by a channel subsystem to update the subchannel.

TEST PENDING INTERRUPTION

TPI $D_2(B_2)$ [S]

'B236'	B_2	D_2
0	16	20 31

The I/O-interruption code for a pending I/O interruption at a subchannel is stored at the location designated by the second-operand address, and the pending I/O-interruption request is cleared.

The second-operand address, when nonzero, is the logical address of the location where the two-word I/O-interruption code, consisting of words 0 and 1, is to be stored. The second-operand address must be designated on a word boundary; otherwise, a specification exception is recognized.

If the second-operand address is zero, the three-word I/O-interruption code, consisting of words 0-2, is stored at real locations 184-195. In this case, low-address protection and key-controlled protection do not apply.

In the access-register mode when the second-operand address is zero, it is unpredictable whether access-register translation occurs for access register B_2. If the translation occurs, the resulting address-space-control element is not used; that is, the interruption code still is stored at real locations 184-195.

Pending I/O-interruption requests are accepted only for those I/O-interruption subclasses allowed by the I/O-interruption-subclass mask in control register 6 of the CPU executing the instruction. If no I/O-interruption requests exist that are allowed by control register 6, the I/O-interruption code is not stored, the second-operand location is not modified, and condition code 0 is set.

If a pending I/O-interruption request is accepted, the I/O-interruption code is stored, the pending I/O-interruption request is cleared, and condition code 1 is set. The I/O-interruption code that is stored is the same as would be stored if an I/O interruption had occurred. However, PSWs are not swapped as when an I/O-interruption occurs.

I/O-Interruption Code

The I/O-interruption code that is stored during the execution of the instruction is defined as follows:

Word	
0	Subsystem-Identification Word
1	Interruption Parameter
2	Interruption-Identification Word
	0 31

Subsystem-Identification Word (SID): Bits 32-63 of the SID are placed in word 0.

See "I/O-Instruction Formats" in Chapter 14.

Interruption Parameter: Word 1 contains a four-byte parameter that was specified by the program and passed to the subchannel in word 0 of the ORB or the PMCW. When a device presents alert status and the interruption parameter was not previously passed to the subchannel by an execution of START SUBCHANNEL or MODIFY SUBCHANNEL, this field contains zeros.

Interruption-Identification Word: Word 2, when stored, contains the interruption-identification word, which further identifies the source of the I/O-interruption. Word 2 is stored only when the second-operand address is zero.

The interruption-identification word is defined as follows:

A	0	ISC	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
0		2	5 31

A bit (A)Bit 0 of the interruption-identification word specifies the type of pending I/O-interruption request that was cleared. When bit 0 is zero, the I/O-interruption request was associated with a subchannel.

I/O-Interruption Subclass (ISC): Bit positions 2-4 of the interruption-identification word contain an unsigned binary integer, in the range 0-7, that specifies the I/O-interruption subclass associated with the subchannel for which the pending I/O-interruption request was cleared.

The remaining bit positions are reserved and stored as zeros.

Special Conditions 15-31

TEST PENDING INTERRUPTION can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of TEST PENDING INTERRUPTION is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Interruption code not stored
1 Interruption code stored
2 —
3 —

Program Exceptions:

- Access (store, operand 2, second-operand address nonzero only)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. TEST PENDING INTERRUPTION should only be executed with a second-operand address of zero when I/O interruptions are masked off. Otherwise, an I/O-interruption code stored by the instruction may be lost if an I/O interruption occurs. The I/O-interruption code that identifies the source of an I/O interruption taken subsequent to TEST PENDING INTERRUPTION is also stored at real locations 184-195, replacing an I/O-interruption code that was stored by the instruction.

2. In the access-register mode when the second-operand address is zero, an access exception is recognized if access-register translation occurs and the access register is in error. This exception can be prevented by making the B_2 field zero or by placing 00000000 hex, 00000001 hex, or any other valid contents in the access register.

TEST SUBCHANNEL

TSCH $D_2(B_2)$ [S]

'B235'	B_2	D_2
0	16	20 31

Control and status information for the subchannel is stored in the designated IRB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the IRB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The information that is stored in the IRB consists of a SCSW, an extended-status word, and an extended-control word. (See “Interruption-Response Block” on page 16-6.)

If the subchannel is status pending, the status-pending bit of the status-control field is stored as one. Whether or not the subchannel is status pending has an effect on the functions that are performed when TEST SUBCHANNEL is executed.

When the subchannel is status pending and TEST SUBCHANNEL is executed, information, as described above, is stored in the IRB, followed by the clearing of certain conditions and indications that exist at the subchannel as described in Figure 14-2 on page 14-21. If the subchannel is in transport mode, the clearing of these conditions, specifically the start function, places the subchannel in command mode. (See Figure 14-2 on page 14-21.If an I/O-interruption request is pending for the subchannel, the request is cleared. Condition code 0 is set to indicate that these actions have been taken.

When the subchannel is not status pending and TEST SUBCHANNEL is executed, information (as described above) is stored in the IRB, and no conditions or indications are cleared. Condition code 1 is set to indicate that these actions have been taken.

Figure 14-2 on page 14-21 describes which conditions and indications are cleared by TEST SUBCHANNEL when the subchannel is status pending. All other conditions and indications at the subchannel remain unchanged.

	Subchannel Conditions*									
Field	**Alert Status Pending**		**Int Status Pending**		**Pri Status Pending**		**Sec. Status Pending**		**Status Pending Alone**	
	CM	TM	CM	TM	CM	TM	CM	TM	CM	TM
Function Control	C	C	Nc	Nm	C	C	C	C	C	C
Activity Control	Cp	Cp	Nr	Nm	Cp	Cp	Cp	Cp	Cp	Cp
Status Control	Cs	Cs	Cs	C	Cs	Cs	Cs	Cs	Cs	Cs
N Condition	C	C	Nr	Nm	C	C	C	C	C	C
Q Condition	–	C	–	C	–	C	–	C	–	C

Explanation:

– N/A.

CM Command-Mode Operation

TM Transport-Mode Operation

* Note that the rightmost column applies to status pending when it is alone. The other four status-pending conditions result in the clearing actions given. These actions apply both when a single status-pending condition occurs and when a combination of the four status-pending conditions occurs. In the combination case, all the clearing actions of the individual cases apply.

C Cleared.

Nm Not reset or modified by TEST SUBCHANNEL.

Cp The resume-, start-, halt-, clear pending, and suspended conditions are cleared.

Cs The status-pending condition is cleared.

Nc Not changed unless function control indicates the halt function and activity control indicates suspended. If both the halt function and suspended are indicated, conditions are cleared as for status pending alone.

Nr Not changed unless activity control indicates suspended and function control indicates the start function with or without the halt function. If the halt function is indicated, the conditions are cleared as for status pending alone. If only the start function is indicated, the resume-pending condition and the N condition are cleared.

Note: The clearing of certain subchannel conditions, places the subchannel in command mode. A subchannel in the idle state, or with the function control bits zero is considered to be in command-mode.

Figure 14-2. Conditions and Indications Cleared at the Subchannel by TEST SUBCHANNEL

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for TEST SUBCHANNEL. A subchannel is not operational for TEST SUBCHANNEL if the subchannel is not provided, has no valid device number associated with it, or is not enabled.

TEST SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

When the execution of TEST SUBCHANNEL is terminated on addressing and protection exceptions, the state of the subchannel is not changed.

Resulting Condition Code:

0 IRB stored; subchannel status pending
1 IRB stored; subchannel not status pending
2 —
3 Not operational

Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification

The priority of recognition of program exceptions for the instruction is shown in Figure 14-3.

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to the address specified by the second operand not being on a word boundary.
8.B	Access exceptions for an access to the subchannel-status-word, extended-status-word, and extended-control-word sections of the IRB designated by the second operand.

Figure 14-3. Priority of Execution: TEST SUBCHANNEL (Part 1 of 2)

8.C	Operand exception due to an invalid field in the subsystem-identification word specified in register 1.
8.D	Access exceptions for an access to the extended-measurement-word section of the IRB designated by the second operand when the extended-I/O-measurement-word mode is enabled at the designated subchannel.

Figure 14-3. Priority of Execution: TEST SUBCHANNEL (Part 2 of 2)

Programming Notes:

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

2. The information that is stored in the IRB is obtained from the subchannel. The TEST SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. When an I/O interruption occurs, it is the result of a status-pending condition at the subchannel, and typically TEST SUBCHANNEL is executed to clear the status. TEST SUBCHANNEL may also be executed at any other time to sample conditions existing at the subchannel.

4. Repeated execution of TEST SUBCHANNEL to determine when a start function has been completed should be avoided because there are conditions under which the completion of the start function may or may not be indicated. For example, if the channel subsystem is holding an interface-control-check (IFCC) condition in abeyance (for any subchannel) because another subchannel is already status pending, and if the start function being tested by TEST SUBCHANNEL has as the only path available for selection the channel path with the IFCC condition, then the start function may not be initiated until the status-pending condition in the other subchannel is cleared, allowing the IFCC condition to be indicated at the subchannel to which it applies.

5. Repeated execution of TEST SUBCHANNEL without an intervening delay, for example, to determine when a subchannel changes state, should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit accessing of the subchannel by the channel subsystem. Execution of TEST SUBCHANNEL

by multiple CPUs for the same subchannel at approximately the same time may have the same effect and also should be avoided.

6. The priority of I/O-interruption handling by a CPU can be modified by the execution of TEST SUBCHANNEL. When TEST SUBCHANNEL is executed and the designated subchannel has an I/O-interruption request pending, that I/O-interruption request is cleared, and the SCSW is stored, without regard to any previously established priority. The relative priority of the remaining I/O-interruption requests is unchanged.

   – Bit position 52 of the IOTA contains zero.

Some I/O instructions specify to the channel subsystem that a function is to be performed. Collectively, these functions are referred to as the basic I/O functions. The basic I/O functions are the clear, halt, start, resume, and channel-path-reset functions.

Control of Basic I/O Functions

Information that is present at the subchannel controls how the clear, halt, resume, and start functions are performed. This information is communicated to the program in the subchannel-information block during the execution of STORE SUBCHANNEL.

Subchannel-Information Block

The subchannel-information block (SCHIB) is the operand of the MODIFY SUBCHANNEL and STORE SUBCHANNEL instructions. The two rightmost bits of the SCHIB address are zeros, designating the SCHIB on a word boundary. The SCHIB contains three major fields: the path-management-control word (PMCW), the subchannel-status word (SCSW), and a model-dependent area. When the extended-I/O-measurement-block facility is installed the SCHIB also contains the measurement-block-address field. (Figure 15-1 on page 15-2. shows the format of the PMCW, and Figure 16-3 on page 16-8 shows the format of the command-mode SCSW and Figure 16-8 on page 16-34 shows the format of the transport-mode SCSW.)

STORE SUBCHANNEL is used to store the current PMCW, the SCSW, model-dependent data, and, when the extended-I/O-measurement-block facility is installed, the measurement-block-address field, for the designated subchannel. MODIFY SUBCHANNEL alters certain PMCW fields and, when the extended-I/O-measurement-block facility is installed, the measurement-block address in the subchannel. When the program needs to change the contents of one or more of the PMCW fields, the normal procedure is to (1) issue STORE SUBCHANNEL to obtain the current contents, (2) perform the required modifications to the PMCW field or the measurement-block-address field in main storage, and (3) issue MODIFY SUBCHANNEL to pass the new information to the subchannel. The SCHIB has the following format:

Word	
0	Path-Management-Control Word
1	
2	
3	
4	
5	
6	
7	Subchannel-Status Word
8	
9	
10	Model-Dependent Area / Measurement-Block Address
11	
12	Model-Dependent Area

Path-Management-Control Word

Words 0-6 of the SCHIB contain the path-management-control word (PMCW). The PMCW has the format shown in Figure 15-1 on page 15-2 when the subchannel is valid (see *"Device Number Valid (V)" on page 15-4).

The format of the PMCW is as follows:

Word				
0	Interruption Parameter			
1	0 0 ISC 0 0 0	E LM MM D T V	Device Number	
2	LPM	PNOM	LPUM	PIM
3	MBI		POM	PAM
4	CHPID-0	CHPID-1	CHPID-2	CHPID-3
5	CHPID-4	CHPID-5	CHPID-6	CHPID-7
6	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 F X S
	0 2 5 8	9 11 13	16	24 29 31

Figure 15-1. PMCW Format

Interruption Parameter: Bit positions 0-31 of word 0 contain the interruption parameter that is stored as word 1 of the interruption code. The interruption parameter can be set to any value by START SUBCHANNEL and MODIFY SUBCHANNEL. The initial value of the interruption parameter is zero.

I/O-Interruption-Subclass Code (ISC): Bits 2-4 of word 1 are an unsigned binary integer, in the range 0-7, that corresponds to the bit position of the I/O-interruption subclass-mask bit in control register 6 of each CPU in the configuration. The setting of that mask bit in control register 6 of a CPU controls the recognition of interruption requests relating to this subchannel by that CPU (see “Priority of Interruptions” on page 16-5). The ISC can be set to any value by MODIFY SUBCHANNEL. The initial value of the ISC is zero.

Reserved: Bits 0, 1, and 5-7 of word 1 are reserved and stored as zeros by STORE SUBCHANNEL. Bits 0, 1, 6, and 7 must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized. Bit 5 of word 1 is ignored when MODIFY SUBCHANNEL is executed.

Enabled (E): Bit 8 of word 1, when one, indicates that the subchannel is enabled for all I/O functions. When the E bit is zero, status presented by the device is not made available to the program, and I/O instructions other than MODIFY SUBCHANNEL and STORE SUBCHANNEL that are executed for the designated subchannel cause condition code 3 to be set. The E bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, all subchannels are not enabled; IPL causes the IPL I/O device to become enabled.

Limit Mode (LM): When the address-limit-checking facility is installed, bits 9 and 10 of word 1 define the limit mode (LM) of the subchannel. The limit mode is used by the channel subsystem when address-limit checking is invoked for an I/O operation. (See “Address-Limit Checking” on page 17-26.) Address-limit checking is under the control of the address-limit-checking-control bit that is passed to the subchannel in the operation-request block (ORB) during the execution of START SUBCHANNEL. (See “Address-Limit-Checking Control (A)” on page 15-27.) The definitions of the LM bits, whose values are used during data transfer, are as follows:

Bit 9	Bit 10	Function
0	0	Initialized value. No limit checking is performed for this subchannel.
0	1	Data address must be equal to or greater than the current address limit.
1	0	Data address must be less than the current address limit.
1	1	Reserved.

Bit positions 9 and 10 can contain any of the first three bit combinations shown above when MODIFY SUBCHANNEL is executed. Specification of the reserved bit combination in the operand causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

When the address-limit-checking facility is not installed, bits 9-10 of word 1 may be set as described above; however, they are ignored and are not set at the specified subchannel. When bits 9-10 are not specified as described above and MODIFY SUBCHANNEL is executed, an operand exception is recognized.

Measurement-Mode Enable (MM): Bits 11 and 12 of word 1 enable the measurement-block-update mode and the device-connect-time-measurement mode, respectively, of the subchannel. These bits can have any value when MODIFY SUBCHANNEL is executed; initially, neither measurement mode is enabled. The definition of each of these bits is as follows:

Bit 11 Measurement-Block-Update Enable:

0 Initialized value. The subchannel is not enabled for measurement-block update. Storing of measurement-block data does not occur.

1 The subchannel is enabled for measurement-block update. If the measurement-block-update mode is active, measurement data is accumulated in the measurement block at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected. (See "Measurement-Block Update" on page 17-2.) If the measurement-block-update mode is inactive, no measurement-block data is stored.

Bit 12 Device-Connect-Time-Measurement Enable:

0 Initialized value. The subchannel is not enabled for device-connect-time measurement. Storing of the device-connect-time interval (DCTI) in the extended-status word (ESW) does not occur.

1 The subchannel is enabled for device-connect-time measurement. If the device-connect-time-measurement mode is active and timing facilities are provided for the subchannel, the value of the DCTI is stored in the ESW when TEST SUBCHANNEL is executed after channel-program execution is completed or suspended at the subchannel, provided no error conditions described by subchannel logout have been detected. If the device-connect-time-measurement mode is inactive, no measurement values are stored in the ESW.

The meaning of the measurement-mode-enable bits (MM), described above, applies when the timing-facility bit for the subchannel is one. When the timing-facility bit is zero, the effect of the MM bits is changed, as described below under "Timing Facility (T)" on page 15-4. (For more discussion on measurement modes, see "Measurement-Block Update" on page 17-2 and "Device-Connect-Time Measurement" on page 17-10.)

Multipath Mode (D): Bit 13 of word 1, when one, indicates that the subchannel operates in the multipath mode when performing an I/O operation or chain of I/O operations. For proper operation in the multipath mode when more than one channel path is available for selection, the associated device must have the dynamic-reconnection feature installed and must be set up for multipath-mode operation. During performance of a start function in the multipath mode, a device is allowed to request service from the channel subsystem over any of the channel paths indicated at the subchannel as being available for selection (see *""Logical-Path Mask (LPM)" on page 15-5 and "Path-Available Mask (PAM)" on page 15-7). Bit 13, when zero, indicates that the subchannel operates in single-path mode when performing an I/O operation or chain of I/O operations. In the single-path mode, the entire start function is performed by using the channel path on which the first command of the I/O operation or chain of I/O operations was accepted by the device. The D bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, the subchannel is in the single-path mode.

Timing Facility (T): Bit 14 of word 1, when one, indicates that the channel-subsystem-timing facility is available for the subchannel and is under the control of the two measurement-mode-enable bits (MM) and SET CHANNEL MONITOR. Bit 14, when zero, indicates that the channel-subsystem-timing facility is not available for the subchannel. When bit 14 is zero, the START SUBCHANNEL count is the only measurement data that can be accumulated in the measurement block for the subchannel. Storing of the START SUBCHANNEL count is under the control of bit 11 and SET CHANNEL MONITOR, as described above under "Measurement-Mode Enable (MM)" on page 15-3. Similarly, if the T bit is zero, no device-connect-time-interval (DCTI) values can be measured for the subchannel. (See "Measurement-Block Update" on page 17-2 and "Device-Connect-Time Measurement" on page 17-10.)

Device Number Valid (V): Bit 15 of word 1, when one, indicates that the device-number field (see below) contains a valid device number and that a device associated with this subchannel may be physically installed. Bit 15, when zero, indicates that the subchannel is not valid, there is no I/O device currently associated with the subchannel, and the contents of all other defined fields of the SCHIB are unpredictable.

Device Number: Bit positions 16-31 of word 1 contain the binary representation of the four-digit hexadecimal device number of the device that is associated with this subchannel. The device number is a system-unique parameter that is assigned to the subchannel and the associated device when the device is installed.

Logical-Path Mask (LPM): Bits 0-7 of word 2 indicate the logical availability of channel paths to the associated device. Each bit of the LPM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A bit set to one means that the corresponding channel path is logically available; a zero means the corresponding channel path is logically not available. When a channel path is logically not available, the channel subsystem does not use that channel path to initiate performance of any clear, halt, resume, or start function, except when a dedicated allegiance exists for that channel path. When a dedicated allegiance exists at the subchannel for a channel path, the logical availability of the channel path is ignored whenever a clear, halt, resume, or start function is performed. (See "Channel-Path Allegiance" on page 15-12). If the subchannel is idle, the logical availability of the channel path is ignored whenever the control unit initiates a request to present alert status to the channel subsystem. The logical availability of a channel path associated with the subchannel can be changed by setting the corresponding LPM bit in the SCHIB and then issuing MODIFY SUBCHANNEL, or by setting the corresponding LPM bit in the ORB and then issuing START SUBCHANNEL. Initially, each installed channel path is logically available.

Path-Not-Operational Mask (PNOM): Any of bits 8-15 of word 2, when one, indicates that a path-not-operational condition has been recognized on the corresponding channel path. Each bit of the PNOM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. Any of bits 8-15 of word 2, when zero, indicates that a path-not-operational condition has not been recognized on the corresponding channel path.

Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a PNOM of all zeros if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

Programming Note: The PNOM indicates those channel paths for which a path-not-operational condition has been recognized during the performance of the most recent clear, halt, resume, or start function. That is, the PNOM indicates which of the channel paths associated with the subchannel have made a transition from the operational to the not-operational state for the subchannel during the performance of the most recent clear, halt, resume, or start function. However, the transition of a channel path from the not-operational to the operational state for the subchannel is indicated in the POM. Therefore, the POM must be examined in order to determine whether any of the channel paths that are associated with a designated subchannel are operational for the subchannel.

Furthermore, while performing either a start function or a resume function, the transition of a channel path from the not-operational to the operational state for the subchannel is recognized by the channel subsystem only during the initiation sequence for the first command specified by the start function or implied by the resume function. Therefore, a channel path that is currently not operational for the subchannel can be used by the device associated with the subchannel when reconnecting to the channel subsystem in order to continue command chaining; however, the channel subsystem does not indicate a transition of that channel path from the not-operational to the operational state for the subchannel in the POM.

POM Value and Device State before Selection Attempt		Value of Specified Bit Subsequent to Selection Attempt		
Device State[1]	POM	POM	PNOM[2]	SCSW N Bit
OP	0	1	0	0
NOP	0	0	0	0
OP	1	1	0	0
NOP	1	0	1	1[3]

Explanation:

[1] Device state as it appears on the corresponding channel path.

[2] Prior to the attempted device selection during the performance of either a start function or a resume function while the subchannel is suspended, the channel subsystem clears all existing path-not-operational conditions, if any, at the designated subchannel.

[3] The N bit (bit 15 of word 0 of the SCSW) is indicated to the program and the N condition is cleared at the subchannel when TEST SUBCHANNEL is executed the next time the subchannel is status pending for other than intermediate status alone provided that it is not also suspended.

NOP The device is not operational on the corresponding channel path.

OP The device is operational on the corresponding channel path.

Figure 15-2. Resulting POM, PNOM, and N-Bit Values Subsequent to Selection Attempt

Last-Path-Used Mask (LPUM): Bits 16-23 of word 2 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. Each bit of the LPUM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB.

For a subchannel operating in command mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The first command of a start or resume function is accepted by the device (see “Activity Control (AC)” on page 16-14).
2. The device and channel subsystem are actively communicating when the suspend function is performed for the channel program in execution.
3. Status has been accepted from the device and is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 16-2).
4. An interface-control-check condition has been recognized (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present in the subchannel.

For a subchannel operating in transport mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.
2. Status has been accepted from the device and is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status or both.
3. An interface-control-check has been recognized and no subchannel-logout information is currently present in the subchannel.

The LPUM field of the PMCW contains the most recent setting. For transport-mode operations the LPUM in the subchannel is set to zeros when the start function is set and no dedicated-allegiance condition exists for the subchannel.

Path-Installed Mask (PIM): Bits 24-31 of word 2 indicate which of the channel paths 0-7 to the I/O device are physically installed. The PIM indicates the validity of the channel-path identifiers (see below) for those channel paths that are physically installed. Each bit of the PIM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PIM bit stored as one indicates that the corresponding channel path is installed. A PIM bit stored as zero indicates that the corresponding channel path is not installed. The PIM always reflects the full complement of installed paths to the device, regardless of how the system is configured. Therefore, some of the channel paths indicated in the PIM may not be physically available in that configuration, as indicated by the bit settings in the path-available mask (see below). The initial value of the PIM indicates all the physically installed channel paths to the device.

Measurement-Block Index (MBI): Bits 0-15 of word 3 form an index value used by the measurement-block-update facility when the measurement-block-update mode is active (see “SET CHANNEL MONITOR” on page 14-13.) and the subchannel is enabled for the mode (see “Measurement-Mode Enable (MM)” on page 15-3).

When the measurement-block index is used, five zero bits are appended on the right, and the result is added to the measurement-block-origin address designated by SET CHANNEL MONITOR. The calculated address, called the measurement-block address, designates the beginning of a 32-byte storage area where measurement data is stored. (See “Measurement Block” on page 17-3.) The MBI can contain any value when MODIFY SUBCHANNEL is executed; the initial value is zero.

Programming Note: The measurement-block-origin address specified by SET CHANNEL MONITOR is used as the origin address for the measurement blocks for subchannels in all subchannel sets available to the program. However, the two-byte measurement-block-index field is capable of supporting a maximum of 65,536 unique MBI values. It is the responsibility of the program to coordinate use of the measurement-block index among subchannels and subchannel sets.

Path-Operational Mask (POM): Bits 16-23 of word 3 indicate the last known operational state of the device on the corresponding channel paths. Each bit of the POM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. If the associated device appeared operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is operational for the subchannel, and the bit corresponding to the channel path in the POM is one. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is also operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as one.

If the associated device appeared not operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is not operational for the subchannel, and the bit corresponding to the channel path in the POM is zero. A channel path is also not operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as zero.

If the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel during an attempted device selection in order to perform a clear, halt, resume, or start function, then the channel subsystem recognizes a path-not-operational condition. If an SCSW is subsequently stored, then bit 15 of word 0 is one, indicating the path-not-operational condition. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel.

When the channel path is not operational for the subchannel, a path-not-operational condition cannot be recognized. Moreover, a channel path that is not operational for the subchannel may be available for selection; if the channel subsystem chooses that channel path while performing a path-management operation, and if, during the attempted device selection, the device appears to be operational again on that channel path, then the state of the channel path changes from not operational for the subchannel to operational for the subchannel.

The POM can contain any value when MODIFY SUBCHANNEL is executed. Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a POM of all ones if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

Path-Available Mask (PAM): Bits 24-31 of word 3 indicate the physical availability of installed channel paths. Each bit of the PAM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PAM bit of one indicates that the corresponding channel path is physically available for use in accessing the device. A PAM bit of zero indicates the channel path is not physically available for use in accessing the device. When a channel path is not physically available, it may, depending on the model and the extent of failure, be used during performance of the reset-channel-path function. A channel path that is physically available may become not physically available as a result of reconfiguring the system, or this may occur as a result of the performance of the channel-path-reset function. The initial value of the PAM reflects the set of channel paths by which the I/O device is physically accessible at the time of initialization.

Note: The change in the availability of a channel path affects all subchannels having access to that channel path. Whenever the setting of a PAM bit is referred to in conjunction with the availability status of a channel path, for brevity, reference is made in this chapter to a single PAM bit instead of to the respective PAM bits in all of the affected subchannels.

Channel-Path Identifiers (CHPIDs): Words 4 and 5 contain eight one-byte channel-path identifiers corresponding to channel paths 0-7 of the PIM. A CHPID is valid if the corresponding PIM bit is one. Each valid CHPID contains the identifier of a physical channel path to a control unit by which the associated I/O device may be accessed. A unique CHPID is assigned to each physical channel path in the system.

Different devices that are accessible by the same physical channel path have, in their respective subchannels, the same CHPID value. The CHPID value may, however, appear in each subchannel in different locations in the CHPID fields 0-7.

Subchannels that share an identical set of channel paths have the same corresponding PIM bits set to ones. The channel-path identifiers (CHPIDs) for these channel paths are the same and occupy the same respective locations in each SCHIB.

Reserved: Bits 0-28 of word 6 are reserved and are stored as zeros by STORE SUBCHANNEL. They must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception may be recognized.

Measurement Block Format Control (F): When the extended-I/O-measurement-block facility is installed, bit 29 of word 6 specifies the format of the measurement block to be stored when the subchannel is enabled for the measurement-block-update mode, and measurement-block-update mode is active. The bit can contain any value when MODIFY SUBCHANNEL is executed. The initial value is zero. The definition of the bit is as follows:

Bit
29 Measurement-Block-Format Control:

0 Format-0 measurement block. Specifies that a format-0 measurement block is used when performing a measurement-block update for the subchannel. The address of the 32-byte measurement block is obtained using the MBI provided by MSCH in conjunction with the MBO provided by SCHM.

1 Format-1 measurement block. Specifies that a format-1 measurement block is used when performing a measurement-block update for the subchannel. The address of the 64-byte format-1 measurement block is provided by MSCH.

If the extended-measurement-block facility is not installed, bit 29 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Extended Measurement Word Mode Enable (X): When the extended-measurement-word facility is installed and enabled, bit 30 of word 6 enables the extended-measurement-word mode for the subchannel. Initially, the extended-measurement-word mode is not enabled. The definition of the bit is as follows:

Bit
30 Measurement-Block-Word-Mode Enable:

0 Initialized value. The subchannel is not enabled for extended-measurement-word mode. Storing of the extended-measurement word does not occur.

1 The subchannel is enabled for extended-measurement-word mode. Measurement data is stored in the extended-measurement word at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected.

If the extended-measurement-word facility is not installed, or is installed but is not enabled, bit 30 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Concurrent Sense (S): Bit 31 of word 6, when one, indicates that the subchannel is in the concurrent-sense mode. When the subchannel is in command mode and concurrent-sense mode, whenever the subchannel becomes status pending with alert status, and the status byte accepted from the device contains the unit-check indication, then the channel subsystem may attempt to retrieve sense information from the associated device and place that sense information in the extended-control word.

When the subchannel is operating in transport mode, any available sense information is provided in the TSB regardless of the setting of bit 31 of word 6.

If the concurrent-sense facility is not installed, bit 31 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Subchannel-Status Word

Words 7-9 of the SCHIB contain a copy of the SCSW. The format of the SCSW is described in “Subchannel-Status Word” on page 16-7. The SCSW is stored by the execution of either STORE SUBCHANNEL or TEST SUBCHANNEL (see “STORE SUBCHANNEL” on page 14-18 and “TEST SUBCHANNEL” on page 14-21).

Model-Dependent Area/Measurement Block Address

When the extended-I/O-measurement-block facility is not installed, words 10-12 of the SCHIB contain model-dependent information.

When the extended-I/O-measurement-block facility is installed, words 10-11 are defined as the measurement-block-address field. Word 12 contains model-dependent information.

When (1) the measurement-block-update mode is active (see “SET CHANNEL MONITOR” on page 14-13), (2) the subchannel is enabled for the mode (see“Measurement-Mode Enable (MM)” on page 15-3), and (3) the format-1-measurement block is specified (see “Measurement Block Format Control (F)” on page 15-8) at the subchannel, the measurement-block-address field contains the absolute storage address of the measurement block used by the measurement-block-update facility. The measurement-block address designates the beginning of a 64-byte storage area and must be designated on 64-byte boundary. The initial value of the measurement block address is zero.

Summary of Modifiable Fields

*Figure 15-3 on page 15-10 lists the initial settings for fields in a subchannel whose device-number-valid bit is one and indicates what modifies the fields.

All of the PMCW fields contain meaningful information when STORE SUBCHANNEL is executed and the designated subchannel is idle. Subchannel fields that the channel subsystem does not modify contain valid information whenever STORE SUBCHANNEL is executed, provided that the device-number-valid bit is one. The validity of the subchannel fields that are modifiable by the channel subsystem depends on the state of the subchannel at the time STORE SUBCHANNEL is executed.

Subchannel Field	Initial Value[1]	Program Modifies by Executing	Modified by Channel Subsystem[2]
Interruption parameter	Zeros	MSCH,SSCH	No
I/O-interruption-subclass code	Zeros	MSCH	No
Enabled (E)	Zero	MSCH	No
Limit mode (LM)	Zeros	MSCH[7]	No
Measurement mode (MM)	Zeros	MSCH	Yes[3]
Multipath mode (D)	Zero	MSCH	No
Timing facility (T)	Installed value[4]	None	No
Device number valid (V)	Installed value[4]	None	No
Device number	Installed value[4]	None	No
Logical-path mask (LPM)	Path-installed-mask value	MSCH,SSCH	No
Path-not-operational mask (PNOM)	Zeros	CSCH,SSCH,RSCH[5]	Yes
Last-path-used mask (LPUM)	Zeros	CSCH	Yes
Path-installed mask (PIM)	Installed value[4]	None	No
Measurement-block index (MBI)	Zeros	MSCH	No
Path-operational mask (POM)	Ones	CSCH,MSCH,RSCH[5]	Yes
Path-available mask (PAM)	Installed values[4] [6]	None	Yes[6]
Channel-path ID 0-7	Installed value$_4$	None	No
Concurrent sense (S)	ZERO	MSCH	No
Subchannel-status word (SCSW)	Zero	TSCH	Yes
Model-dependent area	*	None	*
Measurement-block-format control (F)	Zero	MSCH	No
Extended-measurement-word enable (X)	Zero	MSCH	No
Measurement-block address	Zeros	MSCH	No

Figure 15-3. Modification of Subchannel Fields (Part 1 of 2)

Explanation:

* Model dependent.

[1] These fields are not meaningful if the subchannel is not valid. Initialization of a subchannel is performed when I/O-system reset occurs. (See the section "I/O-System Reset" in Chapter 17, "I/O Support Functions.") One or more of the installed-value parameters that are unmodifiable by the program may be set when the subchannel is idle. In this case, all the program-modifiable fields are set to their initialized values, and the program is notified of such a change by a channel report. (See the section "Channel-Report Word" in Chapter 17, "I/O Support Functions.")

[2] Subchannel fields that are not normally modifiable by the channel subsystem may be modified as a result of dynamic configuration changes or as a result of external actions. When this occurs, the program is notified of the change by a channel report that is made pending at the time of the change.

[3] When any of the following error conditions associated with the measurement-block-update mode is detected, the measurement-block-update mode is disabled by the channel subsystem (bit 11 of word 1 of the SCHIB is zero) in the affected subchannel. The device-connect-time-measurement-enable bit (bit 12 of word 1 of the SCHIB) is never modified by the channel subsystem.

Measurement program check
Measurement protection check
Measurement data check
Measurement key check

[4] This information is entered when the channel-subsystem configuration is established

[5] The mask is modified by the resume function only when the subchannel is in the suspended state at the time RESUME SUBCHANNEL is executed.

[6] The channel subsystem may modify the PAM to reflect changes in the system configuration caused by partitioning or unpartitioning channel paths because of reconfiguration or permanent failure of part of the I/O system.

Figure 15-3. Modification of Subchannel Fields (Part 2 of 2)

Programming Notes:

1. System performance may be degraded if the LPM is not used to make channel paths for which a path-not-operational condition has been indicated in the PNOM logically not available.

2. If, during the performance of a start function, a channel path becomes not physically available because a channel-path failure has been recognized, continued performance of the start function may be precluded. That is, the program may or may not be notified, and the subchannel may remain in the subchannel-and-device-active state until cleared by the performance of the clear function.

3. If the same MBI is placed in more than one subchannel by the program, the channel-subsystem-monitoring facility updates the same locations with measurement data relating to more than one subchannel. In this case, the values stored in the measurement data are unpredictable. (See “Measurement-Block Update” on page 17-2.)

4. Modification of the I/O configuration (reconfiguration) may be accomplished in various ways depending on the model. If the reconfiguration procedure affects the physical availability of a channel path, then any change in availability can be detected by executing STORE SUBCHANNEL for a subchannel that has access to the channel path and by subsequently examining the PAM bits of the SCHIB.

5. The definitions of the PNOM, POM, and N bit are such that a path-not-operational condition is reported to the program only the first time the condition is detected by the channel subsystem after the corresponding POM bit is set to one.

   For example, if the POM bit for every channel path available for selection is one and the device appears not operational on all corresponding channel paths while the channel subsystem is attempting to initiate a start function at the device, the channel subsystem makes the subchannel status pending, with deferred condition code 3 and with the N bit stored as one. The PNOM in the SCHIB indicates the channel path or channel paths that appeared not operational, for which the corresponding POM bits have been set to zeros. The next START SUBCHANNEL causes the channel subsystem to again attempt device selection by choosing a channel path from among all of the channel paths that are available for selection. If device selection is not successful and all channel paths available for selection have again been chosen, deferred condition code 3 is set, but the N bit in the SCSW is zero. The POM contains zeros in at least those bit positions that correspond to the channel paths that are available for selection. (See “Channel-Path Availability” on page 15-13 for a description of the term “available for selection.”) When the N bit in the SCSW is zero, the PNOM is also zero.

6. If the program is to detect path-not-operational conditions, the PNOM should be inspected following the execution of TEST SUBCHANNEL (which results in the setting of condition code zero and the valid storing of the N bit as one) and preceding the performance of another start, resume, halt, or clear function at the subchannel.

Channel-Path Allegiance

The channel subsystem establishes allegiance conditions between subchannels and channel paths. The kind of allegiance established at a subchannel for a channel path or set of channel paths depends upon the state of the subchannel, the device, and the information, if any, transferred between the channel subsystem and device. The way in which path management is handled during the performance of a clear, halt, resume, or start function is determined by the kind of allegiance, if any, currently recognized between a subchannel and a channel path.

Performing the clear function at a subchannel clears any currently existing allegiance condition in the subchannel for all channel paths.

Performing the reset-channel-path function clears all currently existing allegiances for that channel path in all subchannels.

When a channel path becomes not physically available, all internal indications of prior allegiance conditions are cleared in all subchannels having access to the designated channel path.

Note that allegiance rules do not apply for interrogate operations. An interrogate operation may be initiated and successfully complete while a subchannel is in transport mode. Furthermore, interrogate operations do not alter any allegiance conditions that may exist.

Working Allegiance

Working Allegiance for Subchannels Operating in Command Mode

A subchannel has a working allegiance for a channel path when the subchannel is operating in command mode and becomes device active on that channel path. Once a working allegiance is established, the channel subsystem maintains the working allegiance at the subchannel for the channel path until either the subchannel is no longer device active or a dedicated allegiance is recognized, whichever occurs earlier. Unless a dedicated allegiance is recognized, a working allegiance for a channel path is extended to the set of channel paths that are available for selection if the device is specified to be operating in the multipath mode (that is, the multipath-mode bit is stored as one in the SCHIB). Otherwise, the working allegiance remains only for that channel path over which the start function was initiated.

Once a working allegiance is established for a channel path or set of channel paths, the working allegiance is not changed until the subchannel is no longer device active or until a dedicated allegiance is established. If the subchannel is operating in the single-path mode, a working allegiance is maintained only for a single path.

While a working allegiance exists at a subchannel, an active allegiance can occur only for a channel path for which the working allegiance is being maintained, unless the device is specified as operating in the multipath mode. When the device is specified as operating in the multipath mode, an active allegiance may also occur for a channel path that is not available for selection if the presentation of status by the device on that channel path causes an alert interruption condition to be recognized.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

Working Allegiance for Subchannels Operating in Transport Mode

A subchannel has a working allegiance for a channel path when the subchannel is operating in transport mode, becomes start pending, and the designated TCCB is transported over that channel path to the I/O device. Once a working allegiance is established, the channel subsystem maintains the working allegiance at the subchannel for the channel path until a busy condition is encountered or the subchannel is made status pending with primary status. The working allegiance remains only for that channel path over which the start function was initiated.

While a working allegiance exists at a subchannel that is operating in transport mode, an active allegiance can occur only for the channel path for which the working allegiance is being maintained.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

Active Allegiance

A subchannel has an active allegiance established for a channel path no later than when active communication has been initiated on that channel path with an I/O device. The subchannel can have an active allegiance to only one channel path at a time. While the subchannel has an active allegiance for a channel path, the channel subsystem does not actively communicate with that device on any other channel path. When the channel subsystem accepts a no-longer-busy indication from the device that does not cause an interruption condition, this status does not constitute the initiation of active communication. An active allegiance at a subchannel for a channel path is terminated when the channel subsystem is no longer actively communicating with the I/O device on that channel path.

A working allegiance can become an active allegiance.

Dedicated Allegiance

If a channel path is physically available (that is, if the corresponding PAM bit is one), a dedicated allegiance may be recognized for that channel path. If a channel path is not physically available, a dedicated allegiance cannot be recognized for the corresponding channel path. The channel subsystem establishes a dedicated allegiance at the subchannel for a channel path when (1) the subchannel is operating in command mode, the subchannel becomes status pending with alert status, and device status containing the unit-check indication is present but (2) concurrent-sense information is not present at the subchannel. A dedicated allegiance is maintained until the subchannel is no longer start pending (unless it becomes suspended) or resume pending following performance of the next start function, clear function, or channel-path-reset function or the next resume function if applicable. If the subchannel becomes suspended, the dedicated allegiance remains until the resume function is initiated and the subchannel is no longer resume pending. Unless a clear or channel-path-reset function is performed, the subchannel establishes a working allegiance when the dedicated allegiance ends. This occurs when the subchannel becomes device active. While a dedicated allegiance exists at a subchannel for a channel path, only that channel path is available for selection until the dedicated-allegiance condition is cleared.

Dedicated allegiance does not apply to subchannels operating in transport mode. When a subchannel operating in transport mode becomes status pending with unit check indicated, the sense information has already been transferred from the I/O device into the TSB for the I/O operation.

A dedicated allegiance can become an active allegiance. While a dedicated allegiance exists, an active allegiance can only occur for the same channel path.

A currently existing dedicated allegiance is cleared at any subchannel having access to a channel path when the channel path becomes not physically available or whenever the device appears not operational on the channel path for which the dedicated allegiance exists.

Channel-Path Availability

When a channel path is not physically available, the channel subsystem does not use the channel path to perform any of the basic I/O functions except, in some cases, the channel-path-reset function and does not respond to any control-unit-initiated requests on that same channel path. If a channel path is not physically available, the condition is indicated by the corresponding path-available-mask PAM bit being zero when STORE SUBCHANNEL is executed (see“Path-Available Mask (PAM)” on page 15-7). Furthermore, if the channel path is not physically available for the subchannel designated by STORE SUBCHANNEL, then it is not physically available for any subchannel that has a device which is accessible by that channel path.

Unless a dedicated allegiance exists at a subchannel for the channel path, a channel path becomes available for selection if it is logically available and physically available, as indicated by the bits in the LPM and PAM corresponding to the channel path being stored as ones when STORE SUBCHANNEL is executed. If a dedicated allegiance exists at a subchannel for the channel path, only that channel path is available for selection, and the setting of the corresponding LPM bit is ignored. If the channel path is currently being used and a dedicated allegiance exists at the subchannel for the channel path, selection of the device is delayed until the channel path is no longer being used.

The availability status of the eight logical paths to the associated device described in Figure 15-4 on page 15-14 is determined by the hierarchical arrangement of the corresponding bit values contained in the PIM, PAM, and LPM and by existing conditions, if any, recognized by the channel subsystem.

Value of Bit 'n'			Channel-Path	
PIM	PAM	LPM	Condition1	Channel-Path State
0	0[2]	-	X	Not installed
1	0	-	X	Not physically available
1	1	0[3]	X	Not logically available
1	1	1[3]	Active	Available for selection[4]
1	1	1	Inactive	Available for selection

Explanation:

- Bit value is not meaningful.

[1] If the channel path is recognized as being used in active communication with a device, the channel-path condition is described as active. Otherwise, its condition is described as inactive.

[2] A PAM bit cannot have the value one when the corresponding PIM bit has the value zero.

[3] If a dedicated allegiance exists to the channel path at the subchannel, the state of the bit is ignored, and the channel path is considered to be available for selection.

[4] The channel path may appear to be active when a channel-path-terminal condition has been recognized.

X Condition is not meaningful

Figure 15-4. Path condition and Path-Availability Status for PIM, PAM, and LPM Values

Control-Unit Type

In “Clear Function” on page 15-14, “Halt Function” on page 15-16, and “Start Function and Resume Function” on page 15-20, reference is made to type-1, type-2, and type-3 control units. For a description of these control-unit types, see the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974. For the purposes of this definition, all control units attaching to a serial-I/O interface are considered type-2 control units.

Clear Function

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem performs the clear function. Performance of the clear function consists in (1) performing a path-management operation, (2) modifying fields at the subchannel, (3) issuing the clear signal to the associated device, and (4) causing the subchannel to be made status pending, indicating the completion of the clear function.

Clear-Function Path Management

A path-management operation is performed as part of the clear function in order to examine channel-path conditions for the associated subchannel and to attempt to choose an available channel path on which the clear signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.

3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.

4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.

5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path, provided that the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.

2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.

   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.

3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Clear-Function Subchannel Modification

Path-management-control indications at the subchannel are modified during performance of the clear function. Effectively, this modification occurs after the attempt to choose a channel path, but prior to the attempt to select the device to issue the clear signal. The path-management-control indications that are modified are as follows:

1. The state of all eight possible channel paths at the subchannel is set to operational for the subchannel.

2. The last-path-used indication is reset to indicate no last-used channel path.

3. Path-not-operational conditions, if any, are reset.

Clear-Function Signaling and Completion

Subsequent to the attempt to choose a channel path and the modification of the path-management-control fields, the channel subsystem, if conditions allow, attempts to select the device to issue the clear signal. (See “Clear Signal” on page 17-12.) Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the clear signal, and (2) whether the attempt to issue the clear signal is successful. Independent of these conditions, the subchannel is subsequently set status pending, and the performance of the clear function is complete. These conditions and their effect on the clear function are described as follows:

No Attempt Is Made to Issue the Clear Signal: The channel subsystem does not attempt to issue the clear signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Clear-Function Path Management” on page 15-14.)

2. The chosen channel path is no longer available for selection.

3. A channel-path-terminal condition exists for the chosen channel path.

4. For parallel and ESCON channel paths: The chosen channel path is currently being used to actively communicate with a different device.

   For FICON channel paths: The chosen channel path is currently being used to actively communicate with the maximum number of devices that can have concurrent active communications.

5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If any of the conditions above exist, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

The Attempt to Issue the Clear Signal Is Not Successful: When the channel subsystem attempts to issue the clear signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the clear signal.

2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the clear signal.

3. An error condition is encountered when the channel subsystem attempts to issue the clear signal.

If any of the conditions above exists and the channel subsystem either determines that the attempt to issue the clear signal was not successful or cannot determine whether the attempt was successful, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

The Attempt to Issue the Clear Signal Is Successful: When the channel subsystem determines that the attempt to issue the clear signal was successful, the subchannel is no longer clear pending and is set status pending, and the performance of the clear function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated.

Programming Note: Subsequent to the performance of the clear function, any nonzero status, except control unit end alone, that is presented to the channel subsystem by the device is passed to the program as unsolicited alert status. Unsolicited status consisting of control unit end alone or zero status is not presented to the program.

Halt Function

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem performs the halt function. Performance of the halt function consists of (1) performing a path-management operation, (2) issuing the halt signal to the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the halt function.

Halt-Function Path Management

A path-management operation is performed as part of the halt function to examine channel-path conditions for the associated subchannel and to attempt to choose a channel path on which the halt signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.

3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.

4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.

5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path for which the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.

2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.

   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.

3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Halt-Function Signaling and Completion

Subsequent to the attempt to choose a channel path, the channel subsystem, if conditions allow, attempts to select the device to issue the halt signal. (See “Halt Signal” on page 17-12.)

Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the halt signal, (2) whether the attempt to issue the halt signal is successful, and (3) whether the subchannel is made status pending to complete the halt function. These conditions and their effect on the halt function are described as follows:

No Attempt Is Made to Issue the Halt Signal: The channel subsystem does not attempt to issue the halt signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Halt-Function Path Management” on page 15-16.)

2. The chosen channel path is no longer available for selection.

3. A channel-path-terminal condition exists for the chosen channel path.

4. The associated subchannel is status pending with other than intermediate status alone.

5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If the conditions described in items 3, 5, or 6 exist, the associated subchannel remains halt pending until those conditions no longer exist. When the conditions no longer exist (for the channel-path-terminal condition, when the condition no longer exists as a result of executing RESET CHANNEL PATH), the channel subsystem attempts to issue the halt signal to the device.

If any of the remaining conditions above exist, the subchannel remains halt pending and is set status pending, and the halt function is complete.

The Attempt to Issue the Halt Signal Is Not Successful: When the channel subsystem attempts to issue the halt signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the halt signal.
2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the halt signal.
3. An error condition is encountered when the channel subsystem attempts to issue the halt signal.

If the control unit or device signals a busy condition (item 1), the subchannel remains halt pending until the internal indication of busy is reset. When this event occurs, the channel subsystem again attempts to issue the halt signal to the device.

If any of the remaining conditions above exists and the channel subsystem either determines that the attempt to issue the halt signal was not successful or cannot determine whether the attempt was successful, then the subchannel remains halt pending and is set status pending, and the halt function is complete.

The Attempt to Issue the Halt Signal Is Successful: When the channel subsystem determines that the attempt to issue the halt signal was successful and ending status, if appropriate, has been received at the subchannel, the subchannel is no longer halt pending and is set status pending, and the halt function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated. The conditions that affect the receipt of ending status at the subchannel, and the effect of the halt signal at the device are described in the following discussion.

When the subchannel is subchannel-and-device active or only device active during the performance of the halt function, the state continues until the subchannel is made status pending because (1) the device has provided ending status or (2) the channel subsystem has determined that ending status is unavailable.

When the subchannel is operating in command mode and is idle, start pending, start pending and resume pending, suspended, or suspended and resume pending, or when the halt signal is issued during command chaining after the receipt of device end but before the next command is transferred to the device, no operation is in progress at the device, and therefore no status is generated by the device as a result of receiving the halt signal. When the subchannel is neither subchannel active, nor status pending with intermediate status, and no errors are detected during the attempt to issue the halt signal to the device, an interruption condition indicating status pending alone is generated after the halt signal is issued.

When the subchannel is operating in transport mode and is start pending, an operation may or may not be in progress at the device. Regardless of whether an operation is in progress, device status is not generated.

The effect of the halt signal at the device depends partially on the subchannel operation mode, type of device, and its state. The effect of the halt signal on a device that is not active or that is performing a mechanical operation in which data is not transferred across the channel path, such as rewinding tape or positioning a disk-access mechanism, depends upon the control-unit or device model. If the device is performing a type of operation that is unpredictable in duration or in which data is transferred across the channel path, the control unit interprets the signal as one to terminate the operation. Pending status conditions at the device are not reset. When the control unit recognizes the halt signal, it immediately ceases all communication with the channel subsystem until it has reached the normal ending point. The control unit then requests selection by the channel subsystem to present any generated status.

If the subchannel is involved in the data-transfer portion of an I/O operation, data transfer is terminated during the performance of the halt function, and the device is logically disconnected from the channel path. If the halt function is addressed to a subchannel operating in command mode, performing a chain of I/O operations, and the device has already provided channel end for the current I/O operation, the channel subsystem causes the device to be disconnected and command chaining or command retry to be suppressed.

If the subchannel is operating in command mode, performing a chain of I/O operations with the device, and the halt signal is issued during command chaining at a point after the receipt of device end for the previous I/O operation but before the next command is transferred to the device, the subchannel is made status pending with primary and secondary status immediately after the halt signal is issued. The device-status field of the SCSW contains zeros in this case. If the halt function is addressed to a subchannel that is operating in command mode, start pending, and the halt-pending condition is recognized before initiation of the start function, initiation of the start function is not attempted, and the subchannel becomes status pending after the device has been signaled.

If the halt function is addressed to a subchannel operating in transport mode that is start pending, the halt signal is issued as follows

- If the TCCB has been transported to the I/O device for execution, the halt signal is issued and the subchannel becomes status pending.
- If the TCCB has not been transported to the I/O device, the TCCB is not transported and the subchannel becomes status pending.

When the subchannel is not performing an I/O operation with the associated device, the device is selected, and an attempt is made to issue the halt signal as the device responds. If the subchannel is in the device-active state, the subchannel does not become status pending until it receives the device-end status from the halted device. If the subchannel is neither subchannel-and-device active nor device active, the subchannel becomes status pending immediately after selecting the device and issuing the halt signal. The SCSW for the latter case has the status-pending bit set to one (see “Status-Pending (Bit 31)” on page 16-19).

The termination of an I/O operation by performing the halt function may result in two distinct interruption conditions.

The first interruption condition occurs when the device generates the channel-end condition. The channel subsystem handles this condition as it would any other interruption condition from the device, except that the command address in the associated SCSW designates the point at which the I/O operation is terminated as follows:

- When a command-mode IRB is stored, the SCSW contains the address of the last-executed CCW, plus 8, and the subchannel-status bits may reflect unusual conditions that were detected.
- When a transport-mode IRB is stored, the SCSW contains the address of the current TCW, and the subchannel-status, subchannel-extended-status, and FCX bits may reflect unusual conditions that were detected.

If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is indicated, subject to the control of the SLI flag in the current CCW when the subchannel is operating in command mode. The value in the count field of the associated SCSW is unpredictable. If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is not indicated, when the subchannel is operating in transport mode.

The second interruption condition occurs if device-end status was not presented with the channel-end interruption condition. In this situation, the subchannel-key, command-address, and count fields of the associated SCSW are not meaningful.

When HALT SUBCHANNEL terminates an I/O operation, the method of termination differs from that used upon exhaustion of count or upon detection of programming errors to the extent that termination by HALT SUBCHANNEL is not contingent on the receipt of a service request from the associated device.

Programming Notes:

1. When, after an operation is terminated by HALT SUBCHANNEL, the subchannel is status pending with primary, primary and secondary, or secondary status, the extent of data transferred as described by the count field is unpredictable.
2. When the path that is chosen by the path-management operation has a channel-path-terminal condition associated with it, the halt function remains pending until the condition no longer exists. Until the condition is cleared, the associated subchannel cannot be used to perform I/O operations, even if other channel paths become

available for selection. CLEAR SUBCHANNEL can be executed to terminate the halt-pending condition and make the subchannel usable.

Start Function and Resume Function

The start and resume functions initiate I/O operations as described below. The start function applies to subchannels operating in either command mode or transport mode. The resume function applies only to subchannels operating in command mode.

Subsequent to the execution of START SUBCHANNEL and RESUME SUBCHANNEL, the channel subsystem performs the start and resume functions, respectively, to initiate an I/O operation with the associated device. Performance of a start or resume function consists of: (1) performing a path-management operation, (2) performing an I/O operation or chain of I/O operations with the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the start function. (Completion of a start function is described in “I/O Interruptions” on page 16-1.) The start function initiates the execution of a channel program that is designated in the ORB, which in turn is designated as the operand of START SUBCHANNEL, in contrast to the resume function that initiates the execution of a suspended channel program, if any, beginning at the CCW that caused suspension; otherwise, the resume function is performed as if it were a start function (see “Resume-Pending (Bit 20)” on page 16-14).

Start-Function and Resume-Function Path Management

A path-management operation is performed by the channel subsystem during the performance of either a start or a resume function to choose an available channel path that can be used for device selection to initiate an I/O operation with that device. The actions taken are as follows:

1. If the subchannel is currently start pending and device active, the start function remains pending at the subchannel until the secondary status for the previous start function has been accepted from the associated device and the subchannel is made start pending alone. When the status is accepted and does not describe an alert interruption condition, the subchannel is not made status pending, and the performance of the pending start function is subsequently initiated. If the status describes an alert interruption condition, the subchannel becomes status pending with secondary and alert status, the pending start function is not initiated, deferred condition code 1 is set, and the start-pending bit remains one. If the subchannel is currently start pending alone, the performance of the start function is initiated as described below.

2. If a dedicated allegiance exists at the subchannel for a channel path, the channel subsystem chooses that path for device selection. If a busy condition is encountered while attempting to select the device and a dedicated allegiance exists at the subchannel, the start function remains pending until the internal indication of busy is reset for that channel path. When the internal indication of busy is reset, the performance of the pending start function is initiated on that channel path.

3. If no channel path is available for selection and no dedicated allegiance exists in the subchannel for a channel path, a channel path is not chosen.

4. If all channel paths that are available for selection have been tried and one or more of them are being used to actively communicate with other devices, or, alternatively, if the channel subsystem has encountered either a control-unit-busy or a device-busy condition on one or more of those channel paths, or a combination of those conditions on one or more of those channel paths, the start function remains pending at the subchannel until a channel path, control unit, or device, as appropriate, becomes available.

5. If (1) the start function is to be initiated on a channel path with a device attached to a type-1 control unit and (2) no other device is attached to the same control unit whose subchannel has either a dedicated allegiance to the same channel path or a working allegiance to the same channel path where primary status has not been received for that subchannel, then that channel path is chosen if it is available for selection; otherwise, that channel path is not chosen. If, however, another channel path to the device is available for selection and no allegiances exist as described above, that channel path is chosen. If no other channel path is available for selection,

the start or resume function, as appropriate, remains pending until a channel path becomes available.

6. If the device is attached to a type-3 control unit, and if at least one other device is attached to the same control unit whose subchannel has a dedicated allegiance to the same channel path, another channel path that is available for selection may be chosen, or the start function remains pending until the dedicated allegiance for the other device is cleared.

7. If a channel path has been chosen and a busy indication is received during device selection to initiate the execution of the first command of a pending CCW channel program or to transport the TCCB of a pending TCW channel program, the channel path over which the busy indication is received is not used again for that device or control unit (depending on the device-busy or control-unit-busy indication received) until the internal indication of busy is reset.

8. If, during an attempt to select the device in order to initiate the execution of the first command specified for the start or implied for the resume function for a CCW channel program, or to initiate the transportation of the TCCB for the start function for a TCW channel program, (as described in action 7 above), the channel subsystem receives a busy indication, it performs one of the following actions:

   a. If the device is specified to be operating in the multipath mode and the busy indication received is device busy, then the start or resume function remains pending until the internal indication of busy is reset. (See "Multipath Mode (D)" on page 15-4.)

   b. If the device is specified to be operating in the multipath mode and the busy indication received is control unit busy, or if the device is specified to be operating in the single-path mode, the channel subsystem attempts selection of the device by choosing an alternate channel path that is available for selection and continues the path-management operation until either the start or the resume function is initiated or selection of the device has been attempted on all channel paths that are available for selection. If the start or resume function has not been initiated by the channel subsystem after all channel paths available for selection have been chosen, the start or resume function remains pending until the internal indication of busy is reset.

   c. If the subchannel has a dedicated allegiance, then action 2 on page 20 applies.

9. When, during the selection attempt to transfer the first command for a CCW channel program, or to transport the TCCB for a TCW channel program, the device appears not operational and the corresponding channel path is operational for the subchannel, a path-not-operational condition is recognized, and the state of the channel path changes at the subchannel from operational for the subchannel to not operational for the subchannel (see "Path-Not-Operational Mask (PNOM)" on page 15-5). The path-not-operational conditions at the subchannel, if any, are preserved until the subchannel next becomes clear pending, start pending, or resume pending (if the subchannel was suspended), at which time the path-not-operational conditions are cleared. If, however, the corresponding channel path is not operational for the subchannel, a path-not-operational condition is not recognized. When the device appears not operational during the selection attempt to transfer the first command or TCCB on a channel path that is available for selection, one of the following actions occurs:

   a. If a dedicated allegiance exists for that channel path, then it is the only channel path that is available for selection; therefore, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.

   b. If no dedicated allegiance exists and there are alternate channel paths available for selection that have not been tried, one of those channel paths is chosen to attempt device selection and transfer the first command for a CCW channel program, or the TCCB for a TCW channel program.

   c. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared operational on at least one of the channel paths that were tried, the start or resume function remains pending at the subchannel until a channel path, a control unit, or the device, as appropriate, becomes available.

d. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared not operational on all channel paths that were tried, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.

10. When the subchannel is active and an I/O operation is to be initiated with a device, all device selections occur according to the LPUM indication if the multipath mode is not specified at the subchannel. For example, if command chaining is specified for a CCW channel program, the channel subsystem transfers the first and all subsequent commands describing a chain of I/O operations over the same channel path.

Interrogate Function

Subsequent to the execution of CANCEL SUBCHANNEL for a subchannel operating in transport mode, the channel subsystem performs the interrogate function. Performance of the interrogate function consists of (1) transporting the designated interrogate TCCB to the I/O device, (2) storing the interrogate TSB, and (3) causing the subchannel to become intermediate status pending with interrogate-complete status indicated.

All storage accesses used to perform the interrogate operation are made as if a storage-access key of zero is used.

Interrogate-Function Path Management

The same channel path that was used to transport the TCCB for the I/O operation being interrogated is used for the interrogate function.

Interrogate TCCB Transportation and Completion

Subsequent to determining the channel path, the channel subsystem, if conditions allow, attempts to transport the interrogate TCCB. Conditions associated with the subchannel, the interrogate TCCB, and the chosen channel path, if any, affect (1) whether an attempt is made to transport the interrogate TCCB, (2) whether the attempt to transport the interrogate TCCB is successful, and (3) whether the interrogate TSB is stored. These conditions and their effect on the interrogate function are described as follows:

No Attempt Is Made to Transport the Interrogate TCCB: The channel subsystem does not transport the interrogate TCCB if any of the following conditions exists:

- The subchannel is status pending with primary status indicated.
- The subchannel is idle or device active only.
- The TCCB for the I/O operation being interrogated has not been transported to the device.
- Another interrogate function is already in progress on the channel path for the I/O device.
- The interrogate-TCW-address field of the TCW for the I/O operation being interrogated contains zeros.
- The channel subsystem doesn't have the resources to process the interrogate.

The Attempt to Transport the Interrogate TCCB or Store the Interrogate TSB is Unsuccessful: When the channel subsystem attempts to transport the interrogate TCCB, the attempt may not be successful if any of the following conditions exists:

- The interrogate-TCW address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TCW on a 64-byte boundary.
- The TCCB-TIDA flag is one in the flags field of the interrogate TCW and the TCCB-address field in the interrogate TCW does not designate the first TIDAW on a quadword boundary.
- The interrogate-TSB address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TSB on a doubleword boundary.

If any of the above conditions is true, the subchannel is made status pending with program check and interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The attempt to transport the interrogate TCCB is also not successful when a device-detected program check is recognized. In this case, interrogate-failed status is also indicated in the subchannel-extended-status field of the IRB.

If the interrogate TCCB has been sent and the corresponding interrogate response is not received within a model-dependent amount of time, an interface-control check is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The Attempt to Transport the Interrogate TCCB is Successful: When the channel subsystem determines that the attempt to transport the interrogate TCCB was successful and the interrogate data has been received at the subchannel before the completion of the I/O operation being interrogated, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with intermediate status and interrogate-complete status indicated. The status related to the operation being interrogated remains unchanged.

When the channel subsystem determines that the operation being interrogated has completed before the interrogate data has been received at the subchannel, the channel subsystem waits until the interrogate data is received. When received, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with primary status indicated. The status related to the operation being interrogated is unchanged.

Execution of I/O Operations

After a channel path is chosen, the channel subsystem, if conditions allow, initiates the execution of an I/O operation with the associated device. Execution of additional I/O operations may follow the initiation and execution of the first I/O operation.

For subchannels operating in command mode, the channel subsystem can execute seven types of commands: write, read, read backward, control, sense, sense ID, and transfer in channel. Each command, except transfer in channel, initiates a corresponding I/O operation. Except for periods when channel-program execution is suspended at the subchannel (see “Suspension of CCW Channel-Program Execution” on page 15-73), the subchannel is active from the acceptance of the first command until the primary interruption condition is recognized at the subchannel. If the primary interruption condition is recognized before the acceptance of the first command, the subchannel does not become active. Normally, the primary interruption condition is caused by the channel-end signal or, in the case of command chaining, the channel-end signal for the last CCW of the chain. (See “Primary Interruption Condition” on page 16-4.) The device is active until the secondary interruption condition is recognized at the subchannel. Normally, the secondary interruption condition is caused by the device-end signal or, in the case of command chaining, the device-end signal for the last CCW of the chain. (See “Secondary Interruption Condition” on page 16-5.)

For subchannels operating in transport mode, the channel subsystem can transport six types of commands for execution: write, read, control, sense, sense ID, and interrogate. Each command initiates a corresponding device operation. When one or more commands are transported to the I/O device in a TCCB, the subchannel remains start pending until primary status is presented.

Programming Notes:

In the single-path mode, all transfers of commands, data, and status for the I/O operation or chain of I/O operations occur on the channel path over which the first command was transferred to the device.

When the device has the dynamic-reconnection feature installed, an I/O operation or chain of I/O operations may be performed in the multipath mode. To operate in the multipath mode, MODIFY SUBCHANNEL must have been previously executed for the subchannel with bit 13 of word 1 of the SCHIB specified as one. (See “Multipath Mode (D)” on page 15-4.) In addition, the device must be set up for the multipath mode by the execution of certain model-dependent commands appropriate to that type of device. The general procedures for handling multipath-mode operations are as follows:

1. Setup

   a. A set-multipath-mode type of command must be successfully executed by the device on each channel path that is to be a member of the multipath group being set up; otherwise, the multipath mode of operation may give unpredictable results at the subchannel. If, for any reason, one or more physically available channel paths to the device are not included in the multipath group, these channel paths must not be available for selection while the subchannel is operating in the multipath mode. A channel path can be made not available for selection by having the corresponding LPM bit set to zero either in the SCHIB prior to the execution of MODIFY SUBCHANNEL or in the ORB prior to the execution of START SUBCHANNEL.

   b. When a set-multipath-mode type of command is transferred to a device, only a single channel path must be logically available in order to avoid alternate channel-path selection for the execution of that start function; otherwise, device-busy conditions may be detected by the channel subsystem on more than one channel path, which may cause unpredictable results for subsequent multipath-mode operations. This type of setup procedure should be used whenever the membership of a multipath group is changed.

2. Leaving the Multipath Mode

   To leave the multipath mode and continue processing in the single-path mode, either of the following two procedures may be used:

   a. A disband-multipath-mode type of command may be executed for any channel path of the multipath group. This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. A start function must not be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that function or subsequent start functions.

   b. A resign-multipath-mode type of command is executed on each channel path of the multipath group (the reverse of the setup described in item 1 on page 23). This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. No start function may be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that or subsequent start functions.

Blocking of Data

Data recorded by an I/O device is divided into blocks. The length of a block depends on the device; for example, a block can be a card, a line of printing, or the information recorded between two consecutive gaps on magnetic tape.

The maximum amount of information that can be transferred in one I/O operation is one block. An I/O operation is terminated when the associated main-storage area is exhausted or the end of the block is reached, whichever occurs first. For some operations, such as writing on a magnetic-tape unit or at an inquiry station, blocks are not defined, and the amount of information transferred is controlled only by the program.

Operation-Request Block

The operation-request block (ORB) is the operand of START SUBCHANNEL. The ORB specifies the parameters to be used in controlling that particular start function. These parameters include the interruption parameter, the subchannel key, the address of first CCW or the TCW, operation-control bits, priority-control numbers, and a specification of the logical availability of channel paths to the designated device.

The contents of the ORB are placed at the designated subchannel during the execution of START SUBCHANNEL, prior to the setting of condition code 0. If the execution will result in a nonzero condition code, the contents of the ORB are not placed at the designated subchannel.

The two rightmost bits of the ORB address must be zeros, placing the ORB on a word boundary; otherwise, a specification exception is recognized.

When the fibre-channel-extensions (FCX) facility is installed, the channel-program-type control (B) (word 1, bit 13) of the ORB specifies the type of channel program that is designated by the ORB. When B is zero, the ORB designates a CCW channel program. When the B is one, the ORB designates a TCW channel program. Only I/O-devices that support FCX recognize TCW channel programs.

If the contents of an ORB that designates a CCW channel program are placed at the designated subchannel during the execution of START SUBCHANNEL, the subchannel remains in command mode. Thus, such an ORB is also known as a command-mode ORB. If the contents of an ORB that designates a TCW channel program are placed at the designated subchannel during execution of START SUBCHANNEL, the subchannel enters transport mode. Thus, such an ORB is also known as a transport-mode ORB.

Command-Mode ORB

This section describes the command-mode ORB. The term operation-request block (ORB), in this section, means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is zero.

The format of the command-mode ORB is as follows when the ORB-format facility is not installed:

Word																						
0	Interruption Parameter																					
1	Key	S	C	M	Y	F	P	I	A	U	B	H	T	LPM	L	D	0	0	0	0	0	X
2	0	Channel-Program Address																				
3	CSS Priority	Reserved	CU Priority	Reserved																		
4	Reserved																					
5	Reserved																					
6	Reserved																					
7	Reserved																					
	0 1	8	16	24	31																	

Figure 15-5. Command-Mode Operation-Request Block

The fields in the command-mode ORB are defined as follows:

Interruption Parameter: Bits 0-31 of word 0 are preserved unmodified in the subchannel until replaced by a subsequent START SUBCHANNEL or MODIFY SUBCHANNEL instruction. These bits are placed in word 1 of the interruption code when an I/O interruption occurs and when an interruption request is cleared by the execution of TEST PENDING INTERRUPTION.

Subchannel Key: Bits 0-3 of word 1 form the subchannel key for all fetching of CCWs, IDAWs, MIDAWS, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 3-11.

Suspend Control (S): Bit 4 of word 1 controls the performance of the suspend function for the channel program designated in the ORB. The setting of the S bit applies to all CCWs of the channel program designated by the ORB (see “Commands and Flags for CCWs” on page 15-75).

When bit 4 is one, suspend control is specified, and channel-program suspension occurs when a suspend flag set to one is detected in a CCW. When bit 4 is zero, suspend control is not specified, and the presence of a suspend flag set to one in any CCW of the channel program causes a program-check condition to be recognized.

Streaming-Mode Control (C): Bit 5 of word 1 controls streaming-mode enablement for subchannels configured to FICON-converted-I/O-interface channel paths during performance of the specified start function. When bit 5 is zero, the streaming mode is enabled at the subchannel. When bit 5 is one, the streaming mode is disabled at the subchannel. Bit 5 is meaningful only for subchannels configured to FICON-converted-I/O-interface channel paths and is ignored for subchannels configured to other channel-path types.

When the streaming mode is enabled, the channel path considers the first command of the designated channel program to be in progress at the associated device when the channel path receives the indication that the command has been accepted at the device. In addition, the channel path's acceptance of status, under certain conditions, is recognized by the channel path without receiving acknowledgement of status acceptance from the device.

When the streaming mode is not enabled, the channel path does not consider the first command of the designated channel program to be in progress at the associated device until the appropriate channel-path response, indicating that the device-command response or status has been accepted at the channel path, is sent to the device. In addition, when the device sends status to the channel path, the channel path's acceptance of that status is not recognized at the channel path until the channel path's confirmation of acceptance is received and acknowledged by the device.

Modification Control (M): Bit 6 of word 1 specifies whether modification control is required for the channel program. When bit 6 is zero, modification control is specified. When bit 6 is one, modification control is not specified.

When modification control is specified, the channel subsystem forces command synchronization with the addressed I/O device each time a command is executed and the previously executed command has the PCI and chain-command flags set to one and the chain-data and suspend flags set to zero. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device for the current command. The channel subsystem temporarily suspends command chaining and does not fetch (or refetch) the next command-chained CCW until after normal ending status is received for the synchronizing command.

When modification control is not specified, then command synchronization is not required, and the channel subsystem may transfer commands to the I/O device without waiting for status.

The M bit is meaningful only for subchannels configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and is ignored for other subchannels configured to other channel-path types.

Programming Notes:

1. For FICON-I/O-interface and FICON-converted-I/O-interface channel paths, modification control provides the capability to optimize dynamically modified channel programs that use the PCI flag in the CCW to initiate channel-program modification. Specifically, it allows the program to delay the channel-subsystem fetching and transferring of commands until after status is received for the command following the command with the PCI bit set. This increases the likelihood that a program-controlled interruption will be accepted by a CPU and acted upon by the program that dynamically modifies one or more command-chained CCWs that follow the synchronizing command.

   In order to increase the probability that any dynamically modified CCWs are fetched after their modification and not prior to their modification, the modifying program should be executed as soon as possible following the CPU's acceptance of the program-controlled interruption. Additionally, the program should minimize the periods during which the configured CPUs are disabled for I/O interruptions.

   For channel paths other than FICON-I/O-interface or FICON-converted-I/O-interface channel paths, command synchronization is implicit in the signaling protocol between the channel subsystem and the I/O device; therefore no explicit programming action is required to force command synchronization. Regardless, the program should still attempt to accept and process program-controlled interruptions for these channel-path types in as timely a manner as possible for the same reason as stated above.

2. In order to allow the channel subsystem to optimize the execution of channel programs for FICON-I/O-interface or FICON-converted-I/O-interface channel paths, use of the modification-control facility is discouraged except for channel programs that require dynamic modification.

Synchronization Control (Y): Bit 7 of word 1 specifies whether synchronization control is required for the channel program. When bit 7 is zero and the prefetch-control bit, bit 9 of word 1, is one, synchronization control is specified. When bit 7 is one and bit 9 is one, synchronization control is not specified.

When synchronization control is specified, the channel subsystem forces command synchronization with the addressed I/O device whenever the current command in execution describes an input operation and the next CCW to be fetched describes an output operation. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device when the input command is transferred. The transfer of the output command is held pending at the subchannel until normal ending status, signaling the completion of the performance of the input operation by the I/O device, is received. Upon receipt of the ending status, the channel subsystem fetches (or refetches) the data associated with the output command and transfers it to the I/O device.

When synchronization control is not specified, the channel subsystem may transfer commands of the channel program without awaiting status that would signal the completion of the I/O operation for each command.

The Y bit is meaningful only when the subchannel is configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and the prefetch-control bit, bit 9 of word 1, is one. The Y bit is ignored for subchannels configured to other channel-path types and when the prefetch-control bit is zero.

CCW-Format Control (F): Bit 8 of word 1 specifies the format of the channel-command words (CCWs) that make up the channel program designated by the channel-program-address field. When bit 8 of word 1 is zero, format-0 CCWs are specified. When bit 8 is one, format-1 CCWs are specified. (See "Channel-Command Word" on page 15-31 for the definition of the CCW formats.)

Prefetch Control (P): Bit 9 of word 1 specifies whether or not unlimited prefetching of CCWs is allowed for the channel program. When bit 9 is one, unlimited prefetching of CCWs is allowed. (Unlimited prefetching of data, IDAWs, and MIDAWs, associated with the current and prefetched CCWs is always allowed.) It is model dependent whether prefetching is actually performed.

When bit 9 of word 1 is zero, no prefetching is allowed, except in the case of data chaining on output, where the prefetching of one CCW describing a data area is allowed. When bit 9 of word 1 is zero, the synchronization-control bit, bit 7 of word 1, is ignored.

Additional controls may limit the scope of prefetching.

Initial-Status-Interruption Control (I): Bit 10 of word 1 specifies whether or not the channel subsystem must verify to the program that the device has accepted the first command associated with a start or resume function. When the I bit is specified as one in the ORB, then, when the subchannel becomes active, indicating that the first command has been accepted for this start or resume function, the Z bit (see "Zero Condition Code (Z)" on page 16-12) is set to one at this subchannel, and the subchannel becomes status pending with intermediate status.

If the subchannel does not become active — for example, when the device signals channel end immediately upon receiving the first command, command chaining is not specified in the CCW, and command retry is not signaled — the command-accepted condition (Z bit set to one) is not generated; instead, the subchannel becomes status pending with primary status. Intermediate status may also be indicated in this case when the command is accepted if the first CCW contained the PCI flag set to one.

Address-Limit-Checking Control (A): When the address-limit-checking facility is installed, bit 11 of word 1 specifies whether or not address-limit checking is specified for the channel program. When this bit is zero, no address-limit checking is performed for the execution of the channel program, independent of the setting of the limit-mode bits in the subchannel (see "Limit Mode (LM)" on page 15-3). When this bit is one, address-limit checking is allowed for the channel program, subject to the setting of the limit-mode bits in the subchannel.

When the address-limit-checking facility is not installed, the address-limit-checking-control bit (A) must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Suppress-Suspended-Interruption Control (U): Bit 12 of word 1, when one, specifies that the channel subsystem is to suppress the generation of an intermediate interruption condition due to suspension if the subchannel becomes suspended. When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel becomes suspended during the execution of the channel program.

Channel-Program Type Control (B): Bit 13 of word 1 specifies the type of channel program that is designated by the channel-program-address field. When bit 13 is zero, the channel-program-address field designates a CCW channel program. When bit 13 is one, the channel-program-address field designates a TCW channel program. If the FCX facility is not installed and this bit is one, an operand exception or program-check exception is recognized.

Bit 13 also designates the layout of the ORB. When bit 13 is zero, a command-mode ORB is specified. When bit 13 is one, a transport-mode ORB is specified.

Format-2-IDAW Control (H):
Bit 14 of word 1 specifies the format of IDAWs for CCWs that specify indirect data addressing. When

bit 14 of word 1 is one, format-2 (64-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW. When bit 14 of word 1 is zero, format-1 (31-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW.

Programming Note: Format-2 IDAWs and MIDAWs provide the only means by which data can be transferred directly between an I/O device and storage locations with addresses greater than 2G bytes.

2K-IDAW Control (T): Bit 15 of word 1 specifies the main-storage block size for format-2-IDAW data areas. Bit 15 is meaningful only when bit 14 (format-2 IDAW control) is one and is ignored when bit 14 is zero. When bit 15 of word 1 is one, all format-2 IDAWs designate 2 K-byte storage blocks. When bit 15 of word 1 is zero, all format-2 IDAWs designate 4 K-byte storage blocks.

Logical-Path Mask (LPM): Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, resume, or start functions when requested by the program, except when a dedicated-allegiance condition exists for that channel path. If a dedicated-allegiance condition exists, the setting of the LPM is ignored, and a resume, start, halt, or clear function is performed by using the channel path having the dedicated allegiance.

Incorrect-Length-Suppression Mode (L): When bit 8 of word 1 is one, then bit 24 of word 1, when one, specifies the incorrect-length-suppression mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a nonzero value in bit positions 16-31, indication of an incorrect-length condition is suppressed.

When bit 8 of word 1 is one, then bit 24 of word 1, when zero, specifies the incorrect-length-indication mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a nonzero value in bit positions 16-31, indication of an incorrect-length condition is recognized. Command chaining is suppressed unless the SLI flag in the CCW is one and the chain-data flag is zero.

When bit 8 of word 1 is zero, the value of bit 24 is ignored by the channel subsystem, and the subchannel is in the incorrect-length-suppression mode.

Modified-CCW-Indirect-Data-Addressing Control (D) : When the modified-CCW-indirect-data-addressing facility is installed, bit 25 of word 1 specifies whether the channel program may include CCWs that specify modified-CCW-indirect-data-address lists. When bit 25 of word 1 is one, the channel program may include CCWs that specify lists of quadwords each called a modified-CCW-indirect-data-address word (MIDAW). When bit 25 of word 1 is zero, the channel program may not include CCWs that specify modified-CCW-indirect-data-address lists.

When the modified-CCW-indirect-data-addressing facility is not installed, the modified-CCW-indirect-data-addressing control must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

ORB-Extension Control (X): Bit 31 of word 1 specifies whether the ORB is extended. When bit 31 of word 1 is zero, the ORB consists of words 0-2, and words 3-7 are ignored. When bit 31 of word 1 is one, the ORB consists of words 0-7. Words 0 and 1 are described above. Words 2-7 are described below.

Reserved: Bits 26-30 of word 1 are reserved for future use and must be set to zeros. Bit 31 of word 1 must be zero if the ORB-extension facility is not installed. Otherwise, an operand exception or program-check condition is recognized.

Channel-Program Address: Bits 1-31 of word 2 specify the absolute address of the first CCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized. If format-0 CCWs are specified by bit 8 of word 1, then bits 1-7 of word 2 also must be zeros; otherwise, a program-check condition is recognized.

The three rightmost bits of the channel-program address must be zeros, designating the CCW on a doubleword boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

Channel-Subsystem (CSS) Priority: When bit 31 (X) of word 1 of the ORB is one, byte 0 of word 3 contains an unsigned binary integer, called the channel-subsystem-priority number, that is assigned to the designated subchannel and used to order the selection of subchannels when either a start function or a resume function is to be initiated for one or more subchannels that are start pending or resume pending.

The specified channel-subsystem-priority number can be any number in the range of 0 to 255. The numbers 0 and 255 designate the lowest and highest priorities, respectively.

Depending on the model and the configuration:

1. Fewer than 256 priority levels may be provided. For such models, the ORB-specified priority number may be ignored, and an alternative priority number may be implicitly assigned to the subchannel when the subchannel becomes start pending.

2. When bit 31 (X) of word 1 of the ORB is zero, an implicit priority number is assigned to the subchannel.

See “Channel-Subsystem-I/O-Priority Facility” on page 17-32 for details about how the priority number is assigned for both of these cases.

Control-Unit (CU) Priority: When bit 31 (X) of word 1 of the ORB is one, byte 2 of word 3 contains an unsigned binary integer, called the control-unit-priority number, that specifies, for an associated control unit attached by a FICON channel path, the priority level that is applied at the associated control unit for all I/O operations associated with the start function.

The specified control-unit-priority number can be any integer in the range of 1 to 255. The numbers 1 and 255 designate the lowest and highest priorities, respectively. The number 0 designates that no priority is assigned to the I/O operations associated with the start function. The handling of I/O operations when the priority number is 0 depends on the control-unit model.

Also depending on the control-unit model, fewer than 255 priority levels may be supported by the control unit. See the control-unit's System Library publication for additional information regarding the range of priority numbers supported and how this priority number is used.

The specified control-unit-priority number is ignored if any of the following conditions exists:

1. Bit 31 (X) of word 1 is zero. In this case, a control-unit-priority number of 0 is transmitted in the associated outbound frames.

2. The designated subchannel is not associated with a control unit configured to a FICON channel path.

3. The associated control unit does not provide prioritized performance of I/O operations. In this case, the control-unit-priority number in the associated outbound frames is ignored at the control unit.

4. The channel-subsystem model does not provide for the transmission of the control-unit-priority number.

5. The channel-subsystem-I/O-priority facility is not operational due to an operator action.

Reserved: All fields in the ORB that are defined as either "0" or "Reserved" must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

Programming Notes:

1. Bit positions of the ORB that presently are specified to contain zeros may in the future be assigned for the control of new functions.

2. The interruption parameter may contain any information, but ordinarily the information is of significance to the program handling the I/O interruption.

Transport-Mode ORB

This section describes the transport-mode ORB. The term operation-request block (ORB), in this section, means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is one.

The format of the transport-mode ORB is as follows:

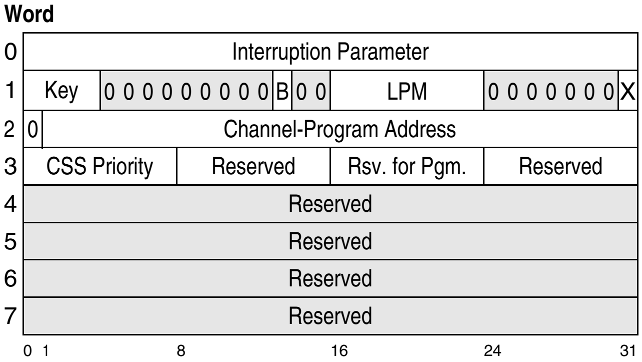

Figure 15-6. Transport-Mode Operation-Request Block

The fields in the transport-mode ORB are defined as follows:

Interruption Parameter: This field has the same meaning as in the ORB that designates a CCW channel program. See “Interruption Parameter” on page 15-2.

Subchannel Key: Bits 0-3 of word 1 form the subchannel key for all fetching of TCWs, TCCBs, TIDAWS, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 3-11.

All storage accesses to the TSB are made as if the subchannel key is zero.

Reserved: All fields in the ORB that are defined as either “0” or “Reserved” must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

Channel-Program Type Control (B): This bit has the same meaning as in the ORB that designates a CCW channel program. For the transport-mode ORB, the value of this bit is one. See “Channel-Program Type Control (B)” on page 15-27.

Logical-Path Mask (LPM): Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, or start functions when requested by the program.

If the LPM specifies a channel path that does not support FCX, either an operand-exception or a program check may be recognized.

ORB-Extension Control (X): This field has the same meaning as in the ORB that designates a CCW channel program. See “ORB-Extension Control (X)” on page 15-28.

Channel-Program Address: Bits 1-31 of word 2 specify the absolute address of the TCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized.

The six rightmost bits of the channel-program address must be zeros, designating the TCW on a 64-byte boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

Channel-Subsystem (CSS) Priority: This field has the same meaning as in the ORB that designates a CCW channel program. See “Channel-Subsystem (CSS) Priority” on page 15-29

Reserved for Program Use (Rsv. for Pgm.): Byte 2 of word 3 is reserved for program use and is not checked or used by the channel subsystem.

Programming Note: See the programming notes on page 29.

Channel-Command Word

The channel-command word (CCW) specifies the command to be executed and, for commands initiating certain I/O operations, it designates the storage area associated with the operation, the action to be taken whenever transfer to or from the area is completed, and other options.

A channel program consists of one or more CCWs that are logically linked such that they are fetched and executed by the channel subsystem in either a sequential or a nonsequential order. Sequential (contiguous) CCWs are linked by the use of the chain-data and chain-command flags, and nonsequential (noncontiguous) CCWs are linked by a CCW specifying the transfer-in-channel command.

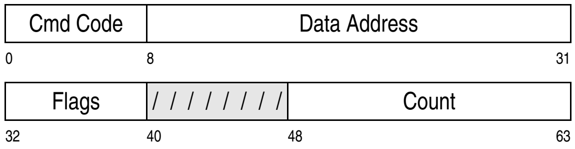
As each CCW is executed, it is recognized as the current CCW. A CCW becomes current (1) when it is the first CCW of a channel program and has been fetched, (2) when, during command chaining, the new CCW is logically fetched, or (3) when, during data chaining, the new CCW takes over control of the I/O operation (see “Data Chaining” on page 15-61). When chaining is not specified, a CCW is no longer current after TEST SUBCHANNEL clears the start-function bit in the subchannel.

The location of the first CCW of the channel program is designated in the ORB that is the operand of START SUBCHANNEL. The first CCW is fetched subsequent to the execution of the instruction. The format of the CCWs fetched by the channel subsystem is specified by bit 8 of word 1 of the ORB. Each additional CCW in the channel program is obtained when the CCW is needed. Fetching of the CCWs by the channel subsystem does not affect those locations in main storage.

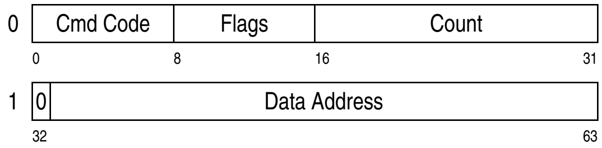
CCWs have either of two different formats, format 0 or format 1. The two formats do not differ in the information contained in the CCW, but they do differ in the size of the address and the arrangement of fields within the CCW.

The formats are defined as follows:

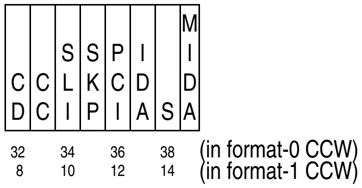
Format-0 CCW



Format-1 CCW



Flags



Format-0 CCWs can be located anywhere in the first 2^{24} (16M) bytes of absolute storage, and format-1 CCWs can be located anywhere in the first 2^{31} (2G) bytes of absolute storage.

If indirect data addressing is specified and the format-2-IDAW-control bit is zero in the ORB associated with the CCW, then:

1. Bits 30 and 31 (format 0) or 62 and 63 (format 1) of the CCW must be zeros, designating a word boundary,
2. Bit 0 of the first entry of the indirect-data-address list must be zero.
3. The MIDA flag must be zero.

If indirect data addressing is specified and the format-2-IDAW-control bit is one in the ORB associated with the CCW, bits 29-31 (format 0) or bits 61-63 (format 1) of the CCW must be zeros, designating a doubleword boundary.

If modified indirect data addressing is specified, then:

1. The modified-CCW-indirect-data-addressing-control bit in the ORB must be one.

2. Bits 28-31 (format 0) or bits 60-63 (format 1) of the CCW must be zeros, designating a quadword boundary.
3. The CCW SKP and IDA flags must be zero.
4. The MIDAW count field must be greater than zero.
5. The combination of the MIDAW count and data-address fields must not specify the transfer of data across a 4 K-byte boundary, unless skipping is in effect for the MIDAW.
6. Reserved bits in the first entry of the modified-CCW-indirect-data-address list must be zero.

When any of these requirements is not met, a program-check condition may be recognized (see "CCW Indirect Data Addressing" on page 15-66 and "Modified CCW Indirect Data Addressing" on page 15-68). Detection of this condition during data chaining causes the I/O device to be signaled to conclude the operation. When a failure to meet these requirements is detected during command chaining or subsequent to the execution of START SUBCHANNEL, the new operation is not initiated, and an interruption condition is generated.

The contents of bit positions 40-47 of a format-0 CCW are ignored.

The fields in the CCWs are defined as follows:

Command Code: Bits 0-7 (both formats) specify the operation to be performed.

Data Address: Bits 8-31 (format 0) or bits 33-63 (format 1) designate a location in absolute storage. The designated location is the first location referred to in the area designated by the CCW. Bit 32 of a format-1 CCW must be zero; otherwise, a program-check condition is recognized. If a byte count of zero is specified, this field is not checked.

When the MIDA flag is one, the data-address field must designate an absolute storage location that is on a quadword boundary; otherwise, a program-check condition is recognized.

See "CCW Indirect Data Addressing" on page 15-66 and "Modified CCW Indirect Data Addressing" on page 15-68 for information about the specification of data addresses greater than 2G bytes.

Chain-Data (CD) Flag: Bit 32 (format 0) or bit 8 (format 1), when one, specifies chaining of data. The bit causes the storage area designated by the next CCW to be used with the current I/O operation. When the CD flag is one in a CCW, the chain-command and suppress-length-indication flags (see below) are ignored.

Chain-Command (CC) Flag: Bit 33 (format 0) or bit 9 (format 1), when one, and when the CD flag and S flag are both zeros, specifies chaining of commands. The bit causes the operation specified by the command code in the next CCW to be initiated upon the normal completion of the current operation.

Suppress-Length-Indication (SLI) Flag: Bit 34 (format 0) or bit 10 (format 1) controls whether an incorrect-length condition is to be indicated to the program. When this bit is one and the CD flag is zero, the incorrect-length indication is suppressed. When both the CC and SLI flags are ones and the CD flag is zero, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified in *all* CCWs where suppression of the incorrect-length indication is desired.

Skip (SKP) Flag: Bit 35 (format 0) or bit 11 (format 1), when one, specifies the suppression of transfer of information to storage during a read, read-backward, sense ID, or sense operation. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

Program-Controlled-Interruption (PCI) Flag: Bit 36 (format 0) or bit 12 (format 1), when one, causes the channel subsystem to generate an intermediate interruption condition when the CCW containing the bit takes control of the I/O operation. When the PCI flag bit is zero, normal operation takes place.

Indirect-Data-Address (IDA) Flag: Bit 37 (format 0) or bit 13 (format 1), when one, specifies indirect data addressing. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

Suspend (S) Flag: Bit 38 (format 0) or bit 14 (format 1), when one, specifies suspension of channel-program execution. When valid, it causes channel-program execution to be suspended prior to the execution of the CCW containing the S flag. A one value of the S flag is valid when bit 4 of word 1 of the associated ORB is one.

Modified-Indirect-Data-Address (MIDA) Flag: Bit 39 (format 0) or bit 15 (format 1), when one, specifies modified indirect data addressing. This bit must be zero when the modified-CCW-indirect-data-addressing-control bit in the ORB is zero, the CCW IDA flag is one, the CCW SKP flag is one, or the channel paths associated with the subchannel do not support modified CCW indirect data addressing; otherwise, a program-check condition is recognized.

Count: Bits 48-63 (format 0) or bits 16-31 (format 1) specify the number of bytes in the storage area designated by the CCW.

Transport Control Word

The transport-control word (TCW) specifies a transport-command-control block (TCCB) whose contents are to be transported to the I/O device for processing. The TCCB contains one or more device-command words (DCWs) and associated options. For a DCW that specifies a command which initiates the transfer of data (with the exception of control data contained within the TCCB), the TCW designates one or more storage areas where the data is located.

When a TCW specifies bidirectional data transfer and the designated DCWs specify write data transfers for storage areas that overlap with the storage areas for read data transfers, the results are unpredictable.

When START SUBCHANNEL is issued specifying a transport-mode ORB, the TCW designated by the ORB becomes the current TCW, the subchannel becomes start pending, and the TCCB designated by the TCW is transported to the I/O device for execution. The TCW remains the current TCW until TEST SUBCHANNEL clears the start-function indication in the subchannel.

The TCW is a 64-byte control block that is designated on a 64-byte boundary. For all operations, except for the interrogate operation, accesses to the TCW by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCW by the channel subsystem are made as if a subchannel storage-access key of zero is used. The channel subsystem does not make any store accesses to a TCW

The format of the TCW is as follows:

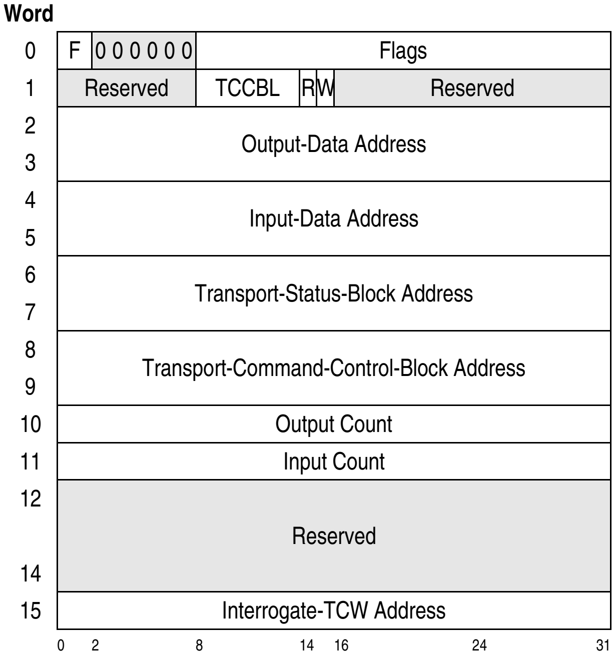


Figure 15-7. Transport-Control Word (TCW)

Format (F): Bits 0-1 of word 0 form the TCW-format that contains a 2-bit unsigned integer value that defines the layout of the TCW. The value of this field must be zero, otherwise a program-check condition is recognized.

Reserved: Bits 2-7 of word 0 are reserved and must be zeros, otherwise a program-check condition is recognized.

Bytes 0 and 2-3 of word 1 and words 12-14 are reserved and not checked. These fields are reserved for future extensions. Programs which place nonzero values in these fields may not operate compatibly on future models.

Flags: Bytes 1-3 of word 0 contain information about the TCW. The meaning of each flag bit is as follows:

Bit ***Meaning***

0-4 Reserved. Bits 0-4 are reserved and must be zero, otherwise a program-check condition is recognized.

5 Input transport-indirect-data addressing (TIDA): When bit 5 is zero and bit 14 of word 1 (the R-bit) is one, the input-data-

address field designates the absolute address of the input location. When bit 5 is one and the R-bit is one, the input-data-address field designates the absolute address of a transport-indirect-data-address word (TIDAW) or the first TIDAW in a list of TIDAWS that designate the input storage location or locations, respectively.

When the R-bit is zero, bit 5 has no meaning.

6 Transport-command-control-block TIDA: When bit 6 is zero, the transport-command-control-block-address field designates the absolute address of the transport-command-control block for the TCW. When bit 6 is one, the transport-command-control-block-address field designates the absolute address of a TIDAW or list of TIDAWs that designate the location or locations, respectively, of the transport-command-control block for the TCW.

7 Output TIDA: When bit 7 is zero and bit 15 of word 1 (the W-bit) is one, the output-data-address field designates an output location in absolute storage. When bit 7 is one and the W-bit is one, the output-data-address field designates the absolute address of a TIDAW or list of TIDAWs that designates the output storage location or locations, respectively.

When the W-bit is zero, bit 7 has no meaning.

8-9 TIDAW format: Bits 8-9 form a 2-bit encoded field that specifies the format of TIDAWs designated by the TCW. This field must contain zeros, otherwise a program-check condition is recognized.

10-23 Reserved. Bits 10-23 are reserved and must be zero, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Length (TCCBL): Bits 8-13 of word 1, with two zeros appended on the right, specify the unsigned integer whose value, when added to 20 for unidirectional data transfers or when added to 24 for bidirectional data transfers, specifies the length of the TCCB in bytes. This field, before having 20 added to it for unidirectional data transfers or before having 24 added to it for bidirectional data transfers, must specify a length that is between 12 and 244 inclusive, otherwise a program-check condition is recognized.

Note: The TCCBL is based on the FCP additional command length and does not include the TCA header (16 bytes), and the transport-count (4 bytes) in the TCA trailer for unidirectional data transfers, nor does it include the write count (4 bytes) and read count (4 bytes) in the TCA trailer for bidirectional data transfers.

Read Operations (R): When bit 14 of word 1 is one, the input count (word 11) is valid and contains a nonzero value, indicating the number of bytes to be transferred into main storage.

Write Operations (W): When bit 15 of word 1 is one, the output count (word 10) is valid and contains a nonzero value, indicating the number of bytes to be transferred from main storage.

If the R-bit and W-bit are both one and the device does not support bidirectional data transfer, and flags bit 10 is zero, a program-check condition is recognized.

If the W-bit is one and the TCW is an interrogate TCW, a program-check condition is recognized.

Output-Data Address: When bit 15 of word 1 (the W-bit) is one and bit 7 of the flags field (the output-TIDA flag) is zero, words 2-3 designate the 64-bit output location in absolute storage. When the W-bit is one and the output-TIDA flag is one, words 2-3 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the output storage location or locations.

When the W-bit is one and the output-TIDA flag is one, words 2-3 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the W-bit is zero, words 2-3 have no meaning and are ignored.

Input-Data Address: When the bit 14 of word 1 (the R-bit) is one and bit 5 of the flags field (the input-TIDA flag) is zero, words 4-5 designate the 64-bit input location in absolute storage. When the R-bit is one and the input-TIDA flag is one, words 4-5 designate the location in absolute storage of a TIDAW or list of TIDAWs that designate the input storage location(s).

When the R-bit is one and the input-TIDA flag is one words 4-5 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the R-bit is zero, words 4-5 have no meaning and are ignored.

Transport-Status-Block Address: Words 6-7 designate the 64-bit location in absolute storage of the transport-status block for the TCW.

Words 6-7 must designate a storage location on an doubleword boundary, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Address: If the transport-command-control-block-TIDA bit (bit 6 of the flags field) is zero, words 8-9 designate 64-bit location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is zero, the transport-command-control block is specified to reside in a contiguous area of storage. If the transport-command-control-block-TIDA bit is one, words 8-9 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is one, the transport-command-control block may be specified to reside in noncontiguous areas of storage.

When the transport-command-control-block-TIDA flag is zero, words 8-9 should designate a storage location on a doubleword boundary, otherwise, degradation of performance is possible.

When the transport-command-control-block-TIDA flag is one:

- Words 8-9 must designate a storage location on a quadword boundary, otherwise a program-check condition is recognized.
- The transport-command-control-block-address and transport-command-control-block-length fields must not specify a list of TIDAWs that cross a 4 K-byte boundary, otherwise a program-check condition is recognized.
- The TIDAW-transfer-in-channel (TTIC) bit should be zero in all specified TIDAWs, otherwise degradation of performance is possible.
- The first TIDAW should designate the TCCB on a doubleword boundary; otherwise, degradation of performance is possible.

.

Output Count: When bit 15 of word 1 (the W-bit) is one, word 10 contains the unsigned integer total count of output bytes for the TCW.

When the W-bit is one and word 10 contains zeros, a program-check condition is recognized.

When the W-bit is one:

- The output-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional data transfers or the value in the write-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.
- The output-count value should equal the sum of the following, otherwise this may lead to a device-detected-program-check condition being recognized.
  - The sum of count field values in all of the DCWs that specify a write command.
  - The sum of the count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 15-42.)
  - The count of any inserted padding and CBC bytes when flags bit 7 (the output-TIDA bit) is one as follows:
    - Four bytes for the CBC information for every TIDAW designated by the output-address field for which the insert-CBC flag bit is one.
    - The count of padding bytes added for every TIDAW designated by the output-address field for which the insert-CBC

flag bit is one. (See “Transport Indirect Data Addressing” on page 15-70.)

When the R-bit is one and word 11 contains zeros, a program-check condition is recognized.

When the W-bit is zero, word 10 is ignored.

Input Count: When bit 14 of word 1 (the R-bit) is one, word 11 contains the unsigned integer total count of input bytes for the TCW.

When the R-bit is one and word 11 contains zeros, a program-check condition is recognized.

When the R-bit is one:

- The input-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional transfer or the value in the read-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.
- The input-count value should equal the sum of count fields in all of the DCWs that specify a read-type command in the associated TCCB and any such DCWs specified in a TCA extension, otherwise this may lead to a device-detected-program-check condition being recognized.

When the R-bit is zero, word 11 is ignored.

Interrogate-TCW Address: When a START SUBCHANNEL designates a TCW, word 15 of the TCW is not checked. When a CANCEL SUBCHANNEL designates a subchannel that is start pending for a TCW channel program and is not status pending, bits 1-31 of word 15 of the TCW designated by START SUBCHANNEL specify the 31-bit location in absolute storage of the interrogate-TCW that is used to initiate an interrogate operation for the subchannel. If word 15 contains zeros when CANCEL SUBCHANNEL is issued, an interrogate operation is not initiated.

When CANCEL SUBCHANNEL is issued, bit 0 of word 15 must be zero, otherwise a program-check condition is recognized with interrogate-failed status indicated. When CANCEL SUBCHANNEL is issued and bits 1-31 of word 15 do not contain zeros, bits 1-31 of word 15 must designate a storage location on a 64-byte boundary, otherwise a program-check condition is recognized with interrogate-failed status indicated.

Transport-Command-Control Block

The transport-command-control block (TCCB) is variable in length, contains header and trailer information, and from 1 to 30 device-command words (DCWs) that are logically linked such that they are executed by the control unit in a sequential manner.

A TCCB may reside as a single block of contiguous storage or it may reside as multiple blocks of noncontiguous storage. The TCCB-TIDA flag specifies whether the TCCB resides in contiguous storage. When the flag is zero, the TCW designates a contiguous TCCB. When the flag is one, the TCW designates one or more TIDAWs that designate the location of the TCCB in noncontiguous storage.

The transport-command-control block is designated on an doubleword boundary and has a maximum length of 264 bytes. For non-interrogate operations, fetch accesses to the TCCB by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCCB by the channel subsystem are made as if a storage-access key of zero is used. The channel subsystem does not make any store accesses to a TCCB nor does it examine its contents.

The format of the TCCB is as follows:

Word	0–31
0 3	Transport-Command-Area Header (TCAH)
4 N	Transport-Command Area (TCA)
N+1 N+2 or N+3	Transport-Command-Area Trailer (TCAT)

Explanation:

The offset of the last word of the TCCB is N+2 for unidirectional data transfers and N+3 for bidirectional data transfers.

Figure 15-8. Transport-Command-Control Block (TCCB)

Transport-Command-Area Header

The transport-command-area header (TCAH) is a 16-byte control block that contains information about the transport-command area and the operations described therein. The TCAH has the following format:

Word (from the beginning of the TCCB)

Word	0	8	16	24–31
0	Format	Reserved		
1	Reserved			TCAL
2	SAC		Reserved	Priority
3	Reserved			

Figure 15-9. Transport-Command-Area Header (TCAH)

Format Control: Byte 0 of word 0 is the TCCB format control. The value of this field must be 7F hex, otherwise a device-detected-program-check is recognized.

Reserved: Byte 1 of word 0 is reserved and must contain zeros, otherwise a device-detected-program-check condition may be recognized. Bytes 2-3 of word 0, bytes 0-2 of word 1, byte 2 of word 2, and bytes 0-3 of word 3 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the future.

Transport-Command-Area Length (TCAL): Byte 3 of word 1 specifies an 8-bit unsigned integer whose value, when reduced by 12, specifies the length of the TCA in bytes. The specified value must be a nonzero multiple of 4 that is between 20 and 252, inclusive, otherwise a device-detected-program-check condition may be recognized.

Service-Action Code (SAC): Bytes 0-1 of word 2 contain an unsigned integer value that must be either 1FFE hex or 1FFF hex. The meanings of these values is device dependent.

Priority: Byte 3 of word 2 contains the 8-bit unsigned binary integer priority value for the TCCB. A value of zero indicates that no priority has been assigned. Valid priority values range from 1, the lowest priority, to 255, the highest priority.

Transport-Command Area

The transport-command area (TCA) is a variable-length area that contains from 1 to 30 device-command words (DCWs). The length of the TCA is an in integral number of words.

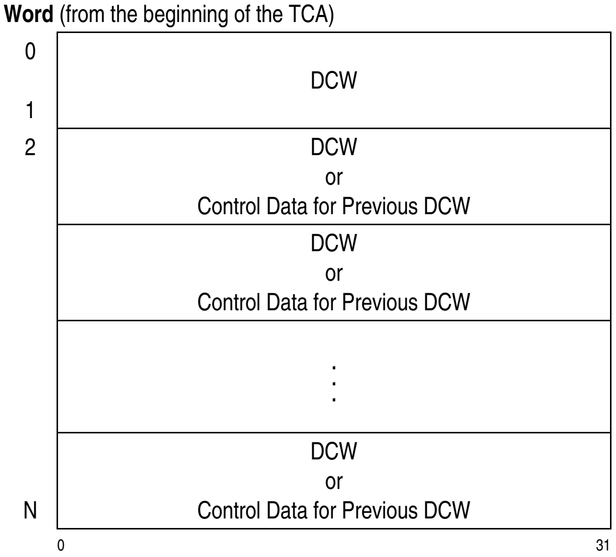
For DCWs that specify control data, the TCA also contains the control data associated with the commands. Each DCW that specifies control data, reduces the maximum-DCW capacity by one or more DCWs, depending on the size of the command-associated data.

For DCWs that specify input or output data, the TCW specifying the TCCB designates the associated storage area or areas (see “Input-Data Address” on page 15-34 and “Output-Data Address” on page 15-34) and the DCW designates the count of bytes to transfer.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as if it were output data; however, the TCAX is treated as a logical continuation of the TCA instead of transfer data. (See “Transport-Command-Area Extension” on page 15-45.) A TCAX is specified by the transfer-TCA-extension DCW. (See “Transfer-TCA-Extension DCW” on page 15-44.)

Whether a device supports TCA extensions is determined by device-dependent means.

The maximum size of the TCA is 240 bytes. The TCA has the following format:



Word (from the beginning of the TCA)
0
1
DCW
2
DCW
or
Control Data for Previous DCW
DCW
or
Control Data for Previous DCW
⋮
DCW
or
Control Data for Previous DCW
N
0
31

Figure 15-10. Transport-Command Area (TCA)

Device-Command Word

A device-command word (DCW) specifies a command to be executed. For commands initiating certain I/O operations, it designates the count of bytes on which the operation is performed, the action to be taken whenever transfer to or from storage is completed, and other options. The storage area or areas associated with a DCW data-transfer operation are designated, depending on the operation specified by the command, by the input-data-address field or the output-data-address field of the TCW that designates the transport-control-block containing the DCW. Whether the input-data-address field or the output-data-address field of the TCW designates the storage directly or indirectly, by use of a TIDAW list, is specified by the input-TIDA and output-TIDA flags in the TCW, respectively.

For commands initiating control operations, the associated data immediately follows the command. If this data is not a multiple of 4 bytes, the field immediately following the data begins on the next word boundary that immediately follows the last byte of specified data. In the TCA, this field will be either the next DCW, if additional DCWs are specified, or the transport-command-area trailer, if additional DCWs are not specified. When the DCW is in a transport-command-area extension (TCAX), this field will be one of the following:

- The next DCW when additional DCWs are specified.
- The TCAX reserved area when present, and additional DCWs are not specified.
- The end of the TCAX when the TCAX reserved area is not present and additional DCWs are not specified.

As each DCW is executed and while it is executing it is recognized as the current DCW. A DCW becomes current when it is the first DCW of a channel program and has been selected by the I/O device for execution or when, during command chaining, the subsequent DCW takes over control of the I/O operation.

The first DCW to be executed is at offset zero of the TCA in the TCCB. Each additional DCW in the channel program is also in the TCA and is used when the DCW is needed by the I/O device.

The DCW is an 8-byte control block that is designated on an word boundary. The format of the DCW is as follows:

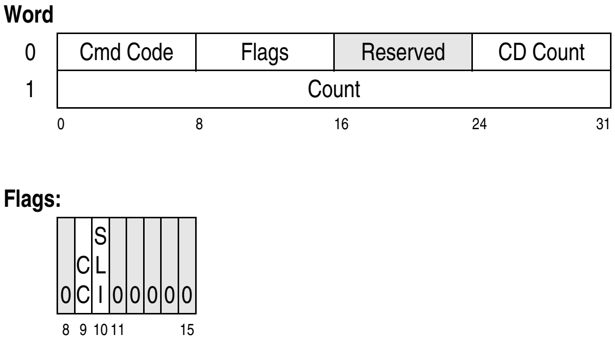


Figure 15-11. Device-Command Word (DCW)

Command Code : Bits 0-7 of word 0 specify the operation to be performed.

Whether a command is valid is device dependent and dependent on the value of the service-action-code field in the TCAH.

Reserved: Bits 8, 11-15, and 16-23 of word 0 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the future. When the FCX-incorrect-length-indication facility is not installed or the device does not support incorrect-length indication, bit 10 of word 0 is reserved and should contain zero, otherwise the channel program may not operate compatibly in the future.

Chain-Command (CC) Flag: Bit 9 of word 0, when one, specifies the chaining of commands. When one, the bit causes the operation specified by the next DCW to be initiated upon normal completion of the current DCW. When the control-data count is zero, the next DCW immediately follows the DCW in the TCA or TCAX. When the control-data count is not zero, the next DCW immediately follows the control-data, rounded to a word boundary, specified for the DCW.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCA and a TCAX is not specified, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCAX, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is zero in a DCW whose offset, plus 8, plus its control-data-count value leaves greater than 3 bytes remaining in the TCA, a device-detected-program-check condition may be recognized.

Note: When the chain-command flag is one, the next DCW location in the TCA or TCAX is determined by adding eight and the value in the CD-count field to the location of the current DCW and rounding upwards to the nearest word boundary. If the chain-command flag is one in a DCW in a TCA, the next DCW location is past the end of the TCA, and a TCAX is specified, the next DCW is at the beginning of the TCAX.

Suppress-Length-Indication (SLI) Flag: When the FCX-incorrect-length-indication facility is installed and the device supports incorrect-length indication, bit 10 of word 0 controls whether an incorrect-length condition is to be indicated to the program when the condition is recognized for the DCW in control as follows:

- When the SLI flag is one, incorrect-length indication is suppressed. When both the CC and SLI flags are ones, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified as one in *all* DCWs where suppression of the incorrect-length indication is desired.
- When the SLI flag is not one, processing of the TCA is terminated (command-chaining is terminated) and the subchannel is made status pending with incorrect length indicated in the subchannel status.

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set to zero, data transfer occurs as follows for read operations:

- If the DCW count is greater than the amount of data available at the device for the command, the data available at the device is transferred.
- If the DCW count is less than the amount of data available at the device for the command, only an amount of data equal to the DCW count is transferred

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set one, data transfer occurs as follows for read operations:

- If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:
  1) The data available at the device is transferred.
  2) Pad bytes of zeros are transferred until the total amount transferred is equal to the DCW count.
- If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:
  1) The data available at the device is transferred
  2) Depending on the device, either data transfer is terminated or pad bytes of zeros are transferred until the total amount transferred is equal to the DCW count.

- If the DCW count is less than the amount of data available at the device for the command, only an amount of data equal to the DCW count is transferred

When an incorrect-length condition exists for a DCW, data transfer occurs as follows for write operations regardless of the setting of the SLI flag:

- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:
  1) The data required by the device is transferred.
  2) Data continues to be transferred until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.
- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:
  1) The data required by the devices is transferred.
  2) Data continues to be transferred until the next intermediate CBC is specified to be inserted or until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.
- For write operations, if the DCW count is less than the amount of data required by the device for the command, only the amount of data specified by the DCW count is transferred.

Whether a device supports the suppression of incorrect-length indication is determined by device-dependent means.

Control-Data (CD) Count: When the command-code field specifies a command that requires control data, the data for the command immediately follows the DCW and byte 3 of word 0 specifies the length of the data, in bytes. If the command code specifies a command that requires control data and byte 3 of word 0 specifies a control-data count that is less than required for the command a unit-check condition is recognized. If the command code specifies a command that requires control data and byte 3 of word 0 contains zero or contains a value that specifies data past the end of the TCA or past the end of the specified TCAX, a device-detected-program-check condition is recognized.

Count: Word 1 specifies the 32-bit unsigned integer count of bytes in the storage area designated by the TCW for this DCW.

Transport-Command-Area Trailer

The transport-command-area trailer (TCAT) contains additional information about the TCCB. When uni-directional data transfer is specified (either the R-bit or the W-bit is set to one) or no data transfer is specified (both the R-bit and W-bit in the TCW are set to zero), the TCAT is two words in length. When bidirectional data transfer is specified (both the R-bit and the W-bit in the TCW are set to one), the TCAT is three words in length. The TCAT has the following format:

Word (from the beginning of the TCA trailer)

Word	0 … 31
0	Reserved
1	Transport Count or Write Count
2	Not Present or Read Count

Figure 15-12. Transport-Command-Area Trailer (TCAT)

Reserved: Word 0 is reserved and not checked.

Transport Count: When uni-directional data transfer is specified, word 1 is the transport count and specifies the 32-bit unsigned integer count of total data to be transferred.

When a read operation is specified (the TCW R-bit is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a read-type command are summed.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

When a read operation is specified, the transport-count value should be equal to the value in the TCW input-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

When a write operation is specified (the W-bit in the TCW is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.
- The count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI are added to the sum. (Note that the size of a TCMI reserved field may be zero. See "Transport-Command DCW" on page 15-42.)
- The total of the counts of any TIDAW-specified CBC bytes and padding bytes (see "Transport Indirect Data Addressing" on page 15-70) is added to the sum.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

When a write operation is specified, the transport-count value should be equal to the value in TCW output-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

When neither a read nor a write operation is specified (both the W-bit and R-bit in the TCW are zero), the transport count value should be zero, otherwise this may lead to a device-detected-program-check condition being recognized.

Write Count: When bidirectional data transfer is specified, word 1 is the write count and specifies the 32-bit unsigned integer count of total output data to be transferred. The value in the write-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.
- The count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI are added to the sum. (Note that the size of a TCMI reserved field may be zero. See "Transport-Command DCW" on page 15-42.)
- The total of the counts of any TIDAW-specified CBC bytes and padding bytes (see "Transport Indirect Data Addressing" on page 15-70) is added to the sum.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

The write-count value should be equal to the value in TCW output-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

Read Count: When uni-directional data transfer is specified the read count field is not present. When a bidirectional data transfer is specified, word 2 is the read count and specifies the 32-bit unsigned integer count of total input data to be transferred. The value in the read-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a read-type command are summed.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

The read-count value should be equal to the value in the TCW input-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

Programming Note: The following table summarizes the determination of the TCW input-count, output-count, and the TCCB transport count values for unidirectional data transfers:

Operation	TCW Input Count	TCW Output Count	TCAT Transport Count
Input operation (TCW R-bit is 1)	Sum of DCW count values in the TCA.	n/a	Sum of DCW count values in TCA, rounded to four,[2] plus four[2]
Output operation (TCW W-bit is 1), TIDAWS not used (TCW output-TIDA flag is 0)	n/a	Sum of DCW count values in TCA.	Sum of DCW count values in TCA, rounded to four,[2] plus four[2]
Output operation (TCW W-bit is 1), TIDAWS used (TCW output-TIDA flag is 1)	n/a	Sum of DCW count values in TCA and TCAX plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes [1]	Sum of DCW count values in TCA and TCAX, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes,[1] rounded to four,[2] plus four[2]

Explanation:

[1] See the description of the insert-CBC control in “Flags” on page 15-70.

[2] The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.

[3] Because of alignment requirements, the size of the reserved area in a TCMI is either 0 or 4.

Figure 15-13. Determination of the TCAT Transport Count, TCW Input Count, and TCW Output Count for Uni-Directional Data Transfers

The following table summarizes the determination of the TCW input-count, output-count, and the TCCB read and write count values for bidirectional data transfers:

Operation	TCW Input Count	TCW Output Count	TCAT Read Count	TCAT Write Count
Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWS not used (TCW output-TIDA flag is 0)	Sum of read DCW count values in the TCA and TCAX.	Sum of write DCW count values in the TCA, plus count values in DCWs that specify the transfer of TCMI	Sum of read DCW count values in the TCA and TCAX, rounded to four,[2] plus four[2]	Sum of write DCW count values in the TCA, plus count values in DCWs that specify the transfer of TCMI, rounded to four,[2] plus four[2]
Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWS used (TCW output-TIDA flag is 1)	Sum of read DCW count values in the TCA and TCAX.	Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCMI, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes.[1]	Sum of read DCW count values in the TCA and TCAX, rounded to four,[2] plus four[2]	Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCMI, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes,[1] rounded to four,[2] plus four[2]

Explanation:

[1] See the description of the insert-CBC control in “Flags” on page 15-70.

[2] The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.

[3] Because of alignment requirements, the size of the reserved area in a TCMI is either 0 or 4.

Figure 15-14. Determination of the TCAT Transport Count, TCW Input Count, TCAT Read Count, and TCAT Write Count for Bidirectional Data Transfers

Transport-Command DCW

A transport-command DCW specifies a transport command that performs a device-support function associated with transport-mode operations. (See “Command Code” on page 15-57.) A transport-command DCW may specify control data and may also specify the transfer of transport-command-meta information (TCMI).

When a transport-command DCW specifies the transfer of TCMI to a device, the TCMI is transferred as output data. The size of the TCMI is command-dependent and is a multiple of 4. Furthermore, the TCMI may be extended by 4 reserved bytes when all of the following are true:

- The size of the TCMI is an even multiple of 4.
- TIDAWs are used to specify the output storage areas.
- The insert-CBC flag is one in the last TIDAW used to specify the storage containing the TCMI.
- The chain-command bit is one in the transport-command DCW that specifies the TCMI.
- A subsequent DCW specifies the transfer of a TCMI or output data.

Note that when a transport command specifies the transfer of a TCMI to a device and the TCMI is extended by 4 reserved bytes because all of the preceding conditions are met, the 4 reserved bytes are not included in the data-count value in the transport-command DCW but are included in the following:

- The count value in the last TIDAW used to specify the storage containing the TCMI.
- The output-count value in the TCW.
- The transport-count value in the associated TCCB for unidirectional data transfers or the write-count value in the associated TCCB for bidirectional transfer.

The following summarizes the transport-command DCWs and identifies the specific TCMI that may be transferred to the device:

Transport-Command DCW	Transport-Command-Meta Information (TCMI)	Page
Transfer-CBC-Offset Block TCOB_	CBC-Offset Block (COB)	15-43
Transfer-TCA Extension (TTE)	TCA Extension (TCAX)	15-44
Interrogate	(none)	15-46
Explanation: (none) - The transport-command DCW does not transfer TCMI.		

Figure 15-15. Summary of Transport-Command DCWs

Transfer-CBC-Offset-Block DCW

For write operations, the transfer-CBC-offset-block (TCOB) DCW specifies that a CBC-offset block (COB) is transported to the device. The content of the TCOB DCW is as follows:

- The command code contains the transfer-CBC-offset-block command which is a value of 60 hex.
- The chain-command flag is one.
- When the CD-count is not zero, the COB immediately follows the TCOB DCW in the TCA and the CD-count specifies the number of CBC offsets in the COB multiplied by 4.
- When the CD-count is zero, the COB is specified as TCMI in the output data, the location of the COB is specified by the output-data-address field in the TCW, and the count field specifies the number of CBC offsets in the COB multiplied by 4.

The incorrect-length condition is not recognized for the transfer-CBC-offset-block command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

When a TCOB DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- A TCOB DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- A TCOB DCW is the only DCW in the TCA. (That is the chain-command flag in the TCOB DCW is zero.)
- A TCOB DCW is not the first DCW in the TCA.
- More than one TCOB DCW is specified
- The control-data-count field and the count field in the TCOB DCW both contain the value zero or both contain a value that is nonzero.
- The control-data-count field contains the value zero, the count field contains a value that is nonzero, but the value in the count field is not a multiple of 4.
- The count field contains the value zero, the control-data-count field contains a value that is nonzero, but the value in the control-data-count field is not a multiple of 4.

When a TCOB is used that specifies the COB in the output data, the following must be true; otherwise, a device-detected program check may be recognized:

- The output-TIDA flag (flags bit 7) in the TCW must be one.
- The insert-CBC control must be set to one in the last or only TIDAW that is used to transfer the COB when the transfer of a TCAX or output data or both is also specified.
- When there is an odd number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4. When there is an even number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4, plus 4.

Whether a device recognizes the TCOB command is determined by device-dependent means.

CBC-Offset Block

The CBC-offset block (COB) is a variable-length control block that contains a list of 4-byte entries, each of which identifies the offset of a CBC specified by a TIDAW to be inserted in the output data. When the COB is specified in the output data, the offset of the CBC inserted by the TIDAW that specifies the transfer of the COB is not included in the COB.

Accesses to a CBC-offset block by the channel subsystem are treated as if a storage-access key of zero is used.

The COB has the following format:

4-Byte Entry

0	CBC Offset 0
1	CBC Offset 1
2 ⋮	. . .
N	CBC Offset *N*

Figure 15-16. CBC-Offset Block (COB)

⋮ *Y*	Reserved (When the COB is in output data.)	
	0	31

Explanation:
- The size of the COB is 4(*N*+1) when the COB is specified in the TCA. (There is no reserved field for this case.)
- The size of the COB is 4(*Y*+1) when the COB is specified in the output data, where *Y* is an even number that is equal to either *N* or *N*+1.

Figure 15-16. CBC-Offset Block (COB) (Continued)

CBC Offsets: Entries 0 through *N* contain CBC offsets. Each CBC offset is a 4-byte field containing a 32-bit unsigned integer value that specifies the relative offset, from the beginning of the output-data area, to a CBC that is specified to be inserted by a TIDAW. When a COB is in the TCA, the beginning of the output-data area is specified by the output-data-address field of the TCW. When a COB is in the output-data, the output-data area begins immediately after the COB.

Reserved: When a COB is specified in the TCA, or a COB is specified in the output data and there is an odd number of CBC offsets in the COB, there are no reserved bytes.

When a COB is specified in the output data and there is an even number of CBC offsets in the COB, the 4 bytes immediately following the last CBC offset are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 15-42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCCB write-count (for bidirectional transfers) and TCCB transport count (for unidirectional data transfers).

Programming Note: When a device indicates that it supports the TCOB command and TIDAWs are used that specify insert-CBC, a TCOB and COB should be used; otherwise, unpredictable results or errors may result.

Transfer-TCA-Extension DCW

The transfer-TCA-extension (TTE) DCW specifies that the TCA is logically extended in the output data and that the TCA extension (TCAX) is transported to the device. The content of the TTE DCW is as follows:

- The command code contains the transfer-TCA-extension command which is the value of 50 hex.
- The chain-command flag is set to one.
- The CD-count is zero.
- The count specifies the length of the TCAX as a multiple of 4.

The incorrect-length condition is not recognized for the transfer-TCA-extension command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

When a TTE DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- When a TCOB DCW is not specified, the TTE DCW is not the first DCW in the TCA. When a TCOB DCW is specified, the TTE DCW is not the second DCW in the TCA.
- The TTE DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- The chain-command flag in the TTE DCW is zero.
- More than one TTE DCW is specified
- The control-data-count field in the TTE DCW does not contain zero.
- The count field contains less than 8 or a value that is not a multiple of 4.
- Any of the following are true for the TCA:
  - The TCA does not contain at least one DCW that is not a transport-command DCW.
  - The TCA contains one or more DCWs that are not transport-command DCWs and the chain-command flag in the last DCW of the TCA is zero.

Whether a device recognizes the TTE command is determined by device-dependent means.

Programming-System Note: When a TTE DCW is used and additional TCMI and/or output data follows the TCAX, the following should be true; otherwise, a device-detected program check may be recognized:

- The output-TIDA flag (flags bit 7) in the TCW must be one.
- When TIDAWs are used for the transfer of a TCAX and for the transfer of data, the insert-CBC control must be set to one in the last or only TIDAW that is used to transfer the TCAX. When TIDAWs are used for the transfer of only the TCAX, it is not necessary to set the insert-CBC control in the last or only TIDAW.

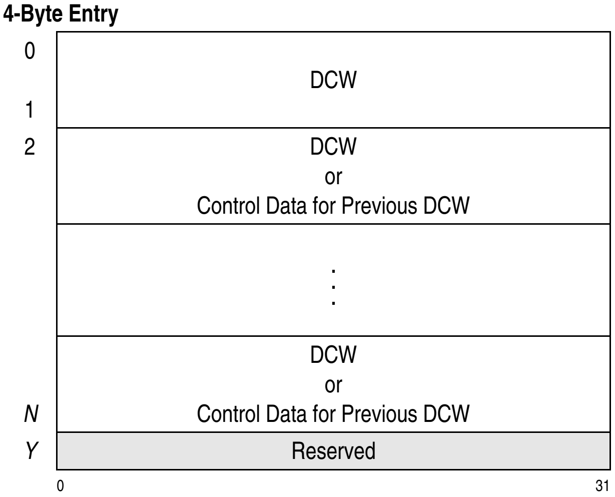
Transport-Command-Area Extension

The transport-command-area extension (TCAX) is a variable-length area that is the logical continuation of the TCA. At a minimum, the TCAX contains one DCW. The length of the TCAX is an integral multiple of 4 and is specified by the TTE DCW.

For DCWs that specify control data, the TCAX also contains the control data associated with the commands.

For DCWs that specify input or output data, the associated TCW designates the associated storage area or areas (see “Input-Data Address” on page 15-34 and “Output-Data Address” on page 15-34) and the DCW designates the count of bytes to transfer.

The maximum size of the TCAX is device dependent. The TCAX has the following format:



Explanation:

The size of the TCAX is 4(*Y*+1), where *Y* is an even number that is equal to either *N* or *N*+1.

Figure 15-17. Transport-Command Area Extension (TCAX)

Device-Command Word (DCW) or Control Data for Previous DCW: For information about DCWs and control data, see “Device-Command Word” on page 15-38.

Reserved: When the last information in the TCAX is a DCW, the end of the DCW defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data ends on a 4-byte boundary, the end of the control data defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data does not end on a 4-byte boundary, padding bytes are appended to the control data to reach a 4-byte boundary and the end of the padding bytes define the end of the meaningful information in the TCAX.

When the size of the meaningful information in the TCAX divided by four is an odd number, there are no reserved bytes; otherwise, the four bytes immediately following the meaningful information in the TCAX are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 15-42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCAT write-count (for bidirectional transfers) and TCAT transport count (for unidirectional data transfers).

Interrogate TCCB

The interrogate TCCB is a TCCB that specifies a service-action code value of 1FFF hex, contains a TCA that is at least 8 bytes in length that specifies an interrogate DCW, and may specify a read operation.

Any data that immediately follows the interrogate DCW and is specified by a nonzero CD-count in the interrogate DCW is transported to the device and may be written to a device-dependent log. Any input data that is specified by the interrogate TCW is device-dependent data and is transferred from the I/O device.

Accesses to the interrogate TCCB by the channel subsystem are treated as if a storage-access key of zero is used.

The format of the interrogate TCA is as follows:

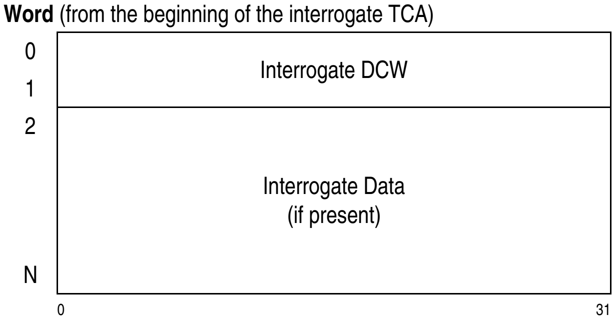


Figure 15-18. Interrogate Transport-Command Area (TCA)

Interrogate DCW

Words 0 and 1 of the interrogate TCA contain a DCW that specifies an interrogate operation. The content of the interrogate DCW is as follows:

- The command code contains the interrogate command which is a value of 40 hex.
- The CD-count field must contain a value that is not greater than 232, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.
- With the exceptions of the command code, SLI flag, count and CD-count fields, all other fields in the DCW must contain zeros, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The incorrect-length condition is not recognized for the interrogate command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

Interrogate Data

If the CD-count of the interrogate DCW is greater than zero, interrogate data is specified. Since interrogate data is for device-dependent logging purposes only, interrogate data that is incorrectly specified does not cause any exception condition to be recognized. The interrogate data has the following format:

Word (from the beginning of the interrogate data)

0	Format	RC	RCQ	LPM
1	PAM	PIM	Timeout	
2	Flags	Reserved		
3	Reserved			
4 5	Time			
6 7	Program Identifier			
8 N	Program-Dependent Data			
	0	8	16	24 31

Figure 15-19. Interrogate Data

Format: Byte 0 of word 0 contains the unsigned integer value that defines the layout of the interrogate data. The value of this field should be zero, otherwise the I/O device may not recognize the layout of the interrogate data

Reason Code (RC): Byte 1 of word 0 contains the unsigned integer value that indicates the reason the interrogate operation was initiated. The following values may be specified. The meaning of RC values is as follows:

Value	***Meaning***
0	Interrogate reason not specified.
1	Timeout: Program-detected timeout for the operation being interrogated.
2-255	Reserved.

Reason-Code Qualifier (RCQ): Byte 2 of word 0 contains the unsigned integer value that indicates additional information about the reason the interrogate operation was initiated.

When the reason-code field contains the value one, the meaning of RCQ values are as follows:

Value	***Meaning***
0	Interrogate reason qualifier not specified.
1	Primary: The timeout was specified by the primary program.
2	Secondary: The timeout was specified by a secondary program.
3-255	Reserved.

When the reason-code field does not contain the value one, the reason-code-qualifier field has no meaning.

Logical-Path Mask (LPM): Byte 3 of word 0 contains the LPM that was used when the operation being interrogated was initiated by START SUBCHANNEL.

Path-Available Mask (PAM): Byte 0 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

Path-Installed Mask (PIM): Byte 1 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

Timeout: When the RC field contains the value one or two, bytes 2-3 of word 1 contain the timeout interval used by the designated program, in unsigned integer seconds.

Flags: Byte 0 of word 2 contains information about the interrogate. The meaning of each flag bit is as follows:

Bit	***Meaning***
0	Multipath mode: This bit has the same setting as the multipath-mode bit (D) at the time the interrogate operation is initiated.
1	Program path recovery: The interrogate is issued during path recovery by the program.
2	Critical: The device is a critical device for the program.
3-7	Reserved.

Reserved: Bytes 1-3 of word 2 and word 3 are reserved.

Time: Words 4-5 contain the time the interrogate operation was initiated.

Program Identifier: Words 6-7 identify the program initiating the interrogate operation. The content of this field is program dependent.

Program-Dependent Data: Words 8-N contain program-dependent information.

Programming Notes:

1. It is assumed that the program will specify the value in the time field as UTC in the same form as the TOD clock.
2. If the interrogate operation does not complete within a model-dependent amount of time, an interface-control check condition is recognized, terminating the I/O operation being interrogated.
3. If a timeout value is specified and the timeout value is less than a device-dependent minimum, the I/O device may not write the interrogate data into its log.

Transport Status Block

When the TSB-valid bit in the IRB is one, the transport-status block (TSB) for the I/O operation may contain additional information about the completion of the associated TCW channel program. When the interrogate-complete (Q) bit in the IRB is one, the interrogate TSB may contain interrogate data.

The TSB is 64 bytes in length and is allocated on a doubleword boundary. Accesses to the TSB by the channel subsystem are treated as if a storage-access key of zero is used.

The format of the TSB is as follows:

Word	
0 2	Transport-Status Header
3 15	Transport Status Area
	0 31

Figure 15-20. Transport-Status Block

Transport-Status Header (TSH)

The transport-status header is a 12-byte control block that contains information about the transport status. The format of the TSH is as follows:

Word (from the beginning of the TSB)			
0	Length	Flags	DCW Offset
1	Count		
2	Reserved		
	0	8	16 31

Figure 15-21. Transport-Status Header (TSH)

Length: Byte 0 of word 0 contains the unsigned binary integer length, in bytes, of the status information stored in the TSB. This length includes the TSH and the transport-status area (TSA), if present. If this value is less than 64, the difference between the length value and 64 specifies the number of bytes, at the end of the TSB, that are not used, have no meaning, and may or may not be stored.

Flags: Byte 1 of word 0 contains information about the TSB. The meaning of each flag bit is as follows.:

Bit ***Meaning***

0 DCW-offset field valid. When bit 0 is one, the DCW-offset field contains a DCW-offset value. When bit 0 is zero, the DCW-offset field has no meaning.

1 Count field valid. When bit 1 is one, the count field contains a count value. When bit 1 is zero, the count field has no meaning.

2 Cache miss. When flag bits 4-7 specify an I/O-status TSB and bit 2 is one, one or more I/O-device cache misses occurred during the I/O operation. When flag bits 4-7 specify an I/O-status TSB and bit 2 is zero, no cache misses occurred.

When flag bits 4-7 do not specify an I/O-status TSB, bit 2 is reserved.

3 Time fields valid. When flag bits 4-7 specify an I/O-status TSB and bit 3 is one, the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA contain time information. When flag bits 4-7 specify an I/O-status TSB and bit

3 is zero, the contents of the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA have no meaning.

When flag bits 4-7 do not specify an I/O-status TSB, bit 3 is reserved.

4 Reserved.

5-7 TSA format. Bits 5-7 form a 3-bit unsigned integer that indicates the layout of the TSA as follows:

Value	***Meaning***
0	TSA contents have no meaning: The other fields of the TSA do not contain meaningful data.
1	I/O Status TSA: The TSA contains ending status in addition to ending status in the IRB for the I/O operation.
2	Device-detected-program-check TSA: The TSA contains information describing the reason for the device-detected program check
3	Interrogate TSA: The TSA contains interrogate response information
4-7	Reserved.

DCW Offset: When bit 0 of the flags field (the DCW-offset-field-valid bit) is one and the DCW-offset value is less than the size of the TCA, bytes 2-3 of word 0 contain the byte offset, from the beginning of the TCA to the DCW either partially or completely executed when the TSB is stored. When bit 0 of the flags field is one and the DCW-offset value is greater than or equal than the size of the TCA, the value in bytes 2-3 of word 0 minus the size of the TCA is the offset, from the beginning of the TCAX to the DCW either partially or completely executed when the TSB is stored.

If the channel program cannot be completed, this offset identifies the DCW for which processing could not be completed. Additional information in the IRB and TSB may be used for recovery purposes. When bit 0 of the flags field is zero, bytes 2-3 of word 0 have no meaning.

Count: When bit 1 of the flags field (the count-field-valid bit) is one, word 1 contains the residual count for the DCW designated by the DCW-offset field.

Reserved: Word 2 is reserved and contains zeros.

Programming Note: If the program sets the length and flags fields to zeros before initiating an operation, the program can determine whether the TSB contains meaningful information after the operation completes by checking that both the length and flags field contain nonzero values.

I/O-Status TSA

When the TSB-format field in the TSH contains one, the TSA has the following format:

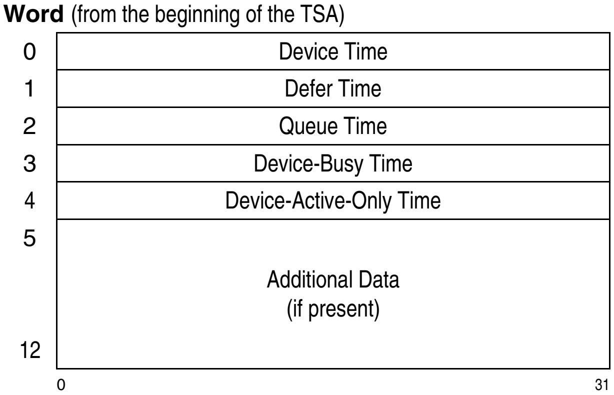

Figure 15-22. I/O-Status Transport-Status Area (TSA)

Device Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 0 contains the 32-bit unsigned integer total count of time intervals between when the I/O device received the information in the TCCB until the I/O device returned the information in the TSB. The resolution of the device time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 0 have no meaning.

Defer Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 1 contains the 32-bit unsigned integer total count of time intervals that the I/O operation was temporarily delayed by the I/O device to perform device-dependent operations or other operations not associated with the current channel program. The resolution of the defer time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 1 have no meaning.

Queue Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 2 contains the 32-bit unsigned integer total count of timer intervals that the I/O operation or portions of the operation were queued at the control unit while waiting for operations not associated with the current operation to complete. The resolution of the queue time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 2 have no meaning.

Device-Busy Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 3 contains the 32-bit unsigned integer total count of time intervals that the I/O device was busy attempting to initiate a command. The resolution of the device-busy time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 3 have no meaning.

Device-Active-Only Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 4 contains the 32-bit unsigned integer total count of time between the time that the channel-end condition existed and the time that the channel-end and device-end conditions were recognized by the device. The resolution of the device-active time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 4 have no meaning.

Additional Data: When the length field in the TSH contains a value greater than 32, additional data has been provided by the I/O device. The count of meaningful additional-data bytes in this field is determined by subtracting 32 from the value in the length field.

When unit check is included in the device status, any additional data provided is sense data. When unit check is not included in the device status, any additional data provided is device dependent.

Device-Detected-Program-Check TSA

When the TSB-format field in the TSH contains two, the TSA has the following format:

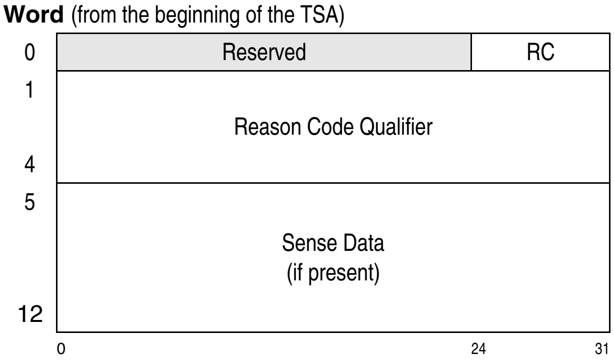

Figure 15-23. Device-Detected-Program-Check Transport-Status Area (TSA)

Reserved: Bytes 0-2 of word 0 are reserved and have no meaning.

Reason Code (RC): Byte 3 of word 0 contains an 8-bit unsigned integer code that indicates the primary reason for the device-detected program check. The meaning of each reason code value is as follows:

Value Meaning

0 No information: Byte 3 has no meaning.

1 TCCB transport failure: An invalid CBC was detected by the I/O device while transporting the TCCB. The reason-code-qualifier (RCQ) field contains additional information.

2 Invalid CBC detected on output data: An invalid CBC was detected while transferring output data. The RCQ field contains additional information.

3 Incorrect TCCB length specification: The RCQ field contains additional information.

4 TCAH specification error: The RCQ field contains additional information.

When a TCAH specification error is recognized, pre-existing allegiance conditions are not cleared.

5 DCW specification error: There is an error with the DCW designated by the

DCW-offset field in the TSH. The RCQ field contains additional information.

6 Transfer-direction specification error: The command specified by the DCW designated by the DCW-offset field in the TSH specifies a direction of data transfer that disagrees with the transfer direction specified in the TCW, or both the read-operation (R) and write-operation (W) bits in the TCW are set to one and the device does not support bidirectional data transfers. The RCQ field contains additional information.

7 Transport-count specification error: The RCQ field contains additional information.

8 Two I/O operations active: While an I/O operation is active at the device a second non-interrogate TCCB has been transported to the device for execution. The RCQ field has no meaning.

9 CBC-offset specification error: One or more CBC offsets in the CBC-offset block indicate that a CBC is at a location that is not recognized by the device or is not recognized for the designated DCW. The RCQ field contains additional information.

10-255 Reserved.

For a summary of the meanings of reason-code values and their associated reason-code-qualifier values see Figure 15-24 on page 15-54.

Reason Code Qualifier (RCQ): Words 1-4 may contain additional information about the reason for the device-detected program check as follows.

When the RC field contains the value one, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 TCCB transport size error: The value of the TCCBL field of the TCW that was sent to the I/O device is not equivalent to the count of bytes actually transported for the TCCB.

2 TCCB CBC error: An invalid CBC was detected while transferring the TCCB.

3-255 Reserved.

When the RC field contains the value two, only words 0-1 of the RCQ field have meaning as follows:

Value Meaning

0 Word 0 contains the 32-bit unsigned integer offset of the first output-data byte for which the invalid CBC was detected.

1 Word 1 contains the 32-bit unsigned integer offset of the last byte of the last output-data word for which the invalid CBC was detected.

When the RC field contains the value three, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 The value specified by the TCAL field is not 8 greater than the value specified by the TCCBL field in the TCW for the operation.

2 The value specified by the TCAL field is less than 20 or greater than 252.

3-255 Reserved.

When the RC field contains the value four, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Format-field specification error: The format field contains an unrecognized

value. See “Format Control” on page 15-37.

2 Reserved-field specification error: A reserved field in the TCAH does not contain zeros.

3 Service-action-code-field specification error: The service-action-code field in the TCAH contains an unrecognized value or a value that is incorrect for command specified by the DCW designated by the DCW-offset field in the TSH. See “Service-Action Code (SAC)” on page 15-37.

4-255 Reserved.

When the RC field contains the value five, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Reserved-field specification error: A reserved field in the DCW does not contain zeros.

2 Flags-field command-chaining specification error: Either of the following is true:

- The chain-command flag is one and the offset of the next DCW is such that all or part of the next DCW extends past the end of the TCA or TCAX.
- The chain-command flag is zero and more than 3 unused bytes remain in the TCA or TCAX (excluding the TCAX reserved field).
- The DCW is the last DCW in the TCA, a TCAX is not specified, and the chain-command flag is one.
- The DCW is the last DCW in the TCAX and the chain-command flag is one.

See “Chain-Command (CC) Flag” on page 15-39.

3 Control-data-count-field specification error: The CD-count field specifies control data past the end of the TCA or TCAX.

See “Control-Data (CD) Count” on page 15-40.

4 TCOB location error: The TCOB DCW is not the first DCW in the TCA

5 TCOB duplication error: More than one TCOB DCW is specified.

6 TCOB multiple-count error: The control-data-count field and the count field in the TCOB DCW both specify the value zero or both specify a nonzero value.

7 TCOB direction error: A TCOB DCW is specified and the write-operation (W) in the TCW is zero.

8 TCOB chaining error: The chain-command bit in the TCOB DCW is zero.

9 TCOB count-specification error: Either of the following is true:

- The count field in the TCOB is zero, the control-data-count field in the TCOB DCW is nonzero, and the control-data-count field in the TCOB specifies a value that is not an even multiple of four
- The control-data-count field in the TCOB is zero, the count field in the TCOB DCW is nonzero, and the count field in the TCOB specifies a value that is not an even multiple of four,

10 TTE location error: Either of the following is true:

- A TCOB DCW is not specified and the TTE DCW is not the first DCW in the TCA.
- A TCOB DCW is specified and the TTE DCW specified is not the second DCW in the TCA.

11 TTE duplication error: More than one TTE DCW is specified.

12 TTE CD-count specification error: The control-data-count field in the TTE DCW specifies a value that is not zero.

13 TTE count specification error: The count field in the TTE DCW specifies a value that is less than 8 or a value that is not a multiple of 4.

14 TTE direction error: A TTE DCW is specified and the write-operation (W) in the TCW is zero.

15 TTE chaining error: The chain-command bit in the TTE DCW is zero.

16 TCAX specification error: A TTE DCW is specified and any of the following is true:

- The TCA does not contain at least one DCW that specifies the transfer of data (that is, at least one DCW that is not a transport-command DCW).
- The TCA contains one or more DCWs that specify the transfer of data and the chain-command flag in the last DCW of the TCA is zero.

17-255 Reserved.

When the RC field contains the value six, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Read-direction specification error: The DCW specifies an input operation, but the R-bit in the TCW used to transport the TCCB is zero.

2 Write-direction specification error: The DCW specifies an output operation, a TCOB operation, or a TTE operation, but the W-bit in the TCW used to transport the TCCB is zero.

3 Read-write-conflict specification error: Both the R-bit and the W-bit are one in the TCW used to transport the TCCB and the device does not support bidirectional data transfers.

4-255 Reserved.

When the RC field contains the value seven, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Read-count specification error: The specified read-count value is incorrect for any of the following reason:

- For unidirectional data transfers, the TCAT transport-count specifies a value that is not equivalent to the TCW input-count value. See “Transport Count” on page 15-40.
- For bidirectional data transfers, the TCAT read-count is not equivalent to the TCW input-count value. See “Read Count” on page 15-41.
- For unidirectional data transfers, the TCAT transport-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX (when specified) that specify read operations.
- For bidirectional data transfers, the TCAT read-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and in the TCAX (when specified), that specify read operations.

2 Write-count specification error: The specified write-count value is incorrect for any of the following reason:

- For unidirectional data transfers, the TCAT transport-count specifies a value that is not equivalent to the TCW output-count value. See “Transport Count” on page 15-40.
- For bidirectional data transfers, the TCAT write-count is not equivalent to

the TCW output-count value. See "Write Count" on page 15-41.

- For unidirectional data transfers, the TCAT transport-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX (when specified) that specify write operations.

- For bidirectional data transfers, the TCAT write-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX that specify write operations, the transfer of a COB, and the transfer of a TCAX.

3-255 Reserved.

When the RC field contains the value nine, only words 1 of the RCQ field has meaning as follows:

Value	***Meaning***
0	Word 0 contains the 32-bit unsigned integer byte offset of the first CBC-offset entry in the COB that specifies a CBC offset that is not at a location that is recognized by the device or is not recognized for the DCW

Sense Data: When the length field in the TSH contains a value greater than 32, sense data has been provided by the I/O device. The count of meaningful sense-data bytes in this field is determined by subtracting 32 from the value in the length field.

Summary of Reason Codes and Associated Reason-Code Qualifiers

Figure 15-24 on page 15-54 provides a summary of the device-detected-program-check RC values and the meanings of their associated RCQ values.

Reason Code Value	Meaning	
0	No information.	
1	TCCB Transport Failure.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB transport size error
	2	TCCB CBC error.
2	Invalid CBC detected on output data.	
	Reason-Code Qualifier	**Meaning**
	Word 0 Value:	Offset of first output-data byte for which the invalid CBC was detected.
	Word 1 Value:	Offset of last output-data byte for which the invalid CBC was detected.
3	Incorrect TCCB length specification.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB TCAL field value not 8 greater than TCW TCCBL field value.
	2	TCCB TCAL field value is less than 20 or greater than 252.
4	TCAH specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB format field specification error.
	2	TCCB reserved field specification error.
	3	TCCB service-action-code field specification error.

Figure 15-24. Summary of Reason-Code (RC) and Reason-Code-Qualifier (RCQ) Values in the Device-Detected-Program-Check TSA (Part 1 of 2)

Reason Code Value	Meaning	
5	DCW specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	DCW reserved field specification error.
	2	DCW flags field command-chaining specification error.
	3	DCW control-data-count field specification error.
	4	TCOB location error
	5	TCOB duplication error
	6	TCOB multiple-count error
	7	TCOB direction error
	8	TCOB chaining error
	9	TCOB count-specification error
	10	TTE location error.
	11	TTE duplication error.
	12	TTE CD-count specification error.
	13	TTE count specification error.
	14	TTE direction error.
	15	TTE chaining error.
	16	TCAX specification error.
6	Transfer-direction specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	Read-direction specification error.
	2	Write-direction specification error.
	3	Read-write conflict error.
7	Transport-count specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	Read-count specification error.
	2	Write-count specification error.
8	Two I/O operations active.	
	Reason-Code Qualifier	No additional information.
9	CBC-offset-specification error.	
	Reason-Code Qualifier	No additional information.
	Word 0 Value:	Offset of first CBC-offset entry that specifies a CBC offset that is not at a location that is recognized.

Explanation:

- Reason-code values and reason-code-qualifier values that have no meaning do not appear in this summary.
- Portions of the reason-code-qualifier field that have no meaning for a specific reason code do not appear in this summary.

Figure 15-24. Summary of Reason-Code (RC) and Reason-Code-Qualifier (RCQ) Values in the Device-Detected-Program-Check TSA (Part 2 of 2)

Interrogate TSA

When the TSB-format field in the TSH contains three, the TSA has the following format:

Word (from the beginning of the TSA)

Word				
0	Format	Flags	CS	DS
1	OS	Reserved		
2 4	State-Dependent Information			
5	Device-Level Identifier			
6 12	Device-Dependent Data			
	0	8	16	24 31

Figure 15-25. Interrogate Transport-Status Area (TSA)

Format: Byte of word 0 contains the unsigned integer value that defines the layout of the interrogate TSA. If the value of this field is not one, the contents of the interrogate TSA are meaningless.

Flags: Byte 1 of word 0 contains information about the interrogate TSA. The meaning of each flag bit is as follows.:

Bit	***Meaning***
0	Control-unit-state valid: When bit 0 is one, the control-unit-state field contains meaningful information. When bit 0 is zero, the control-unit-state field has no meaning.
1	Device-state valid: When bit 1 is one, the device-state field contains meaningful information. When bit 1 is zero, the device-state field has no meaning
2	Operation-state valid: When bit 2 is one, the operation-state field contains meaningful information. When bit 2 is zero, the operation-state field has no meaning.
3-7	Reserved.

Control-Unit State (CS): Byte 2 of word 0 contains an 8-bit unsigned integer that indicates a current state of the control unit for the I/O device. The meaning of each value is as follows:

Value	***Meaning***
0	Busy: The control unit is busy and the device-dependent-data field may contain additional information about the busy state.
1	Recovery: The control unit is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.
2	Interrogate maximum: The control unit is executing the maximum number of interrogate operations that it supports
3-127	Reserved.
128- 255	Device-dependent meanings.

Device State (DS): Byte 3 of word 0 contains an 8-bit unsigned integer that indicates a current state of the I/O device. The meaning of this byte is

Value	***Meaning***
0	Path-group identification: The state-dependent-information field contains information identifying a path group.
1	Long busy: The device is in a long-busy state. The meaning of long busy is device dependent and the device-dependent field may contain additional information about the long-busy state.
2	Recovery: The device is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.
3-127	Reserved.
128- 255	Device-dependent meanings.

Operation State (OS): Byte 0 of word 1 contains an 8-bit unsigned integer that indicates whether an I/O operation is present at the device and, when present, the state of the operation. The meaning of this byte is as follows:

Value	***Meaning***
0	No I/O operation is present.

1 An I/O operation is present and executing.

2 An I/O operation is present and waiting for completion of an I/O operation that was initiated by another configuration.

3 An I/O operation is present and waiting for completion of an I/O operation that was initiated for the same device extent.

4 An I/O operation is present and waiting to perform a device-dependent operation.

5-127 Reserved.

128-255 Device-dependent meanings.

State-Dependent Information: Words 2-4 may contain state-dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

The contents of this field are device dependent. When the device places one or more bytes in this field, they are left justified.

Device-Level Identifier: Word 5 contains a device-dependent token that identifies the implementation level of the device.

Device-Dependent Data: Words 6-12 contain device dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

When the device places one or more bytes in this field, they are left justified.

Note:

1. An interrogate TSA is stored only in a TSB designated by an interrogate TCW.
2. If a program-check condition is recognized for an interrogate TCCB, a device-detect-program-check TSA is stored in the TSB designated by the interrogate TCW.

Command Code

For CCW channel programs, the command code, bit positions 0-7 of the CCW, specifies to the channel subsystem and the I/O device the operation to be performed. For TCW channel programs, the command code, bit positions 0-7 of the DCW, specifies to the I/O device the operation to be performed.

With the exception of transport commands, the two rightmost bits or, when these bits are zeros, the four rightmost bits of the command code identify the operation to the channel subsystem. The channel subsystem distinguishes among the following operations:

- Control
- Output forward (write)
- Input forward (read, sense, sense ID)
- Input backward (read backward)
- Branching (transfer in channel)
- Interrogate
- Transport

For CCW channel programs, the channel subsystem ignores the leftmost four bits of the command code in a format-0 CCW that specifies transfer-in-channel. In a format-1 CCW that specifies transfer in channel, all bits of the command code are decoded by the channel subsystem.

For CCW channel programs, commands that initiate I/O operations (write, read, read backward, control, sense, and sense ID) cause all eight bits of the command code to be transferred to the control unit.

In command codes that initiate I/O operations, the leftmost bit positions contain modifier bits. The modifier bits specify to the device how the command is to be executed. They may, for example, cause the device to compare data received during a write operation with data previously recorded, and they may specify such attributes as recording density and parity. For the control command, the modifier bits may contain the order code specifying the control function to be performed. The meaning of the modifier bits depends on the type of I/O device and is specified in the System Library publication for the device.

The command-code assignment is listed in Figure 15-26 on page 15-58. The symbol x indicates that the bit position is ignored; the symbol m identifies a modifier bit.

Code	Command
x x x x 0 0 0 0	Invalid
m m m m m m 0 1	Write[1]
m m m m m m 1 0	Read[1]
m m m m 1 1 0 0	Read Backward[2]
m m m m m m 1 1	Control
m m m m 0 1 0 0	Sense
1 1 1 0 0 1 0 0	Sense ID
x x x x 1 0 0 0	Transfer in channel[3]
0 0 0 0 1 0 0 0	Transfer in channel[4]
m m m m 1 0 0 0	Invalid[5]
0 1 m m 0 0 0 0	Transport[6]

Explanation:

m	Modifier bit
x	Ignored
1	May designate control data in DCWs.
2	CCW only
3	Format-0 CCW
4	Format-1 CCW
5	Format-1 CCW with any of bits 0-3 nonzero
6	DCW only

Figure 15-26. Command-Code Assignment

Whenever the channel subsystem detects an invalid command code during the initiation of command execution for a CCW channel program, the program-check-interruption condition is generated, and channel-program execution is terminated. The command code is ignored during data chaining, unless it specifies transfer in channel.

Whenever an I/O device detects an invalid command code while executing the commands in a TCCB, a device-detected-program-check condition is recognized and channel-program execution is terminated.

Designation of Storage Area

For CCW channel programs, the main-storage area associated with an I/O operation is defined by one or more CCWs. A CCW defines an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred is specified either directly in the data-address field of the CCW or indirectly in an indirect-data-address word (IDAW) or modified-indirect-data-address word (MIDAW) designated by the data-address field of the CCW. The number of bytes contained in the storage area is specified in the count field.

For TCW channel programs the main-storage area associated with an I/O operation is designated by a TCW. A TCW designates an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred for input operations is specified either directly in the input-data-address field of the TCW or indirectly by a transport-indirect-data-address word (TIDAW) designated by the input-data-address field of the TCW. The number of bytes contained in the storage area for input operations is specified in the input-count field. The address of the first byte of data to be transferred for output operations is specified either directly in the output-data-address field of the TCW or indirectly by a TIDAW designated by the output-data-address field of the TCW. The number of bytes contained in the storage area for output operations is specified in the output-count field. In this case, the actual number of bytes in the storage area is determined by subtracting the number of any inserted padding or CBC bytes from the output-count field value. The address of the first byte of data to be transferred into the TSB is specified in the TSB-address field of the TCW. The number of bytes contained in the storage area for the TSB is dependent on the status being returned and is a maximum of 64.

In general, for write, read, control, and sense operations, storage locations are used in ascending order of addresses. As information is transferred to or from main storage, the address from the appropriate address field is incremented, and the count from the associated count field is decremented. For command-mode operations, the read-backward operation places data in storage in a descending order of addresses, and both the count and the address are decremented. When the associated count reaches zero, the storage area defined by the CCW is exhausted.

When a subchannel is operating in transport mode, the channel subsystem may take advantage of performance optimizations and access storage locations in a non-sequential order within the storage area or areas designated by the current TCW. When a transport-mode operation is concluded, the transfer of specified data, as indicated by information in the I/O-status TSB, is complete.

Any main-storage location available to the start function can be used in the transfer of data to or from an I/O device, provided that the location is not protected against that type of reference. Format-0 CCWs can be located in any available part of the first 2^{24} (16M) bytes of absolute storage, and format-1 CCWs and TCWs can be located in any available part of the first 2^{31} (2G) bytes of absolute storage, provided that, in both cases, the location is not protected against a fetch-type reference. When the channel subsystem attempts to refer to a protected location, the protection-check condition is generated, and the device is signaled to terminate the operation.

A main-storage location is available if it is available in the configuration and access to the location is not prevented by the address-limit-checking facility. CCWs, TCWs, ISDs, TSBs, and the data they address reside in main-storage locations. If a main-storage location is not available, it is said to have an invalid address

If the channel subsystem refers to a location that is not available, the program-check condition is generated. When the first CCW or TCW designated by the channel-program address is at an unavailable location, the start function is not initiated at the device, the status portion of the SCSW is updated with the program-check indication, the subchannel becomes status pending with primary, secondary, and alert status, and deferred condition code 1 is indicated. An invalid data address, as well as any invalid CCW address detected on chaining or subsequent to the execution of START SUBCHANNEL, causes the channel subsystem to signal the device to conclude the operation, if and when the device requests or offers a byte of data or status at the invalid address. In this situation, the subchannel is made status pending with program check indicated in the subchannel status, and the device status is a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

During an output operation, the channel subsystem may fetch data from main storage before the time the I/O device requests the data. Any number of bytes specified by the current CCW or TCW may be prefetched and buffered.

When data chaining during an output operation for a CCW channel program, the channel subsystem may fetch one CCW describing a data area at any time during the execution of the current CCW. If unlimited prefetching is allowed by the setting of the prefetch-control bit in the ORB CCW channel program, any number of CCWs, IDAWs, and MIDAWs and the associated data may be prefetched by the channel subsystem. When the I/O operation uses data or CCWs from locations near the end of the available storage, such prefetching may cause the channel subsystem to refer to locations that do not exist. Invalid addresses detected during prefetching do not affect the performance of the I/O operation and do not cause error indications until the operation actually attempts to use the information. If the operation is concluded by the I/O device or by the execution of HALT SUBCHANNEL or CLEAR SUBCHANNEL before the invalid information is needed, the condition is not brought to the attention of the program.

The count field in the CCW can specify any number of bytes up to 65,535. In format-0 CCWs, the count field is always nonzero unless the command code specifies transfer in channel, in which case the count field is ignored. In format-1 CCWs, the count field may contain the value zero unless data chaining is specified or the CCW is fetched while data chaining. Whenever (1) the count field in a format-1 CCW is zero, (2) data chaining is either not specified or not in effect, and (3) data transfer is requested by the device, the device is signaled to stop, and the I/O operation is terminated. The channel subsystem sets the incorrect-length condition if the SLI flag is not one in the CCW. No data is transferred. If the device does not request data transfer, the operation proceeds to the normal ending point.

If a zero byte count is contained in a format-0 CCW that does not specify transfer in channel, or if a zero byte count is contained in a format-1 CCW that specifies data chaining or was fetched while data chaining, a program-check condition is recognized, and the subchannel is made status pending with combinations of primary, secondary, and alert status as a function of the state of the subchannel and the status received from the device.

The input-count and output-count fields in the TCW can specify any number of bytes up to 2^{32} - 8. For input operations, the input-count field is always nonzero; otherwise, a program-check condition is recognized. For output operations, the output-count field is always nonzero; otherwise, a program-check condition is recognized.

Note: For a description of the storage area associated with a CCW when indirect data addressing is used, see “CCW Indirect Data Addressing” on page 15-66. For a description of the storage area associated with a TCW when indirect data addressing is used, see “Transport Indirect Data Addressing” on page 15-70.

Programming Notes:

1. Since a format-1 CCW with a count of zero is valid, the program can use the CCW count field to specify that no data be transferred to the I/O device. If the device requests a data transfer, the device is signaled to terminate data transfer. If the SLI and chain-command flags are also specified as ones, and no unusual conditions are encountered subsequent to signaling the device to terminate data transfer, the new operation is initiated upon receipt of device end from the device.

2. If the subchannel is in the incorrect-length-suppression mode, the chain-data flag in the current CCW is zero, and the operation is performed as an immediate operation, then incorrect length is not indicated, regardless of the setting of the SLI flag.

   If the subchannel is in the incorrect-length-indication mode, if the chain-data flag in the current CCW is zero, and if the operation is performed as an immediate operation, then incorrect length is indicated if the count field of the current CCW specifies a nonzero value, unless suppressed by the SLI flag of the CCW; incorrect length is not indicated, however, if the count field of the CCW specifies a value of zero.

   If a new CCW that has a count field of zero is fetched during data chaining or if a CCW is fetched with the chain-data flag set to one and a count field of zero, a program-check condition is recognized by the channel subsystem.

3. Since the channel-subsystem may access storage in a non-sequential manner while a subchannel is operating in transport mode, the results may be unpredictable if the program accesses the input storage area or areas designated by a TCW before primary status is indicated.

CCW Channel Program Chaining

When the channel subsystem has completed the transfer of information specified by a CCW, it can continue performing the start function by fetching a new CCW. Such fetching of a new CCW is a form of chaining, and the CCWs belonging to such a sequence are said to be chained.

Chaining takes place between CCWs located in successive doubleword locations in storage. It proceeds in an ascending order of addresses; that is, the address of the new CCW is obtained by adding 8 to the address of the current CCW. Two chains of CCWs located in noncontiguous storage areas can be coupled for chaining purposes by a transfer-in-channel command. All CCWs in a chain apply to the I/O device that is associated with the subchannel designated by the original START SUBCHANNEL instruction.

Two types of chaining are provided for CCWs: Chaining is controlled by the chain-data (CD) and chain-command (CC) flags in conjunction with the suppress-length-indication (SLI) flag in the CCW. These flags specify the action to be taken by the channel subsystem upon the exhaustion of the current CCW and upon receipt of ending status from the device, as shown in Figure 15-27 on page 15-61.

The specification of chaining is effectively propagated through a transfer-in-channel command. When, in the process of chaining, a transfer-in-channel command is fetched, the CCW designated by the transfer-in-channel command is used for the type of chaining specified in the CCW preceding the transfer-in-channel command.

The CD and CC flags are ignored in a format-0 CCW specifying the transfer-in-channel command. In a format-1 CCW specifying the transfer-in-channel command, the CD and CC flags must be zeros; otherwise, a program-check condition is recognized.

Flags in Current CCW			Action at the Subchannel upon Exhaustion of Count or Receipt of Channel End						
			Immediate Operation				Non-immediate Operation		
			Incorrect-Length-Suppression Mode[1]		Incorrect-Length-Indication Mode		Count Exhausted		Count Not Exhausted and CE Received
CD	CC	SLI	CCW Count$\neq$0	CCW Count=0	CCW Count$\neq$0	CCW Count=0	CE Not Received	CE Received	
0	0	0	End, NIL	End, NIL	End, IL	End, NIL	Stop, IL	End, NIL	End, IL

Explanation:

- The selected bit is ignored and may be either zero or one.

* These situations cannot validly occur. When data chaining is specified, the new CCW takes control of the operation after transferring the last byte of data designated by the current CCW, but before the next request for data or status transfer from the device. The new CCW (which cannot contain a count of zero unless a program-check condition is also recognized) is in control of the operation

[1] The count field must contain a nonzero value when format-0 CCWs are specified; otherwise, the operation is terminated with a program-check condition.

CC Command chaining is performed by the channel subsystem upon receipt of device end.

CD The chain-data flag causes the channel subsystem to immediately fetch a new CCW for the same operation. The operation continues unless the CCW thus fetched has a count field of zero, in which case the operation is terminated with a program-check condition.

CE Channel end from the device that indicates end of block.

End Operation is terminated.

IL Incorrect length is indicated with the subsequent interruption condition generated at the subchannel.

NIL Incorrect length is not indicated with the subsequent interruption condition generated at the subchannel.

PC These situations cannot validly occur. The channel subsystem recognizes a program-check condition when a CCW is fetched that has the chain-data flag set to one and a count field of zero.

STOP Device is signaled to terminate data transfer, but subchannel remains subchannel active until channel end is received.

Figure 15-27. Subchannel Chaining Action

Programming Note: When bit 9 of word 1 of the ORB is one, unlimited prefetching of chained CCWs (including CCWs linked by a transfer-in-channel command) by the channel subsystem is permitted. When prefetching is allowed by the ORB, no modification of the channel program should be performed after START SUBCHANNEL is executed and before the primary interruption condition for the operation has been received unless the subchannel is currently suspended and is not resume pending.

Data Chaining

During data chaining, the new CCW fetched by the channel subsystem defines a new storage area for the original I/O operation. If the channel path is of the parallel-I/O-interface type, the performance of the operation at the I/O device is not affected. If the channel path is of the serial-I/O-interface type, then the performance of the operation at the I/O device either is not affected or, depending on the device model, may be terminated with unit-check status. When the operation at the I/O device is not affected and all data designated by the current CCW has been transferred to main storage or to the device, data chaining causes the operation to continue, using the storage area designated by the new CCW. The contents of the command-code field of the new CCW are ignored, unless they specify transfer in channel.

Data chaining is considered to occur immediately after the last byte of data designated by the current CCW has been transferred to main storage or to the device. When the last byte of the data transfer has been placed in main storage or accepted by the device, the new CCW takes over the control of the operation. If the device sends channel end after exhausting the count of the current CCW but before transferring any data to or from the storage area designated by the new CCW, the SCSW associated with the concluded operation pertains to the new CCW.

If programming errors are detected in the new CCW or during its fetching, the error indication is generated, and the device is signaled to conclude the operation when it attempts to transfer data designated by the new CCW. If the device signals the channel-end condition before transferring any data designated by the new CCW, program check or protection check is indicated in the SCSW associated with the termination. The contents of the SCSW pertain to the new CCW unless the address of the new CCW is invalid, the location is protected against fetching, or programming errors are detected in an intervening transfer-in-channel command. A data address referring to a nonexistent or protected area causes an error indication only after the I/O device has attempted to transfer data to or from the invalid location.

Data chaining during an input operation causes the new CCW to be fetched when all data designated by the current CCW has been placed in main storage. On an output operation, the channel subsystem may fetch the new CCW from main storage before data chaining occurs. Any programming errors in the prefetched CCW, however, do not affect the performance of the operation until all data designated by the current CCW has been transferred to the I/O device. If the device concludes the operation before all data designated by the current CCW has been transferred, the conditions associated with the prefetched CCW are not indicated to the program. Unlimited prefetching is allowed under the control of the prefetch bit specified in the ORB. (See “Prefetch Control (P)” on page 15-27.) When unlimited prefetching is not allowed and an output operation is specified, only one CCW describing a data area may be prefetched. If a prefetched CCW specifies transfer in channel, only one more CCW may be fetched before the exhaustion of the current CCW.

Programming Notes:

1. If the ORB does not specify unlimited prefetching, no prefetching of CCWs is performed, except in the case of data chaining on an output operation where one CCW describing a data area may be prefetched at a time.

   If the ORB for the I/O operation specifies that prefetching is allowed, any number of CCWs, IDAWs, and MIDAWs and the associated data areas may be prefetched and buffered in the channel subsystem.

   The same actions for signaling errors and terminating operations take place when unlimited prefetching is allowed by the ORB as when it is not allowed. However, when unlimited prefetching is specified and an error condition is detected, both the channel subsystem and the program must recognize that the points of termination at the channel subsystem and at the I/O device may be different in terms of the channel command in execution at the point of error. The channel subsystem indicates the point of termination at the channel subsystem by storing the appropriate CCW address in word 1 of the subchannel-status word and the point of termination at the device by storing the secondary-CCW address in word 4 of the format-0 extended-status word.

   When prefetching has been specified in the ORB, the result of modifications to CCWs after START SUBCHANNEL has been executed or after self-describing channel programs have been used is unpredictable. (See note 2 for the definition of self-describing channel programs.)

2. Data chaining may be used to rearrange information as it is transferred between main storage and an I/O device. Data chaining permits blocks of information to be transferred to or from noncontiguous areas of storage, and, when used in conjunction with the skipping function, data chaining allows the program to place in main storage specified portions of a block of data.

   When, during an input operation, the program specifies data chaining to a location in which data has been placed under the control of the current CCW, the channel subsystem, in fetching the next CCW, fetches the new contents of the location. This is true even if the location contains the last byte transferred under the control of the current CCW. When a channel program data-chains to a CCW placed in storage by the CCW specifying data chaining, the input block is said to be self-describing. A self-describing block contains one or more CCWs that designate storage locations and counts for subsequent data in the same input block.

   The use of self-describing blocks is equivalent to the use of unchecked data. An I/O data-transfer malfunction that affects validity of a block of information is signaled only at the completion of data transfer. The error condition normally does not prematurely terminate or otherwise affect the performance of the operation. Thus, there is no assurance that a CCW read as data is valid until the operation is completed. If the CCW thus read is in error, use of the CCW in the current operation may cause subsequent data to be placed at wrong locations in main storage with resultant destruction of its contents, subject only to the control of the protection key and the address-limit-checking facility, if used.

3. When, during data chaining, a device transfers data by using the data-streaming feature, an overrun or chaining-check condition may be recognized when a small byte-count value is specified in the CCW. The minimum acceptable number of bytes that can be specified varies as a function of the system model and system activity.

Command Chaining

During command chaining, the new CCW fetched by the channel subsystem specifies a new I/O operation. The channel subsystem fetches the new CCW upon the receipt of the device-end signal for the current operation. If the new CCW does not have its S flag set to one and no unusual conditions are detected, the channel subsystem initiates the new operation. The presence of the S flag set to one or unusual conditions causes command chaining to be suppressed. When command chaining takes place, the completion of the current operation does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new operation is initiated only if no unusual conditions have been detected in the current operation. In particular, the channel subsystem initiates a new I/O operation by command chaining upon receipt of a status byte containing only the following bit combinations: (1) device end, (2) device end and status modifier, (3) device end and channel end, and (4) device end, channel end, and status modifier. In the first two cases, channel end is signaled before device end, with all other status bits zeros. If a condition such as attention, unit check, unit exception, incorrect length, program check, or protection check has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new CCW in this case is not fetched. The incorrect-length condition does not suppress command chaining if the current CCW has the SLI flag set to one.

An exception to sequential chaining of CCWs occurs when the I/O device presents the status-modifier condition with the device-end signal or channel-end and device-end signals. When command chaining is specified and no unusual conditions have been detected, or when command retry has been previously signaled and an immediate retry could not be performed, the combination of status-modifier and device-end bits causes the channel subsystem to alter the sequential execution of CCWs. If command chaining was specified, status modifier and device end cause the channel subsystem to fetch and chain to the CCW whose main-storage address is 16 higher than that of the CCW that specified chaining. If command retry was previously signaled and immediate retry could not be performed, the status causes the channel subsystem to command chain to the CCW whose storage address is 8 higher than that of the CCW for which retry was initially signaled.

When both command and data chaining are specified, the first CCW associated with the operation specifies the operation to be performed, and the last CCW specifies whether another operation follows.

Programming Note: Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. Command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device.

TCW Channel Program Chaining

When the I/O device has completed a control operation or the transfer of information specified by a DCW, the device can continue by executing the next DCW that is specified. Such execution of a new DCW is a form of command chaining, and the DCWs belonging to such a sequence are said to be chained.

Command chaining is controlled by the DCW chain-command (CC) flag in the DCW. This flag specifies the action to be taken upon the exhaustion of the current DCW. Chaining takes place between successive DCWs within the TCA. When a TCAX is specified, chaining also takes place between the last DCW in the TCA and the first DCW in the TCAX, and between successive DCWs within the TCAX.

When a TCCB is transported to an I/O device and selected by the device for processing, the first DCW in the TCA becomes the current DCW and is executed by the device. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, the completion of the current DCW causes the next DCW to become the current DCW and be executed by the device. The TCA offset of the next DCW is determined by adding 8, plus the value of the control-data (CD) count field of the DCW, to the TCA offset of the current DCW and rounding upwards to the next word boundary. If a TCAX is specified and the offset of the next DCW is past the end of the TCA, chaining continues with the first DCW of the TCAX whose TCAX offset is determined by subtracting the TCA length from the calculated offset. Thus, command chaining proceeds in ascending order of TCA offsets and then TCAX offsets when a TCAX is specified.

During command chaining, the new DCW executed by the device specifies a new I/O command. When command chaining takes place, the completion of the execution of the current command does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new command is initiated only if no unusual conditions have been detected in the execution of the current command. In particular, the I/O device initiates a new I/O operation by command chaining upon successful completion of the current command. If a condition such as attention, unit check, unit exception, or incorrect length has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new DCW in this case is not executed.

Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. For command-mode operations, command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device

Skipping

Skipping causes the suppression of main-storage references during an I/O operation. It is defined only for read, read-backward, sense-ID, and sense operations. Skipping is controlled by the skip flag, which can be specified individually for each CCW, MIDAW, or TIDAW. When the skip flag is one, skipping occurs; when it is zero, normal operation takes place. The setting of the skip flag is ignored in all other operations.

Skipping affects only the handling of information by the channel subsystem. The operation at the I/O device proceeds normally, and information is transferred. The channel subsystem keeps updating the count but does not place the information in main storage. Chaining is not precluded by skipping. In the case of CCW data chaining, normal operation is resumed if the skip flag in the new CCW is zero.

No checking for invalid or protected data addresses takes place during skipping.

Programming Note: Skipping, when combined with CCW data chaining, MIDAWs, and TIDAWs, permits the program to place in main storage specified portions of a block of information from an I/O device.

Program-Controlled Interruption

The program-controlled-interruption (PCI) function permits the program to cause an I/O interruption during the performance of an I/O operation. The function is controlled by the PCI flag of the CCW. Neither the value of the PCI flag nor the associated interruption request affects the performance of the current operation.

The value of the PCI flag can be one either in the first CCW designated for the current start or resume function or in a CCW fetched during chaining. If the PCI flag is one in a CCW that has become current, the subchannel becomes status pending with intermediate status, and an I/O-interruption request is generated. The point at which the subchannel becomes status pending depends on the progress of the current start or resume function as follows:

1. If the PCI flag is one in the first CCW associated with a start function or a resume function, the subchannel becomes status pending with intermediate status only after the command has been accepted.
2. If the PCI flag is one in a CCW that has become current while data chaining, the subchannel becomes status pending with intermediate status after all data designated by the preceding CCW has been transferred.
3. If the PCI flag is one in a CCW that has become current while command chaining, the subchannel becomes status pending with intermediate status as that CCW becomes current.

In all cases, if the subchannel is enabled for I/O interruptions, the point of interruption depends on the current activity in the system and may be delayed. No predictable relationship exists between the point at which the interruption request is generated because of the PCI flag and the extent to which data transfer has been completed to or from the area designated by the CCW. However, all the fields within the SCSW pertain to the same instant.

An intermediate interruption condition that is made pending because of a PCI flag remains pending during chaining if not cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL. If another CCW containing a PCI flag that is one becomes current prior to the clearing of the intermediate interruption condition, only one interruption condition is preserved.

An intermediate interruption may occur while the subchannel is subchannel-and-device active with the operation specified by the CCW causing the intermediate interruption condition or with the operation specified by a CCW that has subsequently become current. If the intermediate interruption condition is not cleared prior to the conclusion of the operation or chain of operations, the condition is indicated together with the primary interruption condition at the conclusion of the operation or chain of operations. The intermediate interruption condition may be cleared by TEST SUBCHANNEL while the subchannel is subchannel active.

If the SCSW stored by TEST SUBCHANNEL indicates that the subchannel is status pending with intermediate status and the operation or chain of operations has not been concluded (that is, the activity-control field indicates subchannel-and-device active or suspended), then the CCW-address field contains an address that is 8 higher than the address of the most recent CCW to become current and have a PCI flag that is one, or the CCW-address field contains an address that is 8 higher than the address of a CCW that has subsequently become current. Unless the SCSW also contains the primary-status bit set to one, the device-status field contains zeros, and the count is unpredictable.

Subchannel-status conditions other than PCI may be indicated when the SCSW is stored. If the subchannel is not also status pending with primary status, these conditions may or may not be indicated again. If the subchannel-status condition is detected while prefetching and the operation or chain of operations is concluded before the condition affects an operation, the condition is reset and is not indicated when the subchannel subsequently becomes status pending with primary status. If the subchannel-status condition affects an operation, the condition is indicated when the subchannel becomes status pending with primary status.

If the program-controlled-interruption condition remains pending until the operation or chain of operations is concluded at the subchannel, a single interruption request exists. When TEST SUBCHANNEL is subsequently executed, the status-control field of the SCSW stored indicates both the primary interruption condition and the intermediate interruption condition, and the PCI bit of the subchannel-status field is one.

The value of the PCI flag is inspected in every CCW except for those CCWs that specify the transfer-in-channel command. The PCI flag is ignored during initial program loading.

Programming Notes:

1. The program-controlled interruption provides a means of alerting the program to the progress of chaining during an I/O operation. It permits programmed dynamic main-storage allocation.

2. A CCW with a PCI flag set to one may, if retried because of command retry, cause multiple PCI interruptions to occur. (See “Command Retry” on page 15-77.)

Indirect Storage Addressing

Indirect-storage addressing (ISA) allows for storage areas designated by a channel program to be specified in noncontiguous storage. Depending on the model, more than one form of ISA facility may be installed as follows:

- CCW-indirect-data (see “CCW Indirect Data Addressing” on page 15-66) addressing is installed in all models.

- Modified-CCW-indirect-data (see “Modified CCW Indirect Data Addressing” on page 15-68) addressing may also be installed in a model.

- TCW-indirect-data-addressing (see “Transport Indirect Data Addressing” on page 15-70) may also be installed in a model.

Indirect-Storage Designator (ISD)

Each ISA facility description includes the definition of a facility-unique indirect-storage designator (ISD) that is used to specify a block of storage to the channel subsystem. Thus, a list of ISDs may be used to designate noncontiguous storage blocks. How the location and size of a storage block are specified and whether the specification of the storage block has boundary restrictions, size restrictions, or both is dependent on the method of ISA used. The following ISDs may be used as follows:

- Format-1 and format-2 indirect-data-address word (IDAW). See “CCW Indirect Data Addressing” on page 15-66.

- Modified-indirect-data-address word (MIDAW), when the modified-CCW-indirect-data-addressing facility is installed. See “Modified CCW Indirect Data Addressing” on page 15-68.

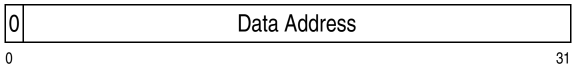
- Transport-indirect-data-address word (TIDAW), when the fibre-channel-extensions (FCX) facility is installed. See “Transport Indirect Data Addressing” on page 15-70.

CCW Indirect Data Addressing

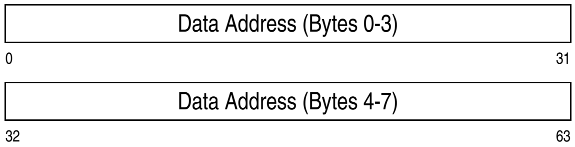
CCW indirect data addressing permits a single channel-command word to control the transfer of data that spans noncontiguous 2 K-byte or 4 K-byte blocks in main storage. The use of CCW indirect data addressing also allows the program to designate data addresses above 16M bytes when using format-0 CCWs or above 2G bytes when using format-1 CCWs. CCW indirect data addressing is specified by a flag in the CCW which, when one, indicates that the data address is not used to directly address data. Instead, the address points to a list of words or doublewords, called indirect-data-address words (IDAWs), each of which contains an absolute address designating a data area in main storage.

IDAWs have either of two formats, called format 1 and format 2, as determined by the format-2-IDAW control, bit 14 of word 1 of the ORB associated with the channel program being executed. When the format-2-IDAW control is zero, the IDAW is format 1 and is a word containing a 31-bit address. When the control is one, the IDAW is format 2 and is a doubleword containing a 64-bit address. The IDAW formats are as follows:

Format-1 IDAW



Format-2 IDAW



Bit 0 (format 1) is reserved for future use and must be zero; otherwise, a program-check condition may be recognized, as described below.

A format-1 IDAW designates a data area within a 2 K-byte block of main storage and is capable of addressing storage in the range of 0 to 2^{31} - 1.

A format-2 IDAW designates a data area within a 2 K-byte or 4 K-byte block of main storage, as determined by the 2K-IDAW control, bit 15 of word 1 of the ORB associated with the channel program being executed, and is capable of addressing storage in the range of 0 to 2^{64} - 1. When the 2K-IDAW-control bit is zero, each format-2 IDAW of the designated channel program designates a 4 K-byte block of main storage. When the 2K-IDAW-control bit is one, each format-2 IDAW designates a 2 K-byte data-area block. All IDAWs associated with the designated channel program must have the same IDAW format, and all of those IDAWs specify the same size of storage block.

When the indirect-data-addressing bit in the CCW is one, the data-address field of the CCW designates the location of the first IDAW to be used for data transfer for the command. Additional IDAWs, if needed for completing the data transfer for the CCW, are in successive locations in storage. The number of IDAWs required for a CCW is determined by the IDAW format as specified in the ORB, by the count field of the CCW, and by the data address in the initial IDAW. When, for example, (1) the ORB specifies format-2 IDAWs with 4 K-byte blocks, (2) the CCW count field specifies 8K bytes, and (3) the first IDAW designates a location in the middle of a 4 K-byte block, then three IDAWs are required.

The IDAW designated by the CCW can designate any location. Data is then transferred, for read, write, control, sense ID, and sense commands, to or from successively higher storage locations or, for a read-backward command, to successively lower storage locations, until a 2 K-byte block boundary (format-1 or format-2 IDAW) or a 4 K-byte block boundary (format-2 IDAW) is reached. The control of data transfer is then passed to the next IDAW. The second and any subsequent IDAWs must designate, depending on the command, the first byte, or the last byte for read backward, of a 2 K-byte block (format-1 or format-2 IDAW) or a 4 K-byte block (format-2 IDAW). Thus, for read, write, control, sense ID, and sense commands, such format-1 IDAWs must have zeros in bit positions 21-31, and such format-2 IDAWs must have zeros in bit positions 53-63 (2 K-byte blocks) or 52-63 (4 K-byte blocks). For a read-backward command, such format-1 IDAWs must have ones in bit positions 21-31, and such format-2 IDAWs must have ones in bit positions 53-63 (2 K-byte blocks) or 52-63 (4 K-byte blocks). If any of these rules is violated, a program-check condition is recognized.

Except for the unique restrictions on the designation of the data address by the IDAW, all other actions taken for the data address, such as for protected storage and invalid addresses, and the actions taken for data prefetching are the same as when indirect data addressing is not used.

IDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of IDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that points to the IDAWs. An IDAW takes control of data transfer when the last byte has been transferred for the previous IDAW. The same actions take place as with data chaining regarding when an IDAW takes control of data transfer during an I/O operation. That is, when the count for the CCW has not reached zero, a new IDAW takes control of the data transfer when the last byte has been transferred for the previous IDAW for that CCW, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new IDAW.

A prefetched IDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous IDAW for that CCW. Program or access errors detected in prefetched IDAWs are not indicated to the program until the IDAW takes control of data transfer. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched IDAW or its associated key, the condition may be indicated to the program, when detected, before the IDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of an IDAW or its associated key, see “Channel-Control Check” on page 16-29.

Bits 1-31 (format 1) or bits 0-63 (format 2) designate the absolute storage location of the first byte to be used in the data transfer. When format-1 IDAWs are specified, the channel subsystem forms a 64-bit absolute main-storage address by appending 33 zero bits on the left of bit 1.

When the IDAW flag of the CCW is set to one and any of the following conditions occurs:

1. Format-1 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a word boundary,
2. Format-2 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a doubleword boundary,
3. The address in the CCW designates a storage location that is not physically available,

4. Access to the storage location specified by the address in the CCW is prohibited by protection, or

5. Bit 0 (format 1 only) of the first IDAW is not zero,

then, depending on the model, one of the following two actions is taken independent of the setting of the skip flag (if condition 5 above is true, action 2 must be taken).

1. The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.

2. The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

Modified CCW Indirect Data Addressing

Modified CCW indirect data addressing (MIDA) permits a single channel-command word to control the transfer of up to 65,535 bytes of data that spans noncontiguous blocks in main storage. Each block of main storage to be transferred may be specified on any boundary and length up to 4K bytes, provided the specified block does not cross a 4 K-byte boundary. The use of modified CCW indirect data addressing requires that the program designate 64-bit data addresses.

Modified CCW indirect data addressing is controlled by a flag in the ORB and specified by a flag in the CCW which, when both are one, indicates that the CCW data address is not used to directly address data. Instead, the address points to a contiguous list of up to 256 quadwords called modified-indirect-data-address words (MIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

Use of modified CCW indirect data addressing may be restricted to certain channel-path types. If the MIDA flag in the CCW is one, specifying the use of modified CCW indirect data addressing, and the subchannel is associated with channel paths that do not support modified CCW indirect data addressing, a program check is recognized.

The MIDAW begins on a quadword boundary and has the following format:

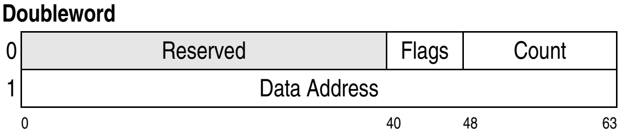


Figure 15-28. Modified-Indirect-Data-Address Word (MIDAW)

Reserved : Bits 0-39 of the MIDAW are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

Flags : Bits 40-47 of the MIDAW contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not shown are reserved.

Bit Meaning

40 Last MIDAW: Bit 40, when one, specifies that the MIDAW is the last in the contiguous list of MIDAWs.

41 Skip: Bit 41, when one, specifies the suppression of transfer of information to main storage during a read, read-backward, sense ID, or sense operation, thus specifying that skipping is in effect. When the operation is not read, read-backward, sense ID, or sense, bit 41 is ignored and skipping is not in effect

When skipping is in effect, no checking for invalid or protected data addresses takes place.

42 Data-transfer-interruption control: Bit 42, when one, specifies that a program-check be recognized when the device attempts to transfer data.

Count : Bits 48-63 of the MIDAW specify the number of bytes in the storage area designated by the data-address field. The count value must not be zero; otherwise a program-check condition is recognized. When skipping is in effect, the count value may be in the range of 1 - 65,535. When skipping is not in effect, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4K-block boundary; otherwise, a program-check condition is recognized. When the count value causes the total data transfer count to exceed that specified in the CCW count field, a program-check condition is recognized.

Data Address : Bits 64-127 of the MIDAW designate the 64-bit address of a location in absolute storage which is the first byte of information to be transferred. If the count field specifies zero, this field is not checked.

When modified CCW indirect data addressing is specified, the data-address field of the CCW designates the location of the first MIDAW to be used for data transfer for the CCW command. Additional MIDAWs, if needed for completing the data transfer for the CCW, are fetched from successive locations in storage. The number of MIDAWs required for a CCW is determined by the count field of the CCW in relation to the count fields in the list of MIDAWs designated by the CCW. The list must not cross a 4 K-byte boundary.

If a list of two or more MIDAWs is designated for a read operation, it is unpredictable in which order the MIDAW data addresses are used to transfer information into main storage. Thus, if two or more MIDAWs in a MIDAW list designate overlapping storage areas, the results are unpredictable.

MIDAWs that specify the transfer of data (MIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 - 4096 bytes, provided the MIDAW does not specify a data transfer that crosses a 4 K-byte boundary; MIDAWs that specify the suppression of the transfer of data (MIDAWs for which skipping is in effect) may specify a skip count in the range of 1 - 65,535 bytes. The total number of bytes that can be transferred or skipped or both by a single MIDAW list is limited by the CCW count field, which is a maximum of 65,535 bytes. The sum of the count fields in all of the MIDAWs in the list designated by the CCW should equal the value in the count field of the CCW; otherwise, a program-check condition may be recognized.

The MIDAW designated by the CCW can designate any location. When the MIDAW skip flag is zero and the CCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is zero and the CCW specifies the read backwards command, data is then transferred to successively lower storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is one and the CCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the MIDAW count field have been skipped. When the MIDAW skip flag is one and the CCW specifies the read backwards command, skipping occurs to successively lower storage locations until the number of bytes specified by the MIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the CCW specifies a subsequent MIDAW, the control of data transfer is then passed to the next MIDAW in the list. Like the MIDAW designated by the CCW, subsequent MIDAWs may designate any location and any length, provided the MIDAW does not specify a data transfer that crosses a 4 K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a MIDAW and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a MIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when modified CCW indirect data addressing is not used.

MIDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of MIDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that designates the MIDAWs. Any MIDAWs that are prefetched for a CCW and are not used are discarded.

Similar to when CCW data chaining occurs, the action of transferring control from one MIDAW to the next is transparent to any attached device. A MIDAW takes control of data transfer when the last byte specified by the previous MIDAW has been transferred, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new MIDAW.

A prefetched MIDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous MIDAW. Program or access errors detected in prefetched MIDAWs are not indicated to the program until the MIDAW takes control of data transfer, even if an attempt had been made to prefetch that data. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched MIDAW or its associated key, the condition may be indicated to the program, when detected, before the MIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a MIDAW or its associated key, see “Channel-Control Check” on page 16-29.

When a CCW specifies a MIDAW list and either the address in the CCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

Transport Indirect Data Addressing

When a designated subchannel is operating in transport mode, transport indirect data addressing (TIDA) may be used. TIDA permits a TCW to specify the transfer of data from noncontiguous blocks in main storage or to specify the transfer-command-control block (TCCB) in noncontiguous blocks of storage or both.

The use of transport indirect data addressing is controlled by flags in the TCW as follows:

> When the input-TIDA flag is one in the TCW, the TCW input-data address is not used to directly address data. Instead, the TCW input-data address points to a list of quadwords called transport-indirect-data-address words (TIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.
>
> When the output-TIDA flag is one in the TCW, the TCW output-data address is not used to directly address data. Instead, the TCW output-data address points to a list of TIDAWs, each of which designates a data area in absolute storage.
>
> When the transport-command-control-block-TIDA flag is one in the TCW, the TCW transport-command-control-block address is not used to directly address a TCCB. Instead, the TCW transport-command-control-block address points to a list of TIDAWs, each of which designates a portion of the TCCB in absolute storage.

A list of one or more TIDAWs is called a transport-indirect-data-addressing list (TIDAL).

Unless otherwise specified, TIDAWs may designate a block of main storage on any boundary and length up to 4K bytes, provided the specified block does not cross a 4 K-byte boundary.

A TIDAW begins on a quadword boundary and has the following format:

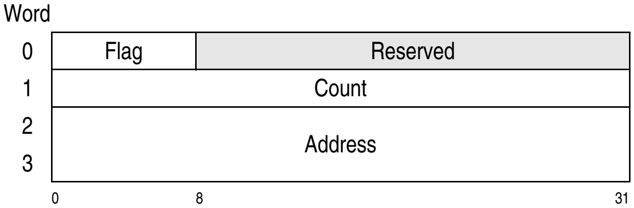

Figure 15-29. Transport-Indirect-Data-Address Word (TIDAW)

Flags : Bits 0-7 of word 0 contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not described below are reserved.

Bit	**Meaning**
0	Last TIDAW: Bit 0, when one, specifies that the TIDAW is the last in the contiguous list of TIDAWs.
1	Skip: Bit 1, when one, specifies the suppression of transfer of information to main storage during an input operation, thus specifying that skipping is in effect.

When the operation is an output operation, bit 1 is ignored and skipping is not in effect. When the TIDAW is being used to transport a TCCB, bit 1 is ignored and assumed to be zero.

When skipping is in effect, no checking for invalid or protected data addresses takes place.

2 Data-transfer-interruption control: Bit 2, when one, specifies that a program-check be recognized when the TIDAW is the current TIDAW.

3 TIDAW-transfer-in-channel (TTIC): Bit 3, when one, specifies that the TIDAW is not used to transfer data or TCCB storage. Instead, the address field designates the address of the next TIDAW to be used for the transfer of data. If bit 3 is one and the address field designates a TIDAW in which bit 3 is one, a program-check condition is recognized. If bit 3 is one and any other TIDAW flag bits are one, a program-check condition is recognized.

4 Insert-CBC control: Bit 4, when one, specifies that the following occurs when an output operation is specified and all of the data specified by the TIDAW has been transferred:

- If the count of data bytes transferred is not a multiple of 4, up to 3 padding bytes are transferred to make the total count of data bytes, plus the count of padding bytes, a multiple of 4.
- A word of CBC information is generated and transferred to the device.

Bit 4 has no meaning for the following cases:

- When the TIDAW is being used for an input data transfer.
- When the TIDAW is being used for an output data transfer and the last-TIDAW flag, bit 0, is one.
- When the TIDAW is in a TIDAW list designated by the TCCB-address field of the TCW.

5-7 Reserved: Bits 5-7 are reserved and must be zero, otherwise a program-check condition is recognized.

Reserved: Bits 8-31 are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

Count : Bits 32-63 specify the number of bytes to be transferred. When skipping is in effect, the count value may be in the range of 1 through 2^{32}-8 for a TIDAW. When skipping is not in effect and the TTIC flag, bit 3, is zero, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4 K-byte block boundary; otherwise, a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the input-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the input-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the output-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the output-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW, the following are true:

- The count value specified in the TIDAW in which the last-TIDAW flag is one and the count of bytes specified by the TCCB-length field in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.
- If the TIDAW specifies the TCCB to cross a 4 K-byte boundary, a program-check condition is recognized.
- If the specified count value is zero or is not evenly divisible by four, a program-check condition is recognized.

When the TTIC flag is zero, the count field must not be zero, otherwise a program-check condition is recognized. When the TTIC flag is one, the count field must be zero, otherwise a program-check condition is recognized.

Address : Bits 64-127 of the TIDAW designate the 64-bit address of a location in absolute storage. When the TTIC flag is zero, this is the location of the first byte of information to be transferred. When the TTIC flag is one, this is the location of the next TIDAW to be used and must specify an address on a quadword boundary, otherwise a program-check condition is recognized.

Input TIDAL: When transport indirect data addressing is specified for input (the input-TIDA flag in the TCW is one), the input-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for an input TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the input-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The input TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

If a list of two or more TIDAWs is designated for an input operation, it is unpredictable in which order the TIDAW data addresses are used to transfer information into main storage. Thus, if two or more TIDAWs in a TIDAW list designate overlapping storage areas, the results are unpredictable.

Output TIDAL: When transport indirect data addressing is specified for output (the output-TIDA flag in the TCW is one), the output-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for a TCW is determined by the output-count field of the TCW. The number of TIDAWs required for an output TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the output-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The output TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

TCCB TIDAL: When transport indirect data addressing is specified for the TCCB (the transport-command-control-block-TIDA flag in the TCW is one), the transport-command-control-block-address field of the TCW designates the location of the first TIDAW to be used to designate the storage location of the TCCB. Additional TIDAWs, if needed for completing the TCCB, are fetched from successive locations in storage. The number of TIDAWs required for a TCCB TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the TCCB-length field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The TCCB TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

Additional Information

TIDAWs that specify the transfer of data (TIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 through 4096 bytes, provided the TIDAW does not specify a data transfer that crosses a 4 K-byte boundary.

TIDAWs that specify the suppression of the transfer of data may specify a skip count in the range of 1 through 2^{32}-8.

The total number of bytes that can be transferred or skipped or both by a single TIDAL is limited by the

TCW count field that applies to the TIDAL, which may be a maximum of 2^{32}-8 bytes. If a TIDAL does not specify the same number of data bytes to be transferred as the count in the TCW for the TIDAL, or does not specify the same number of data bytes to transferred as that specified by the associated TCCB, a program-check condition may be recognized.

A TIDAW can designate any location. When the TIDAW skip flag is zero and a DCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the TIDAW count field have been transferred. When the TIDAW skip flag is one and a DCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the TIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the TCW and DCW specify a subsequent TIDAW, the control of data transfer is then passed to the next TIDAW in the list. Like the TIDAW designated by the TCW, subsequent TIDAWs may designate any location and any length, provided the TIDA does not specify a data transfer that crosses a 4 K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a TIDAW, and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a TIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when transport indirect data addressing is not used.

TIDAWs pertaining to the current TCW may be prefetched. The number of TIDAWs that can be prefetched cannot exceed that required to satisfy the associated count in the TCW that designates the TIDAWs. Any TIDAWs that are prefetched for a TCW and are not used are discarded.

The action of transferring control from one TIDAW to the next is transparent to any attached device. A TIDAW takes control of data transfer when the last byte specified by the previous TIDAW has been transferred, this may occur even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new TIDAW.

Program or access errors when fetching or prefetching TIDAWs are indicated to the program when detected. For output operations, this may preclude transporting the TCCB to the I/O device.

When the channel subsystem detects an invalid CBC on the contents of a prefetched TIDAW or its associated key, the condition may be indicated to the program, when detected, before the TIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a TIDAW or its associated key, see “Channel-Control Check” on page 16-29.

When a TCW specifies a TIDAL and either the address in the TCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and any status presented by the device.

Suspension of CCW Channel-Program Execution

The suspend function, when used in conjunction with RESUME SUBCHANNEL, provides the program with a means to stop and restart the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend control, bit 4 of word 1 of the command-mode ORB. The suspend function is signaled when suspend control has been specified for the subchannel in the ORB and a CCW containing an S flag set to one becomes the current CCW. The flag can be indicated either in the first

CCW of the channel program or in a CCW fetched while command chaining. The S flag is not valid and causes a program-check condition to be recognized if (1) the ORB contains the suspend-control bit set to zero, or (2) the CCW is fetched while data chaining (see “Data Chaining” on page 15-61, concerning the handling of programming errors detected during data chaining).

Upon recognition of the suspend function, suspension of channel-program execution occurs when the CCW becomes current (see “Channel-Command Word” on page 15-31, for a definition of when a CCW becomes current). If suspension occurs during command chaining, the device is signaled that command chaining is no longer in effect.

RESUME SUBCHANNEL signals that the CCW that caused channel-program suspension may have been modified, that the CCW must be refetched, and that the contents of the CCW must be examined to determine the settings of the flags. If the S flag is one, execution of that CCW does not occur. If the CCW is valid and the S flag in the CCW is zero, execution is initiated (see “RESUME SUBCHANNEL” on page 14-10 and “Start Function and Resume Function” on page 15-20).

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. The device is signaled that the chain of operations has been concluded.

2. Channel-program execution is suspended at the subchannel; all prefetched IDAWs, MIDAWs, CCWs, and data are discarded; and the subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.

3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the accrued values of the measurement data, including the start-subchannel and sample count, are added to the accumulated values in the measurement block for the subchannel. The start-subchannel count is the only measurement data that is updated in the measurement block if the channel-subsystem-timing facility is not available for the subchannel. (See “Channel-Subsystem Monitoring” on page 17-1 for more information.)

   If a measurement-check condition is detected during the measurement-block update, the channel program is terminated at the subchannel. The subchannel is made status pending with primary, secondary, and alert status, the device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-12.)

4. The subchannel is placed in the suspended state.

5. If the subchannel is not resume pending at this point, the intermediate interruption condition due to suspension is recognized if the suppress-suspended-interruption bit of the ORB is zero; otherwise, the resume function is performed.

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. Channel-program execution is suspended prior to the selection of the device.

2. The subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.

3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the SSCH+RSCH count is incremented, and the accrued function-pending time (a function of the setting of the timing-facility bit) is added to the accumulated value in the measurement block for the subchannel.

   If a measurement-check condition is detected during the measurement-block update, the channel program is not started at the subchannel. The subchannel is made status pending with primary, secondary, and alert status. Deferred condition code one is set, and the start-pending bit remains set to one. The device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-12.)

4. The subchannel is placed in the suspended state.

5. If the subchannel is not resume pending at this point, the subchannel is made status pending with intermediate status due to suspension if the suppress-suspended-interruption-control bit of the ORB is zero; otherwise, the resume function is performed.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

Programming Notes:

1. The execution of MODIFY SUBCHANNEL and START SUBCHANNEL completes with condition code 2 set if the designated subchannel is suspended. The start function is indicated at the subchannel while the subchannel is in the suspended state.

2. In certain situations, normal resumption of the execution of a channel program that has been suspended may not be desired. Normal termination of the suspended channel-program execution may be accomplished by:

   a. Executing HALT SUBCHANNEL and designating the subchannel.

   b. Modifying the CCWs in storage such that, when channel-program execution is resumed, the command transferred to the device is a control command with all modifier bits specified as zeros (no-operation) and with the chain-command flag specified as zero; and then executing RESUME SUBCHANNEL.

   c. When an IRB indicates measurement check along with zero device status, zero subchannel status, and status pending with primary, secondary, and alert status, it may indicate that the measurement check was detected during an attempt to place the subchannel into the suspended state.

3. If the suspended interruption is suppressed, the N condition and DCTI values applicable to the preceding subchannel-active period are not made available to the program. The execution of RESUME SUBCHANNEL when the subchannel is in the suspended state causes path-not-operational conditions and the N condition to be reset to zeros. Path-not-operational conditions and the N condition are not reset when RESUME SUBCHANNEL is executed and the designated subchannel is not in the suspended state.

Commands and Flags for CCWs

Figure 15-30 on page 15-75 lists the command codes for the seven CCW commands and indicates which flags are defined for each command. Except for a format-1 CCW specifying transfer in channel, the flags are ignored for all commands for which they are not defined. The flags are reserved in a format-1 CCW specifying transfer in channel and must be zeros.

Name	Code	Flags
Write	M M M M M M 0 1	CD CC SLI PCI IDA MIDA
Read	M M M M M M 1 0	CD CC SLI SK PCI IDA MIDA
Read backward	M M M M 1 1 0 0	CD CC SLI SK PCI IDA MIDA
Control	M M M M M M 1 1	CD CC SLI PCI IDA MIDA
Sense	M M M M 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Sense ID	1 1 1 0 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Transfer in Channel	X X X X 1 0 0 0	(See note below)

Explanation:

CC	Chain command
CD	Chain data
IDA	Indirect data addressing
M	Modifier bit
MIDA	Modified indirect data addressing
PCI	Program-controlled interruption
S	Suspend
SK	Skip
SLI	Suppress-length indication
X	Ignored in a format-0 CCW; must be zero in a format-1 CCW
Note:	Flags are ignored in a format-0 transfer-in-channel CCW and must be zeros in a format-1 transfer-in-channel CCW.

Figure 15-30. Command Codes and Flags for CCWs

All flags have individual significance, except for the following cases:

- The CC and SLI flags are ignored when the CD flag is set to one, and, for output forward operations the SK flag is ignored.

- The presence of the SLI flag is ignored for immediate operations involving format-0 CCWs, in which case the incorrect-length indication is suppressed regardless of the setting of the flag.

- The incorrect-length indication may be suppressed for immediate operations when executing a format-1 CCW, depending on the incorrect-length-suppression mode.

- The PCI flag is ignored during initial program loading. All flags, except the PCI flag, are ignored when the S flag is one.

- The MIDA flag is mutually exclusive from both the IDA and SKP flags. If the IDA or SKP flag is specified and the MIDA flag is specified, a program-check condition is recognized.

Programming Notes:

1. A malfunction that affects the validity of data transferred in an I/O operation is signaled at the end of the operation by means of unit check or channel-data check, depending on whether the device (control unit) or the channel subsystem detected the error. In order to make use of the checking facilities provided in the system, data read in an input operation should not be used until the end of the operation has been reached and the validity of the data has been checked. Similarly, on writing, the copy of data in main storage should not be destroyed until the program has verified that no malfunction affecting the transfer and recording of data was detected.

2. An error condition may be recognized and the I/O operation terminated when 256 or more chained commands are executed with a device and none of the executed commands result in the transfer of any data. When this condition is recognized, program check is indicated.

3. All CCWs that require suppression of incorrect-length indications must use the SLI flag.

Commands and Flags for DCWs

Figure 15-31 on page 15-76 lists the command codes for the eight DCW commands and indicates which flags are defined for each command.

Name	Code		DCW Flags	
Write	m m m m	m m 0 1	CC	SLI
Read	m m m m	m m 1 0	CC	SLI
Control	m m m m	m m 1 1	CC	SLI
Sense	m m m m	0 1 0 0	CC	SLI
Sense ID	1 1 1 0	0 1 0 0	CC	SLI
Interrogate	0 1 0 0	0 0 0 0		
Transport COB	0 1 1 0	0 0 0 0	CC	SLI[1]
Transfer TCAX	0 1 0 1	0 0 0 0	CC	SLI[1]

Explanation:

CC	Chain command
m	Modifier bit.
SLI	Suppress-length indication
[1]	Incorrect-length condition not recognized for this command; the SLI flag is ignored

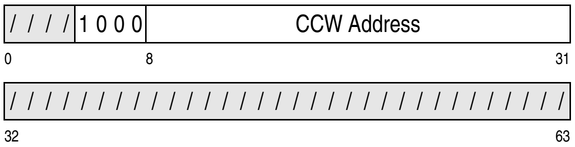
Figure 15-31. Command Codes and Flags for DCWs

Branching in CCW Channel Programs

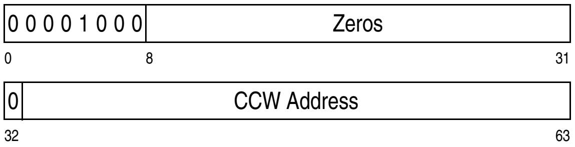
The channel subsystem provides two methods to modify the normal sequential execution of the CCWs in a channel program. One is the transfer-in-channel (TIC) command (described in “Transfer in Channel” on page 15-77), which can be used to loop back to a previously executed CCW, or to connect discontiguous segments of the channel program. The other method, which uses the status-modifier device-status bit (described in the publication *ESA/390 Common I/O-Device Commands*, SA22-7204), allows conditions at the device to cause the channel to bypass the next CCW in the channel program.

Transfer in Channel

Format-0 TIC CCW



Format-1 TIC CCW



The next CCW is fetched from the location in absolute main storage designated by the data-address field of the CCW specifying transfer in channel. The transfer-in-channel command does not initiate any I/O operation, and the I/O device is not signaled of the execution of the command. The purpose of the transfer-in-channel command is to provide chaining between CCWs not located in adjacent doubleword locations in an ascending order of addresses. The command can occur in both data and command chaining.

Bits 29-31 (format 0) or bits 61-63 (format 1) of a CCW that specifies the transfer-in-channel command must be zeros, designating a CCW on a doubleword boundary. Furthermore, a CCW specifying transfer in channel may not be fetched from a location designated by an immediately preceding transfer in channel. When either of these errors is detected or when an invalid address is designated in the transfer-in-channel command, the program-check condition is generated. When a CCW that specifies the transfer-in-channel command designates a CCW at a location protected against fetching, the protection-check condition is generated. Detection of these errors during data chaining causes the operation at the I/O device to be terminated and an interruption condition to be generated, while during command chaining it causes only an interruption condition to be generated.

The contents of the second half of the format-0 CCW, bit positions 32-63, are ignored. Similarly, the contents of bit positions 0-3 of the format-0 CCW are ignored.

Bit positions 0-3 and 8-32 of the format-1 CCW must contain zeros; otherwise, a program-check condition is generated.

Command Retry

The channel subsystem has the capability to perform command retry, a procedure that causes a command to be retried without requiring an I/O interruption. This retry is initiated by the control unit presenting either of two status-bit combinations by means of a special sequence. When immediate retry can be performed, it presents a channel-end, unit-check, and status-modifier status-bit combination, together with device end. When immediate retry cannot be performed, the presentation of device end is delayed until the control unit is prepared. When device end is presented alone, the previous command is transferred again. If device end is accompanied by status modifier, command retry is not performed, and the channel subsystem command-chains to the CCW following the one for which command retry was signaled (for information on status modifier, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204). When the channel subsystem is not capable of performing command retry due to an error condition, or when any status bit other than device end or device end and status modifier accompanies the requested command-retry initiation, the retry is suppressed, and the subchannel becomes status pending. The SCSW stored by TEST SUBCHANNEL contains the status provided by the I/O device.

Programming Note: The following possible results of a command retry must be anticipated by the program:

1. A CCW containing a PCI may, if retried because of command retry, cause multiple PCI interruptions to occur.

2. If a CCW used in an operation is changed before that operation has been successfully completed, the results are unpredictable.

Concluding I/O Operations before Initiation

Subsequent to the execution of START SUBCHANNEL or RESUME SUBCHANNEL for a command-mode operation and before the first command is accepted, the start function can be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL.

Subsequent to the execution of START SUBCHANNEL for a transport-mode operation, the start function may be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL before the TCCB is transported.

For both command-mode and transport-mode operations, if the I/O operation is ended by CANCEL SUBCHANNEL, there is no subsequent interruption condition from the I/O operation, and the subchannel is available for the initiation of another start function. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device. (See also “Clear Function” on page 15-14 and “Halt Function” on page 15-16.)

Concluding I/O Operations during Initiation

After the designated subchannel has been determined to be in a state such that START SUBCHANNEL can be executed, certain tests are performed on the validity of the information specified by the program and on the logical availability of the associated device. This testing occurs during or subsequent to the execution of START SUBCHANNEL and during command chaining and command retry.

A data-transfer operation is initiated at the subchannel and device only when no programming or equipment errors are detected by the channel subsystem and when the device responds with zero status during the initiation sequence. When the channel subsystem detects or the device signals any unusual condition during the initiation of a command-mode I/O operation, the command is said to be not accepted. When the channel subsystem detects or the device signals any unusual condition during the initiation of a transport-mode I/O operation, the I/O-operation initiation is said to be not accepted. For these cases, the subchannel becomes status pending with primary, secondary, and alert status. Deferred condition code 1 is set, and the start-pending bit remains set to one.

Conditions that preclude the initiation of an I/O operation are detailed in the SCSW stored by TEST SUBCHANNEL. In this situation, the device is not started, no interruption conditions are generated subsequent to TEST SUBCHANNEL, and the subchannel is idle. The device is immediately available for the initiation of another operation, provided the command was not rejected because of the busy or not-operational condition.

When an unusual condition causes a command to be not accepted during the initiation of a command-mode I/O operation by command chaining or command retry, an interruption condition is generated, and the subchannel becomes status pending with combinations of primary, secondary, and alert status as a function of the status signaled by the device. The status describing the condition remains at the subchannel until cleared by TEST SUBCHANNEL. The conditions are indicated to the program by means of the corresponding status bits in the SCSW. A path-not-operational condition recognized during command chaining is signaled to the program by means of an interface-control-check indication. The new I/O operation at the device is not started.

START SUBCHANNEL is executed independent of its associated device. Tests on most program-specified information, on device availability and unit status, and on most error conditions are performed subsequent to the execution of START SUBCHANNEL. When any conditions are detected that preclude the performance of the start function, an interruption condition is generated by the channel subsystem and placed at the subchannel, causing it to become status pending.

Immediate Conclusion of Command-Mode I/O Operations

During the initiation of an I/O operation, the device can accept the command and signal the channel-end condition immediately upon receipt of the command code. An I/O operation causing the channel-end condition to be signaled during the initiation sequence is called an *immediate operation*. Status generated by the device for the immediate command, when command chaining is not specified and command retry is not signaled, causes the subchannel to become status pending with combinations of primary, secondary, intermediate, and alert status as a result of information specified in the ORB and CCW and status presented by the device. If the immediate operation is the first operation of the channel program, deferred condition code 1 is set and accompanies the status indications. If intermediate status is indicated, the indication can occur only as a result of the CCW having the PCI flag set to one (see “Program-Controlled Interruption” on page 15-64).

Whenever command chaining is specified after an immediate operation and no unusual conditions have been detected during the operation, or when command retry occurs for an immediate operation, an interruption condition is not generated. The subsequent commands in the chain are handled normally, and, usually, the channel-end condition for the last CCW generates a primary interruption condition. If device end is signaled with channel end, a secondary interruption condition is also generated.

Whenever immediate completion of an I/O operation is signaled, no data has been transferred to or from the device, and the data address in the CCW is not checked for validity. If the subchannel is in the incorrect-length-suppression mode, incorrect length is not indicated to the program, and command chaining is performed when specified. If the subchannel is in the incorrect-length-indication mode, incorrect length and command chaining are under control of the SLI and chain-command flags. The conditions that cause the incorrect-length indication to be suppressed are summarized in Figure 15-27 on page 15-61.

Programming Note: I/O operations for which the entire operation is specified in the command code may be performed as immediate operations. Whether the command is executed as an immediate operation depends on the operation and type of device.

Concluding I/O Operations During Data Transfer

When the subchannel has been passed the contents of an ORB, the subchannel is said to be start pending. When a command-mode I/O operation has been initiated and the command has been accepted, the subchannel becomes subchannel-and-device active. When a transport-mode I/O operation has been initiated, the subchannel remains start pending while the TCCB is transported and executed. The subchannel remains in the respective state unless (1) the channel subsystem detects an equipment malfunction, (2) the operation is concluded by the execution of CLEAR SUBCHANNEL or HALT SUBCHANNEL, or (3) status that causes a primary interruption condition to be recognized (usually channel end) is accepted from the device.

When CCW command chaining and command retry are not specified or when chaining is suppressed because of unusual conditions, the status that is recognized as primary status causes the operation at the subchannel to be concluded and an interruption condition to be generated. The status bits in the associated SCSW indicate primary status and the unusual conditions, if any. The device can present status that is recognized as primary status at any time after the initiation of the I/O operation, and the presentation of status may occur before any data has been transferred.

For operations not involving data transfer, the device normally controls the timing of the channel-end condition. The duration of data-transfer operations may be variable and may be controlled by the device or the channel subsystem.

Excluding equipment errors and the execution of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, and RESET CHANNEL PATH instructions, the channel subsystem signals the device to conclude the performance of an I/O operation during data transfer whenever any of the following conditions occurs:

- The storage areas designated for the operation are exhausted or filled.
- A program-check condition is detected.
- A protection-check condition is detected.
- A CCW chaining-check condition is detected.
- A channel-control-check condition is detected that does not affect the control of the I/O operation.

The first of these conditions occurs when the channel subsystem has decremented the count to zero in the last CCW or current TCW associated with the operation. A count of zero indicates that the channel subsystem has transferred all information specified by the I/O operation. The other four conditions are due to errors and cause premature conclusion of data transfer. In either case, the conclusion is signaled in response to a service request from the device and causes data transfer to cease. If the device has no blocks defined for the operation (such as writing on magnetic tape), it concludes the operation and presents channel-end status.

For command-mode operations, the device can control the duration of an operation and the timing of channel end by blocking of data. On certain operations for which blocks are defined (such as reading on magnetic tape), the device does not present channel-end status until the end of the block is reached, regardless of whether the device has been previously signaled to conclude data transfer.

Checking for the validity of the CCW data address is performed only as data is transferred to or from main storage. When the initial data address in the CCW is invalid, no data is transferred during the operation, and the device is signaled to conclude the operation in response to the first service request. On writing, devices such as magnetic-tape units request the first byte of data before any mechanical motion is started, and, if the initial data address is invalid, the operation is terminated by the channel subsystem before the recording medium has been advanced. However, since the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device also presents device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

Checking for the validity of main-storage addresses of the TCCB is performed before attempting to transport the TCCB to the I/O device. When an applicable address is invalid, a program check condition is recognized and no data is transferred during the operation nor is there any communication with the I/O device. After the TCCB has been transported to the device, the operation is considered initiated at the device and subsequent checks for the validity of main-storage addresses are performed either as information is transferred to or from main storage or as information is prefetched, as specified by the applicable TCW reference to storage (directly or indirectly by a TIDAW). If a main-storage address is found to be invalid after the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device may also present device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

When CCW command chaining takes place, the subchannel is in the subchannel-and-device-active state from the time the first I/O operation is initiated at the device until the device presents channel-end status for the last I/O operation of the chain. The subchannel remains in the device-active state until the device presents the device-end status for the last I/O operation of the chain.

Any unusual conditions cause CCW command chaining to be suppressed and a primary interruption condition to be generated. The unusual conditions can be detected by either the channel subsystem or the device, and the device can provide the indications with channel end, control unit end, or device end. When the channel subsystem is aware of the unusual condition by the time the channel-end status for the operation is accepted, the chain is ended as if the operation during which the condition occurred were the last operation of the chain. The device-end status is recognized as a secondary interruption condition whether presented together with the channel-end status or separately. If the device presents unit check or unit exception together with either control unit end or device end as status that causes the channel subsystem to recognize the primary interruption condition, then the subchannel-and-device-active state of the subchannel is terminated, and the subchannel is made status pending with primary, secondary, and alert status. Intermediate status may also be indicated if an intermediate interruption condition previously existed at the subchannel for the initial-status-interruption condition or the PCI condition and that condition still remains pending at the subchannel. The channel-end status that was presented to the channel subsystem previously when command chaining was signaled is not made available to the program.

Channel-Path-Reset Function

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset function is performed. The performance of the function consists of: (1) issuing the reset signal on the designated channel path and (2) causing a channel report to be made pending, indicating the completion of the channel-path-reset function.

Channel-Path-Reset-Function Signaling

The channel subsystem issues the reset signal on the designated channel path. As part of this operation, the following actions are taken:

1. All internal indications associated with control-unit-busy, device-busy, and allegiance conditions for the designated channel path are reset. These indications are reset at all subchannels that have access to the designated channel path.The reset function has no other effect on subchannels, including those having I/O operations in progress.

2. If the channel path fails to respond properly to the reset signal (see “I/O-System Reset” on page 17-13 for a detailed description) or, because of a malfunction, the reset signal could not be issued, the channel path is made physically not available at each applicable subchannel.

3. If an I/O operation is in progress at the device and the device is actively communicating on the channel path in the performance of that I/O operation when the reset signal is received on that channel path, the I/O operation is reset, and the control unit and device immediately terminate current communication with the channel subsystem. (To avoid possible misinterpretation of unsolicited device-end status, programming measures can be taken as described in programming note 2 on page 82.)

4. If an I/O operation is in progress in the multipath mode at the device and the device is not currently communicating over the channel path in the performance of that I/O operation when the reset signal is received, then the I/O operation may or may not be reset depending on whether another channel path is available for selection in the same multipath group for the device. If there is at least one other channel path in the multipath group for the device that is available for selection, the I/O operation is not reset. However, the channel path on which the system reset is received is removed from the current set of channel paths that form the multipath group. If the channel path on which the reset signal is received is the only channel path of a multipath group, or if the device is operating in the single-path mode, the I/O operation is reset.

5. The channel-path-reset function causes I/O operations to be terminated at the device as described above; however, I/O operations are *never* terminated at the subchannel by the channel-path-reset function.

If an I/O operation is in progress at the subchannel and the channel path designated for the performance of the channel-path-reset function is being used for that I/O operation, the subchannel may or may not accurately reflect the progress of the I/O operation up to that instant. The subchannel remains in the state that exists at the time the channel-path-reset function is performed until the state is changed because of some action taken by the program or by the device.

Channel-Path-Reset-Function-Completion Signaling

After the reset signal has been issued and an attempt has been made to issue the reset signal, or after it has been determined that the reset signal cannot be issued, the channel-path-reset function is completed. (See “Reset Signal” on page 17-12.)

As a result of the channel-path-reset function being performed, a channel report is made pending (see “Channel-Subsystem Recovery” on page 17-27)

to report the results. If the channel path responds properly to the system-reset signal, the channel report indicates that the channel path has been initialized and is physically available for use. If the reset signal was issued but either the channel path failed to respond properly or the channel path was already not physically available at each subchannel having access to the channel path, the channel report indicates that the channel path has been initialized but is not physically available for use. If, because of a malfunction or because the designated channel path is not in the configuration, the reset signal could not be issued, the channel report indicates that the channel path has not been initialized and is not physically available for use.

Programming Notes:

1. If an I/O operation is in progress in the multipath mode when the channel-path-reset function is performed on a channel path of the multipath group, it is possible for the I/O operation to be

continued on a remaining channel path of the group.

2. When the performance of the channel-path-reset function causes the I/O operation at the device to be reset, unsolicited device-end status presented by the device, if any, may be erroneously interpreted by the channel subsystem to be chaining status and thus cause the channel subsystem to continue the chain of commands. If this situation occurs, then the device-end status is not made available to the program, and the device is selected again by the channel subsystem; however, the device may interpret the initiation sequence as the beginning of a new channel program instead of as command chaining. This possibility can be avoided by issuing CLEAR SUBCHANNEL or HALT SUBCHANNEL, designating the affected subchannels, prior to issuing RESET CHANNEL PATH.

3. The performance of the channel-path-reset function may, on some models, cause overruns to occur on other channel paths.

Even though reset is signaled on the designated channel path, by one or more devices may not have been reset because of a malfunction at a control unit or a malfunction at the physical channel path to the control unit.

When an I/O operation or sequence of I/O operations initiated by the execution of START SUBCHANNEL is ended, the channel subsystem and the device generate status conditions. The generation of these conditions can be brought to the attention of the program by means of an I/O interruption or by means of the execution of the TEST PENDING INTERRUPTION instruction. (During certain abnormal situations, these conditions can be brought to the attention of the program by means of a machine-check interruption. See “Channel-Subsystem Recovery” on page 17-27 for details.)

The status conditions, as well as an address and a count indicating the extent of the operation sequence, are presented to the program in the form of a subchannel-status word (SCSW). The SCSW is stored in an interruption-response block (IRB) during the execution of TEST SUBCHANNEL. When a transport-mode IRB is stored, additional information describing the status of the operation is also stored in the transport-status block.

Normally an I/O operation is being performed until the device signals primary interruption status. Primary interruption status can be signaled during initiation of an I/O operation, or later. An I/O operation can be terminated by the channel subsystem performing a clear or halt function when it detects an equipment malfunction, a program check, a chaining check, a protection check, or an incorrect-length condition, or by performing a clear, halt, or channel-path-reset function as a result of the execution of CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH, respectively.

I/O interruptions provide a means for the CPU to change its state in response to conditions that occur at I/O devices or subchannels. These conditions can be caused by the program, by the channel subsystem, or by an external event at the device.

Interruption Conditions

The conditions causing requests for I/O interruptions to be initiated are called I/O-interruption conditions. When an interruption condition is recognized by the channel subsystem, it is indicated at the appropriate subchannel. The subchannel is then said to be status pending. The subchannel becoming status pending causes the channel subsystem to generate an I/O-interruption request. An I/O-interruption request can be brought to the attention of the program only once.

An I/O-interruption request remains pending until it is accepted by a CPU in the configuration, is withdrawn by the channel subsystem, or is cleared by means of the execution of TEST PENDING INTERRUPTION, TEST SUBCHANNEL, or CLEAR SUBCHANNEL, or by means of subsystem reset. When a CPU accepts an interruption request and stores the associated interruption code, the interruption request is cleared. When the pending interruption is cleared by the execution of TEST PENDING INTERRUPTION, the subchannel remains status pending until the associated interruption condition is cleared when TEST SUBCHANNEL or CLEAR SUBCHANNEL is executed or when the subchannel is reset.

An I/O-interruption condition is normally cleared by means of the execution of TEST SUBCHANNEL. If TEST SUBCHANNEL is executed, designating a subchannel that has an I/O-interruption request pending, both the interruption request and the interruption condition at the subchannel are cleared. The interruption request and the interruption condition can also be cleared by CLEAR SUBCHANNEL.

A device-end status condition generated by the I/O device and presented following the conclusion of the last I/O operation of a start function is reset at the subchannel by the channel subsystem without generating an I/O-interruption condition or I/O-interruption request if the subchannel is currently start pending and if the status contains device end either alone or accompanied by control unit end. If any other status bits accompany the device-end status bit, then the channel subsystem generates an I/O-interruption request with deferred condition code 1 indicated.

When an I/O operation is terminated because of an unusual condition detected by the channel subsystem during the command-initiation sequence, status describing the interruption condition is placed at the subchannel, causing it to become status pending. If the unusual condition is detected by the device, the device-status field of the associated SCSW identifies the condition.

When command chaining takes place, the generation of status by the device does not cause an interruption, and the status is not made available to the program.

When the channel subsystem detects any of the following interruption conditions, it initiates a request for an I/O interruption without necessarily communicating with, or having received the status byte from, the device:

- A programming error associated with the contents of the ORB passed to the subchannel by the previous execution of START SUBCHANNEL
- A suspend flag set to one in the first CCW fetched that initiates a CCW channel program execution for either START SUBCHANNEL or RESUME SUBCHANNEL, and suppress suspended interruption not specified in the command-mode ORB.

- A programming error associated with the first CCW, TCW, TIDAW, TCCB fetch, data fetch, IDAW, or MIDAW.

These interruption conditions from the subchannel, except for the suspended condition, can be accompanied by other subchannel-status indications, but the device-status indications are all stored as zeros.

The channel subsystem issues the clear signal to the device when status containing unit check is presented to a subchannel that is disabled or when the device is not associated with any subchannel. However, if the presented status does not contain unit check, the status is accepted by the channel subsystem and discarded without causing the subchannel to become status pending.

An interruption condition caused by the device may be accompanied by multiple device-status conditions. Furthermore, more than one interruption condition associated with the same device can be accepted by the channel subsystem without an intervening I/O interruption. As an example, when the channel-end condition is not cleared at the device by the time device end is generated, both conditions may be cleared at the device concurrently and indicated in the SCSW together. Alternatively, channel-end status may have been previously accepted at the subchannel, and an I/O interruption may have occurred; however, the associated status-pending condition may not have been cleared by TEST SUBCHANNEL by the time device-end status was accepted at the subchannel. In this situation, the device-end status may be merged with the channel-end status without causing an additional I/O interruption. Whether an interruption condition may be merged at the subchannel with other existing interruption conditions depends upon whether the interruption condition is unsolicited or solicited.

Unsolicited Interruption Condition: An unsolicited interruption condition is any interruption condition that is unrelated to the performance of a clear, halt, resume, interrogate, or start function. An unsolicited interruption condition is identified at the subchannel as alert status. An unsolicited interruption condition can be generated only when the subchannel is not device active.

The subchannel and device status associated with an unsolicited interruption condition is never merged with that of any currently existing interruption condition. If the subchannel is currently status pending, the unsolicited interruption condition is held in abeyance in either the channel subsystem or the device, as appropriate, until the status-pending condition has been cleared. Whenever the subchannel is idle and zero status is presented by the device, the status is discarded.

Solicited Interruption Condition: A solicited interruption condition is any interruption condition generated as a direct consequence of performing or attempting to perform a clear, halt, resume, interrogate, or start function. Solicited interruption conditions include any interruption condition generated while the subchannel is either subchannel-and-device active or device active. When the subchannel is operating in transport mode, solicited interruption conditions can be generated when the subchannel is start pending. The subchannel and device status associated with a solicited interruption condition may be merged at the subchannel with that of another currently existing solicited interruption condition. Figure 16-1 on page 16-4 describes the interruption condition that results from any combination of bits in the status-control field of the SCSW.

Status-Control Field	Status-Control-Bit Combinations															
Alert	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
Primary	0	1	1	1	1	0	0	0	1	1	1	1	0	0	0	0
Secondary	0	0	1	1	0	1	1	0	0	1	1	0	1	1	0	0
Intermediate	0	0	0	1	1	0	1	1	0	0	1	1	0	1	1	0
Status pending	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Resulting interruption condition	E	S	S	S	S	S	-	S	S	S	S	S	S	-	S	S

Explanation:

-	Combination does not occur.
E	Unsolicited or solicited interruption condition.
S	Solicited interruption condition.
0	Indicates the bit stored as zero.
1	Indicates the bit stored as one.

Figure 16-1. Interruption Condition for Status-Control-Bit Combinations

Intermediate Interruption Condition

An intermediate interruption condition is a solicited interruption condition that indicates that an event has occurred for which the program had previously requested notification. An intermediate interruption condition is described by any of, or any combination of the following:

- solicited subchannel status
- the Z bit
- the subchannel-suspended condition
- the Q bit

An intermediate interruption condition can occur only after it has been requested by the program through the use of flags in the ORB, CCW, or a CANCEL SUBCHANNEL for a subchannel operating in transport mode that requests an interrogate operation. Depending on the state of the subchannel, the performance or suspension of the I/O operation continues, unaffected by the setting of the intermediate-status bit.

An intermediate interruption condition can be indicated only together with one of the following indications:

1. Subchannel active

2. Status pending with primary status alone

3. Status pending with primary status together with alert status or secondary status or both

4. Suspended

5. Interrogate-complete (Q-bit)

If only the intermediate-status bit and the status-pending bit of the status-control field are ones during the execution of TEST SUBCHANNEL, the device-status field is zero.

Primary Interruption Condition

A primary interruption condition is a solicited interruption condition that indicates the performance of the start function is completed at the subchannel. A primary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with primary status. Once the primary interruption condition is indicated at the subchannel, the channel subsystem is no longer actively participating in the I/O operation by transferring commands or data. When a subchannel is status pending with a primary interruption condition, the execution of any of the following instructions results in the setting of a nonzero condition code: HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, and START SUBCHANNEL. Once the primary interruption condition is cleared by the execution of TEST SUBCHANNEL, the subchannel accepts the START

SUBCHANNEL instruction. (See “START SUBCHANNEL” on page 14-15)

Secondary Interruption Condition

A secondary interruption condition is a solicited interruption condition that normally indicates the completion of an I/O operation at the device. A secondary interruption condition is also generated by the channel subsystem if the start function is terminated because a solicited alert interruption condition is recognized prior to initiating the first I/O operation at the device. A secondary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with secondary status. Once the channel subsystem has accepted status from the device that causes a secondary interruption condition to be recognized, the start function is completed at the device.

Alert Interruption Condition

An alert interruption condition is either a solicited interruption condition that indicates the occurrence of an unusual condition in a halt, resume, or start function or an unsolicited interruption condition that describes a condition unrelated to the performance of a halt, resume, or start function. An alert interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with alert status. An alert interruption condition may be generated by either the channel subsystem or the device. Nonzero alert status is always brought to the attention of the program.

Priority of Interruptions

All requests for an I/O interruption are asynchronous to any activity in any CPU, and interruption requests associated with more than one subchannel can exist at the same time. The priority of interruptions is controlled by two types of mechanisms — one establishes within the channel subsystem the priority among interruption requests from subchannels associated with the same I/O-interruption subclass, and another establishes within a given CPU the priority among requests from subchannels of different I/O-interruption subclasses. The channel subsystem requests an I/O interruption only after it has established priority among requests from its subchannels. The conditions responsible for the I/O-interruption requests associated with subchannels are preserved at the subchannels until cleared by a CPU's execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL or I/O-system reset is performed.

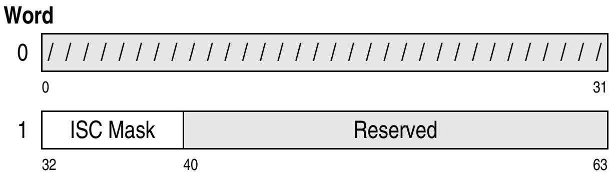
The assignment of priority among requests for interruption from subchannels of the same I/O-interruption subclass is in the order that the need for interruption is recognized by the channel subsystem. The order of recognition by the channel subsystem is a function of the type of interruption condition and the type of channel path. For the parallel-I/O-interface type of channel path, the order depends on the electrical position of the device on the channel path to which it is attached. (A device's electrical position on the parallel-I/O interface is not related to its device address.)

The assignment of priority among requests for interruption from subchannels of different I/O-interruption subclasses is made by the CPU according to the numerical value of the I/O-interruption subclass codes (with zero having highest priority), in conjunction with the I/O-interruption-subclass mask in control register 6. The numerical value of the I/O-interruption-subclass code directly corresponds to the bit position in the I/O-interruption-subclass mask in control register 6 of a CPU. If, in any CPU, an I/O-interruption-subclass-mask bit is zero, then all subchannels having an I/O-interruption-subclass code numerically equal to the associated position in the mask register are said to be masked off in the respective CPU. Therefore, a CPU accepts the highest-priority I/O-interruption request from a subchannel that has the lowest-numbered I/O-interruption subclass code that is not masked off by a corresponding bit in control register 6 of that CPU. When the highest-priority interruption request is accepted by a CPU, it is cleared so that the interruption request is not accepted by any other CPU in the configuration.

The priority of interruption handling can be modified by the execution of either TEST SUBCHANNEL or CLEAR SUBCHANNEL. When either of these instructions is executed and the designated subchannel has an interruption request pending, that interruption request is cleared, without regard to any previous established priority. The relative priority of the remaining interruption requests is unchanged.

Programming Notes:

1. The I/O-interruption subclass mask is in control register 6, which has the following format:



2. Control register 6 is set to all zeros during initial CPU reset.

Interruption Action

An I/O interruption can occur only when the I/O-interruption-subclass-mask bit associated with the subchannel is one and the CPU is enabled for I/O interruptions.

The interruption occurs at the completion of a unit of operation (see "Point of Interruption" on page 5-24). If the channel subsystem establishes the priority among requests for interruption from subchannels while the CPU is disabled for I/O interruptions, the interruption occurs immediately after the completion of the instruction enabling the CPU and before the next instruction is executed, provided that the I/O-interruption subclass-mask bit associated with the subchannel is one. Alternatively, if the channel subsystem establishes the priority among requests for interruption from subchannels while the I/O-interruption-subclass-mask bit is zero for each subchannel that is status pending, the interruption occurs immediately after the completion of the instruction that sets at least one of the I/O-interruption-subclass-mask bits to one, provided that the CPU is also enabled for I/O interruptions. This interruption is associated with the highest-priority I/O-interruption request, as established by the CPU.

If the channel subsystem has not established the priority among requests for interruption from the subchannels by the time the interruption is allowed, the interruption does not necessarily occur immediately after the completion of the instruction enabling the CPU. A delay can occur regardless of how long the interruption condition has existed at the subchannel.

The interruption causes the current PSW to be stored as the input/output old PSW at real locations 368-383 and causes the I/O-interruption code associated with the interruption to be stored at real locations 184-195 of the CPU allowing the interruption. Subsequently, a new input/output PSW is loaded from real locations 496-511 and processing resumes in the CPU state indicated by that PSW. The subchannel causing the interruption is identified by the interruption code.

The I/O-interruption code has the following format when it is stored. The code is described in "TEST PENDING INTERRUPTION" on page 14-19.

Hex.		
B8	184	Subsystem-Identification Word
BC	188	I/O-Interruption Parameter
C0	192	I/O-Interruption-Identification Word

Programming Note: The I/O-interruption subclass code for all subchannels is set to zero by I/O-system reset. It may be set to any of the values 0-7 by the execution of MODIFY SUBCHANNEL. (The operation of the instruction is described in "MODIFY SUBCHANNEL" on page 14-7.)

Interruption-Response Block

The interruption-response block (IRB) is the operand of TEST SUBCHANNEL. The two rightmost bits of the IRB address are zeros, designating the IRB on a word boundary. The IRB contains three major fields: the subchannel-status word, the extended-status word, and the extended-control word. When the extended-I/O-measurement-word mode is enabled at the subchannel, the IRB contains a fourth major field, the extended-measurement word.

IRB Format

The format of the IRB stored depends upon the subchannel status. The status present at the subchannel when a TEST SUBCHANNEL instruction is executed determines whether a command-mode IRB or transport-mode IRB is stored. Bit 11 of word 0 of the IRB is the IRB-format control bit (X). When an IRB is stored with X set to zero, a command-mode IRB is stored. (See "Command-Mode SCSW" on page 16-8.) When an IRB is stored with X set to one, a 3-bit format field is defined. (See "Format (FMT)" on page 16-35.) The format of the IRB is specified according to the table below:

Subchannel Mode	Subchannel Status	Bit (X)	FMT	IRB Mode Stored
Command mode	Any subchannel status or combination of status	0	N	Command mode
Transport mode	Status-pending alone with halt function	1	Y-0	Transport mode
	Status-pending alone with clear function	0	N	Command mode
	Primary status with or without any other status combination	1	Y-0	Transport mode
	Secondary status alone	0	N	Command mode
	Intermediate status	1	Y-0	Transport mode
	Alert status with secondary, without primary or intermediate status	0	N	Command mode
Explanation: N: Format field is not defined. Y-0: Format field is defined and its value is 0.				

Figure 16-2. Summary of IRB Format as Function of Subchannel Status

The general layout of the IRB is as follows:

Word	
0 1 2	Subchannel-Status Word
3 ⋮ 7	Extended-Status Word
8 15	Extended-Control Word
16 ⋮ 23	Extended-Measurement Word
	0 31

The length of the subchannel-status and extended-status words is 12 bytes and 20 bytes, respectively. The length of the extended-control word is 32 bytes. When the extended-control bit, bit 14 of word 0 of the SCSW, is zero, words 8-15 of the interruption-response block may or may not be stored. The length of the extended-measurement word is 32 bytes. When the conditions for storing the extended-measurement word are not met (see "Extended-Measurement Word" on page 16-56), words 16-23 of the interruption-response block may or may not be stored.

Subchannel-Status Word

The subchannel-status word (SCSW) provides to the program indications describing the status of a subchannel and its associated device. When a transport-mode IRB is stored, additional information describing the status of the operation and the associated device may also be stored in the transport-status block associated with the operation. If performance of a halt, resume, or start function has occurred, the SCSW may describe the conditions under which the operation was concluded.

The SCSW is stored when TEST SUBCHANNEL is executed and the designated subchannel is operational. The SCSW is placed in words 0-2 of the IRB that is designated as the TEST SUBCHANNEL operand. When STORE SUBCHANNEL is executed, the SCSW is stored in words 7-9 of the subchannel-information block (described in "Subchannel-Information Block" on page 15-2).

Figure 16-3 on page 16-8 shows the summary and contents of the command-mode SCSW.

Command-Mode SCSW

The format of a command-mode SCSW is as follows:

<table>
<tr><th>Word</th><th colspan="16"></th></tr>
<tr><td>0</td><td>Key</td><td>S</td><td>L</td><td>CC</td><td>F</td><td>P</td><td>I</td><td>X</td><td>U</td><td>Z</td><td>E</td><td>N</td><td>0</td><td>FC</td><td>AC</td><td>SC</td></tr>
<tr><td>1</td><td colspan="16">CCW Address</td></tr>
<tr><td>2</td><td colspan="4">DEVS</td><td colspan="8">SCHS</td><td colspan="4">Count</td></tr>
<tr><td></td><td>0</td><td>4</td><td></td><td>6</td><td>8</td><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td>16</td><td></td><td>20</td><td>27 31</td></tr>
</table>

Figure 16-4. Command-Mode SCSW

The contents of the subchannel-status word (SCSW) depend on the state of the subchannel when the SCSW is stored. Depending on the state of the subchannel and the device, the specific fields of the SCSW may contain (1) information pertaining to the last operation, (2) information unrelated to the performance of an operation, (3) zeros, or (4) meaningless values. The following descriptions indicate when an SCSW field contains meaningful information for a command-mode IRB.

Subchannel Key

When the start-function bit, bit 17 of word 0, is one, bit positions 0-3 of word 0 contain the access key used during performance of the associated start function. These bits are identical with the key specified in bit positions 0-3 of word 1 of the ORB. The subchannel key is meaningful only when the start-function bit, bit 17 of word 0, is one.

Suspend Control (S)

When the start-function bit, bit 17 of word 0, is one, bit 4 of word 0, when one, indicates that the suspend function can be initiated at the subchannel. Bit 4 is meaningful only when bit 17 is one. If bit 17 is one and bit 4 is one, channel-program execution can be suspended if the channel subsystem recognizes an S flag set to one in a CCW. If bit 4 is zero, channel-program execution cannot be suspended, and, if an S flag set to one in a CCW is encountered, a program-check condition is recognized.

Extended-Status-Word Format (L)

When the status-pending bit, bit 31 of word 0, is one, bit 5 of word 0, when one, indicates that a format-0 ESW has been stored. A format-0 ESW is stored when an interruption condition containing any of the following indications is cleared by TEST SUBCHANNEL:

Channel-data check
Channel-control check
Interface-control check
Measurement-block-program check
Measurement-block-data check
Measurement-block-protection check
Path verification required
Authorization check
Extended subchannel logout pending

The extended-status-word-format bit is meaningful whenever the subchannel is status pending. The extended-status information that is used to form a format-0 ESW is cleared at the subchannel by TEST SUBCHANNEL or CLEAR SUBCHANNEL.

Deferred Condition Code (CC)

When the start-function bit, bit 17 of word 0, is one and the status-pending bit, bit 31 of word 0, is also one, bits 6 and 7 of word 0 indicate the general reason that the subchannel was status pending when TEST SUBCHANNEL or STORE SUBCHANNEL was executed. The deferred condition code is meaningful when the subchannel is status pending with any combination of status and only when the start-function bit of the function-control field in the SCSW is one. The meaning of the deferred condition code for each value when the subchannel is status pending is given in Figure 16-5 on page 16-11.

The deferred condition code, if not zero, is used to indicate whether conditions have been encountered that preclude the subchannel becoming subchannel-and-device active while the subchannel is either start pending or suspended.

Deferred Condition Code 0: A normal I/O interruption has taken place.

Deferred Condition Code 1: Status is present in the SCSW that was presented by the associated device or generated by the channel subsystem subsequent to the setting of condition code 0 for START SUBCHANNEL or RESUME SUBCHANNEL. If only the alert-status bit and the status-pending bit of the status-control field of the SCSW are ones, the status present is not related to the execution of a channel program. If the intermediate-status bit, the primary-status bit, or both are ones, then the status is related to the execution of the channel program specified by the most recently executed START SUBCHANNEL instruction or implied by the most recently executed RESUME SUBCHANNEL instruction. (See “Immediate Conclusion of Command-Mode I/O Operations” on page 15-78.) If the secondary-status bit is one and the primary-status bit is zero, the status present is related to the channel program specified by the START SUBCHANNEL instruction or implied by the RESUME SUBCHANNEL instruction that preceded the most recently executed START SUBCHANNEL instruction.

Deferred Condition Code 2: This code does not occur and is reserved for future use.

Deferred Condition Code 3: An attempted device selection has occurred, and the device appeared not operational on all of the channel paths that were available for selection of the device.

A device appears not operational when it does not respond to a selection attempt by the channel subsystem. This occurs when the control unit is not provided in the system, when power is off in the control unit, or when the control unit has been logically switched off the channel path. The not-operational state is also indicated when the control unit is provided and is capable of attaching the device, but the device has not been installed and the control unit is not designed to recognize the device being selected as one of its attached devices. (See also “I/O Addressing” on page 13-5.)

A deferred condition code 3 also can be set by the channel subsystem if no channel paths to the device are available for selection. (See Figure 16-5 on page 16-11.)

Programming Notes:

1. If, during performance of a start function, the I/O device being selected is not installed or has been logically removed from the control unit, but the associated control unit is operational and the control unit recognizes the I/O device being selected as one of its I/O devices, the control unit, depending upon the model, either fails to recognize the address of the I/O device or considers the I/O device to be not ready. In the former case, a path-not-operational condition is recognized, subject to the setting of the path-operational mask. (See “Path-Operational Mask (POM)” on page 15-7.) In the latter case, the not-ready condition is indicated when the control unit responds to the selection and indicates unit check whenever the not-ready state precludes successful initiation of the operation at the I/O device. In this case, unit-check status is indicated in the SCSW, the subchannel becomes status pending with primary, secondary, and alert status, and with deferred condition code 1 indicated. (See the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for a description of unit-check status.) Refer to the System Library publication for the control unit to determine how the condition is indicated.

2. The deferred condition code is 1, and the status-control field contains the status-pending and intermediate-status bits or the status-pending, intermediate-status, and alert-status bits as ones when HALT SUBCHANNEL has been executed and the designated subchannel is suspended and status pending with intermediate status. If the alert-status bit is one, then subchannel-logout information was generated as a result of attempting to issue the halt signal to the device.

Bit 6	Bit 7	Status Control[1]	Meaning
0	0	A I P S X	Normal I/O Interruption
		A I P – X	
		A – P S X	
		A – P – X	
		– I P S X	
		– I P – X	
		– I – – X	
		– – P S X	
		– – P – X	
0	1	A I P S X	Either an immediate operation, with chaining not specified, has ended normally, or the setting of some status condition precluded the initiation or resumption of a requested I/O operation at the device.
		A I P – X	
		A I – – X[2]	
		A – P S X	
		A – P – X	
		A – – S X	
		A – – – X	
		– I P S X	
		– I P – X	
		– I – – X[2]	
		– – P S X	
		– – P – X	
		– – – S X[3]	
		– – – – X[3] [2]	
1	0	Reserved	Reserved
1	1	– – P S X	The device is not operational on any available path or, if a dedicate-allegiance condition exists, the device is not operational on the path to which the dedicated-allegiance is owed.
		– I P S X	

Explanation:

– Bit is zero.
[1] The allowed combinations of status-control-bit settings when the start-function bit is one in the function-control field.
[2] The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently suspended
[3] The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently start pending.
A Alert status.
I Intermediate status.
P Primary status.
S Secondary status.
X Status pending.

Figure 16-5. Deferred-Condition-Code Meaning for Status-Pending Subchannel

CCW Format (F)

When the start-function bit, bit 17 of word 0, is one, bit 8 of word 0 indicates the format of the CCWs associated with an I/O operation. The format bit is meaningful only when bit 17 is one. If bit 8 of word 0 is zero, format-0 CCWs are indicated. If it is one, format-1 CCWs are indicated. (See “Channel-Command Word” on page 15-31 for the description of the two CCW formats.)

Prefetch (P)

When the start-function bit, bit 17 of word 0, is one, bit 9 of word 0 indicates whether or not unlimited prefetching of CCWs, IDAWs, MIDAWS, and associated data is allowed. The prefetch bit is meaningful only when bit 17 is one. If bit 9 is zero, prefetching of one CCW describing a data area is allowed during output-data-chaining operations and is not allowed during any other operations. If bit 9 is one, unlimited prefetching of CCWs, IDAWs, MIDAWS, and associated data is allowed. It is model dependent whether prefetching is actually performed for any or all of the CCWs, IDAWs, MIDAWS, and associated data that comprise the CCW channel program.

Initial-Status-Interruption Control (I)

When the start-function bit, bit 17 of word 0, is one, bit 10 of word 0, when one, indicates that the channel subsystem is to generate an intermediate interruption condition if the subchannel becomes subchannel active (see "Initial-Status-Interruption Control (I)" on page 15-27). Bit 10 of word 0, when zero, indicates that the subchannel becoming subchannel active is not to cause an intermediate interruption condition to be generated.

The program requests the intermediate interruption condition by means of the command-mode ORB. An I/O interruption that results from that request may be due to the channel subsystem performing either a start function or a resume function. (See "Zero Condition Code (Z)" on page 16-12 for details of the indication given by the channel subsystem when the intermediate interruption condition is cleared by TEST SUBCHANNEL.)

Address-Limit-Checking Control (A)

When the address-limit-checking facility is installed and the start-function bit, bit 17 of word 0, is one, bit 11 of word 0, when one, indicates that the channel subsystem has been requested by the program to perform address-limit checking, subject to the setting of the limit mode at the subchannel (see "Address-Limit-Checking Control (A)" on page 15-27). The address-limit-checking-control bit is meaningful only when bit 17 is one.

IRB-Format Control (X)

Bit 11 of word 0 is the IRB-format control bit (X). The value of this bit is zero for the command-mode IRB. See Figure 16-2 on page 16-7.

Suppress-Suspended Interruption (U)

When the start-function bit, bit 17 of word 0, is one, bit 12 of word 0, when one, indicates that the channel subsystem has been requested by the program to suppress the generation of a subchannel-suspended interruption condition when the subchannel is suspended (see "Suppress-Suspended-Interruption Control (U)" on page 15-27). When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel is suspended during the execution of the associated channel program. The suppress-suspended-interruption bit is meaningful only when bit 17 is one.

Subchannel-Control Field

The following subchannel-control-information descriptions apply to the subchannel-control field, bits 13-31 of word 0 of the SCSW.

Zero Condition Code (Z)

Bit 13 of word 0, when one, indicates that the subchannel has become subchannel active and the channel subsystem has recognized an initial-status-interruption condition at the subchannel. The Z bit is meaningful only when the intermediate-status bit, bit 28 of word 0, and the start-function bit, bit 17 of word 0, are both ones.

If the initial-status-interruption-control bit, bit 10 of word 1 of the command-mode ORB, is one when START SUBCHANNEL is executed, then the subchannel becoming subchannel active causes the subchannel to be made status pending with intermediate status indicating the initial-status-interruption condition. The initial-status-interruption condition remains at the subchannel until the intermediate interruption condition is cleared by the execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL. If the initial-status-interruption-control bit of the command-mode ORB is zero when START SUBCHANNEL is executed, then the subchannel becoming subchannel active does not cause an intermediate interruption condition to be generated, and the initial-status-interruption condition is not recognized.

Extended Control (E)

Bit 14 of word 0, when one, indicates that model-dependent information or concurrent-sense information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW, if stored, are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both.

Programming Note: During the execution of TEST SUBCHANNEL, the storing of words 0-7 of the ECW is a model-dependent function subject to the setting of bit 14 as described above. Therefore, the program should always provide sufficient storage to accommodate the storing of at least a 64-byte IRB or, when the extended-I/O-measurement-word mode is enabled at the subchannel, a 96-byte IRB.

Path Not Operational (N)

Bit 15 of word 0, when one, indicates that the N condition has been recognized by the channel subsystem. The N condition, in turn, indicates that one or more path-not-operational conditions have been recognized. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection.

The N bit is meaningful whenever the status-control field contains any of the indications listed below and at least one basic I/O function is also indicated at the subchannel:

- Status pending with any combination of primary, secondary, or alert status
- Status pending alone
- Status pending with intermediate status when the subchannel is also suspended

The N condition is reset whenever the execution of TEST SUBCHANNEL results in the setting of condition code 0 and the N bit is meaningful as described above.

Notes:

1. A path-not-operational condition does not imply a malfunctioning channel path. A malfunctioning channel path causes the generation of an error indication, such as interface-control check.

2. When a path-not-operational condition has been recognized and the subchannel subsequently becomes status pending with only intermediate status, the path-not-operational condition (a) continues to be recognized until the subchannel becomes status pending with primary status or becomes suspended and (b) is indicated by storing the path-not-operational bit as a one during the execution of TEST SUBCHANNEL. When a path-not-operational condition has been recognized and the channel-program execution subsequently becomes suspended, the path-not-operational condition does not remain pending if channel-program execution is subsequently resumed. Instead, the old indication is lost, and the path-not-operational indication, if any, pertains to the attempt by the channel subsystem to resume channel-program execution.

Function Control (FC)

The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

Start Function (Bit 17): When one, bit 17 indicates that a start function has been requested and is either pending or in progress at the subchannel. A start function is requested by the execution of START SUBCHANNEL. A start function is indicated at the subchannel when condition code 0 is set during the execution of START SUBCHANNEL. The start-function indication is cleared at the subchannel when TEST SUBCHANNEL is executed and the subchannel is either status pending alone or status pending with any combination of alert, primary, or secondary status. The start-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Halt Function (Bit 18): When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is subchannel active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least primary status indicated. If the subchannel is device active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least secondary status indicated. If the subchannel is suspended and status pending with intermediate status when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with intermediate status. If the subchannel is idle when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending alone. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. In normal operations, this function is indicated together with bit 17; that is, there is a start function either pending or in progress that is to be halted.

Clear Function (Bit 19): When one, bit 19 indicates that a clear function has been requested and is either pending or in progress at the subchannel. A clear function is requested by the execution of CLEAR SUBCHANNEL. A clear function is indicated at the subchannel when condition code 0 is set for CLEAR SUBCHANNEL (see "CLEAR SUBCHANNEL" on page 14-5). The clear-function indication is cleared at the subchannel when the resulting status-pending condition is cleared by TEST SUBCHANNEL.

Activity Control (AC)

The activity-control field is contained in bit positions 20-26 of the first word of the SCSW. This field indicates the current progress of a basic I/O function previously accepted at the subchannel. By using the contents of this field, the program can determine the degree of completion of the basic I/O function. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

Bit	Meaning
20	Resume pending
21	Start pending
22	Halt pending
23	Clear pending
24	Subchannel active
25	Device active
26	Suspended

When an SCSW is stored that has the status-pending bit of the status-control field zero and all zeros in the activity-control field, the subchannel is said to be idle or in the idle state.

Note: All conditions that are represented by the bits in the function-control field and by the resume-pending, start-pending, halt-pending, clear-pending, subchannel-active, and suspended bits in the activity-control field are reset at the subchannel when TEST SUBCHANNEL is executed and the subchannel is (1) status pending alone, (2) status pending with primary status, (3) status pending with alert status, or (4) status pending with intermediate status and is also suspended.

Resume-Pending (Bit 20): When one, bit 20 indicates that the subchannel is resume pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes resume pending when condition code 0 is set for RESUME SUBCHANNEL. The point at which the subchannel is no longer resume pending is a function of the subchannel state existing when the resume-pending condition is recognized and the state of the device if channel-program execution is resumed.

If the subchannel is in the suspended state when the resume-pending condition is recognized, the CCW that caused the suspension is refetched, the setting of the suspend flag is examined, and one of the following actions is taken by the channel subsystem:

1. If the CCW suspend flag is one, the device is not selected, the subchannel is no longer resume pending, and the channel-program execution remains suspended.

2. If the CCW suspend flag is zero, the channel subsystem attempts to resume channel-program execution by performing a modified start function. The resumption of channel-program execution appears to the device as the initiation of a new channel-program execution. The resume function causes the channel subsystem to perform the path-management operation as if a new start function were being initiated, using the ORB parameters previously passed to the subchannel by START SUBCHANNEL with the exception that the channel-program address is the address of the CCW that caused the suspension of the channel-program execution.

   The subchannel remains resume pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See “Start Function and Resume Function” on page 15-20.)

   The subchannel is no longer resume pending when any of the following events occurs:

   a. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

   b. CLEAR SUBCHANNEL is executed.

   c. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

   d. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

   e. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

If the subchannel is not in the suspended state when the resume-pending condition is recognized, the CCW suspend flag of the most recently fetched CCW, if any, is examined, and one of the following actions is taken by the channel subsystem:

1. If a CCW has not been fetched or the suspend flag of the most recently fetched CCW is zero, the subchannel is no longer resume pending, and the resume function is not performed.

2. If the suspend flag of the most recently fetched CCW is one, the subchannel is no longer resume pending, and the CCW is refetched. The subchannel proceeds with channel-program execution if the suspend flag of the refetched CCW is zero. The subchannel suspends channel-program execution if the suspend flag of the refetched CCW is one.

Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched that has an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

Start-Pending (Bit 21): When one, bit 21 indicates that the subchannel is start pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes start pending when condition code 0 is set for START SUBCHANNEL. The subchannel remains start pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See “Start Function and Resume Function” on page 15-20.)

The subchannel becomes no longer start pending when any of the following occurs:

1. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

2. The subchannel becomes suspended because of a suspend flag validly set to one in the first CCW.

3. CLEAR SUBCHANNEL is executed.

4. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

Halt-Pending (Bit 22): When one, bit 22 indicates that the subchannel is halt pending. The channel subsystem may or may not be in the process of performing the halt function. The subchannel becomes halt pending when condition code 0 is set for HALT SUBCHANNEL. The subchannel remains halt pending when, during the performance of the halt function, the channel subsystem (1) determines that it is not possible to attempt to issue the halt signal to the device, (2) determines that the attempt to issue the halt signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the halt signal is issued to the device. (See “Halt Function” on page 15-16.)

The subchannel is no longer halt pending when any of the following occurs:

1. While performing the halt function, the channel subsystem determines that the halt signal has been issued to the device.

2. CLEAR SUBCHANNEL is executed.

3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

4. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

Clear-Pending (Bit 23): When one, bit 23 indicates that the subchannel is clear pending. The channel subsystem may or may not be in the process of performing the clear function. The subchannel becomes clear pending when condition code 0 is set for CLEAR SUBCHANNEL. The subchannel remains clear pending when, during performance of the clear function, the channel subsystem (1) determines that it is not possible to attempt to issue the clear signal to the device, (2) determines that the attempt to issue the clear signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the clear signal is issued to the device. (See “Clear Function” on page 15-14.)

The subchannel is no longer clear pending when either of the following occurs:

1. While performing the clear function, the channel subsystem determines that the clear signal has been issued to the device.

2. TEST SUBCHANNEL clears the status-pending condition alone.

Subchannel Active (Bit 24): When one, bit 24 indicates that the subchannel is subchannel active. A subchannel is said to be subchannel active when an I/O operation is currently being performed at the subchannel. The subchannel becomes subchannel active when the first command is accepted and the start function or resume function is not immediately concluded at the subchannel. (See “Immediate Conclusion of Command-Mode I/O Operations” on page 15-78.)

The subchannel is no longer subchannel active when any of the following occurs:

1. The subchannel becomes suspended.

2. The subchannel becomes status pending with primary status.

3. CLEAR SUBCHANNEL is executed.

4. The device appears not operational during performance of a halt function.

The subchannel does not become subchannel active during performance of the function specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

Device Active (Bit 25): When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active when the first command is accepted.

The subchannel is no longer device active when any of the following occurs:

1. The subchannel becomes suspended.

2. The subchannel becomes status pending with secondary status.

3. CLEAR SUBCHANNEL is executed.

4. The device appears not operational during performance of a halt function.

If the subchannel is not start pending or if the status accepted from the device also describes an alert condition, the subchannel becomes status pending with secondary status. After the status has been accepted from the device, the device is capable of accepting a command for performing a new I/O operation. If the subchannel is start pending and the status is device end or device end with control unit end, then the channel subsystem discards the status and performs the start function for the new channel program. (See“Start Function and Resume Function” on page 15-20) In this situation, the subchannel does not become status pending with the secondary interruption condition, and the status is not made available to the program.

The subchannel does not become device active during performance of the functions specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

Suspended (Bit 26): When one, bit 26 indicates that the subchannel is suspended. A subchannel is said to be suspended when channel-program execution is currently suspended. The subchannel becomes suspended as part of the suspend function. (See “Suspension of CCW Channel-Program Execution” on page 15-73.)

The subchannel is no longer suspended when any of the following occurs:

1. As part of the resume function following the execution of RESUME SUBCHANNEL when the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted for channel-end and device-end initial status, with or without status modifier, and the CCW does not specify command chaining.
2. CLEAR SUBCHANNEL is executed.
3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
4. TEST SUBCHANNEL clears intermediate status while the halt function is specified.
5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

Programming Note: When an SCSW is stored by STORE SUBCHANNEL or TEST SUBCHANNEL following CLEAR SUBCHANNEL but prior to the subchannel becoming status pending, and the subchannel-active bit, bit 24 of word 0, is stored as zero, this does not mean that data transfer has stopped for the device. The program cannot determine whether data transfer has stopped until the subchannel becomes status pending as a result of performing the clear function.

Status Control (SC)

The status-control field is contained in bit positions 27-31 of the first word of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status, the Z bit, or, in the case of the subchannel-suspended interruption, the suspended bit, bit 26. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see “Enabled (E)” on page 15-3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4); bits 27-30 are meaningful when bit 31 is one. The status-control bits are defined as follows:

Alert Status (Bit 27): When one (and when the status-pending bit is also one), bit 27 indicates an alert interruption condition exists. In such a case, the subchannel is said to be status pending with alert status. An alert interruption condition is recognized when alert status is present at the subchannel. Alert status may be subchannel status or device status. Alert status is status generated by either the channel subsystem or the device under any of the following conditions:

- The subchannel is idle (activity-control bits 20-26 and status-control bit 31 are zeros).
- The subchannel is start pending, and the status condition precludes initiation of the I/O operation.
- The subchannel is subchannel-and-device active, and the status condition has suppressed command chaining or would have suppressed command chaining if chaining had been specified (see “CCW Channel Program Chaining” on page 15-60).
- The subchannel is subchannel-and-device active, command chaining is not specified, the

execution of the channel program has just been concluded, and the status presented by the device is attempting to alter the sequential execution of commands (see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for more information on the use of status modifier to alter the sequential execution of commands).

- The subchannel is device active only, and the status presented by the device is other than device end, control unit end, or device end and control unit end.
- The subchannel is suspended (bit 26 is one).

If the subchannel is start pending when an alert interruption condition is recognized, the subchannel becomes status pending with alert status, deferred condition code 1 is set, the start-pending bit remains one, and the performance of the pending I/O operation is not initiated.

When TEST SUBCHANNEL is executed and stores an SCSW with the alert-status bit and the status-pending bit as ones in the IRB, the alert interruption condition is cleared at the subchannel. The alert interruption condition is also cleared during the execution of CLEAR SUBCHANNEL.

Whenever alert status is present at the subchannel, it is brought to the attention of the program. Examples of alert status include attention, device end (which signals a transition from the not-ready to the ready state), incorrect length, program check, and unit check.

Intermediate Status (Bit 28): When one (and when the status-pending bit is also one), bit 28 indicates an intermediate interruption condition exists. In such a case, the subchannel is said to be status pending with intermediate status. Intermediate status can be indicated when the Z bit (of the subchannel-control field), the suspended bit (of the activity-control field), or the PCI bit (of the subchannel-status field) is one.

When the initial-status-interruption-control bit is one in the command-mode ORB, the subchannel becomes status pending with intermediate status (the Z bit indicated) only after the subchannel is subchannel active. If the subchannel does not become subchannel active, the Z condition is not generated.

When suspend control is specified and the generation of an intermediate interruption condition due to suspension is not suppressed in the command-mode ORB, then the subchannel can become status pending with intermediate status due to suspension if a CCW becomes current that contains the suspend flag set to one. When the suspend flag is specified in the first CCW of a channel program, channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit indicated) before the command in the first CCW is transferred to the device. When the suspend flag is specified in a CCW fetched during command chaining, then channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit is indicated), only after the execution of the preceding CCW is complete.

When the PCI flag is specified in a CCW, the generation of an intermediate interruption condition due to PCI depends on whether the CCW is the first CCW of the channel program. When the PCI flag is specified in the first CCW of a channel program, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after initial status is received for the first CCW of the channel program indicating the command has been accepted. When the PCI flag is specified in a CCW fetched while chaining, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after the execution of the preceding CCW is complete. If chaining occurs before an interruption condition containing PCI is cleared by TEST SUBCHANNEL, the condition is carried over to the next CCW. This carry-over occurs during both data and command chaining, and, in either case, the condition is propagated through the transfer-in-channel command.

If the subchannel is status pending with intermediate status when HALT SUBCHANNEL is executed, the intermediate interruption condition remains at the subchannel, but the interruption request, if any, is withdrawn, and the subchannel becomes no longer status-pending. The subchannel remains no longer status pending until performance of the halt function has ended. The subchannel then becomes status pending with intermediate status indicated (possibly together with any combination of primary, secondary, and alert status).

When TEST SUBCHANNEL is executed and stores an SCSW with the intermediate-status bit and the status-pending bit as ones in the IRB, the intermediate interruption condition is cleared at the subchannel. The intermediate interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Primary Status (Bit 29): When one (and when the status-pending bit is also one), bit 29 indicates a primary interruption condition exists. In such a case, the subchannel is said to be status pending with primary status. A primary interruption condition is a solicited interruption condition that indicates the completion of the start function at the subchannel. The primary interruption condition is described by the SCSW stored. When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with primary status (and secondary status) with both the subchannel-status field and the device-status field set to zero.

When TEST SUBCHANNEL is executed and stores an SCSW with the primary-status bit and the status-pending bit as ones in the IRB, the primary interruption condition is cleared at the subchannel. The primary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Secondary Status (Bit 30): When one (and when the status-pending bit is also one), bit 30 indicates a secondary interruption condition exists. In such a case, the subchannel is said to be status pending with secondary status. A secondary interruption condition is a solicited interruption condition that normally indicates the completion of the I/O operation at the device. The secondary interruption condition is described by the SCSW stored.

When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with secondary status (and primary status if the subchannel is also subchannel active) with zeros for subchannel and device status.

When TEST SUBCHANNEL is executed and stores an SCSW with the secondary-status bit as one in the IRB, the secondary interruption condition is cleared at the subchannel. The secondary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Status-Pending (Bit 31): When one, bit 31 indicates that the subchannel is status pending and that information describing the cause of the interruption condition is available to the program. The subchannel becomes status pending whenever intermediate, primary, secondary, or alert status is generated. When HALT SUBCHANNEL is executed, designating a subchannel that is idle, the subchannel becomes status pending subsequent to performance of the halt function to notify the program that the halt function has been completed. When TEST SUBCHANNEL is executed, thus storing an SCSW with the status-pending bit as one in the IRB, the status-pending condition is cleared at the subchannel. The status-pending condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. When CLEAR SUBCHANNEL is executed and the designated subchannel is operational, the subchannel becomes status pending subsequent to performance of the clear function to notify the program that the clear function has been completed.

Note: The status-pending bit, in conjunction with the remaining bits of the status-control field, indicates the type of status condition. For example, if bits 29 and 31 are ones, the subchannel is status pending with primary status. Alternatively, if only bit 31 is one, then the subchannel is said to be status pending or status pending alone. If only bit 31 is one in the status-control field, the settings of all bits in the subchannel-status and device-status fields are unpredictable. If bit 31 is not one, then the remaining bits of the status-control field are not meaningful.

CCW-Address Field

Bits 1-31 of word 1 form an absolute address. The address indicated is a function of the subchannel state when the SCSW is stored, as indicated in Figure 16-6 on page 16-20. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the CCW-address field is usable for recovery purposes if the CCW-address field-validity flag in the ESW is one.

Programming Note: When a CCW address, either detected in the channel-program address (see "Channel-Program Address" on page 15-28) or generated during chaining, would cause the channel subsystem to fetch a CCW from a location greater than 2^{24} - 1 while format-0 CCWs are specified for the operation, the invalid address is stored in the CCW-address field of the SCSW without truncation.

If the invalid address causes the channel subsystem, while chaining, to fetch a CCW from a location greater than 2^{31} - 1 while format-1 CCWs are specified for the operation, the rightmost 31 bits of the invalid address are stored in the CCW-address field.

Subchannel State[1]	CCW Address[2]
Start pending (UUUU0/AIPSX)[3]	Unpredictable
Start pending and device active (UUUU0/AIPSX)[3]	Unpredictable
Subchannel-and-device active (UUUU0/AIPSX)[3]	Unpredictable
Device active only (UUUU0/AIPSX)	Unpredictable
Suspended (YYYYY/AIPSX)[3]	See note 1
Status pending (10001/AIPSX) because of unsolicited alert status from the device while the subchannel was start pending[3]	Channel-program address + 8
Status pending (0Y111/AIPSX) because the device appeared not operational on all paths[3]	Channel-program address + 8
Status pending (10011/AIPSX) because of solicited alert status from the device while the subchannel was start pending and device active[3]	Channel-program address + 8
Status pending (10111/AIPSX) because of solicited alert status generated by the channel subsystem while the subchannel was start pending[3] or start pending and device active[3]	See note 2
Status pending (01001/AIPSX) for the program-controlled-interruption condition while the subchannel was subchannel-and-device active[3]	CCW + 8 of the CCW that contained the last recognized PCI, or 8 higher than a CCW that has subsequently become current
Status pending (01001/AIPSX) for the initial-status-interruption condition while the subchannel was subchannel-and-device active[3]	CCW + 8 of the CCW causing the intermediate interruption condition, or a CCW that has subsequently become current
Status pending (1Y1Y1/AIPSX); termination occurred because of program check caused by one of the following conditions:[3]	
Bit 24 of word 1 of the ORB set to one; incorrect-length-indication-suppression facility not installed	Channel-program address + 8
Unused bits in ORB not set to zeros	Channel-program address + 8
Invalid CCW-address specification in transfer in channel (TIC)	Address of TIC + 8
Invalid CCW-address specification in the channel-program address in the ORB	Channel-program address + 8[4]

Figure 16-6. (Part 1 of 4) CCW Address as Function of Subchannel State

Subchannel State[1]	CCW Address[2]
Invalid CCW address in TIC	Address of TIC + 8
Invalid CCW address in the channel-program address in the ORB	Channel-program address + 8[4]
Invalid CCW address while chaining	Invalid CCW address + 8
Invalid command code	Address of invalid CCW + 8[5]
Invalid count	Address of invalid CCW + 8[5]
Invalid IDAW-address or MIDAW-address specification	Address of invalid CCW + 8[5]
Invalid IDAW or MIDAW address in CCW	Address of invalid CCW + 8[5]
Invalid IDAW address while sequentially fetching IDAWs or invalid MIDAW address while sequentially fetching MIDAWs	Address of current CCW + 8
Invalid data-address specification, format 1	Address of invalid CCW + 8[5]
Invalid data address in a CCW	Address of invalid CCW + 8[5]
Invalid data address while sequentially accessing storage	Address of current CCW + 8
Invalid data address in IDAW or MIDAW	Address of current CCW + 8
Invalid IDAW or MIDAW specification	Address of current CCW + 8
Invalid CCW, format 0 or 1, for a CCW other than a TIC	Address of invalid CCW + 8[5]
Invalid suspend flag – CCW fetched during data chaining has suspend flag set to one	Address of invalid CCW + 8
Invalid suspend flag – CCW has suspend flag set to one, but suspend control was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one, but modified-CCW-indirect-data addressing was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one and either the skip flag or the IDA flag or both are set to one	Address of invalid CCW + 8
Invalid CCW, format 1, for a TIC	Address of TIC + 8
Invalid sequence – two TICs	Address of second TIC + 8
Invalid sequence – 256 or more CCWs without data transfer	Address of 256th CCW + 8
Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows:[3]	
On a CCW access	Address of protected CCW + 8[5]
On data or an IDAW or a MIDAW access	Address of current CCW + 8

Figure 16-6. (Part 2 of 4) CCW Address as Function of Subchannel State

Subchannel State[1]	CCW Address[2]
Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check[3]	Address of current CCW + 8
Status pending (YY1Y1/AIPSX); termination occurred under count control[3]	Address of current CCW + 8[6]
Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status[3]	Address of current CCW + 8[6]
Status pending (YYYY1/AIPSX) after termination by HALT SUBCHANNEL and the activity-control-field bits indicated below set to ones:	
Status pending alone	Unpredictable
Start pending[3]	Unpredictable
Device active and start pending[3]	Unpredictable
Device active	Unpredictable
Subchannel active and device active[3]	CCW + 8 of the last-executed CCW
Suspended	CCW + 8 of CCW causing suspension
Suspended and resume pending	Unpredictable
Status pending (00001/AIPSX) after termination by CLEAR SUBCHANNEL	Unpredictable
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel[3]	CCW + 8 of the last-executed CCW[6]
Status pending (00011/AIPSX)	Unpredictable
Status pending (10001/AIPSX)	Unpredictable
Status pending (00001/AIPSX)	Unpredictable
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check[3]	Address of current CCW + 8[6]
Status pending (1YYY1/AIPSX) because of alert status for channel-control check or interface-control check[3]	See note 3[6]
Status pending (1Y1Y1/AIPSX) because of channel-data check[3]	See note 3[6]

Figure 16-6. (Part 3 of 4) CCW Address as Function of Subchannel State

Explanation:

[1] The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0 Corresponding condition is not indicated
1 Corresponding condition is indicated
U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

[2] A CCW becomes current when (1) it is the first CCW of a channel program and has been fetched, (2) while command chaining, the previous CCW is no longer current and the new CCW has been fetched, or (3) in the case of data chaining, the new CCW takes over control of the I/O operation (see the section "Data Chaining" in Chapter 15, "Basic I/O Functions"). If chaining is not specified or is suppressed, a CCW is no longer current and becomes the last-executed CCW when secondary status has been accepted by the channel subsystem. During command chaining, a CCW is no longer current when device-end status has been accepted or, in the case of data chaining, when the last byte of data for that CCW has been accepted.

[3] The subchannel may also be resume pending.

[4] The stored address is the channel-program address (in the ORB) + 8 even though it is either invalid or protected.

[5] The stored address is the address of the current CCW + 8 even though it is either invalid or protected.

[6] Incorrect length is indicated as a function of the setting of the suppress-length-indication flag in the current CCW (see the section "Channel-Command Word" in Chapter 15, "Basic I/O Functions").

Notes:

1. Unless the subchannel is also resume pending, the address stored is the address of the CCW that caused suspension, plus 8. Otherwise, the address stored is unpredictable.
2. The address of the CCW is given as a function of the alert status indicated. For example, if a program-check or protection-check condition is recognized, the CCW address stored is the same as for the entry for program check or protection check, respectively, in this table. Alternatively, if alert status for interface-control check or channel-control check is indicated, the CCW address stored is either the channel-program address (in the ORB) + 8 or invalid as specified by the field-validity flags in the subchannel logout. If alert status for path-verification required is indicated, the CCW address stored is the channel-program address (in the ORB) + 8.
3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is CCW + 8 of the last-fetched CCW if the command for the CCW has not been accepted by the device. If the command has been accepted by the device at the time the error condition is recognized, then the address stored is the address of the CCW + 8 of the last-executed CCW.

Figure 16-6. (Part 4 of 4) CCW Address as Function of Subchannel State

Device-Status Field

Device-status conditions are generated by the I/O device and are presented to the channel subsystem over the channel path. The timing and causes of these conditions for each type of device are specified in the System Library publication for the device. The device-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Whenever the subchannel is status pending with intermediate status alone, the device-status field is zero. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the device-status field is usable for recovery purposes if the device-status field-validity flag in the ESW is one. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the device-status field are not meaningful.

If, within a system, the I/O device is accessible from more than one channel path, status related to channel-subsystem-initiated operations in the single-path mode (solicited status) is signaled over the initiating channel path. Devices operating in the multipath mode may signal solicited status over any channel path that belongs to the same path group as the initiating channel path. The handling of conditions not associated with I/O operations (unsolicited alert status), such as attention, unit exception, and device end due to transition from the not-ready to the ready state, depends on the type of device and condition and is specified in the System Library publication for the device.

The channel subsystem does not modify the status bits received from the I/O device. These bits appear in the SCSW as received over the channel path. For more information on the status bits received from the I/O device, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204.

Subchannel-Status Field

Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt, resume, or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Individual bits contained in the subchannel-status field may be unpredictable even when the subchannel-status field is meaningful. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful.

Program-Controlled Interruption

An intermediate interruption condition is generated after a CCW with the program-controlled-interruption (PCI) flag set to one becomes the current CCW. The I/O interruption due to the PCI flag may be delayed an unpredictable amount of time because of masking of the interruption request or other activity in the system. (See “Program-Controlled Interruption” on page 15-64.) When the channel subsystem recognizes an alert interruption condition due to either a channel-control-check condition or an interface-control-check condition, then any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem.

Detection of the PCI condition does not affect the progress of the I/O operation.

Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device. Incorrect length is indicated for one of the following reasons:

Long Block on Input: During a read, read-backward, or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the SCSW is zero.

Long Block on Output: During a write or control operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the SCSW is zero.

Short Block on Input: The number of bytes transferred during a read, read-backward, or sense operation is insufficient to fill the main-storage areas assigned to the operation. The count in the SCSW is not zero.

Short Block on Output: The device terminated a write or control operation before all information contained in the assigned main-storage areas was transferred to the device. The count in the SCSW is not zero.

The incorrect-length indication is suppressed when the current CCW has the SLI flag set to one and the CD flag set to zero. The indication does not occur for operations rejected during the initiation sequence. The indication also does not occur for immediate operations when the count field is nonzero and the subchannel is in the incorrect-length-suppression mode. The incorrect-length indication is not meaningful when the count field of the SCSW is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the CCW is one or unless the condition occurs in an immediate operation when the subchannel is in the incorrect-length-suppression mode.

Program Check

Program check occurs when programming errors are detected by the channel subsystem. The condition can be due to the following causes:

Invalid CCW-Address Specification: The channel-program address (CPA) or the transfer-in-channel command does not designate the CCW on a doubleword boundary, or bit 0 of the CPA or bit 32 of a format-1 CCW specifying the transfer-in-channel command is not zero.

Invalid CCW Address: The channel subsystem has attempted to fetch a CCW from a main-storage location that is not available. An invalid CCW address can occur because the program has designated an invalid address in the channel-program-address field of the command-mode ORB or in the transfer-in-channel command or because, on chaining, the channel subsystem attempts to fetch a CCW from an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute CCW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute CCW address is greater than 2^{24} - 1.
3. Format-1 CCWs are specified in the ORB, and the absolute CCW address is greater than 2^{31} - 1

Invalid Command Code: There are zeros in the four rightmost bit positions of the command code in the CCW designated by the CPA or in a CCW fetched on command chaining. The command code is not tested for validity during data chaining.

Invalid Count, Format 0: A CCW, which is other than a CCW specifying transfer in channel, contains zeros in bit positions 48-63.

Invalid Count, Format 1: A CCW that specifies data chaining or a CCW fetched while data chaining contains zeros in bit positions 16-31.

Invalid IDAW-Address or MIDAW-Address Specification: Indirect data addressing or modified indirect data addressing is specified, and any of the following conditions is detected:

1. The ORB specifies format-1 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a word boundary; that is, bits 30 and 31 (format-0 CCW) or 62 and 63 (format-1 CCW) are not zeros.
2. The ORB specifies format-2 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a doubleword boundary; that is, bits 29-31 (format-0 CCW) or 61-63 (format-1 CCW) are not zeros.
3. The ORB specifies modified-CCW-indirect-data addressing, the CCW specifies modified-indirect-data addressing, and the contents of the data-address field in the CCW do not designate the first MIDAW on a quadword boundary.

Invalid IDAW or MIDAW Address: The channel subsystem has attempted to fetch an IDAW or MIDAW from a main-storage location that is not available. An invalid IDAW or MIDAW address can occur because the program has designated an invalid address in a CCW that specifies indirect data addressing or modified indirect data addressing, or because the channel subsystem, on sequentially fetching IDAWs or MIDAWs, attempts to fetch from an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute IDAW or MIDAW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than 2^{24} - 1.
3. Format-1 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than 2^{31} - 1.

Invalid Data-Address Specification: Bit 32 of a format-1 CCW is not zero.

Invalid Data Address: When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.
2. Use of the data address has caused the channel subsystem to attempt to wrap from zero to the maximum storage address during a read-backward operation.
3. The channel subsystem has attempted to transfer data to a storage location that is unavailable.

An invalid data address can occur because the program has designated an unavailable location in a CCW or in an IDAW or MIDAW, or because the channel subsystem, on sequentially accessing storage, attempted to access an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute address of the location does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than 2^{24} - 1.
3. Format-1 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than 2^{31} - 1.
4. Format-1 IDAWs are specified in the ORB, indirect data addressing is specified in the CCW, and the absolute address is greater than 2^{31} - 1.
5. When the address-limit-checking facility is installed, the absolute address is outside the addressing range specified by SET ADDRESS LIMIT, and the limit mode at the subchannel is active.

Note: The maximum storage address is determined as a function of the CCW and IDAW formats used or MIDAWs used. When neither an IDAW nor a MIDAW is used, the maximum storage address is a function of the CCW format specified, as follows:

1. When 24-bit (format 0) CCWs are specified, the maximum storage address recognized by the channel subsystem is 2^{24} - 1.
2. When 31-bit (format 1) CCWs are specified, the maximum storage address recognized by the channel subsystem is 2^{31} - 1.

When an IDAW is used, the maximum storage address is a function of the IDAW format specified, as follows:

1. When 31-bit (format 1) IDAWs are specified, the maximum storage address recognized by the channel subsystem is 2^{31} - 1.
2. When 64-bit (format 2) IDAWs are specified, the maximum storage address recognized by the channel subsystem is 2^{64} - 1

When a MIDAW is used, the maximum storage address recognized by the channel subsystem is 2^{64} - 1.

Invalid IDAW or MIDAW Specification: When any of the following conditions is detected, an invalid IDAW specification is recognized by the channel subsystem:

1. Bit 0 of a format-1 IDAW is not zero.
2. A second or subsequent format-1 IDAW does not designate the location of the beginning byte of a 2 K-byte block or, for read-backward operations, the location of the ending byte of a 2 K-byte block.
3. A second or subsequent format-2 IDAW does not designate the location of the beginning byte of a 2 K-byte or 4 K-byte block, as required by the 2K-IDAW control in the ORB, or, for read-backward operations, the location of the ending byte of a 2 K-byte or 4 K-byte block.

When bit 0 of a format-1 IDAW is not zero, the subchannel is made status pending with program-check indicated only after the I/O device attempts to transfer data, just as when an invalid data address that refers to a nonexistent data area is detected. If the device ends the operation prior to the transfer of data, no error condition is reported. See “CCW Indirect Data Addressing” in Chapter 15 for additional information about the reporting of program-check conditions.

When any of the following conditions is detected, an invalid MIDAW specification is recognized by the channel subsystem:

1. One or more bits defined as reserved in the MIDAW are not zero.
2. The MIDAW count field contains zeros.
3. The combination of the MIDAW data-address and count fields specify data addresses that cross a 4 K-byte block boundary, unless skipping is in effect for the MIDAW.
4. The MIDAW in control has its last-MIDAW flag set to zero and the sum of the count values of the previous MIDAWs in the MIDAW list (MIDAL) and the MIDAW in control is greater than or equal to the count value in the CCW.
5. The MIDAW in control has its last-MIDAW flag set to one and the sum of the count values in the previous MIDAWs in the MIDAL and the MIDAW in control do not equal the count value in the CCW.
6. The MIDAW in control is a second or subsequent MIDAW whose address is on a 4 K-byte boundary.

Invalid CCW, Format 0: A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 39.

Invalid CCW, Format 1: A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 15, or a CCW specifying transfer in channel does not contain zeros in bit positions 0-3 and 8-31.

Invalid Suspend Flag: A format-0 or format-1 CCW fetched during data chaining, other than a CCW specifying transfer in channel, does not contain a zero in bit position 38 or 14, respectively. A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 38 for a format-0 CCW or bit position 14 for a format-1 CCW, and suspend control was not specified by bit 4 of word 1 of the ORB.

Invalid MIDA Flag: When either of the following conditions is detected, an invalid MIDA flag condition is recognized by the channel subsystem.

1. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing; however, modified CCW indirect data addressing was not specified by bit 25 of word 1 of the ORB.

2. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 35 (format 0) or bit 11 (format 1) of the CCW is one, specifying skip.

3. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 37 (format 0) or bit 13 (format 1) of the CCW is one, specifying indirect data addressing.

4. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and the designated subchannel is not associated with channel paths that support modified CCW indirect data addressing.

Invalid ORB Format: One or more reserved bit positions in the operation-request block (ORB) is not zero. (See “Operation-Request Block” on page 15-24 for more information.) If the incorrect-length-indication-suppression facility is not installed, then bit 24 of word 1 of the command-mode ORB must also be zero.

Invalid Sequence: The channel subsystem has fetched two successive CCWs both of which specify transfer in channel, or, depending on the model, a sequence of 256 or more CCWs with command chaining specified was executed by the channel subsystem and did not result in the transfer of any data to or from an I/O device.

Detection of the program-check condition during the initiation of an operation at the device causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When the condition is detected after the

I/O operation has been initiated at the device, the device is signaled to conclude the operation the next time the device requests or offers a byte of data or status. In this situation, the subchannel is made status pending as a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

Protection Check

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. Protection applies to the fetching of CCWs, IDAWs, MIDAWs, and output data and to the storing of input data. The subchannel key provided in the ORB is used as the access key for storage accesses associated with an I/O operation.

Detection of the protection-check condition during the fetching of the first CCW, IDAW, or MIDAW causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation after the available data logically prior to the protection check has been transferred. However, if an access violation occurs when the channel subsystem is in the process of fetching either a new IDAW, MIDAW, or a new CCW while data chaining, and if the device signals the channel-end condition before transferring any data designated by the new CCW, IDAW or MIDAW, then the status is accepted, and the subchannel becomes status pending with primary and alert status and with protection check indicated. Other indications may accompany the protection-check indication as a function of the operation specified by the CCW, the status received from the device, and the current state of the subchannel. The protection-check condition causes command chaining and command retry to be suppressed.

Channel-Data Check

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. The condition may be indicated when detected, even if the data is not used when prefetched. Channel-data check is indicated when data or the associated key has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored in the SCSW, when used in conjunction with the storage-access code and the CCW address, designates a byte location within the block of main storage in which the channel-data-check condition was recognized.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary and alert status, or with primary, secondary, and alert status, as a function of the status received from the device. The count and address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to prefetched data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected on prefetched data while the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored.

Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition includes invalid CBC on a CCW, an IDAW, a MIDAW, or the respective associated key. The condition may be indicated when an invalid CBC is detected on a prefetched CCW, IDAW, MIDAW, or the respective associated key, even if that CCW, IDAW, or MIDAW is not used.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The count and data-address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-control-check condition pertains to an invalid CBC detected on a prefetched CCW, a prefetched IDAW, a prefetched MIDAW, or the key associated with the prefetched CCW, the prefetched IDAW, or the prefetched MIDAW, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while prefetching when the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that will be stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored.

Programming Note: If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the channel-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device while the subchannel is subchannel-and-device

active or device active has an invalid checking-block code.

2. The status byte received from a device while the subchannel is idle, start pending, suspended, or halt pending has an invalid checking-block code.

3. A device responded with an address other than the address designated by the channel subsystem during initiation of an operation.

4. During command chaining, the device appeared not operational.

5. A signal from an I/O device either did not occur or occurred at an invalid time or had an invalid duration.

6. The channel subsystem recognized the I/O-error-alert condition (see “I/O-Error Alert (A)” on page 16-50).

7. ESW bit 26, indicating device-status check, is set to one.

Detection of an interface-control check during a CCW-type IPL I/O operation on a machine that retries IPL I/O operations on an alternate channel path causes the channel subsystem to terminate operations on the current channel path and to retry the IPL I/O operation on another logically-available channel path to the designated device, if one is available, without causing the subchannel to become status-pending. (See “CCW-type IPL” on page 17-17 for additional information.) In all other cases and when an interface-control check has been detected for a CCW-type IPL operation on all logically-available channel paths to the designated device, detection of the interface-control-check condition causes the current operation, if any, to be terminated immediately, and the subchannel is made status pending with alert status, primary and alert status, secondary and alert status, or primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes an interface-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

If, while initiating a signaling sequence with the channel subsystem for the purpose of presenting status or transferring data, the device presents an address with invalid parity, the error condition is not made available to the program since the identity of the device and associated subchannel are unknown.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored.

Programming Note: If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the interface-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

Chaining Check

Chaining check is caused by channel-subsystem overrun during data chaining on input operations. The condition occurs when the I/O-data rate is too high for the particular resolution of data addresses. Chaining check cannot occur on output operations.

Detection of the chaining-check condition causes the I/O device to be signaled to conclude the operation. It causes command chaining to be suppressed.

Count Field

Bit positions 16-31 of word 2 contain the residual count. The count is to be used in conjunction with the original count specified in the last CCW and, depending upon existing conditions (see Figure 16-7 on page 16-32), indicates the number of bytes transferred to or from the area designated by the CCW. The count field is meaningful whenever the subchannel is status pending with primary status that consists of either (1) device status only or (2) device status together with subchannel status of incorrect length only, PCI only, or both.

In Figure 16-7 on page 16-32, the contents of the count field are listed for all cases where the subchannel is start pending, subchannel-and-device active, device active, suspended, or status pending.

Subchannel State[1]	Count[2]
Start pending (UUUU0/AIPSX)[2]	Not meaningful[3]
Start pending and status pending (10YY1/AIPSX)[2]	Not meaningful[3]
Start pending and status pending (00111/AIPSX) because the device appeared not operational on all paths[2]	Not meaningful[3]
Start pending and device active (UUUU0/AIPSX)[2]	Not meaningful[3]
Suspended (YYYYY/AIPSX)[2]	Not meaningful[3]
Subchannel-and-device active (UUUU0/AIPSX)[2]	Not meaningful[3]
Device active (UUUU0/AIPSX)	Not meaningful[3]
Status pending (01001/AIPSX) because of program-controlled-interruption condition or initial-status interruption	Not meaningful[3]
Status pending (1Y1Y1/AIPSX); termination occurred because of:[2]	
Program check	Not meaningful[3]
Protection check	Not meaningful[3]
Chaining check	Not meaningful[3]
channel-control check	See note 1
Interface-control check	Not meaningful[3]
Channel-data check	See note 2
Status pending (YY1Y1/AIPSX); termination occurred under count control[2]	Correct
Status pending (Y0011/AIPSX)[2]	Not meaningful[3]
Status pending (1Y1Y1/AIPSX)[2]	Correct; residual count of last used CCW
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status[2]	Correct; residual count of last used CCW
Status pending (YYYY1/AIPSX); after termination by HALT SUBCHANNEL[2]	Unpredictable
Status pending (00001/AIPSX); after termination by CLEAR SUBCHANNEL	Not meaningful[3]
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel[2]	Correct; indicates the residual count
Status pending (1Y111/AIPSX); command chaining terminated because of alert status[2]	Correct; original count of CCW specifying the new I/O operation
Status pending (10001/AIPSX) because of alert status	Not meaningful[3]

Figure 16-7. (Part 1 of 2) Contents of Count Field in SCSW

Explanation:

[1] In situations where more than a single condition exists because of, for example, alert status that is described by program check and unit check, the entry appearing first in the table takes precedence.

The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

The allowed combinations of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0 Corresponding condition is not indicated
1 Corresponding condition is indicated
U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

[2] The subchannel may also be resume pending.

[3] The contents of the count field are not meaningful because the count field is not valid when the SCSW is stored and the subchannel is in the given state.

Notes:

1. The count is unpredictable unless IDAW/MIDAW check is indicated, in which case the count may not correctly reflect the number of bytes transferred to or from main storage but will (when used in conjunction with the CCW address) designate a byte location within the page in which the channel-control-check condition was recognized.
2. During a storage access, the maximum number of bytes that can be stored by a channel subsystem is model dependent. If a channel-data-check condition is recognized during that access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored when used in conjunction with the storage-access code and the CCW address designates a byte location within the page in which the channel-data-check condition was recognized.

Figure 16-7. (Part 2 of 2) Contents of Count Field in SCSW

Transport-Mode SCSW

The format of a transport-mode SCSW is as follows:

Word														
0	Key	0	L	CC	FMT	X	Q	0	E	N	0	FC	AC	SC
1	TCW Address													
2	DEVS	SCHS	FCXS	SCHXS										

0 4 6 8 11 16 20 24 27 31

Figure 16-8. Transport-Mode SCSW Format

Figure 16-9 on page 16-34 shows the summary and contents of the transport-mode SCSW:

Bits	Name
Word 0	
0-3	Subchannel Key
4	Reserved
5	ESW format (L)
6-7	Deferred condition code (CC)
8-10	Format (FMT)
11	IRB-Format control (X)
12	Interrogate-complete (Q)
13	Reserved
14	Extended control (E)
15	Path not operational (N)
16	Reserved
17-19	**Function Control (FC)**
17	Start function
18	Halt function

Figure 16-9. Transport-Mode SCSW (Continued)

The following descriptions indicate when an SCSW field contains meaningful information for a transport-mode IRB.

Subchannel Key

This bit has the same meaning as in the command mode SCSW. (See “Subchannel Key” on page 16-9).

Reserved

SCSW bits 4, 13, 16, 20, 24, and 26 of word 0, bits 0 of word 1, and bits 1, 8, 15, and 16-22 of word 2 are reserved and stored as zeros.

Extended-Status-Word Format (L)

This bit has the same meaning as in the command-mode SCSW. (See “Extended-Status-Word Format (L)” on page 16-9).

Deferred Condition Code (CC)

This field has the same meaning as in the command-mode SCSW. (See “Deferred Condition Code (CC)” on page 16-9).

Format (FMT)

Bits 8-10 of word 0 are the IRB-format field that contains a 3-bit, unsigned integer whose value specifies the layout of the IRB, when the IRB-format control bit (X), is set to one.

FMT	Description
0	Transport-Mode IRB
1-7	Reserved

IRB-Format Control (X)

Bit 11 of word 0 is the IRB-format control bit. The value of this bit is one for the transport-mode IRB. (See Figure 16-2 on page 16-7).

Interrogate Complete (Q)

Bit 12 of word 0 is the interrogate-complete bit (Q). When one, Q indicates that the interrogate operation has completed successfully, and the subchannel is made status-pending with intermediate interruption status. If the pending intermediate interruption condition has not been cleared by TEST SUBCHANNEL by the time the primary interruption condition for the original interrogated operation is presented at the subchannel, both conditions may be merged and indicated together in the SCSW.

Subchannel-Control Field

The subchannel-control information is contained in bit positions 13-31 of the first word of the SCSW.

Extended Control (E)

Bit 14 of word 0, when one, indicates that model-dependent information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both. The concurrent sense information has no meaning when a transport-mode IRB is stored.

Path Not Operational (N)

This bit has the same meaning as in the command-mode SCSW. See “Path Not Operational (N)” on page 16-13.

Function Control (FC)

The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Function Control (FC)” on page 16-13). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

Start Function (Bit 17): This bit has the same meaning as in the command-mode SCSW. (See “Start Function (Bit 17)” on page 16-13).

Halt Function (Bit 18): When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is start pending or device active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least primary status indicated. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Clear Function (Bit 19): This bit has the same meaning as in the command-mode SCSW. (See "Clear Function (Bit 19)" on page 16-14).

Activity Control (AC)

The activity-control field is contained in bit positions 20-26 of word 0 of the SCSW. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

Bit	Meaning
20	Reserved
21	Start pending
22	Halt pending
23	Clear pending
24	Reserved
25	Device active
26	Reserved

Start Pending (Bit 21): This bit has the same meaning as in the command-mode SCSW with the exception that the subchannel remains start pending until a primary interruption condition is generated. (See "Start-Pending (Bit 21)" on page 16-15).

Halt Pending (Bit 22): This bit has the same meaning as in the command-mode SCSW. (See "Halt-Pending (Bit 22)" on page 16-16).

Clear Pending (Bit 23): This bit has the same meaning as in the command-mode SCSW. (See "Clear-Pending (Bit 23)" on page 16-16).

Device Active (Bit 25): When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active, only when primary status is presented without secondary.

Status Control (SC)

The status-control field is contained in bit positions 27-31 of word 0 of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status or the Q bit. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see "Enabled (E)" on page 15-3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4); bits 27-30 are meaningful when bit 31 is one.The status-control bits are defined as follows:

Alert Status (Bit 27): This bit has the same meaning as in the command-mode SCSW with the exception that a command-mode IRB is stored when alert status is presented with secondary status. (See "Alert Status (Bit 27)" on page 16-17).

Intermediate Status (Bit 28): Intermediate status can be indicated when the interrogate operation associated with the TCW is completed, and the Q-bit (interrogate-complete) is one.

Primary Status (Bit 29): This bit has the same meaning as in the command-mode SCSW. (See "Primary Status (Bit 29)" on page 16-19).

Secondary Status (Bit 30): This bit has the same meaning as in the command-mode SCSW. (See "Secondary Status (Bit 30)" on page 16-19).

Status Pending (Bit 31): This bit has the same meaning as in the command-mode SCSW. (See "Status-Pending (Bit 31)" on page 16-19).

TCW Address Field

Bits1-31 of word 1 form an absolute address of a TCW. The TCW address indicated is the address of the current TCW when the subchannel becomes pending with primary interruption. When the subchannel-status field indicates channel-control check, channel-data check, program check or interface-control check, the TCW-address field is usable for recovery purposes if the TCW-address field-validity flag in the ESW is one.

Subchannel State	TCW Address
Start pending (UUUU0/AIPSX)	Unpredictable
Start pending and device active (UUUU0/AIPSX)	Unpredictable
Subchannel-and-device active (UUUU0/AIPSX)	N/A
Device active only (UUUU0/AIPSX)	Unpredictable
Suspended (YYYYY/AIPSX)	N/A
Status pending (10001/AIPSX) because of unsolicited alert status from the device while the subchannel was start pending	Address of current TCW[3]
Status pending (0Y111/AIPSX) because the device appeared not operational on all paths	Address of current TCW[3]
Status pending (10011/AIPSX) because of solicited alert status from the device while the subchannel was start pending and device active	Address of current TCW[3]
Status pending (10111/AIPSX) because of solicited alert status generated by the channel subsystem while the subchannel was start pending or start pending and device active	See note 2
Status pending (01001/AIPSX) for the program-controlled-interruption condition while the subchannel was subchannel-and-device active	N/A
Status pending (01001/AIPSX) for the initial-status-interruption condition while the subchannel was subchannel-and-device active	N/A
Status pending (01001/AIPSX) for the intermediate/interrogate	Address of current TCW[2]
Status pending (1Y1Y1/AIPSX); termination occurred because of program check caused by one of the following conditions:	
Bit 24 of word 1 of the ORB set to one; incorrect-length-indication-suppression facility not installed	N/A
Unused bits in ORB not set to zeros	Address of current TCW[2]
Invalid TCW-address specification in the channel-program address in the ORB	Address of invalid TCW
Invalid TCW address in the channel-program address in the ORB	Address of invalid TCW
Invalid TCW address while DCW data chaining	N/A
Invalid TCW count or TIDAW count	Address of invalid TCW[4]
Invalid TIDAW-address specification	Address of invalid TCW[4]
Invalid TIDAW address in TCW	Address of invalid TCW[4]
Invalid TIDAW address while sequentially fetching TIDAWs	N/A
Invalid data-address specification	Address of invalid TCW[4]
Invalid data address in a TCW	Address of invalid TCW[4]
Invalid data address while sequentially accessing storage	Address of current TCW
Invalid data address in TIDAW	Address of current TCW
Invalid TIDAW	Address of current TCW

Figure 16-10. (Part 1 of 3) TCW Address as Function of Subchannel State

Subchannel State	TCW Address
Invalid TSB-address specification	Address of current TCW
Invalid TSB address	Address of current TCW
Invalid TCCB address specification	Address of current TCW
Invalid TCCB address	Address of current TCW
Device-detected program checks	Address of current TCW
Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows:	
On a TCW access	Address of protected TCW[4]
On data or an TIDAW access	Address of current TCW
Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check	N/A
Status pending (YY1Y1/AIPSX); termination occurred under count control	Address of current TCW
Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status	Address of current TCW[3]
Status pending (YYYY1/AIPSX) after termination by HALT SUBCHANNEL and the activity-control-field bits indicated below set to ones:	
Status pending alone	Unpredictable
Start pending	Unpredictable
Device active and start pending	Unpredictable
Device active	Unpredictable
Status pending (00001/AIPSX) after termination by CLEAR SUBCHANNEL	Unpredictable
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel	Address of current TCW
Status pending (00011/AIPSX)	Unpredictable
Status pending (10001/AIPSX)	Unpredictable
Status pending (00001/AIPSX)	Unpredictable
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check	N/A
Status pending (1YYY1/AIPSX) because of alert status for channel-control check or interface-control check	See note 3
Status pending (1Y1Y1/AIPSX) because of channel-data check	Address of current TCW
Status pending (1Y1Y1/AIPSX) because of channel-subsystem retry failed	Address of current TCW

Explanation:

[1] The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

Figure 16-10. (Part 2 of 3) TCW Address as Function of Subchannel State (Continued)

Subchannel State	TCW Address
The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols: 0 Corresponding condition is not indicated 1 Corresponding condition is indicated U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending. Y The corresponding condition is not significant and is indicated as a function of the subchannel state.	
[2] A TCW becomes current when start subchannel is issued, specifying a transport-mode ORB, and the instruction completes with condition code 0.	
[3] Command-mode IRB may be stored depending on the current subchannel status	
[4] The stored address is the address of the current TCW even though it is either invalid or protected.	
[5] Not applicable	
Notes:	
1. The address stored is unpredictable.	
2. The address of the TCW is given as a function of the alert status indicated.	
3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is the address of the current TCW.	

Figure 16-10. (Part 3 of 3) TCW Address as Function of Subchannel State (Continued)

Device-Status Field

The device-status field is contained in bit positions 0-7 of word 2 of the SCSW. Each bit of the device-status field has the same meaning as in the command-mode SCSW. See "Device-Status Field" on page 16-24 for details.

Subchannel-Status Field

The subchannel-status field is contained in bit positions 8-15 of word 2 of the SCSW. Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful. The following subchannel-status conditions are described:

Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device.

When the FCX-incorrect-length-indication facility is not installed and an incorrect-length condition is detected, the processing of the transport-mode channel program is terminated with program-check status.

When the FCX-incorrect-length-indication facility is installed, the device supports incorrect-length indication, incorrect-length-indication is not being suppressed, and an incorrect-length condition is detected, incorrect length is indicated for one of the following reasons:

Long Block on Input: During a read or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the TSB header (TSH) is zero.

Long Block on Output: During a write operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the TSH is zero.

Short Block on Input: The number of bytes transferred during a read or sense operation is insufficient to fill the main-storage areas assigned to the operation. The count in the TSH is not zero.

Short Block on Output: The device terminated a write before all of the information contained in the assigned main-storage areas was transferred to the device. The count in the TSH is not zero.

The incorrect-length indication is suppressed when the current DCW has the SLI flag set to one. The incorrect-length indication is not meaningful when the count field of the TSH is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the DCW is one.

Program Check

Program check occurs when programming errors are detected by the channel subsystem. For a transport-mode operation, programming errors may also be detected by the I/O device and are reported as program checks. When a program check condition is recognized, additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field when a program check is indicated.

Whenever the program-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the program-check condition is generated is stored in the ESW failing-storage-address field.

A program check condition can be due to any of the following reasons:

Invalid TCW Specification: When any of the following conditions is detected, an invalid TCW specification is recognized:

1. A reserved field that is checked for zeros in the TCW does not contain zeros.
2. A nonzero value is specified in the TCW format field.
3. The read and write bits in the TCW are both one, bit 10 of the TCW flags field is zero, and either or both of the following are true.
   - The FCX-bidirectional-data-transfer facility is not installed.
   - The specified device does not support bidirectional data transfers.
4. The TCCB-length field in a TCW specifies a length that is less than 12 or greater than 244.

Invalid TCW-Address Specification: An invalid TCW address specification can occur because the TCW address is not designated on a 64-byte boundary.

Invalid TCW Address: The channel-subsystem has attempted to fetch a TCW from a main-storage location that is not available. An invalid TCW address can occur because the program has designated an invalid address in the channel-program-address field of the transport-mode ORB, when the B-bit (channel-program-type control), is one. A main-storage location is unavailable when the absolute TCW address does not correspond to a physical location.

Invalid TCW Counts: When any of the following conditions is detected by the channel subsystem, an invalid TCW byte count is recognized:

1. The write-bit is one in the TCW and the value in the TCW output-count field is zero.
2. The read-bit is one in the TCW and the value in the TCW input-count field is zero.

Invalid TSB-Address Specification: An invalid transport-status-block address specification can occur if the content of the transport-status-block-address field specified in the TCW does not designate a storage location on a doubleword boundary.

Invalid TSB Address: The channel-subsystem has attempted to store a TSB to a main-storage location that is not available. An invalid transport-status-block address can occur because the program has designated an unavailable location in a TCW, or the channel-subsystem has attempted to store the transport status to a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.

Invalid TCCB Address: The channel-subsystem has attempted to fetch a TCCB from a main-storage location that is not available. An invalid transport-command-control-block address can occur because the program has designated an unavailable location in a TCW, or has specified a transport-command-control-block address and a length which caused a list of TIDAW to cross a 4 K-byte when the transport-command-control-block-TIDA flag in the TCW is one. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location. ***Invalid TIDAW-Address Specification:*** Transport-indirect data addressing is specified, and any of the following conditions is detected:

1. A write operation is requested, the output-TIDA flag in a TCW is one, and the contents of the output-data-address field in the TCW do not designate a storage location on a quadword boundary.
2. A read operation is requested, the input-TIDA flag in a TCW is one, and the contents of the input-data-address field in the TCW do not designate a storage location on a quadword boundary.
3. The transport-command-control-block-TIDA flag in the TCW is one, and the contents of the transport-command-control-block-address do not designate a storage location on a quadword boundary.

Invalid Data Address: An invalid data address can occur because the program has designated an unavailable location specified by a TCW or a TIDAW. When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. The channel-subsystem has attempted to access a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.
2. The channel subsystem, on sequentially accessing storage for a data fetch or data store, attempted to access an unavailable location.
3. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.

Invalid TIDAW Specification: When the use of TIDAW is specified, an invalid TIDAW specification is recognized when any of the following conditions is detected by the channel subsystem:

1. Any of the bits defined as reserved in the TIDAW are not zero.
2. The TIDAW-transfer-in-channel flag (TTIC) in a TIDAW is one, and one or more other flag bits are also one.
3. The TTIC points to a TIDAW in which the TTIC flag is one.
4. The TIDAW count field contains zeros when the TTIC flag is zero.
5. The combination of a TIDAW data-address and count fields specify data that crosses a 4 K-byte block boundary, when skipping is not in effect.
6. The count value specified in the TIDAW in which the last-TIDAW flag is one and the value for either input-count or output-count specified in a TCW did not both decrement to zero for the same byte of data transferred.
7. For a read operation only, the TIDAW in control has its data-transfer-interruption control flag set to one when data transfer was attempted by the device.
8. The TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW and the count field of the TIDAW contains either a value that is zero or a value that is not evenly divisible by four.

Invalid TIDAW Address: The channel-subsystem has attempted to fetch a TIDAW from a main-storage location that is not available. An invalid TIDAW address can occur because the program has designated an invalid address in a TCW that specifies TIDAW addressing, or because the channel subsystem, on sequentially fetching TIDAWs, attempts to fetch from an unavailable location. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.***Storage-Requests Limit Exceeded:*** The use of TIDAWs is specified, and the model-dependent maximum number of storage requests required to satisfy the transfer of a block of data has been reached.

Max Data-Count Exceeded: The model-dependent maximum count of data for a single transport-control area (TCA) has been reached or exceeded for the current operation.

Device-Detected Program Check: Device-detected program checks are errors detected during a transport-mode operation by the I/O device and the channel-subsystem is requested to present a program-check condition. When a device-detected-program-check condition is recognized, additional information is available in the subchannel-extended status field, and the TSB is stored with a transport-status-area format of two. (See device-detected-program check in chapter 15.)

Protection Check

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. A protection check condition is indicated as a result of a storage operation that detects any of the following errors:

1. Protection applies to the fetching of TCW.
2. Protection applies to the fetching of TCCB.
3. Protection applies to the fetching of TIDAWs.
4. Protection applies to the fetching of output data.
5. Protection applies to the storing of input data.

The subchannel key provided in the transport-mode ORB is used as the access key for storage accesses associated with an I/O operation except for the TSB store.

Detection of the protection-check condition during the fetching of a TCW, TCCB, or a TIDAW would cause the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device may be signaled to conclude the operation. Other indications may accompany the protection-check indication as a function of the operation specified by the TCW, the status received from the device, on a read operation, and the current state of the subchannel. The protection-check condition may or may not causes the execution of subsequent DCWs in a TCCB to be suppressed.

Whenever the protection-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the protection-check condition is generated is stored in the ESW failing-storage-address field.

Additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field when a protection check condition check is indicated.

Channel-Data Check

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. Channel-data check is indicated when data has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. When a channel-data-check condition is recognized during a storage access, the channel subsystem stores the address where the storage exception is encountered.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary, secondary and alert status, as a function of the status received from the device. The TCW address field of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to the fetching of data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected during data access causes the operation to be terminated. In this case the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field.

Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition may be indicated when an invalid CBC is detected on a TCW, TIDAW, TCCB, TSB, or the respective associated key.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition may or may not be recognized by the channel subsystem.

Whenever the channel-control-check condition pertains to an invalid CBC detected on fetching a TCW or a TCCB, or a TIDAW or storing a TSB, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while fetching when the subchannel is start pending cause the operation to be terminated. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that is stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field.

Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device has an invalid checking-block code.
2. A signal from an I/O device either did not occur or occurred at an invalid time.
3. ESW bit 26, indicating device-status check, is set to one.
4. A failed interrogate function or a recovery operation.
5. The TCW residual count did not match the residual count in the response from the device.

When the channel subsystem recognizes an interface-control-check condition, any previously existing intermediate interruption condition may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may also be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field.

Channel-Subsystem Retry Failed

Channel-subsystem retry failed indicates that internal channel-subsystem conditions exist that prevent the fetching of the TCCB, a TIDAW, or data. The channel subsystem retried the fetch and the retry failed.

FCX-Status Field

The FCX-status field is contained in bit positions 16-23 of word 2 of the SCSW. This field contains channel specific status information returned by the I/O device.

TSB Valid (Bit 23): Bit 23, when set to one, indicates that additional status information for the I/O operation designated by the subchannel is available in the transport-status block. When zero, the contents of the transport-status block do not contain any additional status information for the completed I/O operation.

Subchannel-Extended-Status Field

The subchannel-extended-status field is contained in bit positions 24-31 of word 2 of the SCSW. This field may contain information used to further qualify the reason for any the following conditions, when indicated in the subchannel-status: interface-control check, channel-control check, channel-data check, program check, and protection check. If none of these bits are active in the subchannel-status byte, the fields of the subchannel-extended-status contain no meaningful information. When more than one condition is indicated, the interface-control check takes priority over the other conditions.

Interrogate Failed (F): Bit 24 is the interrogate-failed operation bit. When set to one, the F bit indicates that an interrogate operation failed because of a program check, channel-control check, or interface-control check.

Subchannel-Extended-Status Qualifier (SESQ): Bits 25-31 are the subchannel-extended-status qualifier and contain an unsigned integer value. When the subchannel-status field indicates program check, interface-control check, protection check, data check, or channel-control check, bits 25-31 may contain additional information as follows:

Value	Description	IFCC	CCC	CDC	PGC	PTC	
0	No status available for the exception condition indicated.	X	X	X	X	X	
1	Storage-request limit exceeded, a model-dependent number of storage requests has been exceeded for the requested block of data.	-	-	-	X	-	

Figure 16-11. Subchannel-Extended Status Qualifiers

Value	Description	IFCC	CCC	CDC	PGC	PTC	
2	Program check when all of the following conditions are met: (1) The TCW read or write data count did not go to zero and either the incorrect-length indication facility is not installed or incorrect-length indication is not supported by the device. (2) CE only or CE and DE only status was received, or unit-check with CE or CE and DE status was received. (3) The operation is not an interrogate, transfer-COB, or transfer-TCAX operation.	-	-	-	X	-	
3	Transport mode not supported by the I/O device.	-	-	-	X	-	
4	Transport mode not supported on the selected channel path.	-	-	-	X	-	
5	Reserved						
6	Program check on the TCW: An invalid TCW was detected.	-	-	-	X	-	
7	A device-detected program check condition exists due to indeterminate cause.	-	-	-	X	-	
8	A device-detected program check condition exists.	-	-	-	X	-	
9[a]	Program check on a TIDAW: An invalid TIDAW was detected.	-	-	-	X	-	-
10-31	Reserved.	-	-	-	-	-	
32[b]	TCW access exception: An exception was detected on while fetching a TCW.	-	X	-	X	X	
33[c]	TSB access exception: An exception was detecting while storing a TSB.	-	X	-	X	-	
34[d]	TCCB access exception: An exception was detected while fetching a TCCB.	-	X	-	X	X	
35[e]	TIDAW access exception: An exception was detected while fetching a TIDAW.	-	X	-	X	X	
36[f]	Data access exception: An exception was detected while storing or fetching data.	-	-	X	X	X	
37-63	Reserved.	-	-	-	-	-	
64	An invalid CBC error on read data	X	-	-	-	-	
65	Reserved	-	-	-	-	-	
66	A link protocol error condition has occurred.	X	-	-	-	-	
67	A failed device-level recovery operation.	X	-	-	-	-	
68	IFCC occurred because a device-level recovery operation failed. A program, protection or data check may also be set to one in the Subchannel status.	X	-	-	-	-	
69	The residual count between the TCW and the response from the device are not the same.	X	-	-	-	-	
70	An Invalid CBC was detected on the status portion of the transport response from the device.	X	-	-	-	-	
71	An Invalid CBC was detected on the TSB transported from the device.	X	-	-	-	-	
72-127	Reserved.	-	-	-	-	-	

Figure 16-11. Subchannel-Extended Status Qualifiers (Continued)

Value	Description	IFCC	CCC	CDC	PGC	PTC	

Explanation:

X	Applicable
-	Not applicable
IFCC	Interface-control check
CCC	Channel-control check
CDC	Channel-data check
PGC	Program check
PTC	Protection check

Footnotes:

[a] The failing-storage-address (FSA) field in the ESW is valid and contains the address of the TIDAW which was determined to be invalid.

[b] The FSA field is valid and contains the address of the current TCW.

[c] The FSA field is valid and contains the address of the TSB designated by the current TCW.

[d] The FSA field is valid and contains the address of the TCCB designated (directly or indirectly) by the TCW.

[e] The FSA field is valid and contains the address of the TIDAW for which the exception was detected.

[f] The FSA field is valid and contains the address of the input or output data designated (directly or indirectly) by the TCW.

Note: If the FSA field is valid for any SESQ value other than those identified by footnotes a-f, the FSA field contains the address of the current TCW.

Figure 16-11. Subchannel-Extended Status Qualifiers (Continued)

Extended-Status Word

The extended-status word (ESW) provides additional information to the program about the subchannel and its associated device. The ESW is placed in words 3-7 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed and the subchannel designated is operational. If the subchannel is status pending or status pending with any combination of primary, secondary, intermediate, or alert status (except as noted in the next paragraph) when TEST SUBCHANNEL is executed, the ESW may have any of the following types of extended-status format:

Format 0 Subchannel logout in word 0, an ERW in word 1, a failing-storage address or zeros in words 2 and 3, and a secondary-CCW address or zeros in word 4.

Format 1 Zeros in bytes 0, 2, and 3 of word 0, the LPUM in byte 1 of word 0, an ERW in word 1, and zeros in words 2-4.

Format 2 Zeros in byte 0, the LPUM in byte 1, and the device-connect time in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Format 3 Zeros in byte 0, the LPUM in byte 1, and unpredictable values in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Words 0-4 of the ESW contain unpredictable values if any of the following conditions is met:

1. The subchannel is not status pending.
2. The subchannel is status pending alone, and the extended-status-word-format bit is zero.
3. The subchannel is status pending with intermediate status alone for other than the intermediate interruption condition due to suspension.

The type of extended-status format stored depends upon conditions existing at the subchannel at the time TEST SUBCHANNEL is executed. The conditions under which each of the types of formats is stored are described in the remainder of this section.

Extended-Status Format 0

The ESW stored by TEST SUBCHANNEL is a format-0 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is one and the subchannel is status pending with any combination of status as defined in Figure 16-12 on page 16-51. In this case, subchannel-logout information and an ERW are stored in the extended-status word. Subchannel logout provides detailed model-independent information relating to a subchannel and describing equipment errors detected by the channel subsystem. The information is provided to aid the recovery of an I/O operation, a device, or both. Whenever subchannel logout is provided, the error conditions relate only to the subchannel reporting the error. If I/O operations involving other subchannels have been affected by the error condition, those subchannels also provide similar subchannel-logout information. An extended-report word provides additional information relating to the cause of the malfunction.

A format-0 ESW has the following format:

Word	
0	Subchannel Logout
1	Extended-Report Word
2	Failing-Storage Address or ESLD
3	
4	Secondary-CCW Address or Zeros
	0 … 31

Subchannel Logout

The subchannel logout has the following format:

0	ESF	LPUM	R	FVF	SA	TC	D	E	A	SC
0	1	8	16	17	22	24	26	27	28	29 31

Extended-Status Flags (ESF): Any of bits 1-7, when one, specifies that an error-check condition has been detected by the channel subsystem. The following indications are provided in the ESF field:

Key Check. Bit 1, when one, indicates that the channel subsystem, when accessing data, when attempting to update the measurement block, or when attempting to fetch either a CCW, an IDAW, MIDAW, TCW, TCCB, TIDAW, or when accessing a TSB, has detected an invalid checking-block code (CBC) on the associated storage key. The channel-data-check bit, bit 12 of word 2 of the

SCSW, the measurement-block data-check bit, bit 3 of word 0 of the ESW, the CCW-check bit, bit 5 of word 0 of the ESW, or the IDAW/MIDAW-check bit, bit 6 of word 0 of the ESW, identifies the source of the key error.

Note: This condition may be indicated to the program when an invalid checking-block code on a key is detected but the data, CCW, IDAW, TIDAW, or MIDAW then is not used after being prefetched. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location within the storage block having the key is stored in words 2 and 3 of the ESW.

Measurement-Block Program Check. Bit 2, when one, indicates that the channel subsystem, in attempting to update the measurement block, has either detected an invalid absolute address when combining the measurement-block origin with the measurement-block index for this subchannel or has detected an invalid measurement-block address at the subchannel.

Measurement-Block Data Check. Bit 3, when one, indicates that a malfunction has been detected involving the data of the measurement block in main storage. (See “Measurement Block” on page 17-3.) Measurement-block data check is indicated when the measurement block is updated and an invalid checking-block code (CBC) is detected on the storage used to contain the measurement data or on the associated key. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

Measurement-Block Protection Check. Bit 4, when one, indicates that the channel subsystem, when attempting to update the measurement block, has been prohibited from accessing the measurement block because the storage key does not match the measurement-block key (see “Measurement Block” on page 17-3.) The key provided by SET CHANNEL MONITOR is used for the access of storage associated with measurement-block-update operations (see “SET CHANNEL MONITOR” on page 14-13.).

Note: Whenever any of the measurement-check conditions is indicated by bits 2-4, the channel subsystem sets the subchannel measurement-block-update-enable bit to zero, disabling the storing of measurement data for the subchannel (see “Measurement-Mode Enable (MM)” on page 15-3).

CCW Check. When a command-mode IRB is stored, bit 5, when one, indicates that an invalid CBC on the contents of the CCW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is stored as one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

When a transport-mode IRB is stored, bit 5 is reserved and set to zero.

Note: This condition may be indicated to the program when an invalid checking-block code on a prefetched CCW is detected but the CCW is not used. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW.

IDAW/MIDAW Check. When a command-mode IRB is stored, bit 6, when one, indicates that an invalid CBC on the contents of an IDAW or MIDAW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated with the device, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also one.

When a transport-mode IRB is stored, bit 6 is reserved and set to zero.

Note: This condition may be indicated to the program when an invalid checking-block code on the contents of a prefetched IDAW or MIDAW is detected but the IDAW or MIDAW is not used. In this case, the failing-storage-address-validity bit,

bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW. Detection of a channel-data-check condition does not cause the CCW-check and IDAW/MIDAW-check bits to be stored as ones.

Reserved. Bit 7 is stored as zero.

Last-Path-Used Mask (LPUM): Bits 8-15 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. When a command-mode IRB is stored, the bit corresponding to the channel path in use is set whenever any of the following occurs:

1. The first command of a start-subchannel function is accepted by the device (see “Activity Control (AC)” on page 16-14).
2. The device and channel subsystem are actively communicating when the channel subsystem performs the suspend function for the channel program in execution.
3. The channel subsystem accepts status from the device that is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 16-2).
4. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present at the subchannel.

When a transport-mode IRB is stored, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.
2. The channel subsystem accepts status from the device that is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status, or both.
3. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present at the subchannel.

The LPUM field contains the most recent setting and is valid whenever the ESW contains information in one of the formats 0-3 (see “Extended-Status Word” on page 16-47) and the SCSW is stored. When subchannel-logout information is present in the ESW, a zero LPUM-field-validity flag indicates that the LPUM setting is not consistent with the other subchannel-logout indications.

Ancillary Report (R): Bit 16, when one, indicates that a malfunction of a system component has occurred that has been recognized previously or that has affected the activities of multiple subchannels. When the malfunction affects the activities of multiple subchannels, an ancillary-report condition is recognized for all of the affected subchannels except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful only when a channel-control check, channel-data check, or an interface-control check is indicated in bit positions 12-14 of word 2 of the SCSW.

Depending on the model, recognition of an ancillary-report condition may not be provided or it may not be provided for all system malfunctions that effect subchannel activity. When ancillary-report recognition is not provided, bit 16 is set to zero

Field-Validity Flags (FVF): Bits 17-21 indicate the validity of the information stored in the corresponding fields of either the SCSW or the extended-status word. When the validity bit is one, the corresponding field has been stored and is usable for recovery purposes. When the validity bit is zero, the corresponding field is not usable.

This bit-significant field has meaning when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. When these checks are not indicated, this field, as well as the termination-code and sequence-code fields, has no meaning. Furthermore, when these checks are not indicated, the last-path-used-mask, device-status, and the TCW address or the CCW-address fields are all valid. The fields are defined as follows:

17	Last-path-used mask
18	Termination code
19	Sequence code
20	Device status

21 CCW address or TCW address

Storage-Access Code (SA): Bits 22-23 indicate the type of storage access that was being performed by the channel subsystem at the time of error. The SA field pertains only to the access of storage for the purpose of fetching or storing data during the performance of an I/O operation. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the subchannel status. The access-code assignments are as follows:

00 Access type unknown
01 Read
10 Write
11 Read backward for a command-mode operation.

Termination Code (TC): Bits 24 and 25 indicate the type of termination that has occurred. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. The types of termination are as follows:

00 Halt signal issued
01 Stop, stack, or normal termination
10 Clear signal issued
11 Reserved

When at least one channel check is indicated in the SCSW but the termination-code-field-validity flag is zero, it is unpredictable which, if any, termination has been signaled to the device. If more than one channel-check condition is indicated in the SCSW, the device may have been signaled one or more termination codes that are the same or different. In this situation, if the termination-code-field-validity flag is one, the termination code indicates the most severe of the terminations signaled to the device. The termination codes, in order of increasing severity, are: stop, stack, or normal termination (01); halt signal issued (00); and clear signal issued (10)

Device-Status Check (D): When the status-verification facility is installed, bit 26, when one, indicates that the subchannel logout in the ESW resulted from the channel subsystem detecting device status that had valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. When the device-status-check bit is one, the interface-control-check status bit is set to one. If, additionally, bit 20 of the subchannel-logout field has been stored as one, then the status byte in error has been stored in the device-status field of the SCSW. If the status-verification facility is not installed, bit 26 is stored as zero.

Secondary Error (E): Bit 27, when one, indicates that a malfunction of a system component that may or may not have been directly related to any activity involving subchannels or I/O devices has occurred. Subsequent to this occurrence, the activity related to this subchannel and the associated I/O device was affected and caused the subchannel to be set status pending with either channel-control check or interface-control check.

I/O-Error Alert (A): Bit 28, when one, indicates that subchannel logout in the ESW resulted from the signaling of I/O-error alert. The I/O-error-alert signal indicates that the control unit or device has detected a malfunction that must be reported to the channel subsystem. The channel subsystem, in response, issues a clear signal and, except as described in the next paragraph, causes interface-control check to be set and extended-status-format-0 (logout) information to be stored in the ESW.

When I/O-error alert is signaled and the subchannel has previously been set disabled or no subchannel is associated with the device, the clear signal is issued to the device, and the I/O-error-alert indication is ignored by the channel subsystem.

Sequence Code (SC): When a command-mode IRB is stored, bits 29-31 identify the I/O sequence in progress at the time of error. The sequence code pertains only to I/O operations initiated by the execution of START SUBCHANNEL or RESUME SUBCHANNEL. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW.

When a transport-mode IRB is stored, and the validity bit corresponding to the sequence-code field is one, bits 29-31 are stored as zeros.

The sequence-code assignments are:

000 Reserved

001 A nonzero command byte has been sent by the channel subsystem, but a response has not yet been analyzed by the channel subsystem. This code is set during the initiation sequence.

010 The command has been accepted by the device, but no data has been transferred.

011 At least one byte of data has been transferred between the channel subsystem and the device. This code may be used when the channel path is in an idle or polling state.

100 The command in the current CCW (1) has not yet been sent to the device, (2) was sent but not accepted by the device, or (3) was sent and accepted but command-retry status was presented. This code is set when any of the following conditions occurs:

1. The command address is updated during command chaining or during the initiation of a start function or resume function at the device.
2. During the initiation sequence, the status includes attention, control unit end, unit check, unit exception, busy, status modifier (without channel end and device end), or device end (without channel end).
3. Command retry is signaled.
4. The channel subsystem interrogates the device in the process of clearing an interruption condition.
5. The channel subsystem signals the conclusion of the chain of operations to the device during command chaining while performing the suspend function.

101 The command in the current CCW has been accepted, but data transfer is unpredictable. This code applies from the time a device is logically connected to a channel path until the time it is determined that a new sequence code applies. This code may also be used when the channel subsystem places a channel path in the polling or idle state and it is impossible to determine that code 010 or 011 applies. It may also be used at other times when a channel path cannot distinguish between code 010 or 011.

110 Reserved.

111 Reserved.

Figure 16-12 on page 16-51 defines the relationship between indications provided as subchannel-logout data and the appropriate SCSW bits.

	Logout Condition for SCSW Indication of[1]		
Subchannel-Logout Condition Indicated	CDC	CCC	IFCC
Key check	V	V	-
Measurement-block-program check[2]	-	-	-
Measurement-block-data check[2]	-	-	-
Measurement-block-protection check[2]	-	-	-
CCW check	-	V	-
IDAW/MIDAW check	-	V	-
Last-path-used mask[3]	V	V	V
Field-validity flags	V	V	V
Termination code[3]	V	V	V
Device-status check	-	-	V
Secondary error	-	V	V
I/O-error alert	-	-	V
Sequence code[3]	V	V	V

Explanation:

- No relationship.

[1] When more than one SCSW indication is signaled, the subchannel-logout conditions that are valid are the logical OR for each of the respective SCSW indications.

[2] Only one measurement-block check may be indicated in a specific subchannel logout.

[3] This field has a field-validity flag.

CCC Channel-control check.

CDC Channel-data check.

IFCC Interface-control check.

V Bit setting valid.

Figure 16-12. Relationship Between Subchannel-Logout Data and SCSW Bits

Extended-Report Word

The extended-report word (ERW) provides information to the program describing specific conditions that may exist at the device, subchannel, or channel subsystem. The ERW is stored whenever the extended-status word is stored. When the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the extended-control bit, bit 14 of word 0 of the SCSW, are both zeros, the ERW contains all zeros. When the extended-status-word-format bit or the extended-control bit or both are ones, the ERW has the following format:

0	L	E	A	P	T	F	S	C	R	SCNT	Reserved
0	1			4				8		10	16 31

Request Logging Only (L) : Bit 1, when one, requests that the program only record information about the condition that caused the extended-status word to be stored.

Extended-Subchannel-Logout Pending (E): Bit 2, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that an extended-subchannel logout is pending and that words 2-3 of the ESW contain the extended-subchannel-logout descriptor.

Bit 2 is set to zero when bit 6 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

Authorization Check (A): Bit 3, when one, indicates that the start or resume function was terminated because the channel subsystem has been placed in the isolated state in which pending I/O operations are not initiated and I/O operations currently being performed either are in the process of being terminated or have been terminated.

Path Verification Required (P): Bit 4, when one, indicates that the program must verify the identity of the device. The LPUM, when valid, indicates the channel path for which device verification is to be performed. When a valid LPUM is not available, the identity of the device must be verified for each available channel path.

Channel-Path Timeout (T): Bit 5, when one, indicates that, during a signaling sequence, an appropriate signal from the device did not occur within a predetermined time interval. Bit 5 is meaningful when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the interface-control-check bit, bit 14 of word 2 of the SCSW, are both ones.

Failing-Storage-Address Validity (F): Bit 6, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an invalid CBC on a CCW, a data location, an IDAW, a MIDAW, a TCW, TCCB, a TIDAW, a TSB or on the respective associated key and has stored, in words 2 and 3 of the ESW, the absolute address of a location associated with the invalid CBC.

Bit 6 is set to zero when bit 2 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

Concurrent Sense (S) : When a command-mode IRB is stored, bit 7, when one, indicates that the concurrent-sense facility has placed sense information accepted from the device in the extended-control word and has stored a value, in bit positions 10-15 of the ERW, that specifies the number of sense bytes that have been stored in the extended-control word. When bit 7 is one, bit 14 of word 0 of the SCSW is also one.

When a transport-mode IRB is stored, bit 7 is reserved and set to zero.

Concurrent-Sense Count (SCNT): When bit 7 is one, bit positions 10-15 contain a value, in the range 1-32, that specifies the number of sense bytes stored into the extended-control word by the concurrent-sense facility. When bit 7 is zero, bit positions 10-15 contain zeros.

Secondary-CCW-Address Validity (C): When a command-mode IRB is stored, bit 8, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an error condition that precludes the continued performance of an I/O operation. When prefetching applies (bit 9 of word 1 of the ORB is one) and certain error conditions identified by channel-control check, channel-data check, or interface-control check are recognized by the channel subsystem, situations may exist where the termination point of execution of the channel program differs between the channel subsystem and the I/O device. To properly identify the termination points, bit 8 is set to one, and a second CCW address (secondary-CCW address) is provided in the ESW and designates the last CCW executed at the device. When the validity bit is zero for the previously mentioned errors, the channel subsystem was unable to determine the termination point of the control-unit execution, and the secondary-CCW-address field contains zeros.

Bit 8 is not set to one unless the program has permitted prefetching by setting the prefetch-control bit, bit 9 of word 1 of the ORB, to one for the channel program in execution.

When a transport-mode IRB is stored, bit 8 is reserved and set to zero.

Failing-Storage-Address Format (R): Bit 9 indicates the format of the failing-storage address when the failing-storage-address validity bit, bit 6 of the ERW, is one. When bit 6 is zero, bit 9 is not meaningful and is stored as zero. When bit 6 is one and bit 9 is zero, a format-1 failing-storage address is stored in words 2 and 3 of the ESW. When bit 6 is one and bit 9 is one, a format-2 failing-storage address is stored in words 2 and 3. See “Failing-Storage Address” below for a description of format-1 and format-2 addresses.

Failing-Storage Address

Words 2 and 3 of the extended-status contain a 24-, 31-, or 64-bit absolute address. When the failing-storage-address-validity flag, bit 6 of the ERW, is one, words 2 and 3 contain either a format-1 failing-storage address or a format-2 failing-storage address. When bit 6 is one**,** the failing-storage-address field designates a byte location within the invalid checking block associated with an invalid CBC for a CCW, data location, IDAW, MIDAW, TCW, TCCB, TIDAW, TSB, or their respective associated key.

When a transport-mode IRB is stored, and the failing-storage-address validity flag, bit 6 of the ERW, is one, the failing-storage address contains the absolute address associated with the reported failing condition.

When an error condition is detected and a command-mode IRB is stored, the form of the address stored in words 2 and 3 depends on the format-2-IDAW control, bit 14 of word 1 of the ORB, and on the MIDA control, bit 25 of word 1 of the ORB, as follows:

1. When the format-2-IDAW control is zero, specifying that fullword IDAWs containing 31-bit addresses are used, and the modified-CCW-indirect-data-addressing-control is zero, a format-1 address is stored, and the failing-storage-address-format bit, bit 9 of the ERW, is stored as zero.

2. When either the format-2-IDAW control is one, specifying that doubleword IDAWs containing 64-bit addresses are used, or the modified-CCW-indirect-data-addressing-control is one, or both are one, a format-2 address is stored, and the failing-storage-address-format bit is stored as one.

When an error condition is detected and a transport-mode IRB is stored, a format-2 failing-storage address is stored. A format-2 failing-storage address is stored for a transport-mode IRB when a program-check, protection check, channel-data check or channel-control check condition is indicated by the subchannel status.

When a format-1 address is stored, bits 1-31 of word 2 form the address associated with the reported error condition, and bit 0 of word 2 and all of word 3 are stored as zeros. When a format-2 address is stored, bits 0-31 of word 2 followed by bits 0-31 of word 3 form the 64-bit address associated with the reported error condition.

Extended-Subchannel-Logout Descriptor (ESLD)

When the extended-status-word-format (L) bit, bit 5 of SCSW word 0, is one and the extended-subchannel-logout pending (E) flag, bit 2 of the ERW, is one, an extended-subchannel-logout descriptor is provided in words 2-3 of the ESW. The ESLD identifies the logout and the channel path for which the extended-subchannel logout is pending.

Secondary-CCW Address

When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check and the secondary-CCW-address-validity flag, bit 8 of word 1, is one, bits 1-31 of word 4 form an absolute address of the last CCW executed by the I/O device at the point the reported check condition caused channel-program termination. When provided, the secondary-CCW address may be used for recovery purposes. When the secondary-CCW-address-validity flag is zero, this field contains zeros.

When a transport-mode IRB is stored and the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, word 4 is reserved and contains zeros.

Extended-Status Format 1

The ESW stored by TEST SUBCHANNEL is a format-1 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.

2. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:

   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,

   b. The primary-status bit and other status-control bits, or

   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

3. At least one of the following conditions is indicated:

   a. The device-connect-time-measurement mode is inactive.

   b. The channel-subsystem-timing facility is not available for the subchannel.

   c. The subchannel is not enabled for the device-connect-time-measurement mode.

Zeros are stored in bytes 0, 2, and 3 of word 0, and the LPUM is stored in byte 1 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

The device-connect-time-measurement mode is made inactive when SET CHANNEL MONITOR is executed and bit 31 of general register 1 is zero.

A format-1 ESW has the following format:

Word	0	8	16 31
0	Zeros	LPUM	Zeros
1	Extended-Report Word		
2	Zeros		
3			
4			

Last-Path-Used Mask (LPUM): For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-49.

Extended-Report Word (ERW): For a definition of the ERW, see “Extended-Report Word” on page 16-51.

Extended-Status Format 2

The ESW stored by TEST SUBCHANNEL is a format-2 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.

2. The channel-subsystem-timing facility is available for the subchannel.

3. The subchannel is enabled for the device-connect-time-measurement mode.

4. The device-connect-time-measurement mode is active.

5. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:

   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,

   b. The primary-status bit and other status-control bits, or

   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

Zeros are stored in byte 0 of word 0, the LPUM is stored in byte 1 of word 0, and the device-connect time is stored in bytes 2 and 3 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-2 ESW has the following format:

Word	0	8	16 31
0	Zeros	LPUM	DCTI
1	Extended-Report Word		
2	Zeros		
3			
4			

Last-Path-Used Mask (LPUM): For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-49.

Device-Connect-Time Interval (DCTI): Bit positions 16-31 contain the binary count of time increments accumulated by the channel subsystem during the time that the channel subsystem and the device were actively communicating and the subchannel was subchannel active for a command-mode operation, or start pending for a transport-mode operation. The time increment of the DCTI is 128 microseconds.

If the above conditions for the storing of the DCTI value in the ESW are met but the device-connect-time-measurement mode was made active by SET CHANNEL MONITOR subsequent to the execution of START SUBCHANNEL for this subchannel, the DCTI value stored is greater than or equal to zero and less than or equal to the correct DCTI value.

Note: The DCTI value stored in the ESW is the same as that used to update the corresponding measurement-block data for the subchannel if the measurement-block-update mode is in use for the subchannel. If the measurement-block-update mode for the channel subsystem is active and the subchannel is enabled for the device-connect-time-measurement mode but no DCTI value is stored in the ESW (because of the presence of subchannel-logout information), or if the DCTI is zero, then nothing is added to the corresponding measurement-block data.

Extended-Report Word (ERW): For a definition of the ERW, see “Extended-Report Word” on page 16-51.

Extended-Status Format 3

The ESW stored by TEST SUBCHANNEL is a format-3 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero and the subchannel is status pending with (1) secondary status, alert status, or both when primary status is not also present, or (2) intermediate status when the subchannel is not suspended. Zeros are stored in byte 0 of word 0, and the LPUM is stored in byte 1 of word 0. Bytes 2 and 3 of word 0 contain unpredictable values; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-3 ESW has the following format:

Word			
0	Zeros	LPUM	XXXXXXXXXXXXXXXX
1	Extended-Report Word		
2			
3	Zeros		
4			
	0	8	16 31

Last-Path-Used Mask (LPUM): For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-49.

An “X” in the format indicates the bit may be zero or one.

Extended-Report Word (ERW): For a definition of the ERW, see “Extended-Report Word” on page 16-51.

Figure 16-13 on page 16-56 summarizes the conditions at the subchannel under which each type of information is stored in the ESW.

Subchannel Conditions When IRB is stored						Extended-Status Word (ESW), Word 0	
Subchannel-Status Word				Path-Management-Control Word			
Status-Control Field AIPSX	L Bit	Sus-pen-ded Bit	Device Connect-Time-Msrmnt Mode	Timing-Facility Bit	Device-Connect-Time-Msrmnt-Mode-Enable Bit	For-mat	Contents Bytes 0,1,2,3

/ Information not relevant in this situation.
A Alert status.
D Accumulated device-connect-time-interval (DCTI) value stored in bytes 2 and 3.
I Intermediate status.
L Extended-status-word format.
M Last-path-used mask (LPUM) stored in byte 1.
P Primary status.
R Subchannel-logout information stored in word 0.
S Secondary status.
U No format defined.
X Status pending.
Z Bits are stored as zeros.

Figure 16-13. Information Stored in ESW

Extended-Control Word

The extended-control word, which is words 8-15 of an interruption-response block (see "Interruption-Response Block" on page 16-6), provides additional information to the program describing conditions that may exist at the channel subsystem, subchannel, or device. The extended-control (E) bit, bit 14 of word 0 of the SCSW, when one, indicates that model-dependent information or concurrent-sense information has been stored in the extended-control word.

The information provided in the extended-control word is as follows:

SCSW Bits 5	SCSW Bits 14	ERW Bit 7	ERW Bits 10-15	ECW Words 0-7
0	0	0	Zeros	Unpredictable[1]
0	1	0	([5])	([5])
0	1	1	([3])	Concurrent-sense information[4]
1	0	0	Zeros	Unpredictable[1]
1	1	0	Zeros	Model-dependent information[2]
1	1	1	([3])	Concurrent-sense information[4]

Explanation:

[1] If stored, the value of these words is unpredictable.
[2] Unused bits in the model-dependent information are stored as zeros.
[3] Bit positions 10-15 contain a value equal to the number of sense bytes returned.
[4] Unused bytes in the concurrent-sense information are stored as zeros.
[5] The combination of SCSW bit 5 as 0, SCSW bit 14 as one, and ERW bit 7 as zero does not occur.

Extended-Measurement Word

The extended-measurement word (EMW) provides I/O measurement information to the program for the most recent start or resume operation performed at the subchannel. When the extended-I/O-measurement-word facility is installed and enabled, the EMW is conditionally stored in words 16-23 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed. The EMW is stored by TEST SUBCHANNEL when all of the following conditions are met:

1. The extended-status-word-format (L) bit (bit 5, word 0 of the SCSW) is zero.

2. The channel-subsystem-timing facility is available for the subchannel, as indicated by the timing facility bit (T) at the subchannel.

3. The extended-I/O-measurement-word-mode enable bit (X) at the subchannel is one.

4. The subchannel status-control field has the status-pending bit (bit 31, word 0 of the SCSW) set to one, together with:

   a. The primary-status bit (bit 29, word 0 of the SCSW) alone, or

   b. The primary-status bit and other status-control bits, or

   c. The secondary-status bit (bit 29, word 0 of the SCSW) alone, or

   d. The intermediate-status bit (bit 28, word 0 of the SCSW) and the suspended bit (bit 26, word 0 of the SCSW).

Words 16-23 of the IRB contain unpredictable values when the extended-I/O-measurement-word facility is installed and enabled but the conditions listed above are not met.

When the extended-I/O-measurement-word facility is not installed, or the facility is installed but not enabled, words 16-23 of the IRB are not accessed by the channel subsystem.

The format of the extended-measurement word is shown below:

Word	
0	Device-Connect Time
1	Function-Pending Time
2	Device-Disconnect Time
3	Control-Unit-Queuing Time
4	Device-Active-Only Time
5	Device-Busy Time
6	Initial Command Response Time
7	Reserved
	0 31

Each field in the EMW, when valid, contains a 32 bit binary count in which each increment of the count represents a value of 0.5 microseconds. A value of 00000000 hex represents a time period of zero seconds; the maximum value of FFFFFFFF hex represents approximately 35.79 minutes.

The accuracy of each of the measurement fields stored by the measurement facility is undefined and may vary depending on the resolution of timers implemented at the channel subsystem, the types of channels used to perform the operation, the capabilities of control units accessed during the operation, and the overall length of the I/O operation that was performed. The maximum value of FFFFFFFF hex is stored if a counter overflows; the program is not alerted when an overflow occurs.

Device-Connect Time: Bit positions 0-31 of word 0 contain the measured device-connect time for the operation. The device-connect time is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active for a command-mode operation, or start-pending for a transport-mode operation, and the device is actively communicating with the channel path, as defined in the section "Device-Connect Time" on page 17-4.

Function-Pending Time: Bit positions 0-31 of word 1 contain the SSCH- or RSCH-function-pending time for the operation. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device, as defined in the section "Function-Pending Time" on page 17-5.

Device-Disconnect Time: Bit positions 0-31 of word 2 contain the device-disconnect time for the operation. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel-active for a command-mode operation, or start-pending for a transport-mode operation, as defined in the section "Device-Disconnect Time" on page 17-5.

Control-Unit-Queuing Time : Bit positions 0-31 of word 3 contain the control-unit-queuing time for the operation. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system, as defined in the section "Control-Unit-Queuing Time" on page 17-5.

Device-active-only time: Bit positions 0-31 of word 4 contain the device-active-only time for the operation. For a command-mode operation, device-active-only time is the sum of the time intervals when the subchannel is device-active but not subchannel-active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function, as defined in section “Device-Active-Only Time” on page 17-6. When a transport-mode IRB is stored, device-active-only time is the sum of the times that the I/O device was active executing device command and the time interval between when channel-end and device-end status were presented.

Device-busy time: Bit positions 0-31 of word 5 contain the device-busy time for the operation. When a command-mode IRB is stored, the device-busy time is the sum of the time intervals when the device is found to be device busy during an attempt to initiate a start function or resume function at the subchannel, as defined in the section “Device-Busy Time” on page 17-6. When a transport-mode IRB is stored, device-busy time is the sum of the times that the I/O device was busy attempting to initiate a command and the device busy time accumulated by the channel subsystem.

Initial Command Response Time: Bit positions 0-31 of word 6 contain the initial-command-response time for the operation. When a command-mode IRB is stored, initial-command-response time for an operation is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command. When a transport-mode IRB is stored, the initial-command-response time, is the time interval difference between when a TCCB is sent to the I/O device until the response is received from the I/O device, minus the time from when the control unit receives the TCCB until the channel subsystem receives the response from the control unit.

Multiple-Subchannel-Set Facility. 17-35

The I/O support functions are those functions of the channel subsystem that are not directly related to the initiation or control of I/O operations. The following I/O support functions are described in this chapter:

- Channel-subsystem monitoring
- Signals and resets
- Externally initiated functions
- Status verification
- Address-limit checking
- Configuration alert
- Incorrect-length-indication suppression
- Concurrent sense
- Channel-subsystem recovery
- I/O-priority facility
- Restore-subchannel facility
- Multiple-subchannel-set facility

Channel-Subsystem Monitoring

Monitoring facilities are provided in the channel subsystem so that the program can retrieve measured values on performance for a designated subchannel. The use of these facilities is under program control by means of the execution of the SET CHANNEL MONITOR instruction and the MODIFY SUBCHANNEL instruction.

The principal components of the channel-subsystem-monitoring facilities are the channel-subsystem-timing facility, measurement-block-update facility, and device-connect-time-measurement facility. The measurement-block-update facility and device-connect-time-measurement facility both use the channel-subsystem-timing facility but otherwise are logically distinct and operate independent of one another.

Other components of the channel-subsystem-monitoring facilities are the control-unit-queuing-measurement facility, the control-unit-defer-time facility, the device-active-only-measurement facility, the initial-command-response-measurement facility, the extended-I/O-measurement-block facility, and the extended-I/O-measurement-word facility. These enhance the measurements of the measurement-block-update facility if they are available as described in later sections, where each of the facilities that constitute the channel-subsystem-monitoring facilities is described in this chapter.

Channel-Subsystem Timing

The channel-subsystem-timing facility provides the channel subsystem with the capability of measuring the elapsed time required for performing several different phases of the processing of a start function initiated by START SUBCHANNEL. These elapsed-time measurements are used by both the measurement-block-update facility and the device-connect-time-measurement facility to provide subchannel performance information to the program.

While every channel subsystem has a channel-subsystem-timing facility, it may or may not be provided for use with all subchannels. Subchannels for which the facility is provided have the timing-facility bit, bit 14 of word 1, stored as one in the associated subchannel-information block. (See “Timing Facility (T)” on page 15-4.) If the channel-subsystem-timing facility is not provided for the subchannel, the subchannel's timing-facility bit is stored as zero.

Subchannels that do not have the channel-subsystem-timing facility provided are those for which the characteristics of the associated device, the manner in which it is attached to the channel subsystem, or the channel-subsystem resources required to support the device are such that use of the channel-subsystem-timing facility is precluded.

The channel-subsystem-timing facility consists of at least one channel-subsystem timer and the associated logic and storage required for computing and recording the elapsed-time intervals for use by the two measurement facilities. The aspects of the channel-subsystem-timing facility that are of importance to the program are described below.

Channel-Subsystem Timer

Each channel-subsystem timer is a binary counter that is not accessible to the program. The channel-subsystem timer provides a minimum timer resolution of 128 microseconds. A timer resolution of 1.0 microseconds is provided when FICON-I/O-interface channel paths are supported. When incrementing the channel-subsystem timer causes a carry out of the leftmost bit position, the carry is ignored, and counting continues from zero. No indications are generated as a result of the overflow.

Just as every CPU has access to a TOD clock, every channel subsystem has access to at least one channel-subsystem timer. When multiple channel-subsystem timers are provided, synchronization among these timers is also provided, creating the effect that all the timing facilities of the channel subsystem share a single timer. Synchronization among these timers may be supplied either through some TOD clock or independently by the channel subsystem.

If the TOD clocks are not synchronized, the elapsed times measured by the channel-subsystem-timing facility may have unpredictable values for some or all of the subchannels, depending on the model and on the particular channel-subsystem timer and the way the associated devices are physically attached to the system. The values are unpredictable for those devices attached to the system by separately configurable channel paths whose associated CPU TOD clocks are not synchronized.

Synchronization: If either the measurement-block-update mode or the device-connect-time-measurement mode is active and any of the channel-subsystem timers is found to be out of synchronization, a channel-subsystem-timer-sync check is recognized, and a channel report is generated to alert the program (see “Channel-Subsystem Recovery” on page 17-27). If neither of these modes is active, the lack of synchronization is not recognized.

Measurement-Block Update

The measurement-block-update facility provides the program with the capability of accumulating performance information for subchannels that are enabled for the measurement-block-update mode when the measurement-block-update mode is active. A subchannel is enabled for the measurement-block-update mode by setting bit 11 of word 1 of the SCHIB operand to one and then issuing MODIFY SUB-

CHANNEL. The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR when bit 62 of general register 1 is one.

When the measurement-block-update mode is active and the subchannel is enabled for the measurement-block-update mode, information is accumulated in a measurement block associated with the subchannel. A measurement block is either a 32-byte area (format-0 measurement block) or a 64-byte area (format-1 measurement block) in main storage that is associated with a subchannel for the purpose of accumulating measurement data.

For format-0 measurement blocks, the program specifies a contiguous area of absolute storage, referred to as the measurement-block area, and subdivides this area into 32-byte blocks, one block for each subchannel for which measurement data is to be accumulated. The measurement-block-update facility uses the measurement-block index contained at the subchannel in conjunction with the measurement-block origin established by the execution of SET CHANNEL MONITOR to compute the absolute address of the measurement block associated with a subchannel.

For format-1 measurement blocks, the program provides a 64-byte contiguous area of absolute storage for the subchannel. The measurement-block-update facility uses the measurement-block address provided by the MSCH instruction to access the measurement block.

Measurement data is stored in the measurement block associated with the subchannel each time an I/O operation or chain of I/O operations initiated by a START SUBCHANNEL instruction or RESUME SUBCHANNEL instruction is suspended or is completed at the device The completion of an I/O operation or chain of I/O operations at the device is normally determined when secondary status is accepted from the device.

The measurement data accumulated in the format-0 and format-1 measurement blocks by the measurement-block-update facility is described in the following section, “Measurement Block”.

Measurement Block

A measurement block is either a 32-byte area (format-0 measurement block) at a location designated by the program by its use of a measurement-block-origin address in conjunction with the measurement-block index, or a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction.

The measurement block contains the accumulated values of the measurement data described below. When the measurement-block-update mode is active and the subchannel is enabled for measurement-block update, the measurement-block-update facility accumulates the values for the measurement data that accrue during the performance of an I/O operation or chain of I/O operations initiated by START SUBCHANNEL.

When the I/O operation or chain of I/O operations is suspended or completed and no error condition is encountered, the accrued values are added to the accumulated values in the measurement block for that subchannel. If an error condition is detected and subchannel-logout information is stored in the extended-status word (ESW), the accrued values are not added to the accumulated values in the measurement block for the subchannel, and the two count fields in the measurement block are not incremented.

If (1) any of the accrued time values is detected to exceed the internal storage provided for containing these values, (2) the control unit cannot provide an accurate queuing time or defer time for the current operation, or (3) the channel subsystem successfully recovers from certain error conditions, none of the accrued values is added to the measurement block for the subchannel, and the sample count in the measurement block is not incremented, but the SSCH+RSCH count in the block is incremented.

References to the measurement block by the measurement-block-update facility, in order to accumulate measurement data at the suspension or completion of an I/O function, are single-access references and appear to be word concurrent as observed by CPUs.

The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a suspended I/O operation prior to putting the subchannel into the suspended state. The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a completed I/O operation prior to making the subchannel status pending with secondary status or, if the subchannel is start pending for a subsequent operation, prior to initiating the start function.

A format-0 measurement block is stored when the measurement-block-format-control bit at the subchannel is zero; a format-1 measurement block is stored when the measurement-block-format-control bit at the subchannel is one.

The format-0 measurement block has the following format:

Word		
0	SSCH+RSCH Count	Sample Count
1	Device-Connect Time	
2	Function-Pending Time	
3	Device-Disconnect Time	
4	Control-Unit-Queuing Time	
5	Device-Active-Only Time	
6	Device-Busy Time	
7	Initial Command Response Time	
	0	16 31

The format-1 measurement block has the following format:

Word	
0	SSCH+RSCH Count
1	Sample Count
2	Device-Connect Time
3	Function-Pending Time
4	Device-Disconnect Time
5	Control-Unit-Queuing Time
6	Device-Active-Only Time
7	Device-Busy Time
8	Initial Command Response Time
9	Interrupt Delay Time
10	I/O Priority Delay Time
11	Reserved
15	
	0 31

SSCH+RSCH Count: Bits 0-15 of word 0 in the format-0 measurement block and bits 0-31 of word 0 in the format-1 measurement block are used as a binary counter. During the performance of a start function for which measurement-block update is active, when (1) the secondary status condition is recognized or (2) the suspend function is performed, the counter is incremented by one, and the measurement data is stored. The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs.

If the measurement-block-update mode is active and the subchannel is enabled for measuring, the SSCH+RSCH count is incremented even when the lack of measured values for an individual start function precludes the updating of the remaining fields of the measurement block or when the timing-facility bit for the subchannel is zero. The SSCH+RSCH count is not incremented if the measurement-block-update mode is inactive, if the subchannel is not enabled for the measurement-block update, or if subchannel-logout information has been generated for the start function.

Sample Count: Bits 16-31 of word 0 in the format-0 measurement block and bits 0-31 of word 1 in the format-1 measurement block are used as a binary counter. When the time-accumulation fields following word 0 of the format-0 measurement block or following word 1 of the format-1 measurement block are updated, the counter is incremented by one. On some models, certain conditions may prevent the measurement-block-update facility from obtaining the accrued values of the measurement data for an individual start function, even when the measurement-block-update mode is active and the subchannel is enabled for that mode. The control unit may also signal that it was not able to accumulate an accurate queuing time. In these situations, the sample-count field is not incremented.

The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The System Library publication for the system model specifies the conditions, if any, that preclude the updating of the sample count and time-accumulation fields of the measurement block.

Device-Connect Time: Bit positions 0-31 of word 1 in the format-0 measurement block and bit positions 0-31 of word 2 in the format-1 measurement block contain the accumulation of measured device-connect-time intervals. The device-connect-time interval (DCTI) is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active and the device is actively communicating with the channel path. The device-connect time does not include the intervals when a device is logically connected to a channel path but is not actively communicating with the channel. The device reports the accumulation of time intervals when the device is logically connected but not actively communicating with the channel path as control-unit-defer time. The control-unit-defer time is not included in the device-connect-time measurement but, instead, is added to the accrued device-disconnect-time measurement for the operation.

The time intervals are stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if (1) the channel-subsystem-timing facility is not provided for the subchannel, (2) the measurement-block-update mode is inactive, or (3) any of the time values accrued for the current start function has been detected to exceed the internal storage in which it was accrued.

Accumulation of device-connect-time intervals for a subchannel and storing this data in the ESW are not affected by whether the measurement-block-update mode is active. (See “Device-Connect-Time Measurement” on page 17-10.)

Function-Pending Time: Bit positions 0-31 of word 2 in the format-0 measurement block and bit positions 0-31 of word 3 in the format-1 measurement block contain the accumulated SSCH- and RSCH-function-pending time. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device.

When channel-program execution is suspended because of a suspend flag in the first CCW of a channel program, the suspension occurs prior to transferring the first command to the device. In this case, the function-pending time accumulated up to that point is added to the value in the function-pending-time field of the measurement block. Function-pending time is not accrued while the subchannel is suspended. Function-pending time begins to be accrued again, in this case, when RESUME SUBCHANNEL is subsequently executed while the designated subchannel is in the suspended state.

The function-pending-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Device-Disconnect Time: Bit positions 0-31 of word 3 in the format-0 measurement block and bit positions 0-31 of word 4 in the format-1 measurement block contain the accumulated device-disconnect time. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel active. The device-disconnect time also includes the sum of control-unit-defer-time intervals reported by the device during the I/O operation.

Device-disconnect time is not accrued while the subchannel is in the suspended state. Device-disconnect time begins to be accrued again, in this case, on the first device disconnection after channel-program execution has been resumed at the device (the subchannel is again subchannel active).

The device-disconnect-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The device-disconnect time does not include the interval between the primary status condition and the secondary status condition at the end of an I/O operation when the subchannel is no longer subchannel active but the I/O device is active. If the channel subsystem provides the device-active-only measurement facility, this time is accumulated in the device-active-only-time field of the measurement block.

Control-Unit-Queuing Time: Bit positions 0-31 of word 4 in the format-0 measurement block and bit positions 0-31 of word 5 in the format-1 measurement block contain the accumulated control-unit-queuing time. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system.

Control-unit-queuing time is not accrued while the subchannel is in the suspended state. Control-unit-queuing time may be accrued for the channel program after the subchannel becomes subchannel active following a successful resumption.

The control-unit-queuing-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the control unit does not provide a queuing time.

Device-Active-Only Time: Bit positions 0-31 of word 5 in the format-0 measurement block and bit positions 0-31 of word 6 in the format-1 measurement block contain the accumulated device-active-only time. Device-active-only time is the sum of the time intervals when the subchannel is device active but not subchannel active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function.

Device-active-only time is not accumulated when the subchannel is device active during periods when the subchannel is active; such time is accumulated as device-connect time or device-disconnect time, as appropriate.

The device-active-only-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Device-Busy Time: When the extended-I/O-measurement-block facility is installed, bit positions 0-31 of word 6 in the format-0 measurement block, and bit positions 0-31 of word 7 in the format-1 measurement block contain the accumulated device-busy time. Device-busy time is the sum of the time intervals when the subchannel is device busy during an attempt to initiate a start function or resume function at the subchannel.

The device-busy-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Initial-Command-Response Time: Bit positions 0-31 of word 7 in the format-0 measurement block, and bit positions 0-31 of word 8 in the format-1 measurement block contain the accumulated initial-command-response time for the subchannel.

The initial-command-response time for a start or resume function is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command.

The initial-command-response time is stored at a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs.

This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the initial-command-response-measurement facility is not installed.

Control-Unit-Defer Time: Control-unit-defer time is the sum of the time intervals measured by the control unit whenever the device is logically connected to the channel subsystem during an I/O operation but is not actively communicating with the channel because of device-dependent delays in channel-program execution. The control-unit-defer time is not stored in the measurement block as a separate measurement field but is used in the calculation of device-connect-time measurement and device-disconnect-time measurement for an operation.

Control-unit-defer time, if provided by a control unit, is accrued while the device is logically connected to the channel. The time is reported to the channel when channel-end status is presented that causes a device disconnection or terminates the I/O operation. Control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for the operation.

Interrupt-Delay Time: When the interrupt-delay-measurement facility is installed, bit positions 0-31 of word 9 in the format-1 measurement block contain the accumulated interrupt-delay time for the subchannel. Interrupt-delay time is the time interval from when a subchannel is made status pending with primary status to when the status is cleared by TSCH. When the interrupt-delay-measurement facility is not installed, bit positions 0-31 of word 9 in the format-1 measurement block are not updated and contain zeros.

The interrupt-delay time is accumulated in the measurement block when a measurement-block update is performed on a subsequent SSCH since the interrupt-delay time is not known when the measurement block is updated for the current SSCH. Consequently, the interrupt-delay time contains the accumulated interrupt-delay time for SSCH operations completed prior to the last completed SSCH operation.

The interrupt-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

I/O-Priority-Delay Time: Bit positions 0-31 of word 10 in the format-1 measurement block contain the accumulated I/O-priority-delay time for the subchannel. The I/O-priority-delay time is that portion of the queue time that can be attributed to delay due to I/O-priority management performed by the control unit. The measurement applies only to TCW I/O operations and is reported in the additional data area of the TSB according to device-dependent definition. If the control unit does not support I/O-priority management or if there is no I/O-priority delay, bit positions 0-31 of word 10 in the format-1 measurement block are not updated.

The I/O-priority-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Programming Note: This time is a direct measurement of the effect of the software setting I/O priorities for the I/O executed at the control unit for all I/O devices. Times will vary depending if priorities are kept low for some work. Software uses the time to validate the correctness of the algorithms used for I/O priority management.

Reserved: The remaining words of the measurement block, along with any words associated with facilities that are not provided by the channel subsystem or the subchannel, are reserved for future use. They are not updated by the measurement-block-update facility.

Programming Note: It is possible for the program to fetch a portion of a measurement block immediately prior to, or during, a measurement block update by the measurement-block-update facility. To ensure that a consistent measurement block is fetched, the program should not fetch measurement data for a subchannel during the time from when a start or resume function is initiated at the subchannel until the operation is suspended or completes with secondary status.

Measurement-Block Format

The measurement block is stored as either a format-0 measurement block or a format-1 measurement block. The format-0 measurement block is a 32-byte area (format-0 measurement block) at a location designated by the program using the measurement-block origin in conjunction with the measurement-block index. The format-1 measurement block is a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction. The measurement-block-format-control bit at the subchannel indicates whether a format-0 or format-1 measurement block is stored when measurement-block-update mode is active and enabled at the subchannel.

Measurement-Block Origin

The measurement-block origin is the beginning of the measurement-block area in main storage, used to store format-0 measurement blocks. The absolute address of the measurement-block origin, specified on a 32-byte boundary, is passed in general register 2 to the measurement-block-update facility when SET CHANNEL MONITOR is executed with bit 62 of general register 1 set to one.

Measurement-Block Address

The measurement-block address is set at the subchannel through the execution of MODIFY SUBCHANNEL. The measurement block address specifies the absolute address of the beginning of the 64-byte area to be used for accumulating format-1 measurement-block parameters for that subchannel.

Programming Note: The initial value of the measurement-block address is zero. The program is responsible for setting the measurement-block address to the proper value prior to enabling the subchannel for the measurement-block-update mode for format-1 measurement blocks and making the mode active.

Measurement-Block Key

Bits 32-35 of general register 1 form the four-bit access key to be used for subsequent measurement-block updates when SET CHANNEL MONITOR causes the measurement-block-update mode to be made active. The measurement-block key is passed to the measurement-block-update facility whenever the measurement-block-update mode is made active. The key is used for format-0 and format-1 measurement block updates.

Measurement-Block Index

The measurement-block index is set in the subchannel through the execution of MODIFY SUBCHANNEL. The measurement-block index specifies which 32-byte measurement block, relative to the measurement-block origin, is to be used for accumulating the format-0 measurement-block parameters for that subchannel. The location of the format-0 measurement block of a subchannel is computed by the measurement-block-update facility by appending five rightmost zeros to the measurement-block index of the subchannel and adding the result to the measurement-block origin. The result is the absolute address of the 32-byte format-0 measurement block for that subchannel. When the computed measurement-block address exceeds 2^{31}1, a measurement-block program-check condition is recognized, and measurement-block updating does not occur for the preceding subchannel-active period.

Programming Note: The initial value of the measurement-block index is zero. The program is responsible for setting the measurement-block index to the proper value prior to enabling the subchannel for the measurement-block-update mode and making the mode active. To ensure predictable results for the measured parameters in the measurement block, each subchannel for which measured parameters are to be accumulated must have a different value for its measurement-block index.

Measurement-Block-Update Mode

The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR with bit 62 of general register 1 set to one. If bit 62 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive. When the measurement-block-update mode is inactive, no measurement values are accumulated in main storage. When the measurement-block-update mode is made active, the contents of general register 2 are passed to the measurement-block-update facility as the absolute address of the measurement-block origin and is used to calculate the address of format-0 measurement blocks. The measurement-block origin is not used for format-1 measurement blocks. The MBK is also passed to the measurement-block-update facility as the access key to be used when updating either format-0 or format-1 measurement blocks for each subchannel. When the measurement-block-update mode is active, the measurement-block-update facility accumulates measurements in individual measurement blocks for subchannels whose measurement-block-update-enable bit is one. (See the section “Measurement Block” on page 17-3 for a description of the measured parameters.)

If the measurement-block-update mode is already active when SET CHANNEL MONITOR is executed, the values for the measurement-block origin and measurement-block key that are used for a subchannel enabled for measuring by the measurement-block-update facility are dependent upon whether SET CHANNEL MONITOR is executed prior to, during, or subsequent to the execution of START SUBCHANNEL for that subchannel. If SET CHANNEL MONITOR is executed prior to START SUBCHANNEL, the current measurement-block origin and measurement-block key are in control. If SET CHANNEL MONITOR is executed during or subsequent to execution of START SUBCHANNEL, it is unpredictable whether the measurement-block origin and measurement-block key that are in control are old or current.

Measurement-Block-Format Control

Bit 29, word 6, of the SCHIB is the measurement-block-format-control bit. This bit provides the capability of specifying whether a format-0 or format-1 measurement block is stored on a subchannel basis. The initial value of the bit is zero. When MODIFY SUBCHANNEL is executed with the measurement-block-format-control bit in the SCHIB operand set to one, the format-1 measurement block is specified for the subchannel. If the measurement-block-update mode is active and enabled at the subchannel, the measurement-block-update facility stores a format-1 measurement-block for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel. Similarly, if MODIFY SUBCHANNEL is executed with measurement-block-format-control bit of the SCHIB operand set to zero by the program, the measurement-block-update facility stores a format-0 measurement-block for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel.

Measurement-Block-Update Enable

Bit 11 of word 1 of the SCHIB is the measurement-block-update-enable bit. This bit provides the capability of controlling the accumulation of measurement-block parameters on a subchannel basis. The initial value of the enable bit is zero. When MODIFY SUBCHANNEL is executed with the enable bit set to one in the SCHIB, the subchannel is enabled for the measurement-block-update mode. If the measurement-block-update mode is active, the measurement-block-update facility accumulates measurement-block parameters for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel. Conversely, if MODIFY SUBCHANNEL is executed with bit 11 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the measurement-block-update mode, and no additional measurement-block parameters are accumulated for that subchannel.

Control-Unit-Queuing Measurement

The control-unit-queuing-measurement facility allows the channel subsystem to accept queuing times from control units and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block.

The System Library publication for the control-unit model specifies its ability to supply queuing time. If a control-unit model is capable of supplying queuing time, the publication specifies the conditions that prevent the control unit from accumulating an accurate control-unit-queuing time.

Control-Unit-Defer Time

The control-unit-defer-time facility allows the channel subsystem to accept defer times from control units and, in conjunction with the measurement-block-update facility, to modify the device-connect and device-disconnect times reported in the measurement block to reflect the defer time. The control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for an I/O operation.

The System Library publication for the control-unit model specifies its ability to supply defer time. If a control-unit model is capable of supplying defer time, the publication specifies the conditions that prevent the control unit from accumulating an accurate control-unit-defer time.

Device-Active-Only Measurement

The device-active-only-measurement facility permits the channel subsystem to report the times that the device is disconnected between primary status and secondary status at the end of an I/O operation or chain of I/O operations.

The measurement-block updates are performed at the time that secondary status is accepted from the I/O device, in order that the device-active time between primary status and secondary status can be reported.

If the subchannel is start pending when secondary status is accepted from the I/O device and the measurement-block update is to be performed, the measurement-block update is performed prior to performing the start function. If measurement-block errors occur, they are reported to the program along with the secondary status instead of performing the start function.

Initial-Command-Response Measurement

The initial-command-response-measurement facility allows the channel subsystem to calculate initial-command-response time for I/O operations and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block. The initial-command-response time is accumulated in word 7 of the measurement block.

Time-Interval-Measurement Accuracy

On some models, when time intervals are to be measured and condition code 0 is set for START SUBCHANNEL (or RESUME SUBCHANNEL in the case of a suspended subchannel), a period of latency may occur prior to the initiation of the function-pending time measurement. The System Library publication for the system model specifies the mean latency value and variance for each of the measured time intervals.

Programming Notes:

1. Excessive delays may be encountered by the channel subsystem when attempting to update measurement data if the program is concurrently accessing the same measurement-block area. A programming convention should ensure that the storage block designated by SET CHANNEL MONITOR is made read-only while the measurement-block-update mode is active.

2. To ensure that programs written to support measurement functions are executed properly, the program should initialize all the measurement blocks to zeros prior to making the measurement-block-update mode active. Only zeros should appear in the reserved and unused words of the measurement blocks.

3. When the incrementing of an accumulated value causes a carry to be propagated out of bit position 0, the carry is ignored, and accumulating continues from zero on.

Device-Connect-Time Measurement

The device-connect-time-measurement facility provides the program with the capability of retrieving the length of time that a device is actively communicating with the channel subsystem while executing a channel program. The measured length of time that the device spends actively communicating on a channel path during the execution of a channel program is called the device-connect-time interval (DCTI). Control-unit-defer time is not included in the DCTI.

If timing facilities are provided for the subchannel, the DCTI value is passed to the program in the extended-status word (ESW) at the completion of the operation when the primary-status condition is cleared by TEST SUBCHANNEL and when TEST SUBCHANNEL clears an intermediate-status condition alone while the subchannel is suspended. The DCTI value passed in the ESW pertains to the previous subchannel-active period. The passing of the DCTI in the ESW is under program control by the SET CHANNEL MONITOR device-connect-time-measurement mode-control bit and the corresponding enable bit in the subchannel. However, the DCTI value is not stored in the ESW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout. See the section “Extended-Status Format 0” on page 16-47. In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 16-47 for the description of the logout information. If the accrued DCTI value exceeded 8.388608 seconds during the previous subchannel-active period, then the maximum value (FFFF hex) is passed in the ESW.

Device-Connect-Time-Measurement Mode

The device-connect-time-measurement mode is made active by the execution of SET CHANNEL MONITOR when bit 63 of general register 1 is one. If bit 63 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive, and DCTIs are not passed to the program. When timing facilities are provided for the subchannel, the device-connect-time-measurement mode is active, and the subchannel is enabled for the mode, the DCTI value is passed to the program in the ESW stored when TEST SUBCHANNEL (1) clears the primary-interruption condition with no logout information indicated in the SCSW (extended-status-word-format bit is zero) or (2) clears the intermediate-status condition alone while the subchannel is suspended.

If a start function is currently being executed with a subchannel enabled for the device-connect-time-measurement mode when SET CHANNEL MONITOR makes this mode active for the channel subsystem, the value of the DCTI stored under the appropriate conditions may be zero, a partial result, or the full and correct value, depending on the model and the progress of the start function at the time the mode was activated.

Provision of the DCTI value in the measurement-block area is not affected by whether the device-connect-time-measurement mode is active.

Device-Connect-Time-Measurement Enable

Bit 12 of word 1 of the SCHIB is the device-connect-time measurement-mode-enable bit. This bit provides the program with the capability of selectively controlling the storing of DCTI values for a subchannel when the device-connect-time-measurement mode is active. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled for the device-connect-time-measurement mode. If the device-connect-time-measurement mode is active, the device-connect-time-measurement facility begins providing DCTI values for the subchannel, starting with the next START SUBCHANNEL issued to the subchannel. In this situation, the DCTI values are provided in the ESW (see the section "Extended-Status Format 2" on page 16-54). Similarly, if MODIFY SUBCHANNEL is executed with bit 12 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the device-connect-time-measurement mode, and no further DCTI values are passed to the program for that subchannel.

Extended Measurement Word

The extended-I/O-measurement-word facility provides the program with the capability of retrieving measurement information for a channel program. The measurement information is stored into the extended-measurement word (EMW) in the Interruption Response Block when the extended-measurement-word enable bit is one at the subchannel. See the section "Extended-Measurement Word" on page 16-56 in Chapter 16, "I/O Interruptions," for the description of the extended-measurement word.

When the extended-measurement-word is enabled for the subchannel, measurement values are passed to program in the EMW when TEST SUBCHANNEL clears a primary-status condition, secondary-status condition alone, or an intermediate-status condition alone while the subchannel is suspended. The measurement values stored in the EMW pertain to the previous subchannel-active and device-active period. Measurement values are not stored in the EMW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout (see the section "Extended-Status Format 0" on page 16-47). In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section "Extended-Status Word" on page 16-47. for the description of the logout information. If any of the accrued measurement values exceeded the maximum value capable of being measured during the previous subchannel-active and device-active period, then the maximum value is stored for that value in the EMW.

Extended-Measurement-Word Enable

Bit 30 of word 6 of the SCHIB is the extended-measurement-word enable bit. This bit provides the program with the capability of selectively controlling the storing of measurement values for a subchannel. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled for the extended-measurement-word and the extended-measurement-word facility begins providing measurement values for the subchannel starting with the next START SUBCHANNEL issued to the subchannel. Similarly, if MODIFY SUBCHANNEL is executed with bit 30, word 6, of the SCHIB operand set to zero by the program, the subchannel is disabled for the extended-measurement-word and no further measurement values are passed to the program for that subchannel.

Signals and Resets

During system operation, it may become necessary to terminate an I/O operation or to reset either the I/O system or a portion of the I/O system. (The I/O system consists of the channel subsystem plus all of the attached control units and devices.) Various signals and resets are provided for this purpose. Three signals are provided for the channel subsystem to notify an I/O device to terminate an operation or perform a reset function or both. Two resets are provided to cause the channel subsystem to reinitialize certain information contained either at the I/O device or at the channel subsystem.

Signals

The request that the channel subsystem initiate a signaling sequence is made by one of the following:

1. The program's issuance of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH instruction

2. The I/O device's signaling of I/O-error alert

3. The channel subsystem itself, upon detecting certain error conditions or equipment malfunctions

The three signals are the halt signal, the clear signal, and the reset signal.

Halt Signal

The halt signal is provided so the channel subsystem can terminate an I/O operation. The halt signal is issued by the channel subsystem as part of the halt function performed subsequent to the execution of HALT SUBCHANNEL. The halt signal is also issued by the channel subsystem when certain error conditions are encountered.

For the parallel-I/O-interface type of channel path, the halt signal results in the channel subsystem using the interface-disconnect sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the halt signal results in the channel subsystem using the cancel function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the halt signal results in the channel subsystem using the cancel function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).*

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the halt signal results in the channel subsystem using the transport-mode abort-sequence function.

Clear Signal

The clear signal is provided so the channel subsystem can terminate an I/O operation and reset status and control information contained at the device. The clear signal is issued as part of the clear function performed subsequent to the execution of CLEAR SUBCHANNEL. The clear signal is also issued by the channel subsystem when certain error conditions or equipment malfunctions are detected by the I/O device or the channel subsystem.

For the parallel-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the clear signal results in the channel subsystem using the selective-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).*

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the clear signal results in the channel subsystem using the selective-reset function.

When the subchannel is operating in command mode, if an I/O operation is in progress at the device and the device is actively communicating over a channel path in the performance of that I/O operation when a clear signal is received on that channel path, the device disconnects from that channel path upon receiving the clear signal. Data transfer and any operation using the facilities of the control unit are immediately concluded, and the I/O device is not necessarily positioned at the beginning of a block. Mechanical motion not involving the use of the control unit, such as rewinding magnetic tape or positioning a disk-access mechanism, proceeds to the normal stopping point, if possible. The device may appear busy until termination of the mechanical motion or the inherent cycle of operation, if any, whereupon it becomes available. Status information in the device and control unit is reset, but an interruption condition may be generated upon the completion of any mechanical operation.

Reset Signal

The reset signal is provided so the channel subsystem can reset all I/O devices on a channel path. The reset signal is issued by the channel subsystem as part of the channel-path-reset function performed subsequent to the execution of RESET CHANNEL PATH. The reset signal is also issued by the channel subsystem as part of the I/O-system-reset function.

For the parallel-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset sequence control defined in the System Library publication *IBM System/360 and*

System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974.

For the ESCON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

Resets

Two resets are provided so the channel subsystem can reinitialize certain information contained at either the I/O device or the channel subsystem. The request that the channel subsystem initiate one of the reset functions is made by one of the following:

1. The program's issuance of the RESET CHANNEL PATH instruction
2. The operator's activation of a system-reset-clear or system-reset-normal key or a load-clear or load-normal key
3. The channel subsystem itself upon detecting certain error conditions or equipment malfunctions

The resets are channel-path reset and I/O-system reset.

Channel-Path Reset

The channel-path-reset facility provides a mechanism to reset certain indications that pertain to a designated channel path at all associated subchannels. Channel-path reset occurs when the channel subsystem performs the channel-path-reset function initiated by RESET CHANNEL PATH. (See “RESET CHANNEL PATH” on page 14-9.) All internal indications of dedicated allegiance, control unit busy, and device busy that pertain to the designated channel path are cleared in all subchannels, and reset is signaled on that channel path.

The receipt of the reset signal by control units attached to that channel path causes all operations in progress and all status, mode settings, and allegiance, pertaining to that channel path, of the control unit and its attached devices to be reset. (See also the description of the system-reset-signal actions in “I/O-System Reset” on page 17-13.)

The results of the channel-path-reset function on the designated channel path are communicated to the program by means of a subsequent machine-check-interruption condition generated by the channel subsystem (see “Channel-Subsystem Recovery” on page 17-27).

I/O-System Reset

The I/O-system-reset function is performed when the channel subsystem is powered on, when initial program loading is initiated manually (see “Initial Program Loading” on page 17-16), and when the system-reset-clear or system-reset-normal key is activated. The I/O-system-reset function cannot be initiated under program control; it must be initiated manually. I/O-system reset may fail to complete due to malfunctions detected at the channel subsystem or on a channel path. I/O-system reset is performed as part of subsystem reset, which also resets all floating interruption requests, including pending I/O interruptions. (See “Subsystem Reset” on page 4-80.) Detailed descriptions of the effects of I/O-system reset on the various components of the I/O system appear later in this chapter.

I/O-system reset provides a means for placing the channel subsystem and its attached I/O devices in the initialized state. I/O-system reset affects only the channel-subsystem configuration in which it is performed, including all channel-subsystem components configured to that channel subsystem. I/O-system reset has no effect on any system components that are not part of the channel-subsystem configuration that is being reset. The effects of I/O-system reset on the configured components of the channel subsystem are described in the following sections.

Channel-Subsystem State: I/O-system reset causes the channel subsystem to be placed in the initialized state, with all the channel-subsystem components in the states described in the following sections. All operations in progress are terminated and reset, and all indications of prior conditions are reset. These indications include status information, interruption conditions (but not pending interruptions), dedicated-allegiance conditions, pending channel reports, and all internal information regarding prior conditions and operations. In the initialized state, the channel subsystem has no activity in progress and is ready to perform the initial-program-loading (IPL) function or respond to I/O instructions, as described in "I/O Instructions" on page 14-1.

Control Units and Devices: I/O-system reset causes a reset signal to be sent on all configured channel paths, including those which are not physically available (as indicated by the PAM bit being zero) because of a permanent error condition detected earlier. When the reset signal is received by a control unit, control-unit functions in progress, control-unit status, control-unit allegiance, and control-unit modes for the resetting channel path are reset. Device operations in progress, device status, device allegiance, and the device mode for the resetting channel path are also reset. Control-unit and device mode, allegiance, status, and I/O functions in progress for other channel paths are not affected.

For devices that are operating in the single-path mode, an operation can be in progress for, at most, one channel path. Therefore, if the reset signal is received on that channel path, the operation in progress is reset. Devices that have the dynamic-reconnection feature and are operating in the multipath mode, however, have the capability to establish an allegiance to a group of channel paths during an I/O operation, where all the channel paths of the path group are configured to the same channel subsystem. If an operation is in progress for a device that is operating in the multipath mode and the reset signal is received on one of the channel paths of that path group, then the operation in progress is reset for the resetting channel path only. Although the operation in progress cannot continue on the resetting channel path, it can continue on the other channel paths of the path group, subject to the following restrictions:

1. If the device is actively communicating with the channel subsystem on a channel path when it receives the reset signal on that channel path, then the operation is reset unconditionally, regardless of path groups.

2. If the operation is in progress in the multipath mode but the path group consists only of the resetting path, then the operation is reset.

3. Except as noted in item 2, if the operation in progress is currently in a disconnected state (device not actively communicating with the channel subsystem) or is active on another channel path of a path group, system reset has no effect upon the continued performance of the operation.

A control unit is completely reset after the reset signal has been received on all its channel paths, provided no new activity is initiated at the control unit between the receipt of the first and last reset signal. "Completely reset" means that the current operation, if any, at the control unit is terminated and that control-unit allegiance, control-unit status, and the control-unit mode, if any, are reset.

An I/O device is completely reset after the reset signal has been received on all channel paths of all control units by which the device is accessible, provided no new activity is initiated at the device between the receipt of the first and last reset signal. "Completely reset" means that the current operation, if any, at the device is terminated and that device allegiance, device status, and the device mode are reset.

In summary, system reset always causes an operation in progress to be reset for the channel path on which the reset signal is received. If the resetting channel path is the only channel path for which the operation is in progress, then the operation is completely reset. If a device is actively communicating on a channel path over which the reset signal is received, then the operation in progress is unconditionally and completely reset.

The reset signal is not received by control units and devices on channel paths from which the control unit has been partitioned. A control unit is partitioned from a channel path by means of an enable/disable switch on the control unit for each channel path by which it is accessible. Multi-tagged, unsolicited status, if any, remains pending at the control unit for such a channel path in this case. However, from the point of view of the program, the control unit and device appear to be completely reset if the reset signal is received by the control unit on all the channel paths by which it is currently accessible.

The resultant reset state of individual control units and devices is described in the System Library publication for the control unit.

Channel Paths: I/O-system reset causes a reset signal to be sent on all configured channel paths and causes the channel subsystem to be placed in the reset and initialized state, as described in the previous sections. As a result of these actions, all communication between the channel subsystem and its attached control units and devices is terminated and the components reset, and all configured channel paths are made quiescent or are deconfigured.

Subchannels: I/O-system reset causes all operations on all subchannels to be concluded. Status information, all interruption conditions (but not pending interruptions), dedicated-allegiance conditions, and internal indications regarding prior conditions and operations in all subchannels are reset, and all valid subchannels are placed in the initialized state.

In the initialized state, the subchannel parameters of all valid subchannels are set to their initial values. The initial values of the following subchannel parameters are zeros:

- Interruption parameter
- I/O-interruption-subclass code (ISC)
- Enabled
- Limit mode when the address-limit-checking facility is installed
- Measurement mode
- Multipath mode
- Path-not-operational mask
- Last-path-used mask
- Measurement-block index
- Concurrent sense

The initial values of the following subchannel parameters are assigned as part of the installation procedure for the device associated with each valid subchannel:

- Timing facility
- Device number
- Logical-path mask (same value as path-installed mask)
- Path-installed mask
- Path-available mask
- Channel-path ID 0-7

The values assigned may depend upon the particular system model and the configuration; dependencies, if any, are described in the System Library publication for the system model. Programming considerations may further constrain the values assigned.

The initial value of the path-operational mask is all ones.

The device-number-valid bit is one for all subchannels having an assigned I/O device.

The initial value of the model-dependent area of the subchannel-information block is described in the System Library publication for the system model.

The initial value of the subchannel-status word and extended-status word is all zeros.

The initialized state of the subchannel is the state specified by the initial values for the subchannel parameters described above. The description of the subchannel parameters can be found in “Subchannel-Information Block” on page 15-2, “Subchannel-Status Word” on page 16-7, and “Extended-Status Word” on page 16-47.

Channel-Path-Reset Facility: I/O-system reset causes the channel-path-reset facility to be reset. A channel-path-reset function initiated by RESET CHANNEL PATH, either pending or in progress, is overridden by I/O-system reset. The machine-check-interruption condition, which normally signals the completion of a channel-path-reset function, is not generated for a channel-path-reset function that is pending or in progress at the time I/O-system reset occurs.

Address-Limit-Checking Facility: When the address-limit-checking facility is installed, I/O-system reset causes the address-limit-checking facility to be reset. The address-limit value is initialized to all zeros and validated.

Channel-Subsystem-Monitoring Facilities: I/O-system reset causes the channel-subsystem-monitoring facilities to be reset. The measurement-block-update mode and the device-connect-time-measurement mode, if active, are made inactive. The measurement-block origin and the measurement-block key are both initialized to zeros and validated.

Pending Channel Reports: I/O-system reset causes pending channel reports to be reset.

Channel-Subsystem Timer: I/O-system reset does not necessarily affect the contents of the channel-subsystem timer. In models that provide channel-subsystem-timer checking, I/O-system reset may cause the channel-subsystem timer to be validated.

Pending I/O Interruptions: I/O-system reset does not affect pending I/O interruptions. However, during subsystem reset, I/O interruptions are cleared concurrently with the performance of I/O-system reset. (See “Subsystem Reset” on page 4-80.)

Area Affected	Effect on I/O-System Reset[1]
Channel-subsystem state	Reset and initialized
Control units and devices	Reset
Channel paths	Quiescent
Subchannels	Reset and initialized
Interruption parameter	Zeros[2]
I/O-interruption-subclass code (ISC)	Zeros[2]
Enabled bit	Zero[2]
Address-limit-mode bits[4]	Zeros[2]
Timing-facility bit	Installed value[2]
Multipath-mode bit	Zero[2]
Measurement-mode bits	Zeros[2]
Device-number-valid bit	Installed value[2]
Device number	Installed value[2]
Logical-path mask	Equal to path-installed mask value[2]
Path-not-operational mask	Zeros[2]
Last-path-used mask	Zeros[2]
Path-installed mask	Installed value[2]
Measurement-block index	Zeros[2]
Path-operational mask	Ones[2]
Path-available mask	Installed value[2 3]
Channel-path ID 0-7	Installed value[2]
Concurrent-sense bit	Zero[2]
Subchannel-status word	Zeros[2]
Extended-status word	Zeros[2]
Model-dependent area	Model dependent[2]
Channel-path-reset facility	Reset
Address-limit-checking facility[4]	Reset and initialized
Address-limit value	Zeros[2]
Channel-subsystem-monitoring facility	Reset and initialized
Measurement-block-update mode	Inactive[2]
Device-connect-time-measurement mode	Inactive[2]
Measurement-block origin	Zeros[2]
Measurement-block key	Zeros[2]
Pending channel-report words	Cleared
Channel-subsystem timer	Unchanged/validated

Explanation:

[1] For a detailed description of the effect of I/O-system reset on each area, see the text.

[2] Initialized value.

[3] Also subject to model-dependent configuration controls, if any.

[4] When the FCX facility is not installed.

Figure 17-1. Summary of I/O-System-Reset Actions

Externally Initiated Functions

I/O-system reset, which is an externally initiated function, is described in “I/O-System Reset” on page 17-13.

Initial Program Loading

Initial program loading (IPL) provides a manual means for causing a program to be read from a designated device and for initiating the execution of that program.

Some models may provide additional controls and indications relating to IPL; this additional information is specified in the System Library publication for the model.

There are two types of IPL: CCW-type IPL and list-directed IPL. CCW-type IPL is provided by all machine configurations. List-directed IPL may be provided, depending on the model.

CCW-type IPL

CCW-type IPL is initiated manually by setting the load-unit-address controls to a four-digit number to designate an input device and by subsequently activating the load-clear or load-normal key.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, activating the load-clear or load-normal key sets the architectural mode to the ESA/390 mode (or ESA/390 compatibility mode). When the CZAM facility is installed, activating the load-clear or load-normal key leaves the architectural mode unchanged (that is, it remains in the z/Architecture architectural mode).

Activating the load-clear key causes a clear reset to be performed on the configuration.

Activating the load-normal key causes an initial CPU reset to be performed on this CPU, CPU reset to be propagated to all other CPUs in the configuration, and a subsystem reset to be performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, this CPU enters the load state. This CPU does not necessarily enter the stopped state during performance of the reset. The load indicator is on while the CPU is in the load state.

Subsequently, if conditions allow, a read operation is initiated from the designated input device and associated subchannel. The read operation is performed as if a START SUBCHANNEL instruction were executed that designated (1) the subchannel corresponding to the device number specified by the load-unit-address controls and (2) a command-mode ORB containing all zeros, except for a byte of all ones in the logical-path-mask field.

Figure 17-2 illustrates the ORB parameters used by the channel subsystem for a CCW-type IPL.

ORB				
Word	Bit(s)	Field		Value
0	0-31	Interruption parameter		Zeros
1	0-3	Key:	Subchannel key	Zeros
1	4	S:	Suspend control	0
1	5	C:	Streaming-mode control	0
1	6	M:	Modification control	0
1	7	Y:	Synchronization control	0
1	8	F:	CCW-format control	0
1	9	P:	Prefetch control	0
1	10	I:	Initial-status-interruption control	0
1	11	A:	Address-limit-checking control	0
1	12	U:	Suppress-suspended-interruption control	0
1	13	B:	Channel-program-type control	0
1	14	H:	IDAW control	0
1	15	T:	2K-IDAW control	0
1	16-23	LPM:	Logical Path Mask	Ones
1	24	L:	Incorrect-length-suppression-mode control	0
1	25	D:	Modified-CCW-IDA control	0
1	31	X:	ORB-extension control	0
2	1-31	CCW Address (absolute address)		Zeros

Figure 17-2. ORB Parameters Used in a CCW-Type IPL

The first CCW to be executed is not fetched from storage. Instead, the effect is as if an implied format-0 CCW, beginning in absolute location 0 and having the following detailed format, were executed:

Loc.	0	8	16 31
0	0 0 0 0 0 0 1 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	
4	0 1 1 0 0 0 0 0	/ / / / / / / /	0 0 0 0 0 0 0 0 0 0 0 1 1 0 0 0

In the illustration above, the CCW specifies a read command with the modifier bits zeros, a data address of 0, a byte count of 24, the chain-command flag one, the suppress-incorrect-length-indication flag one, the chain-data flag zero, the skip flag zero, the program-controlled-interruption (PCI) flag zero, the indirect-data-address (IDA) flag zero, and the suspend flag zero. The CCW fetched, as a result of command chaining, from location 8 or 16, as well as any subsequent CCW in the IPL sequence, is interpreted the same as a CCW in any I/O operation, except that any PCI flags that are specified in the IPL channel program are ignored.

At the time the subchannel is made start pending for the IPL read, it is also enabled, which ensures proper handling of subsequent status from the device by the channel subsystem and facilitates subsequent I/O operations using the IPL device. (Except for the subchannel used by the IPL I/O operation, each subchannel must first be made enabled by MODIFY SUBCHANNEL before it can accept a start function or any status from the device.)

When the IPL subchannel becomes status pending for the last operation of the IPL channel program, no I/O-interruption condition is generated. Instead, the subsystem ID is stored in absolute locations 184-187, zeros are stored in absolute locations 188-191, and the subchannel is cleared of the pending status as if TEST SUBCHANNEL had been executed but without storing information usually stored in an IRB. If the subchannel-status field that would normally have been stored is all zeros and the device-status field that would normally have been stored contains only the channel-end indication, with or without the device-end indication, the IPL I/O operation is considered to be completed successfully. If the device-end status for the IPL I/O operation is provided separately after channel-end status, it causes an I/O-interruption condition to be generated.

If an interface-control check is detected during execution of the IPL channel program, some models may re-initiate the same channel program on another channel path. The other path chosen is any logically-available channel path to the designated device on which the IPL channel program has not previously been initiated during the current IPL operation. (See programming note 6 on page 17-19 for additional information.)

When the IPL I/O operation is completed successfully, a new PSW is loaded from absolute locations 0-7. When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).

If the PSW loading is successful and no malfunctions are recognized that preclude the completion of IPL, then the CPU leaves the load state, and the load indicator is turned off. If the rate control is set to the process position, the CPU enters the operating state, and CPU operation proceeds under control of the new PSW. If the rate control is set to the instruction-step position, the CPU enters the stopped state, with the manual indicator on, after the new PSW has been loaded.

If the IPL I/O operation or the PSW loading is not completed successfully, the CPU remains in the load state, and the load indicator remains on.

IPL does not complete when any of the following occurs

- No subchannel contains a valid device number equal to the IPL device number specified by the load-unit-address controls.

- A malfunction is detected in the CPU, main storage, or channel subsystem that precludes the completion of IPL.

- Unsolicited alert status is presented by the device subsequent to the subchannel becoming start pending for the IPL read and before the IPL subchannel becomes subchannel active. The IPL read operation is not initiated in this case.

- There were no available channel paths to the IPL device.

- On every available channel path to the IPL device, either the IPL device appeared not operational or an interface-control check was detected.

- The IPL device presented a status byte containing indications other than channel end, device end, status modifier, control unit end, control unit busy, device busy, or retry status during the IPL I/O operation. Whenever control unit end, control unit busy, or device busy is presented in the status byte, normal path-management actions are taken.

- A subchannel-status indication other than PCI was generated during the IPL I/O operation, except that on some models, detection of an interface-control check may cause the I/O operation to be retried on another available channel path to the IPL device.

- The PSW loaded from absolute locations 0-7 has a PSW-format error of the type that is recognized early.

Except in the cases of no corresponding subchannel for the device number entered or a machine malfunction, the subsystem ID of the IPL device is stored in absolute locations 184-187; otherwise, the contents of these locations are unpredictable. In all cases of unsuccessful IPL, the contents of absolute locations 0-7 are unpredictable.

Subsequent to a successful IPL, the subchannel parameters contain the normal values as if an actual START SUBCHANNEL had been executed, designating the ORB as described above.

Programming Notes:

1. The information read and placed at absolute locations 8-15 and 16-23 may be used as CCWs for reading additional information during the IPL I/O operation: the CCW at location 8 may specify reading additional CCWs elsewhere in storage, and the CCW at location 16 may specify the transfer-in-channel command, causing transfer to these CCWs.

2. The status-modifier bit has its normal effect during the IPL I/O operation, causing the channel subsystem to fetch and chain to the CCW whose address is 16 higher than that of the current CCW. This applies also to the initial chaining that occurs after completion of the read operation specified by the implicit CCW.

3. The PSW that is loaded at the completion of the IPL operation may be provided by the first eight bytes of the IPL I/O operation or may be placed at absolute locations 0-7 by a subsequent CCW.

4. Activating the load-normal key implicitly specifies the use of the first 24 bytes of main storage and the eight bytes at absolute locations 184-191. Since the remainder of the IPL program may be placed in any part of storage below the 2 G-byte boundary, it is possible to preserve such areas of storage as may be helpful in debugging or recovery. The IPL program should not be placed in the low 512 bytes of storage since that area is reserved as described in a programming note under “Compatibility between z/Architecture and ESA/390” on page 1-37. When the load-clear key is activated, the IPL program starts with a cleared machine in a known state, except that information on external storage remains unchanged.

5. When the PSW at absolute location 0 has bit 14 set to one, the CPU is placed in the wait state after the IPL operation is completed. At that point, the load and manual indicators are off, and the wait indicator is on.

6. When the program receives control after the machine leaves the load state during IPL, the last-path-used mask (LPUM) in the subchannel-information block (SCHIB) for the IPL device should be saved. The program should use this saved LPUM as the logical-path mask (LPM) in the ORB until the program reaches the point in its initialization where it has the ability to process and recover from interface-control checks, and verify that all of the channel paths associated with the subchannel are connected to the same device.

   When multiple paths are associated with the subchannel of the IPL device, it is possible that miscabling of one or more of the paths can cause the program initialization to proceed on different devices. This affects the integrity of the IPL process. The program should ensure that all paths are connected to the same device, but this typically is not possible before program initialization completes. Thus the use of the saved LPUM ensures that all I/O operations to the IPL device during program initialization are executed on the same device, allowing postponement of the checking of the paths.

   Using the saved LPUM also helps to ensure that the channel subsystem will not select a path on which errors would prevent completion of the program initialization, since the path indicated in the LPUM has demonstrated its functionality. On some models, using the saved LPUM also ensures that the path selection will not re-select a path on which an interface-control check was detected while the machine was in the load state.

7. Because the CCW-format control (bit 8 of word 1 in the implied ORB) used during the IPL I/O operation is zero, the CCWs are limited to format-0 CCWs with 24-bit addresses. However, the IPL process may read in additional CCWs that specify indirect addressing using IDAWs. Because the IDAW control (bit 14 of word 1 in the implied ORB) is zero, the IDAWs are limited to format-1 IDAWs with 31-bits addresses. Therefore, the IPL process can read into (or write from) any location below the 2 G-byte boundary.

List-Directed IPL

List-directed IPL supports the use of I/O devices which are not accessed by CCWs. List-directed IPL may be provided for a logical partition or virtual machine, depending on the model and the amount of memory available to the logical partition or virtual machine. The terms logical partition and virtual machine are not defined in this publication. The term logical partition is defined in the System Library publications. The term virtual machine is defined in the virtual-machine product manuals.

List-directed IPL is initiated by activating the load-clear-list-directed or load-with-dump key. Prior to activating either of these keys, the list-directed-IPL parameters are entered using a model-dependent console. List-directed-IPL parameters include the following information:

- Information which identifies the I/O device from which a program is to be loaded. This I/O device is referred to as the load device.
- Information which identifies a location on a load device from which a program will be loaded.
- Information to be used by the program which will be loaded from the load device.

The list-directed-IPL parameters required by a specific machine and the means by which they are entered are specified in the System Library publications.

After the list-directed-IPL parameters have been entered, the load-clear-list-directed or load-with-dump key for a particular CPU is activated. In the description which follows, the term “this CPU” refers to the CPU in the configuration for which the load-clear-list-directed key was activated.

Activating the load-clear-list-directed key causes a clear reset to be performed on all of the CPUs in the configuration.

Activating the load-with-dump key causes a store-status operation to be performed on this CPU. After the store-status operation, an initial-CPU-reset operation is performed on this CPU, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, the operations listed below are performed.

- If the rate control is not in the process position, it is forced into the process position.
- If the list-directed IPL operation was initiated by activating the load-with-dump key, the contents of a model-dependent number of contiguous logical-partition or virtual-machine storage locations starting with absolute location 0 are stored in a model-dependent holding area. The data stored includes the contents of all storage locations into which the program will be loaded from the load device. See Programming Note 4 for additional information.
- The program to be loaded from the load device is loaded into logical-partition or virtual-machine storage at the locations specified on the load device.
- A system IPL-parameter block used by the machine during list-directed IPL is placed in storage in the format shown in Figure 17-3 on page 17-21. The absolute address of the first word of the system IPL-parameter block is stored in absolute address locations 20-23. When the secure-IPL facility is installed in the z/Architecture architectural mode. an XML document is not present; otherwise, the presence of an XML document is model dependent. If an XML document is present, it contains the system IPL parameters and it immediately follows the last byte of the system IPL-parameter block. (See Reference [22.] on page xxx for information regarding XML.) When the IPL-Information-Report (IPLIR), bit 2 of word 2 of the system IPL-parameter block , is one, an IPL-information-report block (IIRB) containing the IPL information report immediately follows the last byte of the system IPL-parameter block (instead of an XML document) and is aligned on a doubleword boundary; otherwise, an IIRB containing the system IPL information report is not present.

The system IPL-parameter block has the following format:

Word	
0	Length
1 n	System IPL Parameters
	0 31

Figure 17-3. System IPL-Parameter Block

Bits 0-31 of word 0 of the system IPL-parameter block contains a length field. The length field contains a 32-bit binary number representing the number of bytes occupied by the system IPL-parameter block. When the secure-IPL facility is installed in the z/Architecture architectural mode, the system IPL-parameter block length field must contain a value that is multiple of 8-bytes to ensure the IPL-information-report block (IIRB) immediately follows the last byte of the system IPL-parameter block and is aligned on a doubleword boundary. Words 1 through n contain the system IPL parameters.

IPL Information Report Block

The IPL-information-report block (IIRB) contains information used to locate various IPL records and to report the results of signature verification of one or more secure components of the load device. IIRB is generated by the machine loader after DIAGNOSE x'0308' functions are used to update the system IPL-parameter block. The generated IIRB is stored immediately following the system IPL-parameter block by the machine loader and is aligned on a doubleword boundary.

The IPL-information-report block has the following format:

Word	
0 3	IPL-Information-Report BlockHeader
4 n	IPL-Information Block(s)
	0 31

Figure 17-4. IPL-Information-Report Block

The IPL-information-report block contains an IPL-information-report block header, followed by one or more IPL-information blocks.

The IPL-information-report block header has the following format:

Word			
0	IPL-Information-Report Block Length		
1	IIRB Flags	Reserved	Version
2 3	Reserved		
	0	8	24 31

Figure 17-5. IPL-Information-Report BlockHeader

The IPL-information-report block header contains the following fields:

IPL-Information-Report Block Length: Word 0 contains a 32-bit unsigned binary integer specifying the number of bytes in the IIRB. Byte 0 of word 0 must be zero to indicate XML file is not present following the system IPL-parameter block and to limit the length to a maximum of 16-Megabytes; otherwise, an error is reported.

IIRB Flags: Byte 0 of word 1 contains a flag field defined as follows:

Bit	**Meaning**
0-7	Reserved.

Version: Bits 24-31 of word 1 contain an 8-bit unsigned binary integer specifying the version number of the IPL-information-report block. This field is set to zero.

IPL Information Blocks

One or two IPL-information blocks follow the IPL-information-report block header. The first type of IPL-information block identifies an IPL-signature-certificate list. A second type of IPL-information block identifies an IPL-device-component list.

Each IPL-information block contains a common header followed by one or more specific types of IPL-information block entries.

The IPL-information block header has the following format:

Word	0-7	8-31
0	IPL-Information Block Length	
1	IBT	Reserved
2 3	Reserved	

Figure 17-6. IPL-Information *Block Header*

The IPL-information block header contains the following fields:

IPL-Information Block Length: Word 0 contains a 32-bit unsigned binary integer specifying the number of bytes in the IPL-information block.

IPL-Information Block Type (IBT): Byte 0 of word 1 contains a value that specifies the format of the specific IPL-information block type. The IBT field values are defined as follows:

Value	Meaning
0	Reserved.
1	The IPL-information block specifies an IPL-signature-certificate list.
2	The IPL-information block specifies an IPL-device-component list.
3-255	Reserved.

IPL Signature Certificate List

The IPL-information block identifying an IPL-signature-certificate list has the following format:

Word	0-31
0 ⋮ 3	IPL-Information Block Header
4 ⋮ 7	IPL-Signature-Certificate Entry 0
8 ⋮ 11	IPL-Signature-Certificate Entry 1
12 ⋮ ⋮ n-4	⋮
n-3 ⋮ n	IPL-Signature-Certificate Entry X

Figure 17-7. IPL-Information *Block for IPL-Signature-Certificate List*

IPL Signature Certificate Entry

The IPL-signature-certificate entry has the following format:

Word	0-31
0 1	IPL-Signature-Certificate Address
2 3	IPL-Signature-Certificate Length

Figure 17-8. IPL-Signature-Certificate Entry

The IPL-signature-certificate entry contains the following fields:

IPL-Signature-Certificate Address: Words 0-1 contain a 64-bit absolute storage location of an X.509 certificate.

IPL-Signature-Certificate Length: Words 2-3 contain a 64-bit unsigned binary integer specifying the number of bytes in an X.509 certificate.

IPL Device Component List

The IPL-information block identifying an IPL-device-component list has the following format:

Word	0–31
0 ⋮ 3	IPL-Information Block Header
4 ⋮ 11	IPL-Device-Component Entry 0
12 ⋮ 19	IPL-Device-Component Entry 1
20 ⋮ n-8	⋮
n-7 ⋮ n	IPL-Device-Component Entry X

Figure 17-9. IPL-Information *Blockfor IPL-Device-Component List*

IPL Device Component Entry

The IPL-device-component entry has the following format:

Word	0	8	16	31
0 1	IPL-Device-Component Address			
2 3	IPL-Device-Component Length			
4	DCF	Reserved		
5	Reserved		SCI	
6 7	Reserved			

Figure 17-10. IPL-Device-Component Entry

The IPL-device-component entry contains the following fields:

IPL-Device-Component Address: Words 0-1 contain a 64-bit absolute storage location of the binary code of a component.

IPL-Device-Component Length: Words 2-3 contain a 64-bit unsigned binary integer specifying the number of bytes in the binary code of a component.

IPL-Device-Component Flags (DCF): Byte 0 of word 4 contains a flag field defined as follows:

Bit Meaning

0 Signed Component (SC). When bit 0 is one, the binary code of the component is signed. When bit 0 is zero, the binary code of the component is not signed.

1 Component-Signature-Verified (CSV). When bit 1 is one, the component signature verification is successful. When bit 1 is zero, the component signature verification is not successful.

CSV bit is meaningful only when SC bit is set to one. When SC bit is set to zero, CSV bit should also be set to zero.

2-7 Reserved.

IPL-Signature-Certificate Index (SCI): Bytes 2-3 of word 5 contain a 16-bit unsigned binary integer specifying the index of the IPL-signature-certificate entry containing the X.509 certificate that was used to verify this signed component.

The IPL-signature-certificate index (SCI) field is meaningful only when the signed Component (SC) bit is set to one, indicating that the binary code of the component is signed.

If no errors occur during the operations listed above, then if a subchannel is associated with the IPL-device, the subsystem-identification word is stored in absolute locations 184-187; otherwise zeros are stored in absolute locations 184-187. Additionally, zeros are stored in absolute locations 188-191, and a new PSW is loaded from absolute locations 0-7.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).

If the PSW loading is successful and if no malfunctions are recognized which preclude execution of the program which was loaded from the load device, then operation proceeds under control of the new PSW.

If errors occur during the operations listed above, or if the PSW loading is not successful, then this CPU remains in the operating state. See the appropriate System Library publications for additional information.

When list-directed IPL was initiated by activating the load-clear-list-directed key, the state of the machine resources at the time when the loaded program is initiated is the same as it was immediately after the clear reset was performed except as indicated below. For a description of the state of the machine resources immediately after the clear reset was performed, see “Resets” on page 4-74.

- This CPU is in the operating state. The contents of the ALB and TLB for this CPU are unpredictable.
- The PSW for this CPU is set from the contents of absolute storage locations 0-7. When the CZAM facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).
- Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23 and 184-191. Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with this absolute address contain the system IPL-parameter block, immediately followed by an XML document containing the same system IPL parameters or IIRB containing the IPL information report (if present). If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros. The contents of all other storage locations are unpredictable.
- The ACC and F bits of the storage keys associated with all main storage locations are set to zero. The R and C bits of the storage keys associated with the first 4 K-byte block of storage, the blocks of storage containing the XML document or IIRB (if present), and IPL-parameter list, and the blocks of storage containing the loaded program are set to one. The R and C bits of the storage keys associated with all other blocks of storage are unpredictable.
- The TOD clock is unaffected by initial-program loading.

When list-directed IPL was initiated by activating the load-with-dump key, the state of the machine resources when control is passed to the loaded program is as follows:

- The I/O system has been reset.
- The state of all CPUs in the configuration except for this CPU is the same as it was immediately after the CPUs were reset.
- This CPU is in the operating state. The contents of all registers, the ALB, and the TLB for this CPU are unpredictable.
- The PSW for this CPU is set from the contents of absolute storage locations 0-7. When the CZAM facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).
- The contents of all main storage locations which were not stored in the model-dependent holding area are unchanged from the time when the load-with-dump key was activated.
- The contents of all main storage locations which were stored in the model-dependent holding area are unpredictable except as follows:
  - Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23.

- Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with the absolute address indicated by the contents of absolute addresses 20-23 contain the system IPL-parameter block, which is immediately followed by an XML document containing the system IPL parameters or IIRB containing the IPL information report (if present).
- If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros.

- The storage keys associated with the blocks of main storage which were stored in the model-dependent holding area are unpredictable. The storage keys associated with all other blocks of main storage are in the same state as they were immediately after the CPUs were reset.
- The TOD clock is unaffected by initial-program loading.

List-directed IPL does not complete if any of the following occurs:

- A malfunction is detected in the CPU, channel subsystem, or main storage which precludes the completion of IPL.
- The list-directed IPL parameters did not contain sufficient information to identify the load device or the program on the load device.
- An I/O device designated by the list-directed-IPL parameters is not in the machine configuration.
- The I/O device designated by the list-directed-IPL parameters is a CCW-type device and is not supported by list-directed IPL.
- The I/O device appeared not operational.
- The amount of storage in the logical partition or virtual machine is insufficient to allow list-directed IPL to complete.
- The PSW to be loaded from locations 0-7 has a PSW-format error of the type that is recognized early.

Programming Notes:

1. The executable portion of the program loaded during list-directed IPL should be located in absolute storage starting at absolute storage locations 8192 and higher. This is necessary in order to avoid use of the architecturally assigned storage locations. See “Assigned Storage Locations” on page 3-73.
2. When the address indicated by storage locations 20-23 is above 16 MB, it is necessary for the machine to be in 31-bit addressing mode in order to access the IPL-parameter list and XML document or IIRB (if present).
3. When list-directed IPL is initiated by activation of the load-clear-list-directed key, the program loaded from the load device is typically an operating-system loader. In this case, the load device may also contain the operating system to be loaded by the operating-system loader. See the applicable operating-system manuals for additional information.
4. When list-directed IPL is initiated by activation of the load-with-dump key, the contents of storage which are affected by the IPL operation are stored in a model-dependent holding area so that they can be retrieved by the program which was loaded from the load device. The program loaded from the load device is typically an O/S-specific system dump program which stores the retrieved data onto a dump device. This process ensures that the contents of storage affected by the IPL operation are preserved for analysis during subsequent debug operations. See the applicable operating system manuals for additional information.

Reconfiguration of the I/O System

Reconfiguration of the I/O system is handled in a model-dependent manner. For example, changes may be made under program control, by using the model-dependent DIAGNOSE instruction; or manually, by using system-operator configuration controls; or by using a combination of DIAGNOSE and manual controls. The method used depends on the system model. The System Library publication for the system model specifies how the changes are made. The partitioning of channel paths because of reconfiguration is indicated by the setting of the PAM bits in the SCHIB stored when STORE SUBCHANNEL is executed (see "Path-Available Mask (PAM)" on page 15-7).

Status Verification

The status-verification facility provides the channel subsystem with a means of indicating that a device has presented a device-status byte that has valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. The indication provided to the program in the ESW by the channel subsystem is called device-status check. When the channel subsystem recognizes a device-status-check condition, an interface-control-check condition is also recognized. For a summary of the status combinations considered to be appropriate or inappropriate, see the System Library publications *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202, and *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, and the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

Address-Limit Checking

The address-limit-checking facility may be installed on a model and when installed provides a storage-protection mechanism for I/O data accesses to storage that augments key-controlled protection. The address-limit-checking facility is not installed when the FCX facility is installed. When address-limit checking is used, absolute storage is divided into two parts by a program-controlled address-limit value. I/O data accesses can then be optionally restricted to only one of the two parts of absolute storage by the limit mode at each subchannel. The address-limit constraint applies at a higher priority than key-controlled protection, that is, I/O data accesses to the part of main storage that is protected by address-limit checking are prevented even when the subchannel key is zero or matches the key in storage. Address-limit checking does not apply to the fetching of CCWs, IDAWs and MIDAWs.

The address-limit-checking facility consists of the following elements:

- The I/O instruction SET ADDRESS LIMIT.
- The limit mode at each subchannel.
- The address-limit-checking-control bit in the ORB.

The execution of SET ADDRESS LIMIT passes the contents of general register 1 to the address-limit-checking facility to be used as the address-limit value. Bits 32 and 48-63of general register 1 must be zeros to designate a valid absolute address on a 64 K-byte boundary; otherwise, an operand exception is recognized, and the execution of the instruction is suppressed.

The limit mode at each subchannel indicates the manner in which address-limit checking is to be performed. The limit mode is set by placing the desired value in bit positions 9 and 10 of word 1 in the SCHIB and executing MODIFY SUBCHANNEL. The settings of these bits in the SCHIB have the following meanings:

00 No limit checking (initialized value).

01 Data address must be equal to or greater than the current address limit.

10 Data address must be less than the current address limit.

11 Reserved. This combination of limit-mode bits causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

The address-limit-checking-control bit, bit 11 of word 1 of the ORB, specifies whether address-limit checking is to be used for the start function that is accepted when the execution of START SUBCHANNEL causes the contents of the ORB to be passed to the subchannel. If the address-limit-checking-control bit is zero when the contents of the ORB are passed, address-limit checking is not specified for that start function. If the bit is one, address-limit checking is specified and is under the control of the current address limit and the current setting of the limit mode at the subchannel.

During the performance of the start function, an attempt to access an absolute storage location for data that is protected by an address limit (either high or low) is recognized as an address-limit violation, and the access is not allowed. A program-check condition is recognized, and channel-program execution is terminated, just as when an attempt is made to access an invalid address.

Configuration Alert

The configuration-alert facility provides a detection mechanism for devices that are not associated with a subchannel in the configuration. The configuration-alert facility notifies the program, by means of a channel report, that a device which is not associated with a subchannel has attempted to communicate with the program.

Each device must be assigned to a subchannel during an installation procedure; otherwise, the channel subsystem is unable to generate an I/O-interruption condition for the device. This is because the I/O-interruption code contains the subchannel number that identifies the particular device causing the I/O-interruption condition. When a device that is not associated with a subchannel attempts to communicate with the channel subsystem, the configuration-alert facility generates a channel report in which the unassociated device is identified. For a description of the means by which the program is notified of a pending channel report and how the information in the channel report is retrieved, see “Channel Report” on page 17-28.

Incorrect-Length-Indication Suppression

The incorrect-length-indication-suppression facility allows the indication of incorrect length for immediate operations to be suppressed in the same manner when using format-1 CCWs as when using format-0 CCWs. When the incorrect-length-indication-suppression facility is installed, bit 24 of word 1 of the ORB specifies whether the channel subsystem is to suppress the indication of incorrect length for an immediate operation when format-1 CCWs are used or whether this indication will remain under the control of the SLI flag of the current CCW (as is the case for CCWs not executed as immediate operations). This bit provides the capability for a channel program to operate in the same manner regarding the indication of incorrect length regardless of whether format-0 or format-1 CCWs are used.

Concurrent Sense

The concurrent-sense facility provides a mechanism whereby sense information that is provided by the device can be presented by the channel subsystem to the program in the same command-mode IRB that contains the unit-check indication when the subchannel is in the concurrent-sense mode. The concurrent-sense mode is made active at a subchannel for which the concurrent-sense facility is applicable when MODIFY SUBCHANNEL is executed and bit 31 of word 6 of the SCHIB operand is set to one. The concurrent-sense facility is applicable to subchannels that are operating in command-mode and are associated with channel paths by which the channel subsystem can attempt to retrieve sense information from the device without requiring program intervention.

The concurrent-sense facility is not applicable when a subchannel is operating in transport mode. When a transport-mode IRB is presented that contains the unit-check indication, the associated sense information is found in the TSB for the associated TCW channel program. Therefore, the concurrent sense facility is not necessary with FCX.

Channel-Subsystem Recovery

The channel subsystem provides various methods for extensive detection of malfunctions and other conditions to ensure the integrity of channel-subsystem operation and to achieve automatic recovery of some malfunctions.

The method used to report a particular malfunction or other condition is dependent upon the severity of the malfunction or other condition and the degree to which the malfunction or other condition can be isolated. A malfunction or other condition in the channel subsystem may be indicated to the program by information being stored by one of the following methods:

1. Information is provided in the IRB describing a condition that has been recognized by either the channel subsystem or device that must be brought to the attention of the program. Generally, this information is made available to the program by the execution of TEST SUBCHANNEL, which is usually executed in response to the

occurrence of an I/O interruption. (See “Interruption Action” on page 16-6, for a definition of the information stored, as well as “Interruptions” on page 6-1.)

2. Information is provided in a channel report describing a machine malfunction affecting the identified facility associated with the channel-subsystem. This information is made available to the program by the execution of STORE CHANNEL REPORT WORD, which is usually executed in response to the occurrence of a machine-check interruption. (See “Machine-Check Handling” on page 11-1 for a description of the machine-check-interruption mechanism and the contents of the machine-check-interruption code.)
3. Information is provided in a channel report describing a malfunction or other condition affecting a collection of channel-subsystem facilities. This information is made available to the program as indicated in item 2.
4. Information is provided in the machine-check-interruption code (MCIC) describing a malfunction affecting the continued operational integrity of the channel subsystem. (See “Channel-Subsystem Damage” on page 11-17.)
5. Information is provided in the MCIC describing a malfunction affecting the continued operational integrity of a process or of the system. (See “Instruction-Processing Damage” on page 11-15 and “System Damage” on page 11-15.)

Channel reports are used to report malfunctions or other conditions only when the use of the I/O-interruption facility is not appropriate and in preference to reporting channel-subsystem damage, instruction-processing damage, or system damage.

Channel Report

When a malfunction or other condition affecting elements of the channel subsystem has been recognized, a channel report is generated. The performance of recovery actions by the program or by external means may be required to gain recovery from the error condition. The channel report indicates the source of the channel report and the recovery state to the extent necessary for determining the proper recovery action. A channel report consists of one or more channel-report words (CRWs) that have been generated from an analysis of the malfunction or other condition. The inclusion of two or more CRWs within a channel report is indicated by the chaining flag being stored as one in all of the CRWs of the channel report except the last one in the chain.

When a channel report is made pending by the channel subsystem for retrieval and analysis by the program (by means of the execution of STORE CHANNEL REPORT WORD), a malfunction or other condition that affects the normal operation of one or more of the channel-subsystem facilities has been recognized. If the channel report that is made pending is an initial channel report, a machine-check-interruption condition is generated that indicates one or more CRWs are pending at the channel subsystem. A channel report is initial either if it is the first channel report to be generated after the most recent I/O-system reset or if no previously generated reports are pending and the last STORE CHANNEL REPORT WORD instruction that was executed resulted in the setting of condition code 1, indicating that no channel report was pending. When the machine-check interruption occurs and bit 9 of the machine-check-interruption code (channel report pending) is one, a channel report is pending. If the program clears the first CRW of a channel report before the associated machine-check interruption has occurred, some models may reset the machine-check-interruption condition, and the associated machine-check interruption does not occur. A machine-check interruption indicating that a channel report is pending occurs only if the machine-check mask (PSW bit 13) and the channel-report-pending subclass mask, bit 3 of control register 14, are both ones.

If the channel report that is made pending is not an initial channel report, a machine-check-interruption condition is not generated. The CRW that is presented to the program in response to the first STORE CHANNEL REPORT WORD instruction that is executed after a machine-check interruption may or may not be part of the initial channel report that caused the machine-check condition to be generated. A pending channel-report word is cleared by any CPU executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU. If a CRW is not pending and STORE CHANNEL REPORT WORD is executed, condition code 1 is set, and zeros are stored at the location designated by the second-operand address. During the execution of STORE CHANNEL REPORT WORD as a result of receiving a machine-check interruption, condition code 1 may be set, and zeros may be stored because (1) the related channel report has been cleared by another CPU or (2) a malfunction occurred during the generation of a channel report. In the latter case, if, during a subsequent attempt, a valid channel report can be made pending, an additional machine-check-interruption condition is generated.

When a channel report consists of multiple chained CRWs, they are presented to the program in the same order that they are placed in the chain by the channel subsystem as a result of consecutive executions of STORE CHANNEL REPORT WORD. If, for example, the first CRW of a chain is presented to the program as a result of executing STORE CHANNEL REPORT WORD, the CRW that is presented as a result of the next execution of STORE CHANNEL REPORT WORD is the second CRW of the same chain and not a CRW that is part of another channel report.

Channel reports are not presented to the program in any special order, except for channel reports whose first or only CRW indicates the same reporting-source code and the same reporting-source ID. These channel reports are presented to the program in the same order that they are generated by the channel subsystem, but they are not necessarily presented consecutively. For example, suppose the channel subsystem generates channel reports A, B, and C, in that order. The first CRW of channel reports B and C indicates the same reporting-source code and the same reporting-source ID. Channel report B is presented to the program before channel report C is presented, but channel report A may be presented after channel report B and before channel report C.

Programming Notes:

1. The information that is provided in a single CRW may be made obsolete by another CRW that is subsequently generated for the same channel-subsystem facility. Therefore, the information that is provided in one channel report should be interpreted in light of the information provided by all of the channel reports that are pending at a given instant.

2. A machine-check-interruption condition is not always generated when a channel report is made pending. The conditions that result in a machine-check-interruption condition being generated are described earlier in this section.

3. After a machine-check interruption has occurred with bit 9 of the machine-check-interruption code set to one, STORE CHANNEL REPORT WORD should be issued repeatedly until all of the pending channel reports have been cleared and condition code 1 has been set.

4. A CRW-overflow condition can occur if the program does not issue successive STORE CHANNEL REPORT WORD instructions in a timely manner after the machine-check interruption occurs.

5. The number of CRWs that can be pending at the same time is model dependent. During the existence of an overflow condition, CRWs that would have otherwise been made pending are lost and are never presented to the program.

Channel-Report Word

The channel-report word (CRW) provides information to the program that can be used to facilitate the recovery of an I/O operation, a device, or some element of the channel subsystem, such as a channel path or subchannel.

The format of the CRW is as follows:

0	S	R	C	RSC	A	0	ERC	Reporting-Source ID	
0	1	2	3	4	8		10	16	31

Solicited CRW (S): Bit 1, when one, indicates a solicited CRW. A CRW is considered by the channel subsystem to be solicited if it is made pending as the direct result of some action that is taken by the program. When bit 1 is zero, the CRW is unsolicited and has been made pending as the result of an action taken by the channel subsystem that is independent of the program.

Overflow (R): Bit 2, when one, indicates that a CRW-overflow condition has been recognized since this CRW became pending and that one or more CRWs have been lost. This bit is one in the CRW that has most recently been set pending when the overflow condition is recognized. When bit 2 is zero, a CRW-overflow condition has not been recognized.

A CRW that is part of a channel report is not made pending, even though the overflow condition does not exist, if an overflow condition prevented a previous CRW of that report from being made pending.

Chaining (C): Bit 3, when one, and when the overflow flag is zero, indicates chaining of associated CRWs. Chaining of CRWs is indicated whenever a malfunction or other condition is described by more than a single CRW. The chaining flag is zero if the channel report is described by a single CRW or if the CRW is the last CRW of a channel report.

The chaining flag is not meaningful if the overflow bit, bit 2, is one.

Reporting-Source Code (RSC): Bits 4-7 identify the channel-subsystem facility that is associated with the channel report. Some facilities are further identified in the reporting-source-identification field (see below). The following combinations of bits identify the facilities:

Bits				
4	**5**	**6**	**7**	**Facility**
0	0	1	0	Monitoring facility
0	0	1	1	Subchannel
0	1	0	0	Channel Path
1	0	0	1	Configuration-alert facility
1	0	1	1	Channel subsystem

All other bit combinations in the reporting-source-code field are reserved.

Ancillary Report (A): Bit 8, when one, indicates that a malfunction of a system component has occurred that was recognized previously or which has affected the activity of multiple channel-subsystem facilities. When the malfunction affects the activity of multiple channel-subsystem facilities, an ancillary-report condition is recognized for all of the affected facilities except one. This bit, when zero, indicates that this malfunction of a system component was not recognized previously. This bit is meaningful for all channel reports.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions that affect channel-subsystem facilities. When ancillary-report recognition is not provided, bit 8 is set to zero.

Error-Recovery Code (ERC): Bits 10-15, when zero, indicate that the channel subsystem has error information regarding the channel-subsystem facility identified in the reporting-source code, and that the program can now request that information. Otherwise, bit positions 10-15 contain the error-recovery code that defines the recovery state of the channel-subsystem facility identified in the reporting-source code. This field, when used in conjunction with the reporting-source code, can be used by the program to determine whether the identified facility has already been recovered and is available for use or whether recovery actions are still required. The following error-recovery codes are defined:

		Bits				
10	**11**	**12**	**13**	**14**	**15**	**State**
0	0	0	0	0	0	Event-information pending
0	0	0	0	0	1	Available
0	0	0	0	1	0	Initialized
0	0	0	0	1	1	Temporary error
0	0	0	1	0	0	Installed parameters initialized
0	0	0	1	0	1	Terminal
0	0	0	1	1	0	Permanent error with facility not initialized
0	0	0	1	1	1	Permanent error with facility initialized
0	0	1	0	0	0	Installed parameters modified
0	0	1	0	1	0	Installed parameters restored[1]

Explanation:

[1]. Installed-parameters restored is presented only if reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility.

All other bit combinations in the error-recovery-code field are reserved.

The specific meaning of each error-recovery code depends on the particular reporting-source code that accompanies it in a CRW. The error-recovery codes are defined as follows:

Event-Information Pending: Event information for the identified facility is available for retrieval by the program. This CRW does not indicate the state of the identified facility.

Available: The identified facility is in the same state that the program would expect if the CRW had not been generated.

Initialized: The identified facility is in the same state that existed immediately following the I/O-system reset that was part of the most recent system IPL.

Temporary Error: The identified facility is not operating in a normal manner or has recognized the occurrence of an abnormal event. It is expected that subsequent actions either will restore the facility to normal operation or will record the appropriate information describing the abnormal event.

Installed Parameters Initialized: This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed.

On some models that do not implement the restore-subchannel facility, or in the absence of enablement by the program of reporting of the installed-parameters-restored CRW by the restore-subchannel facility, the installed-parameters-initialized CRW may be reported as a result of the channel subsystem's recovery of the facility designated by the reporting-source ID.

Terminal: The identified facility is in a state such that an operation that was in progress can neither be completed nor terminated in the normal manner.

Permanent Error with Facility Not Initialized: The identified facility is in a state of malfunction, and the channel subsystem has not caused a reset function to be performed for that facility.

Permanent Error with Facility Initialized: The identified facility is in a state of malfunction, and the channel subsystem has caused or may have caused a reset function to be performed for that facility.

Installed Parameters Modified: One or more parameters of the specified facility have been changed.

Installed Parameters Restored: This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed from their most recent values back to their initialized values a result of the channel subsystem's recovery of the facility.

Reporting-Source ID (RSID): Bit positions 16-31 contain the reporting-source ID, which may, depending upon the condition that caused the channel report and the reporting-source code, either further identify the affected channel-subsystem facility or provide additional information describing the condition that caused the channel report. The RSID field has the following format as a function of the bit settings of the reporting-source code.

Reporting-Source Code				Reporting-Source ID			
4	5	6	7	Bits 16-31			
0	0	1	0	0000	0000	0000	0000
0	0	1	1	xxxx	xxxx	xxxx	xxxx
0	0	1	1	0000	0000	00ss	0000
0	1	0	0	0000	0000	yyyy	yyyy
1	0	0	1	0000	0000	yyyy	yyyy
1	0	1	1	0000	0000	0000	0000

Note:

xxxx xxxx xxxx xxxx	Subchannel Number
ss	Subchannel-set ID when the MSS facility is installed and the CRW is chained immediately following a CRW for a subchannel.
yyyy yyyy	Channel-path ID (CHPID)

When the MSS facility is installed an additional CRW is chained to every channel report for subchannels. The content of this chained CRW is identical to the original CRW except for the RSID field. In this chained CRW, bit positions 10-11 of the RSID field contain the SSID identifying the subchannel set.

Restore-Subchannel Facility

The restore-subchannel facility may be available on a model implementing z/Architecture. This facility provides the means for the channel subsystem to recover a damaged subchannel and report the recovery to the program by means of a CRW. When the facility is installed and reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters restored. When the facility is installed and reporting of the installed-parameters-restored CRW is not enabled, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters initialized.

In some models that do not implement the restore-subchannel facility, the channel subsystem may nevertheless recover a damaged subchannel, and make a CRW pending that indicates installed-parameters initialized.

Extended-Subchannel-Logout Facility

When the extended-subchannel-logout facility is installed and enabled, all fibre-channel (FC) channel paths can create extended-subchannel logouts, under applicable error conditions, and generate I/O interruptions that indicate such a logout is pending retrieval. The extended-subchannel logouts are stored in and retrieved from a model-dependent number of extended-subchannel-logout buffers associated with each channel path supported by the facility.

When TEST SUBCHANNEL for a subchannel that specifies an FC channel path stores an interruption-response block (IRB) containing a format-0 ESW in which the extended-subchannel-logout-pending (E) bit is 1, an extended-subchannel logout is pending for the specified subchannel. Words 2-3 of the format-0 ESW contain the extended-subchannel-logout descriptor (ESLD) that identifies the logout and the channel path for which the logout is pending.

If all of the buffers for a given channel contain pending extended-subchannel logouts, the logouts will remain pending for a model-dependent time interval. If, during that time interval, a subsequent condition occurs that warrants a new extended-subchannel logout, that logout is not made and is lost. If the time interval has been exceeded and the program has not used the ESLD to retrieve a pending logout, the logout may be removed from the buffer or the buffer may be reused to contain a subsequent logout. When a logout is removed from a buffer and the buffer is not reused, the ESLD is no longer recognized as a valid logout identifier. When a buffer is reused, the ESLD may be recognized as a valid logout identifier albeit for a logout different from the logout for which the original I/O interruption was generated.

Channel-Subsystem-I/O-Priority Facility

The channel-subsystem-I/O-priority facility provides a means by which the program can establish a priority relationship, at the channel subsystem, among the subchannels that are placed into the start-pending state when START SUBCHANNEL is executed and condition code 0 is indicated. For I/O-subchannels that are configured to fibre-channel channel paths (FICON and FICON-converted channel paths), it also provides a means by which the program can establish a priority relationship for I/O operations at the fibre-channel-attached control units.

The program assigns the desired channel-subsystem priority and control-unit priority by specifying the desired priority numbers in the ORB extension when START SUBCHANNEL is executed.

The channel-subsystem-priority number specified in the ORB is used by the channel subsystem to determine the order in which start-pending and resume-pending subchannels are selected when the channel subsystem attempts to initiate a start function or a resume function. See the section “Start Function and Resume Function” on page 15-20 for details about these functions. In general, I/O subchannels that are in the start-pending or resume-pending state and have a higher priority number are selected for start-function or resume-function initiation by the channel subsystem before start-pending or resume-pending subchannels that have a lower priority number. The specific priority selection algorithm used by the channel subsystem for this purpose depends on the model. Additionally, the channel subsystem also applies a fairness selection algorithm in conjunction with the priority selection algorithm when selecting I/O subchannels. The specific fairness selection algorithm also depends on the model. For all models, the channel-subsystem priority and fairness selection algorithms are always applied to I/O subchannels that are either start pending or resume pending. Some models may also apply both algorithms to subchannels that are either clear pending or halt pending. See a model's System-Library publication for a description of the priority and fairness selection algorithms that the model provides and whether these algorithms are also applied to clear-pending or halt-pending subchannels.

The control-unit-priority number specified in the ORB is used by control units attached to fibre-channel channel paths in order to determine the priority of the execution of CCWs at the control unit. See “Control-Unit (CU) Priority:” on page 15-29 for additional information.

Number of Channel-Subsystem-Priority Levels

Depending on the model, fewer than 256 channel-subsystem-priority levels may be provided by the channel subsystem. Each priority level that the model provides is designated by an eight-bit unsigned binary integer. The lowest provided channel-subsystem-priority level is designated by the integer 0, and each succeeding higher priority level is designated by the next-higher sequential integer. For example, if the model provides 16 priority levels, they are numbered 0-15, respectively, from the lowest priority level to the highest priority level.

Multiple-Subchannel-Set Facility

The multiple-subchannel-set (MSS) facility increases the maximum number of subchannels that can be configured to a program. When the MSS facility is not provided, a single set of subchannels, in the range 0-65,535 may be provided for a program. When the MSS facility is provided, a maximum of four sets of subchannels may be provided for a program. Each subchannel set provides from one to 64K subchannels in the range 0 to-65,535. A two-bit unsigned binary integer, in the range of 0-3, called the subchannel-set identifier (SSID) is used to specify each provided subchannel set. The default subchannel set for a program is SSID 0. The initialized state of the MSS facility is disabled, in this state the MSS facility functions are not provided to programs executing in logical partitions.

When the MSS facility is provided, a subchannel is specified by a unique address formed by the concatenation of:

1. The subchannel-set identifier (SSID) of the subchannel-image set to which the designated subchannel-image is configured,
2. The subchannel number of the subchannel-image being accessed.

HFP Arithmetic

HFP Number Representation

A hexadecimal-floating-point (HFP) number consists of a sign bit, a hexadecimal fraction, and an unsigned seven-bit binary integer called the characteristic. The characteristic represents a signed exponent and is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63. The magnitude of an HFP number is the product of its fraction and the number 16 raised to the power of the exponent that is represented by its characteristic. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The fraction of an HFP number is treated as a hexadecimal number because it is considered to be multiplied by a number which is a power of 16. The name, fraction, indicates that the radix point is assumed to be immediately to the left of the leftmost fraction digit.

When an HFP operation would cause the result exponent to exceed 63, the characteristic wraps around from 127 to 0, and an HFP-exponent-overflow condition exists. The result characteristic is then too small by 128. When an operation would cause the exponent to be less than -64, the characteristic wraps around from 0 to 127, and an HFP-exponent-underflow condition exists. The result characteristic is then too large by 128, except that a zero characteristic is produced when a true zero is forced.

A true zero is an HFP number with a zero characteristic and zero fraction. A true zero may arise as the normal result of an arithmetic operation because of the particular magnitude of the operands. For HFP operations, the result is forced to be a positive true zero when:

1. An HFP exponent underflow occurs and the HFP-exponent-underflow mask bit in the PSW is zero.
2. The result fraction of a normalized or unnormalized addition or subtraction operation is zero and the HFP-significance mask bit in the PSW is zero.
3. The operand of the CONVERT FROM FIXED instruction is zero.
4. The dividend in the DIVIDE instruction has a zero fraction.
5. The operand of the HALVE, LOAD FP INTEGER, or SQUARE ROOT instruction has a zero fraction.
6. One or both operands of a multiplication operation has a zero fraction.

When a program interruption for HFP exponent underflow occurs, a true zero is not forced; instead, the fraction and sign remain correct, and the characteristic is too large by 128. When a program interruption for HFP significance occurs, the fraction remains zero, the sign is positive, and the characteristic remains correct.

The sign of a sum, difference, product, quotient, square root, the result of CONVERT FROM FIXED, or the result of LOAD FP INTEGER with a zero fraction is positive. The sign for a zero fraction resulting from other HFP operations is established from the operand sign, the same as for nonzero fractions.

Normalization

A quantity can be represented with the greatest precision by an HFP number of a given fraction length when that number is normalized. A normalized HFP number has a nonzero leftmost hexadecimal fraction digit. If one or more leftmost fraction digits are zeros, the number is said to be unnormalized.

Unnormalized numbers are normalized by shifting the fraction left, one digit at a time, until the leftmost hexadecimal digit is nonzero and reducing the characteristic by the number of hexadecimal digits shifted. A number with a zero fraction cannot be normalized; either its characteristic remains unchanged or its characteristic is made zero when the result is forced to be a true zero.

Addition and subtraction with extended operands, as well as the MULTIPLY, DIVIDE, CONVERT FROM FIXED, HALVE, LOAD FP INTEGER, and SQUARE ROOT operations, are performed only with normalization. Addition and subtraction with short or long operands may be specified as either normalized or unnormalized. For all other operations, the result is produced without normalization.

With unnormalized operations, leftmost zeros in the result fraction are not eliminated. The result may or may not be in normalized form, depending upon the original operands.

In both normalized and unnormalized operations, the initial operands need not be in normalized form. The operands for multiply, divide, and square-root operations are normalized before the arithmetic process. For other normalized operations, normalization takes place when the intermediate arithmetic result is changed to the final result.

When the intermediate result of addition, subtraction, or rounding causes the fraction to overflow, the fraction is shifted right by one hexadecimal-digit position, and the value one is supplied to the vacated leftmost digit position. The fraction is then truncated to the final result length, while the characteristic is increased by one. This adjustment is made for both normalized and unnormalized operations.

Figure 18-1 on page 18-3 summarizes, for all instructions producing HFP results, the handling of zero results and whether normalization occurs for nonzero results.

Programming Note: Up to three leftmost bits of the fraction of a normalized number may be zeros, since the nonzero test applies to the entire leftmost hexadecimal digit.

HFP Data Formats

HFP numbers have a 32-bit (short) format, a 64-bit (long) format, or a 128-bit (extended) format. Numbers in the short and long formats may be designated as operands both in storage and in the floating-point registers, whereas operands having the extended format can be designated only in the floating-point registers.

In all formats, the first bit (bit 0) is the sign bit (S). The next seven bits are the characteristic. In the short and long formats, the remaining bits constitute the fraction, which consists of six or 14 hexadecimal digits, respectively.

Instruction	Nonzero Result Normalized	Zero Result Forced to True Zero		Zero Result Made Positive	
		Short and Long	Extended	Short and Long	Extended

127

An extended HFP number has a 28-digit fraction and consists of two long HFP numbers that are called the high-order and low-order parts. The high-order part may be any long HFP number. The fraction of the high-order part contains the leftmost 14 hexadecimal digits of the 28-digit fraction. The characteristic and sign of the high-order part are the characteristic and sign of the extended HFP number. If the high-order part is normalized, the extended number is considered normalized. The fraction of the low-order part contains the rightmost 14 digits of the 28-digit fraction. The sign and characteristic of the low-order part of an extended operand are ignored.

When a result is generated in the extended format and placed in a register pair, the sign of the low-order part is made the same as that of the high-order part, and, unless the result is a true zero, the low-order characteristic is made 14 less than the high-order characteristic. When the subtraction of 14 would cause the low-order characteristic to become less than zero, the characteristic is made 128 greater than its correct value. (Thus, the subtraction is performed modulo 128.) HFP exponent underflow is indicated only when the high-order characteristic underflows.

When an extended result is made a true zero, both the high-order and low-order parts are made a true zero.

The range covered by the magnitude (M) of a normalized HFP number depends on the format.

In the short format:

$16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}$

In the long format:

$16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}$

In the extended format:

$16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}$

In all formats, approximately:

$5.4 \times 10^{-79} \leq M \leq 7.2 \times 10^{75}$

Although the final result of an HFP operation has six hexadecimal fraction digits in the short format, 14 fraction digits in the long format, and 28 fraction digits in the extended format, intermediate results have one additional hexadecimal digit on the right. This digit is called the guard digit. The guard digit may increase the precision of the final result because it participates in addition, subtraction, and comparison operations and in the left shift that occurs during normalization.

The entire set of HFP operations with normalized results is available for short, long, and extended operands in register-register versions; and for short and long operands in register-storage versions. Most instructions generate a result that has the same format as the source operands, except that there are multiplication operations which can generate a long product from short operands or an extended product from long operands. Other exceptions are instructions which convert operands from one floating-point format to another or between floating-point and fixed-point (binary-integer) formats.

Programming Notes:

1. In the absence of an HFP exponent overflow or HFP exponent underflow, the long HFP number constituting the low-order part of an extended result correctly expresses the value of the low-order part of the extended result when the characteristic of the high-order part is 14 or higher. This applies also when the result is a true zero. When the high-order characteristic is less than 14 but the number is not a true zero, the low-

order part, when considered as a long HFP number, does not express the correct characteristic value.

2. The entire fraction of an extended result participates in normalization. The low-order part alone may or may not appear to be a normalized long HFP number, depending on whether the 15th digit of the normalized 28-digit fraction is nonzero or zero.

Instructions

The HFP instructions and their mnemonics and operation codes are listed in Figure 18-2 on page 18-5. The figure indicates, in the column labeled "Characteristics", the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All HFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the HFP instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for HFP instructions to represent operand-format length and normalization, as follows:

F	Thirty-two-bit fixed point
G	Sixty-four-bit fixed point
D	Long normalized
E	Short normalized
U	Short unnormalized
W	Long unnormalized
X	Extended normalized

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CER is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The following additional HFP instructions are available when the HFP-multiply-and-add/subtract facility is installed:
   - MULTIPLY AND ADD (MAD, MADR, MAE, MAER)
   - MULTIPLY AND SUBTRACT (MSD, MSDR, MSE, MSER)
2. The following additional HFP instructions are available when the HFP-unnormalized-extensions facility is installed:
   - MULTIPLY AND ADD UNNORMALIZED (MAY, MAYH, MAYHR, MAYL, MAYLR, MAYR)
   - MULTIPLY UNNORMALIZED (MY, MYH, MYHR, MYL, MYLR, MYR)

Mnemonic2 R_1,D_2(X_2,B_2) [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic2	Op Code	Operands
AE	'7A'	Short HFP
AD	'6A'	Long HFP

The second operand is added to the first operand, and the normalized sum is placed at the first-operand location.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the two operands are compared, and the fraction accompanying the smaller characteristic is aligned with the other fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift until the two characteristics agree.

When a fraction is shifted right during alignment, the leftmost hexadecimal digit shifted out is retained as a guard digit. The fraction that is not shifted is considered to be extended with a zero in the guard-digit position. When no alignment shift occurs, both operands are considered to be extended with zeros in the guard-digit position. The fractions with signs are then added algebraically to form a signed intermediate sum.

The intermediate-sum fraction consists of seven (short format), 15 (long format), or 29 (extended format) hexadecimal digits, including the guard digit, and a possible carry. If a carry is present, the sum is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

If the addition produces no carry, the intermediate-sum fraction is shifted left as necessary to eliminate any leading hexadecimal zero digits resulting from the addition, provided the fraction is not zero. Zeros are supplied to the vacated rightmost digits, and the characteristic is reduced by the number of hexadecimal digits of shift. The fraction thus normalized is then truncated on the right to six (short format), 14 (long format), or 28 (extended format) hexadecimal digits. In the extended format, a characteristic is generated for the low-order part, which is 14 less than the high-order characteristic.

The sign of the sum is determined by the rules of algebra, unless all digits of the intermediate-sum fraction are zero, in which case the sign is made plus.

An HFP-exponent-overflow exception exists when a carry from the leftmost position of the intermediate-sum fraction would cause the characteristic of the normalized sum to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. For extended results, the characteristic of the low-order part remains correct.

An HFP-exponent-underflow exception exists when the characteristic of the normalized sum would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

The result fraction is zero when the intermediate-sum fraction, including the guard digit, is zero. With a zero result fraction, the action depends on the setting of the HFP-significance mask bit in the PSW. If the HFP-significance mask bit in the PSW is one, no normalization occurs, the intermediate and final result characteristics are the same, and a program interruption for HFP significance occurs. If the HFP-significance mask bit in the PSW is zero, the program interruption does not occur; instead, the result is made a positive true zero.

For AXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0	Result is zero
1	Result is less than zero
2	Result is greater than zero
3	--

Program Exceptions:

- Access (fetch, operand 2 of AE and AD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (AXR only)
- Transaction constraint

Programming Notes:

1. An example of the use of the ADD NORMALIZED instruction (AE) is given in Appendix A.

2. Interchanging the two operands in an HFP addition does not affect the value of the sum.

3. The ADD NORMALIZED instruction normalizes the sum but not the operands. Thus, if one or both operands are unnormalized, precision may be lost during fraction alignment.

ADD UNNORMALIZED

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	**Op Code**	**Operands**
AUR	'3E'	Short HFP
AWR	'2E'	Long HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic2	**Op Code**	**Operands**
AU	'7E'	Short HFP
AW	'6E'	Long HFP

The second operand is added to the first operand, and the unnormalized sum is placed at the first-operand location.

The execution of ADD UNNORMALIZED is identical to that of ADD NORMALIZED, except that:

1. When no carry is present after the addition, the intermediate-sum fraction is truncated to the proper result-fraction length without a left shift to eliminate leading hexadecimal zeros and without the corresponding reduction of the characteristic.
2. HFP exponent underflow cannot occur.
3. The guard digit does not participate in the recognition of a zero result fraction. A zero result fraction is recognized when the fraction (that is, the intermediate-sum fraction, excluding the guard digit) is zero.

Resulting Condition Code:

0 Result fraction zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of AU and AW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance
- Transaction constraint

Programming Notes:

1. An example of the use of the ADD UNNORMALIZED instruction (AU) is given in Appendix A.
2. Except when the result is made a true zero, the characteristic of the result of ADD UNNORMALIZED is equal to the greater of the two operand characteristics, increased by one if the fraction addition produced a carry, or set to zero if HFP exponent overflow occurred.

COMPARE

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	**Op Code**	**Operands**
CER	'39'	Short HFP
CDR	'29'	Long HFP

Mnemonic2 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic2	**Op Code**	**Operands**
CXR	'B369'	Extended HFP

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic3	**Op Code**	**Operands**
CE	'79'	Short HFP
CD	'69'	Long HFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

The comparison is algebraic and follows the procedure for normalized subtraction, except that the difference is discarded after setting the condition code and both operands remain unchanged. When the difference, including the guard digit, is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

An HFP-exponent-overflow, HFP-exponent-underflow, or HFP-significance exception cannot occur.

For CXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 2 of CE and CD only)
- Data with DXC 1, AFP register
- Specification (CXR only)
- Transaction constraint

Programming Notes:

1. Examples of the use of the COMPARE instruction (CDR) are given in Appendix A.

2. An exponent inequality alone is not sufficient to determine the inequality of two operands with the same sign, because the fractions may have different numbers of leading hexadecimal zeros.

3. Numbers with zero fractions compare equal even when they differ in sign or characteristic.

CONVERT FROM FIXED

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
CEFR	'B3B4'	32-bit binary-integer operand, short HFP result
CDFR	'B3B5'	32-bit binary-integer operand, long HFP result
CXFR	'B3B6'	32-bit binary-integer operand, extended HFP result
CEGR	'B3C4'	64-bit binary-integer operand, short HFP result
CDGR	'B3C5'	64-bit binary-integer operand, long HFP result
CXGR	'B3C6'	64-bit binary-integer operand, extended HFP result

The fixed-point second operand is converted to the HFP format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The result is normalized and rounded toward zero (truncated) before it is placed at the first-operand location.

For CXFR and CXGR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (CXFR and CXGR)
- Transaction constraint

CONVERT TO FIXED

Mnemonic R_1,M_3,R_2 [RRF-e]

Op Code	M_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CFER	'B3B8'	Short HFP operand, 32-bit binary-integer result
CFDR	'B3B9'	Long HFP operand, 32-bit binary-integer result
CFXR	'B3BA'	Extended HFP operand, 32-bit binary-integer result
CGER	'B3C8'	Short HFP operand, 64-bit binary-integer result
CGDR	'B3C9'	Long HFP operand, 64-bit binary-integer result
CGXR	'B3CA'	Extended HFP operand, 64-bit binary-integer result

The HFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

The second operand is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	Round toward 0
1	Round to nearest with ties away from 0
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

For details on rounding see the section “Rounding Methods” on page 9-14.

A modifier other than 0, 1, or 4-7 is invalid.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

If the rounded result would have a value exceeding the range that can be represented in the result format, the largest (in magnitude) representable number of the same sign as the source is placed at the target location, and condition code 3 is set.

HFP exponent underflow is not recognized because small values are rounded to one (with the appropriate sign) or to zero, depending on the rounding mode.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CFXR and CGXR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

Program Exceptions:

- Data with DXC 1, AFP register
- Specification
- Transaction constraint

DIVIDE

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	**Op Code**	**Operands**
DER	'3D'	Short HFP
DDR	'2D'	Long HFP

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic2	**Op Code**	**Operands**
DXR	'B22D'	Extended HFP

Mnemonic3 R_1,D_2(X_2,B_2) [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic3	**Op Code**	**Operands**
DE	'7D'	Short HFP
DD	'6D'	Long HFP

The first operand (the dividend) is divided by the second operand (the divisor), and the normalized quotient is placed at the first-operand location. No remainder is preserved.

HFP division consists in characteristic subtraction and fraction division. The operands are first normalized to eliminate leading hexadecimal zeros. The difference between the dividend and divisor characteristics of the normalized operands, plus 64, is used as the characteristic of an intermediate quotient.

All dividend and divisor fraction digits participate in forming the fraction of the intermediate quotient. The intermediate-quotient fraction can have no leading hexadecimal zeros, but a right shift of one digit position may be necessary, with this causing an increase of the characteristic by one. The fraction is then truncated to the proper result-fraction length.

An HFP-exponent-overflow exception exists when the characteristic of the final quotient would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

An HFP-exponent-underflow exception exists when the characteristic of the final quotient would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands or when the intermediate-quotient characteristic is less than zero, as long as the final quotient can be represented with the correct characteristic.

When the divisor fraction is zero, an HFP-divide exception is recognized. This includes the case of division of zero by zero.

When the dividend fraction is zero but the divisor fraction is nonzero, the quotient is made a positive true zero. No HFP exponent overflow or HFP exponent underflow occurs.

The sign of the quotient is the exclusive or of the operand signs, except that the sign is always plus when the quotient is made a positive true zero.

For DXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of DE and DD only)
- Data with DXC 1, AFP register
- HFP divide
- HFP exponent overflow
- HFP exponent underflow
- Specification (DXR only)
- Transaction constraint

Programming Note: Examples of the use of the DIVIDE instruction (DER) are given in Appendix A.

HALVE

Mnemonic R_1,R_2 [RR]

Op Code	R_1	R_2

0 8 12 15

Mnemonic	Op Code	Operands
HER	'34'	Short HFP
HDR	'24'	Long HFP

The second operand is divided by 2, and the normalized quotient is placed at the first-operand location.

The fraction of the second operand is shifted right one bit position, placing the contents of the rightmost bit position in the leftmost bit position of the guard digit, and a zero is supplied to the leftmost bit position of the fraction. The intermediate result, including the guard digit, is then normalized, and the final result is truncated to the proper length.

An HFP-exponent-underflow exception exists when the characteristic of the final result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

When the fraction of the second operand is zero, the result is made a positive true zero, and no HFP exponent underflow occurs.

The sign of the result is the same as that of the second operand, except that the sign is always plus when the quotient is made a positive true zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- HFP exponent underflow
- Transaction constraint

Programming Notes:

1. An example of the use of the HALVE instruction (HDR) is given in Appendix A.

2. With short and long operands, the halve operation is identical to a divide operation with the number 2 as divisor. Similarly, the result of HDR is identical to that of MD or MDR with one-half as a multiplier, and the result of HER is identical to that of MEE or MEER with one-half as a multiplier.

LOAD AND TEST

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2

LTER	'32'	Short HFP
LTDR	'22'	Long HFP

Mnemonic2 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic2	Op Code	Operands
LTXR	'B362'	Extended HFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

For short and long operands, the second operand is placed unchanged in the first-operand location.

For extended operands, the high-order sign and the entire fraction of the source are placed unchanged in the result, and the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the high-order sign bit of the source).

For LTXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LTXR only)
- Transaction constraint

Programming Note: When, for LTER and LTDR, the same register is designated as the first-operand and second-operand location, the operation is equivalent to a test without data movement.

LOAD COMPLEMENT

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	Op Code	Operands
LCER	'33'	Short HFP
LCDR	'23'	Long HFP

Mnemonic2 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic2	Op Code	Operands
LCXR	'B363'	Extended HFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the sign inverted from the source (the high-order and low-order sign bits of the result are inverted from the high-order sign bit of the source).

For LCXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LCXR only)
- Transaction constraint

LOAD FP INTEGER

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
FIER	'B377'	Short HFP
FIDR	'B37F'	Long HFP
FIXR	'B367'	Extended HFP

The second operand is truncated (rounded toward zero) to an integer value in the same floating-point format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

For FIXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (FIXR only)
- Transaction constraint

Programming Notes:

1. LOAD FP INTEGER truncates (rounds toward zero) an HFP number to an integer value. These integers, which remain in the HFP format, should not be confused with binary integers, which use a fixed-point format.
2. If the HFP operand has a large enough exponent so that it is already an integer, the result value remains the same, except that an unnormalized operand is normalized, and an operand with a zero fraction is changed to a positive true zero.

LOAD LENGTHENED

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
LDER	'B324'	Short HFP operand 2, long HFP operand 1
LXDR	'B325'	Long HFP operand 2, extended HFP operand 1
LXER	'B326'	Short HFP operand 2, extended HFP operand 1

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
LDE	'ED24'	Short HFP operand 2, long HFP operand 1
LXD	'ED25'	Long HFP operand 2, extended HFP operand 1
LXE	'ED26'	Short HFP operand 2, extended HFP operand 1

The second operand is extended to a longer format, and the result is placed at the first-operand location.

For all operand lengths, the source fraction is extended with zeros and placed in the result. The sign bit of the result is set the same as the sign of the source even when the result is made a true zero.

For long results, the source characteristic is placed unchanged in the result.

For extended results, the low-order sign is set equal to the high-order sign. If the fraction is nonzero, the source characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the sign bit of the source).

For LXD, LXDR, LXE, and LXER, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LDE, LXE, and LXD only)
- Data with DXC 1, AFP register
- Specification (LXE, LXER, LXD, LXDR)
- Transaction constraint

LOAD ROUNDED

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2

0 8 12 15

Mnemonic1	**Op Code**	**Operands**
LEDR	'35'	Long HFP operand 2, short HFP operand 1
LDXR	'25'	Extended HFP operand 2, long HFP operand 1

The above mnemonics are alternatives to the following older mnemonics that are less descriptive of operand lengths:

LRER	'35'	Long HFP operand 2, short HFP operand 1
LRDR	'25'	Extended HFP operand 2, long HFP operand 1

Mnemonic2 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2

0 16 24 28 31

Mnemonic2	**Op Code**	**Operands**
LEXR	'B366'	Extended HFP operand 2, short HFP operand 1

The second operand is rounded to a shorter format, and the result is placed at the first-operand location.

Rounding consists in adding a one to the leftmost bit position of the second operand that is to be dropped and propagating any carry through the fraction. The sign of the second operand is ignored, and addition is performed as if the fraction were positive.

If rounding causes a carry out of the leftmost hexadecimal digit position of the fraction, the fraction is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

The intermediate fraction is then truncated to the proper result-fraction length. For LEDR and LEXR, the result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. For LDXR, the 64-bit result is placed in a floating-point register, not a floating-point register pair.

The sign of the result is the same as the sign of the second operand. There is no normalization to eliminate leading zeros.

An HFP-exponent-overflow exception exists when shifting the fraction right would cause the characteristic to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP-exponent-underflow and HFP-significance exceptions cannot occur.

For LDXR (or LRDR) and LEXR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- HFP exponent overflow
- Specification (LDXR, LEXR, LRDR)
- Transaction constraint

Programming Note: The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

MXDR	'27'	Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDER is an alternative to the following older mnemonic that is less descriptive of operand lengths:

MER	'3C'	Short HFP multiplier and multiplicand, long HFP product

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic3	**Op Code**	**Operands**
MEE	'ED37'	Short HFP

Mnemonic4 $R_1,D_2(X_2,B_2)$ [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic4	**Op Code**	**Operands**
MD	'6C'	Long HFP
MDE	'7C'	Short HFP multiplier and multiplicand, long HFP product
MXD	'67'	Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDE is an alternative to the following older mnemonic that is less descriptive of operand lengths:

ME	'7C'	Short HFP multiplier and multiplicand, long HFP product

The normalized product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The operands are first normalized to eliminate leading hexadecimal zeros. The sum of the characteristics of the normalized operands, less 64, is used as the characteristic of the intermediate product.

The fraction of the intermediate product is the exact product of the normalized operand fractions. If the intermediate-product fraction has one leading hexadecimal zero digit, the fraction is shifted left one digit position, bringing the contents of the guard-digit position into the rightmost position of the result fraction, and the intermediate-product characteristic is reduced by one. The fraction is then truncated to the proper result-fraction length.

For MDE and MDER, the multiplier and multiplicand fractions have six hexadecimal digits; the product fraction has the full 14 digits of the long format, with the two rightmost fraction digits always zeros. For MEE and MEER, the multiplier and multiplicand fractions have six digits, and the final product fraction is truncated to six digits; the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

For MD and MDR, the multiplier and multiplicand fractions have 14 digits, and the final product fraction is truncated to 14 digits. For MXD and MXDR, the multiplier and multiplicand fractions have 14 digits, with the multiplicand occupying the high-order part of the first operand; the final product fraction contains 28 digits and is an exact product of the operand fractions. For MXR, the multiplier and multiplicand fractions have 28 digits, and the final product fraction is truncated to 28 digits.

An HFP-exponent-overflow exception exists when the characteristic of the final product would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

HFP exponent overflow is not recognized when the intermediate-product characteristic is initially 128 but is brought back within range by normalization.

An HFP-exponent-underflow exception exists when the characteristic of the final product would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands, as long as the final product can be represented with the correct characteristic.

If either or both operand fractions are zero, the result is made a positive true zero, and no HFP exponent overflow or HFP exponent underflow occurs.

The sign of the product is the exclusive or of the operand signs, except that the sign is always plus when the result is made a true zero.

The R_1 field for MXD, MXDR, and MXR, and the R_2 field for MXR must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MDE, MEE, MD, and MXD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Specification (MXD, MXDR, MXR)
- Transaction constraint

Programming Notes:

1. An example of the use of the MULTIPLY instruction (MDR) is given in Appendix A.
2. Interchanging the two operands in an HFP multiplication does not affect the value of the product.

MULTIPLY AND ADD

Mnemonic1 R_1,R_3,R_2 [RRD]

Op Code	R_1	////	R_3	R_2

Op Code	R_3	X_2	B_2	D_2	R_1	////	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2	Op Code	Operands
MSE	'ED2F'	Short HFP
MSD	'ED3F'	Long HFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$$op_1 = op_3 \bullet op_2 \pm op_1$$

The third and second HFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate result. The exponent and fraction of the intermediate product and intermediate result are maintained exactly. The intermediate result, if nonzero, is normalized and truncated to the operand format and then placed at the first-operand location.

The sign of the result is determined by the rules of algebra, unless the intermediate-result fraction is zero, in which case the result is made a positive true zero.

An HFP-exponent-overflow exception exists when the characteristic of the normalized result would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP exponent overflow is not recognized on intermediate values, provided the normalized result can be represented with the correct characteristic.

An HFP-exponent-underflow exception exists when the characteristic of the normalized result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

HFP exponent underflow is not recognized on input operands and intermediate values, provided the normalized result can be represented with the correct characteristic.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MAE, MAD, MSE, MSD)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Operation (if the HFP multiply-add/subtract facility is not installed)
- Transaction constraint

Programming Note: MULTIPLY AND ADD (SUBTRACT) differs from MULTIPLY followed by ADD (SUBTRACT) NORMALIZED in the following ways:

1. The product is maintained to full precision, and overflow and underflow are not recognized on the product.

2. The HFP-significance exception is not recognized for MULTIPLY AND ADD (SUBTRACT).

3. ADD (SUBTRACT) NORMALIZED maintains only a single guard digit and does not prenormalize input operands; thus, in some cases, an unnormalized input operand may cause loss of precision in the result. MULTIPLY AND ADD (SUBTRACT) maintains the entire intermediate sum (difference), which is normalized before the truncation operation is performed; thus, unnormalized operands do not cause any additional loss of precision.

4. On most models, the execution time of MULTIPLY AND ADD (SUBTRACT) is less than the combined execution time of MULTIPLY followed by ADD (SUBTRACT) NORMALIZED. The performance of MULTIPLY AND ADD (SUBTRACT) may be severely degraded in the case of unnormalized input operands.

MULTIPLY AND ADD UNNORMALIZED

Mnemonic1 R_1,R_3,R_2 [RRD]

Op Code	R_1	////	R_3	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
MAYR	'B33A'	Long HFP sources, extended HFP result
MAYHR	'B33C'	Long HFP sources, high-order part of extended HFP result
MAYLR	'B338'	Long HFP sources, low-order part of extended HFP result

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]

Op Code	R_3	X_2	B_2	D_2	R_1	////	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2	Op Code	Operands
MAY	'ED3A'	Long HFP sources, extended HFP result
MAYH	'ED3C'	Long HFP sources, high-order part of extended HFP result
MAYL	'ED38'	Long HFP sources, low-order part of extended HFP result

The second and third HFP operands are multiplied, forming an intermediate product; the first operand (addend) is then added algebraically to the intermediate product to form an intermediate sum; the intermediate-sum fraction is truncated on the left or on the right, if need be, to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R_1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

The MULTIPLY AND ADD UNNORMALIZED operations may be summarized as:

$t_1 \leftarrow op_3 \bullet op_2 + op_1$

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting in the subsequent addition.

In all cases, the first operand is located in the floating-point register designated by the R_1 field and the first-operand fraction has 14 digits.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the intermediate product and the addend are compared. If the characteristics are equal, no alignment is required. If the characteristic of the addend is smaller than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift. If the characteristic of the addend is larger than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a left shift, with its characteristic decreased by one for each hexadecimal digit of shift. Shifting continues until the two characteristics agree. All hexadecimal digits shifted out are preserved and participate in the subsequent addition.

After alignment, the fractions with signs are then added algebraically to form a signed intermediate sum. The fraction of the intermediate sum is maintained exactly. The intermediate-sum fraction is not inspected for leading hexadecimal zero digits and is not shifted. Only those 28 hexadecimal digits of the intermediate-sum fraction which are aligned with the 28 hexadecimal digits of the intermediate-product fraction are used as the fraction of the intermediate extended-result.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

The sign of the result is determined by the rules of algebra, unless the entire intermediate-sum fraction is zero, in which case the sign of the result is made positive.

For MAY and MAYR, the entire intermediate extended result is placed in the floating-point register-pair designated by the R_1 field; the R_1 field may designate either the lower-numbered or higher-numbered register of a floating-point-register pair. For MAYH and MAYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the low-order part is discarded. For MAYL and MAYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MAYH, MAY, and MAYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Transaction constraint

Programming Notes:

1. While performance of MULTIPLY AND ADD may be severely degraded for the case of unnormalized input operands, this is not the case for MULTIPLY AND ADD UNNORMALIZED.

2. MULTIPLY AND ADD UNNORMALIZED can be used to efficiently perform multiple precision arithmetic on numbers of any arbitrary size. This is accomplished by organizing the numbers into big digits of 52 bits each, with each big digit maintained as an integer in the HFP long format. Using a radix of 2^{52} and big digits which can hold up to 56 bits provides a redundant representation. This redundant representation permits multiplication and addition using a “carry save” technique and permits maximum utilization of the floating-point pipeline.

3. By setting the multiplier to an integer value of 1 with the proper characteristic, the multiplicand can be scaled by any power of 16 and then added to the addend. This permits, for example, adding the “carry” from one stage of a multiplication to the “sum” of the next stage to the left. In the same manner, the “sum” of one stage can be scaled to be added to the “carry” of the stage to the right.

4. In the first round of a multiply and accumulate, the step of clearing the accumulated value to zero, may be avoided by using the MULTIPLY UNNORMALIZED instead of MULTIPLY AND ADD UNNORMALIZED.

5. For additional notes concerning the unnormalized operations see the programming notes under the MULTIPLY UNNORMALIZED instruction.

MULTIPLY UNNORMALIZED

Mnemonic1 R_1,R_3,R_2 [RRD]

Op Code	R_1	////	R_3	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
MYR	'B33B'	Long HFP multiplier and multiplicand, extended HFP product
MYHR	'B33D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYLR	'B339'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

Mnemonic2 R_1,R_3,D_2(X_2,B_2) [RXF]

Op Code	R_3	X_2	B_2	D_2	R_1	////	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2	Op Code	Operands
MY	'ED3B'	Long HFP multiplier and multiplicand, extended HFP product
MYH	'ED3D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYL	'ED39'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

The second and third HFP operands are multiplied, forming an intermediate product, which, in turn, is used to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R_1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting as the fraction of the intermediate extended result.

The sign of the result is the exclusive or of the operand signs, including the case when the result fraction is zero.

For MY and MYR, the entire intermediate extended result is placed in the floating-point-register pair designated by the R_1 field. For MYH and MYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the low-order part is discarded. For MYL and MYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

The R_1 field for MY and MYR must designate a valid floating-point-register pair. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MYH, MY, and MYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Specification (MY and MYR)
- Transaction constraint

Programming Notes:

1. The formal definition of Long HFP numbers is in terms of a 14-digit fraction and a signed exponent in “excess-64 notation”. But, without change in function, these numbers can also be described as having a 14-digit integer and a signed exponent in “excess-78 notation”. When using the unnormalized instructions, the programmer may find it more convenient to consider these values in the later terms rather than the former. Thus, in these terms, MULTIPLY UNNORMALIZED multiplies two 14-digit integers to produce a 28-digit integer result. The characteristic of the low-order part is the sum of the operand characteristics less 78 and the high-order characteristic is set 14 larger than the low-order part. When considered as described above, MULTIPLY UNNORMALIZED provides the exact 28-digit integer product of two 14-digit integers.

2. Rather than using MY (or MYR) to provide the entire 28-digits in a floating-point-register pair, the programmer may find it more convenient to issue two separate instructions, MYH and MYL (or MYHR and MYLR), to place the high-order part and low-order part in any floating-point register. It is expected that on most machines, the performance of these two approaches is essentially the same.

3. The MULTIPLY UNNORMALIZED instruction format designates three operand locations and can be used to produce a product without overlaying the source operands. In many cases this saves an extra load.

SQUARE ROOT

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
SQER	'B245'	Short HFP
SQDR	'B244'	Long HFP
SQXR	'B336'	Extended HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
SQE	'ED34'	Short HFP
SQD	'ED35'	Long HFP

The normalized and rounded square root of the second operand is placed at the first-operand location.

When the fraction of the second operand is zero, the sign and characteristic of the second operand are ignored, and the operation is completed by placing a positive true zero at the first-operand location.

If the second operand is less than zero, an HFP-square-root exception is recognized.

If the second operand is normalized and greater than zero, the characteristic, fraction, and sign of the result are produced as follows:

- The result characteristic is one-half of the sum of the operand characteristic and either 64, if the operand characteristic is even, or 65, if it is odd.
- If the operand characteristic is odd, the operand fraction is shifted right one digit position, the rightmost digit entering the guard-digit position.
- An intermediate-result fraction is produced by computing without rounding the square root of the operand fraction, after any right shift as described. The intermediate-result fraction consists of the 29 most significant hexadecimal digits of the square-root result in the extended format, 15 in the long format, or seven in the short format, where all three formats include a guard digit on the right.
- A one is added to the leftmost bit of the guard digit of the intermediate result, any carry is prop-

agated to the left, and the guard digit is dropped to produce the result fraction.

- The result sign is made plus.

If the second operand is unnormalized and greater than zero, the operand is first normalized. The operation then proceeds as for normalized operands.

For SQXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of SQE and SQD only)
- Data with DXC 1, AFP register
- HFP square root
- Specification (SQXR only)
- Transaction constraint

Programming Notes:

1. The use of the SQUARE ROOT instruction with short operands (SQER) is illustrated by the examples in the following table:

Operand (hex)	Decimal Value	Result (hex)	Decimal Value
42 190000	25.0	41 500000	5.0
40 400000	0.250	40 800000	0.50
40 800000	0.50	40 B504F3	0.7071...
41 800000	8.0	41 2D413D	2.8284...

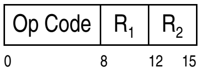
2. The result fraction is correctly normalized without any further left or right shifts of the intermediate-result fraction and without any further exponent adjustment. Rounding cannot cause a carry out of the leftmost digit.

3. Although a characteristic greater than 127 or less than zero may temporarily be generated during the operation, the result characteristic is always within the representable range, and no HFP exponent overflow or underflow occurs.

   Specifically, the smallest nonzero operand in the long format consists of a one bit, preceded on the left by 63 zeros. This operand is an unnormalized number with a value of 16^{-78}, and its square root is 16^{-39}. The normalized representation of this result has a characteristic of 26 (decimal). Similarly, the square root of the largest representable operand has a characteristic of 96 (decimal). The instruction, therefore, cannot produce a nonzero result with a characteristic outside the range of 26 to 96.

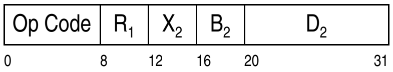
SUBTRACT NORMALIZED

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
SER	'3B'	Short HFP
SDR	'2B'	Long HFP
SXR	'37'	Extended HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic2	Op Code	Operands
SE	'7B'	Short HFP
SD	'6B'	Long HFP

The second operand is subtracted from the first operand, and the normalized difference is placed at the first-operand location.

The execution of SUBTRACT NORMALIZED is identical to that of ADD NORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

For SXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of SE and SD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (SXR only)
- Transaction constraint

SUBTRACT UNNORMALIZED

Mnemonic1 R_1,R_2 [RR]

Op Code	R_1	R_2
0	8	12 15

Mnemonic1	Op Code	Operands
SUR	'3F'	Short HFP
SWR	'2F'	Long HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]

Op Code	R_1	X_2	B_2	D_2
0	8	12	16	20 31

Mnemonic2	Op Code	Operands
SU	'7F'	Short HFP
SW	'6F'	Long HFP

The second operand is subtracted from the first operand, and the unnormalized difference is placed at the first-operand location.

The execution of SUBTRACT UNNORMALIZED is identical to that of ADD UNNORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

Resulting Condition Code:

0 Result fraction zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of SU and SW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance
- Transaction constraint

Binary-Floating-Point Facility

The binary-floating-point (BFP) facility provides instructions to operate on binary (radix-2) floating-point data.

BFP provides a number of important advantages over hexadecimal floating point (HFP):

- Greater precision and exponent range (except for numbers in the short format where HFP has the greater range).
- Automatic rounding to the nearest value for all arithmetic operations. There are directed-rounding options that may be used instead.
- Special entities of "infinity" and "Not-a-Number" (NaN), which are accepted and handled by arithmetic operations in a reasonable fashion. They provide better defaults for exponent overflow and invalid operations (such as division of zero by zero). This allows most programs to continue running without hiding such errors and without using specialized exception handlers.
- Exponent underflow gives "subnormal" numbers as the default, which provides more consistent results than the abrupt result of zero produced by the HFP instructions.
- The greater exponent range makes exponent overflow and underflow in correctly written programs very unlikely, so that programmers may often be able to ignore these conditions.
- Both mask and flag bits are provided for all IEEE exceptions. The mask bits enable or disable interruptions. When interruptions are disabled, the flag bits keep track of exceptions during execution so that warning messages may be issued.
- Programs can be migrated from and to workstations and other systems using different architectures and still give consistent results, provided that floating-point operations on the other sys-

tems also conform to ANSI/IEEE Standard 754-2008 (see Reference [20.] on page xxx). This does not mean, however, that bit-wise compatible results can be guaranteed, because the standard allows implementation flexibility, especially in the presence of exceptions.

Programming Note: The bit representation of the BFP data formats in storage is defined to be left-to-right in a manner that is uniform for all numeric operands in the z/Architecture architecture. Although the format diagrams in ANSI/IEEE Standard 754-2008 appear to use the same left-to-right bit sequence, the standard only defines the meaning of the bits without specifying how they appear in storage; the storage arrangement is left to the implementation. Several implementations in fact use other sequences; this may affect programs which are dependent on the bit representation of floating-point data in storage.

Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. The FPC register is described in the section “Floating-Point-Control (FPC) Register” on page 9-9. An overview of the FPC register is shown in Figure 9-5 on page 9-9. Details are shown in Figure 9-6 on page 9-9, Figure 9-7 on page 9-10, and in Figure 9-8 on page 9-10. (In Figure 9-6 on page 9-9, the abbreviations “IM” and “SF” are based on the terms “interruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

BFP Arithmetic

BFP Data Formats

Binary-floating-point data may be represented in any of three formats: short, long, or extended.

BFP Short Format

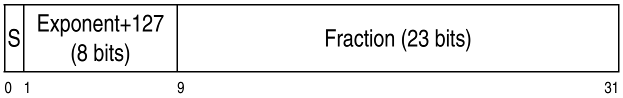

Figure 19-1. BFP Short Format (4 bytes)

When an operand in the BFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

BFP Long Format

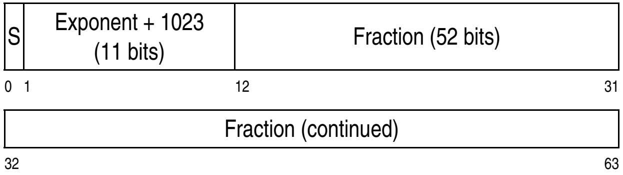

Figure 19-2. BFP Long Format (8 bytes)

When an operand in the BFP long format is loaded into a floating-point register, it occupies the entire register.

BFP Extended Format

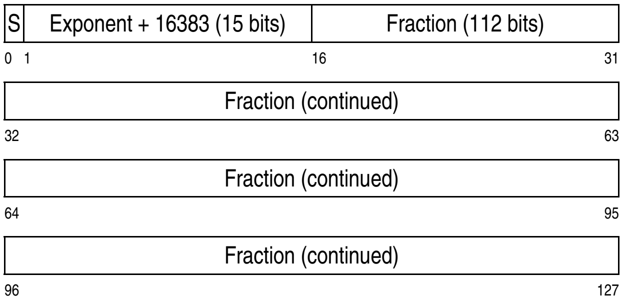

Figure 19-3. BFP Extended Format (16 bytes)

An operand in the BFP extended format occupies a register pair. The sign and biased exponent are in the leftmost 16 bits of the lower-numbered register of the pair and are followed by the leftmost 48 bits of the fraction. The rightmost 64 bits of the fraction are in the higher-numbered register of the pair.

The properties of the three formats are tabulated in Figure 19-4 on page 19-3.

Biased Exponent

For each format, the bias that is used to allow all exponents to be expressed as unsigned numbers is shown in the Figure 19-4 on page 19-3. Biased exponents are similar to the characteristics of the HFP format, except that special meanings are attached to

Property	Format		
	Short	Long	Extended
Format length (bits)	32	64	128
Biased-exponent length (bits)	8	11	15
Fraction length (bits)	23	52	112
Precision (p)	24	53	113
Maximum left-units-view (LUV) exponent (Emax)	127	1023	16383
Minimum left-units-view (LUV) exponent (Emin)	-126	-1022	-16382
Left-units-view (LUV) bias	127	1023	16383
Nmax	$(1-2^{-24})x2^{128}$ $\approx 3.4x10^{38}$	$(1-2^{-53})x2^{1024}$ $\approx 1.8x10^{308}$	$(1-2^{-113})x2^{16384}$ $\approx 1.2x10^{4932}$
Nmin	$1.0x2^{-126}$ $\approx 1.2x10^{-38}$	$1.0x2^{-1022}$ $\approx 2.2x10^{-308}$	$1.0x2^{-16382}$ $\approx 3.4x10^{-4932}$
Dmin	$1.0x2^{-149}$ $\approx 1.4x10^{-45}$	$1.0x2^{-1074}$ $\approx 4.9x10^{-324}$	$1.0x2^{-16494}$ $\approx 6.5x10^{-4966}$

Explanation:

≈ Value is approximate.
Dmin Smallest (in magnitude) representable subnormal number.
Nmax Largest (in magnitude) representable finite number.
Nmin Smallest (in magnitude) representable normal number.

Figure 19-4. Summary of BFP Data Formats

biased exponents of all zeros and all ones, which are discussed in the section “Classes of BFP Data” on page 19-4.

Significand

In each format, the binary point of a BFP number is considered to be to the left of the leftmost fraction bit. To the left of the binary point there is an implied unit bit, which is considered to be one for normal numbers and zero for zeros and subnormal numbers. The fraction with the implied unit bit appended on the left is the *significand* of the number.

The value of a normal BFP number is the significand multiplied by the radix 2 raised to the power of the unbiased exponent. The value of a subnormal BFP number is the significand multiplied by the radix 2 raised to the power of the minimum exponent.

A value of one in the rightmost bit position of the significand in each format is sometimes referred to as one ulp (unit in the last place).

Values of Nonzero Numbers

The values of nonzero numbers in the various formats are shown in Figure 19-5.

Number Class	Format	Value
Normal	Short	$\pm 2^{e-127}x(1.f)$
	Long	$\pm 2^{e-1023}x(1.f)$
	Extended	$\pm 2^{e-16383}x(1.f)$
Subnormal	Short	$\pm 2^{-126}x(0.f)$
	Long	$\pm 2^{-1022}x(0.f)$
	Extended	$\pm 2^{-16382}x(0.f)$

Explanation:

e Biased exponent (shown in decimal).
f Fraction (in binary).

Figure 19-5. Values of Nonzero Numbers

Programming Note: ANSI/IEEE Standard 754-2008 specifies minimum requirements for the extended format but does not include details. The BFP extended format meets these requirements, far exceeding them in the area of precision.

Classes of BFP Data

There are six classes of BFP data, which include numeric and related nonnumeric entities. Each data item consists of a sign, an exponent, and a significand. The exponent is biased such that all biased exponents are nonnegative unsigned numbers and the minimum biased exponent is zero. The significand consists of an explicit fraction and an implicit unit bit to the left of the binary point. The sign bit is zero for plus and one for minus.

All nonzero finite numbers permitted by a given format have a unique BFP representation. There are no unnormalized numbers, which numbers might allow multiple representations for the same values, and there are no unnormalized arithmetic operations. Tiny numbers of a magnitude below the minimum normal number in a given format are represented as *subnormal* numbers, but those values are also represented uniquely. The implied unit bit of a normal number is one, and that of a subnormal number or a zero is zero.

The six classes of BFP data are summarized in Figure 19-6 on page 19-4.

Data Class	Sign	Biased Exponent	Unit Bit*	Fraction
Zero	±	0	0	0
Subnormal numbers	±	0**	0	Not 0
Normal numbers	±	Not 0, not all ones	1	Any
Infinity	±	All ones	—	0
Quiet NaN	±	All ones	—	F0=1, Fr=any
Signaling NaN	±	All ones	—	F0=0, Fr≠0

Explanation:

—	Does not apply.
*	The unit bit is implied.
**	The biased exponent is treated arithmetically as if it had the value one.
F0	Leftmost bit of fraction.
Fr	Remaining bits of fraction.
NaN	Not-a-number.

Figure 19-6. Classes of BFP Data

The instruction TEST DATA CLASS may be used to determine the class of a BFP operand.

Zeros

Zeros have a biased exponent of zero and a zero fraction. The implied unit bit is zero. A +0 is distinct from -0, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers are numbers which are smaller than the smallest normal number and greater than zero in magnitude. They have a biased exponent of zero and a nonzero fraction. The biased exponent is treated arithmetically as if it were one, which causes the exponent to be the minimum exponent. The implied unit bit is zero. (In ANSI/IEEE Standard 754-1985, subnormal numbers were called “denormalized numbers”.)

Normal Numbers

Normal numbers have a biased exponent greater than zero but less than all ones. The implied unit bit is one, and the fraction may have any value. (In some early documentation, normal numbers were called “normalized numbers”.)

Infinities

An infinity is represented by a biased exponent of all ones and a zero fraction. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, +∞ compares greater than any finite number, and -∞ compares less than any finite number.

Signaling and Quiet NaNs

A NaN (not-a-number) entity is represented by a biased exponent of all ones and a nonzero fraction. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the leftmost fraction bit: zero for the SNaN and one for the QNaN. A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a leftmost fraction bit of one, with the remaining fraction bits being set to zeros.

Normally, QNaNs are just propagated during computations so that they will remain visible at the end. An

SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by setting the leftmost fraction bit to one, and the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Programming Notes:

1. The program can generate and assign meanings to any nonzero fraction values of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format may truncate significant bits on the right.

2. ANSI/IEEE Standard 754-2008 requires SNaNs to signal the invalid-operation exception for the arithmetic, comparison, and conversion operations that are part of the standard, but it makes it an implementation option whether copying an SNaN without a change of format signals the exception. In the appendix, the standard also makes it an implementation option whether SNaNs should signal the invalid-operation exception for the recommended functions of copying the sign, taking the absolute value, reversing the sign, and testing the data class of a datum.

   The above functions generally correspond to the instructions LOAD, LOAD COMPLEMENT, LOAD NEGATIVE, LOAD POSITIVE, and TEST DATA CLASS. These instructions do not signal the invalid-operation exception but, instead, treat SNaNs like any other data; giving an exception would be disruptive when the intention is to include SNaNs. TEST DATA CLASS does not give an exception since it is the instruction with which to test for the presence of SNaNs.

3. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option permitted by ANSI/IEEE Standard 754-2008.

4. Load-type instructions which change the precision signal the invalid-operation exception when the operand is an SNaN, as this is required by ANSI/IEEE Standard 754-2008.

BFP-Format Conversion

BFP format conversion is described in the section “IEEE Same-Radix Format Conversion” on page 9-23.

BFP Rounding

BFP rounding is described in the section “IEEE Rounding” on page 9-13.

BFP Comparison

BFP comparison is described in the section “IEEE Comparison” on page 9-24.

Remainder

The instruction DIVIDE TO INTEGER produces two floating-point results, an exact integer quotient and the corresponding remainder. The remainder is defined as follows:

Let

a = Dividend
b = Divisor
q = Exact quotient (a÷b)
r = Remainder

in the selected floating-point format. Then

$r = a - b \bullet n$

where n is an integer. If q is an integer, then n equals q. Otherwise, n is obtained by rounding q according to a final-quotient-rounding method.

When the final-quotient-rounding method is round to nearest with ties to even or round toward zero, the remainder is exact for any finite dividend and any nonzero divisor. The remainder cannot overflow.

If the integer quotient has a value that lies outside the range of the operand format, a scaled result is provided.

In certain cases where the number of bits in the integer quotient exceeds or may exceed the maximum number of bits provided in the precision of the operand format, partial results are produced, and more than one execution of the instruction is required to obtain the final result; this may be done with a simple instruction loop.

Partial results are produced when the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient. This situation exists when the precise quotient is greater than 2^P, where P is the precision of the operand format, and the remainder is not zero. When the remainder is zero, then the quotient is an integer, and the number of bits required to represent the quotient is never more than the precision of the target.

Programming Note: The remainder result of DIVIDE TO INTEGER with a final-quotient-rounding method of round to nearest with ties to even corresponds to the *Remainder* function in ANSI/IEEE Standard 754-2008. This function is similar to the *MOD* function found in some languages and to the mathematical *modulo* function, but they are not the same. They differ in the definition of n:

Remainder	n is q rounded to nearest with ties to even.
modulo	n is q rounded toward -∞.
MOD	n is q rounded toward 0.

Another important difference is that implementations of modulo and MOD may put range restrictions on the result because they may simply use the DIVIDE instruction and accept its range restrictions.

The MOD definition provides an exact result, as does Remainder, but the modulo definition may result in rounding errors.

The differences between the various methods may be illustrated by the simple example of computing a divided by b to obtain an integer quotient n, where a is a series of integers, and b is +4 or -4. Figure 19-7 shows the results for the three definitions.

	a																	
	-8	-7	-6	-5	-4	-3	-2	-1	-0	+0	+1	+2	+3	+4	+5	+6	+7	+8

r	0	+1	+2	+3	0	+1	+2	+3	0		+1	+2	+3	0	+1	+2	+3	0
b=-4: n	+2	+1	+1	+1	+1	0	0	0	0		-1	-1	-1	-1	-2	-2	-2	-2
r	0	-3	-2	-1	0	-3	-2	-1	0		-3	-2	-1	0	-3	-2	-1	0

Explanation:

a	Dividend.
b	Divisor.
n	Integer quotient.
r	Result (Remainder, MOD, or modulo).

Figure 19-7. Comparison of Remainder with MOD and Modulo

The result of Remainder lies in the range of zero to one-half the divisor, inclusive, in magnitude. A zero result is defined to have the sign of the dividend. A zero divisor is invalid.

The modulo and MOD results can both be computed from the Remainder result; the reverse may not be true, because of rounding errors and, depending on the implementation, range restrictions.

An extreme example of the rounding error that can occur with the modulo definition is the following, where the result is restricted to two significant decimal digits:

modulo(0.01,-95) = -94.99, which rounds to -95

Remainder(0.01,-95) = 0.01

The properly rounded modulo result is completely wrong since it is equal to the divisor instead of being smaller in magnitude. The Remainder result is exact and can be used to compute the theoretical result of modulo.

Remainder is included as an arithmetic operation because of its usefulness in argument reduction when computing elementary transcendental functions. Thus, SIN(X) can be computed to full precision for any value of X in degrees by first reducing the argument to Remainder(X,360).

IEEE Exceptions

The IEEE exceptions for the BFP instructions are described in the section “IEEE Exceptions” on page 9-18.

Summary of Rounding And Range Actions

Figure 19-8 summarizes the BFP rounding and range actions.

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is				
		To Nearest with ties to even	Toward 0	Toward $+\infty$	Toward $-\infty$	Prepare for shorter precision
$v < -\mathrm{Nmax}, g < -\mathrm{Nmax}$	Overflow	$-\infty$[1]	-Nmax	-Nmax	$-\infty$[1]	-Nmax
$v < -\mathrm{Nmax}, g = -\mathrm{Nmax}$	Normal	-Nmax	-Nmax	-Nmax	–	-Nmax
$-\mathrm{Nmax} \leq v \leq -\mathrm{Nmin}$	Normal	g	g	g	g	g
$-\mathrm{Nmin} < v \leq -\mathrm{Dmin}$	Tiny	d*	d	d	d*	d
$-\mathrm{Dmin} < v < -\mathrm{Dmin}/2$	Tiny	-Dmin	-0	-0	-Dmin	-Dmin
$-\mathrm{Dmin}/2 \leq v < 0$	Tiny	-0	-0	-0	-Dmin	-Dmin
$v = 0$	Exact zero difference[2]	+0	+0	+0	-0	+0
$0 < v \leq +\mathrm{Dmin}/2$	Tiny	+0	+0	+Dmin	+0	+Dmin
$+\mathrm{Dmin}/2 < v < +\mathrm{Dmin}$	Tiny	+Dmin	+0	+Dmin	+0	+Dmin
$+\mathrm{Dmin} \leq v < +\mathrm{Nmin}$	Tiny	d*	d	d*	d	d
$+\mathrm{Nmin} \leq v \leq +\mathrm{Nmax}$	Normal	g	g	g	g	g
$+\mathrm{Nmax} < v, g = +\mathrm{Nmax}$	Normal	+Nmax	+Nmax	–	+Nmax	+Nmax
$+\mathrm{Nmax} < v, +\mathrm{Nmax} < g$	Overflow	$+\infty$[1]	+Nmax	$+\infty$[1]	+Nmax	+Nmax

Explanation:

– This situation cannot occur.

* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.

[1] The nontrap result r is considered to have been incremented.

[2] The exact-zero-difference case applies only to ADD, SUBTRACT, MULTIPLY AND ADD, and MULTIPLY AND SUBTRACT. For all other BFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.

d The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value (a).

Dmin Smallest (in magnitude) representable subnormal number in the target format.

Nmax Largest (in magnitude) representable finite number in the target format.

Nmin Smallest (in magnitude) representable normal number in the target format.

Tiny	Yes	–	1	–	–	–	Yes	Yes	Tw(g÷Ψ), PIDuy(1C)

Explanation:

– The results do not depend on this condition or mask bit.
[1] This condition is true by virtue of the state of some condition to the left of this column.
[2] The IEEE-inexact-exception control (XxC) is defined only if the floating-point extension facility is installed.
Ψ Scale factor. For overflow, $\Psi = 2^{+\alpha}$. For underflow, $\Psi = 2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all BFP operations except LOAD ROUNDED, α depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For LOAD ROUNDED, α depends on the source format, and is 512 for long and 8192 for extended.
g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
r Nontrap result as defined in Part 1 of this figure.
v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-10 on page 19-11.
SFo IEEE overflow flag, FPC 1.2.
SFu IEEE underflow flag, FPC 1.3.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand location.
Tw(x) The scaled result x is placed at the target operand location. For all operations except BFP LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 19-8. Action for R(v): Rounding and Range Function (Part 2 of 2)

Result Figures

Concise descriptions of the results produced by many of the BFP instructions are made by means of figures which contain columns and rows representing all possible combinations of BFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 19-10 on page 19-11.

Data-Exception Codes (DXC) and Abbreviations

Figure 19-9 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i, z, o, u, and x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 of byte 2 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

Exception		FPC IEEE Mask Bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

Explanation:

[1] The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

[2] The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 19-9. IEEE Exception and Flag Abbreviations

Figure 19-10 on page 19-11 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

Abbr.	DXC (Hex)	Data-Exception-Code Name	Instruction Ending
PIDx	08	IEEE inexact and truncated	Complete
PIDy	0C	IEEE inexact and incremented	Complete
PIDu	10	IEEE underflow, exact	Complete, scale exponent
PIDux	18	IEEE underflow, inexact and truncated	Complete, scale exponent
PIDuy	1C	IEEE underflow, inexact and incremented	Complete, scale exponent
PIDo	20	IEEE overflow, exact	Complete, scale exponent
PIDox	28	IEEE overflow, inexact and truncated	Complete, scale exponent
PIDoy	2C	IEEE overflow, inexact and incremented	Complete, scale exponent
PIDz	40	IEEE division by zero	Suppress
PIDi	80	IEEE invalid operation	Suppress

Figure 19-10. IEEE Data-Exception Codes (DXC) and Abbreviations

Instructions

The BFP instructions and their mnemonics and operation codes are listed in Figure 19-11 on page 19-12.

The figure indicates, in the column labeled "Characteristics", the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All BFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the BFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a BFP-instruction data exception, DXC 2, is recognized.

Mnemonics for the BFP instructions are distinguished from the corresponding HFP instructions by a B in the mnemonic. Mnemonics for the BFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the BFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for BFP instructions to represent operand-format length, as follows:

F	Thirty-two-bit signed fixed point
G	Sixty-four-bit signed fixed point
LF	Thirty-two-bit unsigned fixed point
LG	Sixty-four-bit unsigned fixed point
D	Long
E	Short
X	Extended

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CEBR is the mnemonic and R_1,R_2 the operand designation.

Programming Note: The floating-point extension facility includes the following BFP features:

- The following new BFP instructions are added:
  - CONVERT FROM LOGICAL (CXLFBR, CDLFBR, CELFBR, CXLGBR, CDLGBR, and CELGBR).
  - CONVERT TO LOGICAL (CLFXBR, CLFDBR, CLFEBR, CLGXBR, CLGDBR, and CLGEBR)
- One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER
- An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD FP INTEGER.

- An effective rounding method field and an IEEE-inexact-exception control (XxC) are added to CONVERT FROM FIXED and LOAD ROUNDED.

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
AEB	'ED0A'	Short BFP
ADB	'ED1A'	Long BFP

The second operand is added to the first operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward $-\infty$, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand is an infinity and the other is a finite number, the result is that infinity. If both operands are infinities of the same sign, the result is the same infinity. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 19-13 on page 19-16 for a detailed description of the results of this instruction. (Figure 19-12 is referred to by Figure 19-13.)

For AXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of AEB and ADB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (AXBR only)
- Transaction constraint

Programming Note: Interchanging the two operands in a BFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

Value of Result (r)	Condition Code
r=0	0

Mnemonic2 R_1,D_2(X_2,B_2) [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
CEB	'ED09'	Short BFP
CDB	'ED19'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-14 on page 19-18 for a detailed description of the results of this instruction.

For CXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0	Operands equal
1	First operand low
2	First operand high
3	Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of CEB and CDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (CXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to not recognize an exception when the result is unordered due to a QNaN.

2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTHENED may be used before COMPARE to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE (a:b) when Second Operand (b) Is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN

Mnemonic2	Op Code	Operands
KEB	'ED08'	Short BFP
KDB	'ED18'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operands are treated as if they were SNaNs.

See Figure 19-16 on page 19-19 for a detailed description of the results of this instruction.

For KXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of KEB and KDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (KXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE AND SIGNAL may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.

2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTHENED may be used before COMPARE AND SIGNAL to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE AND SIGNAL (a:b) when Second Operand (b) Is

CEGBR	'B3A4'	64-bit binary-integer operand, short BFP result
CDGBR	'B3A5'	64-bit binary-integer operand, long BFP result
CXGBR	'B3A6'	64-bit binary-integer operand, extended BFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
CEFBRA	'B394'	32-bit binary-integer operand, short BFP result
CDFBRA	'B395'	32-bit binary-integer operand, long BFP result
CXFBRA	'B396'	32-bit binary-integer operand, extended BFP result
CEGBRA	'B3A4'	64-bit binary-integer operand, short BFP result
CDGBRA	'B3A5'	64-bit binary-integer operand, long BFP result
CXGBRA	'B3A6'	64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0

6 Round toward +∞
7 Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For CXFBR, CXFBRA, CXGBR, and CXGBRA, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CEFBR, CEFBRA, CDGBR, CDGBRA, CEGBR, CEGBRA)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

Instruction	Results for Instructions with a Single Operand (a) when Operand (a) Is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**
CONVERT FROM FIXED	–	Rf(a)	–	T(+0)	Rf(a)	–	–	–

SQUARE ROOT	Xi: T(dNaN)	Xi: T(dNaN)	T(-0)	T(+0)	$R(\sqrt{a})$	T(+∞)	T(a)	Xi: T(a*)

Explanation:

–	This situation cannot occur.
*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
1	The operand is extended to the longer format by appending zeros on the right before it is placed at the target operand location.
2	The NaN is shortened to the target format by truncating the rightmost bits.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 19-8 on page 19-9.
Rf(a)	The value a is converted to the precise intermediate value floating-point number v, and then action R(v) is performed.
T(x)	The value x is placed in the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-17. Results: Single-Operand Instructions

CONVERT FROM LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CELFBR	'B390'	32-bit binary-integer operand, short BFP result
CDLFBR	'B391'	32-bit binary-integer operand, long BFP result
CXLFBR	'B392'	32-bit binary-integer operand, extended BFP result
CELGBR	'B3A0'	64-bit binary-integer operand, short BFP result
CDLGBR	'B3A1'	64-bit binary-integer operand, long BFP result
CXLGBR	'B3A2'	64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CXLFBR and CXLGBR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The result always has a plus sign.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CELFBR, CDLGBR, CELGBR)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future
2. Using either the round toward 0 or the round toward -∞ rounding method produces the same result.

Mnemonic1	Op Code	Operands
CFEBR	'B398'	Short BFP operand, 32-bit binary-integer result
CFDBR	'B399'	Long BFP operand, 32-bit binary-integer result
CFXBR	'B39A'	Extended BFP operand, 32-bit binary-integer result
CGEBR	'B3A8'	Short BFP operand, 64-bit binary-integer result
CGDBR	'B3A9'	Long BFP operand, 64-bit binary-integer result
CGXBR	'B3AA'	Extended BFP operand, 64-bit binary-integer result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
CFEBRA	'B398'	Short BFP operand, 32-bit binary-integer result
CFDBRA	'B399'	Long BFP operand, 32-bit binary-integer result
CFXBRA	'B39A'	Extended BFP operand, 32-bit binary-integer result
CGEBRA	'B3A8'	Short BFP operand, 64-bit binary-integer result
CGDBRA	'B3A9'	Long BFP operand, 64-bit binary-integer result
CGXBRA	'B3AA'	Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-18 for a detailed description of the results of this instruction.

Figure 19-18. Results: CONVERT TO FIXED

Operand (a)	Is n Inexact (n≠a)	Inv.-Op. Mask (FPC 0.0)	IEEE Inexact Exception Control (XxC)	Inexact Mask (FPC 0.4)	Is n Incre-mented (|n|>|a|)	Results
NaN	–	1	–	–	–	PIDi(80)

Explanation:

– The results do not depend on this condition or mask bit.
[1] This condition is true by virtue of the state of some condition to the left of this column.
[2] The n=MP condition only applies to CFDBR, CFDBRA, CFXBR, CFXBRA, CGXBR. and CGXBRA.
[3] Floating-point extension facility is installed and XxC bit in the M$_4$ field is 1.
[4] Bit 21 of the instruction is 0, regardless of whether the floating-point extension facility is installed.
† Result differs from DFP CONVERT TO FIXED. The DFP instruction combines two cases as it does not recognize inexact for this case and does not test the inexact mask.
ccn Condition code is set to n.
f The value n converted to a fixed-point result.
n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MN Maximum negative number representable in the target fixed-point format.
MP Maximum positive number representable in the target fixed-point format.
PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 19-10 on page 19-11.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand location.

Figure 19-18. Results: CONVERT TO FIXED

If the M$_3$ field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M$_3$ field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For CFXBR, CFXBRA, CGXBR and CGXBRA, the R$_2$ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Note: Unassigned bits in the M$_4$ field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

CONVERT TO LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CLFEBR	'B39C'	Short BFP operand, 32-bit binary-integer result
CLFDBR	'B39D'	Long BFP operand, 32-bit binary-integer result
CLFXBR	'B39E'	Extended BFP operand, 32-bit binary-integer result
CLGEBR	'B3AC'	Short BFP operand, 64-bit binary-integer result
CLGDBR	'B3AD'	Long BFP operand, 64-bit binary-integer result
CLGXBR	'B3AE'	Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CLFXBR and CLGXBR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

See Figure 19-19 for a detailed description of the results of this instruction.

DIVIDE

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
DEBR	'B30D'	Short BFP
DDBR	'B31D'	Long BFP
DXBR	'B34D'	Extended BFP

Mnemonic2 R_1,D_2(X_2,B_2) [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
DEB	'ED0D'	Short BFP
DDB	'ED1D'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the first operand is divided by the second operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 19-20 on page 19-27 for a detailed description of the results of this instruction.

For DXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Dividend (a)	**Results for DIVIDE (a÷b) when Divisor (b) Is**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (DXBR only)
- Transaction constraint

DIVIDE TO INTEGER

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	**Op Code**	**Operands**
DIEBR	'B353'	Short BFP
DIDBR	'B35B'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor). An integer quotient in BFP form is produced and placed at the third-operand location. The remainder replaces the dividend at the first-operand location. The first, second, and third operands must be in different registers. The condition code indicates whether partial or final results have been produced.

The remainder result is

$r = a - b \bullet n$

where a is the dividend, b the divisor, and n an integer obtained by rounding the precise quotient

$q = a \div b$.

The first-operand result is r with the sign determined by the above expression. The third-operand result is n with a sign that is the exclusive or of the dividend and divisor signs.

If the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient, then a partial quotient and partial remainder are formed. (In all other cases, a final quotient and final remainder are formed.) This partial quotient n and the corresponding partial remainder

$r = a - b \bullet n$

are used as the results. The sign of a partial remainder is the same as the sign of the dividend. The sign of a partial quotient is the exclusive or of the dividend and divisor signs.

If the remainder is zero, then the precise quotient is an integer and can be represented exactly in the precision of the quotient.

The M_4 field, called the modifier field, specifies rounding of the final quotient. This rounding is called the “final-quotient-rounding method” as contrasted to the “current BFP rounding mode” specified by the BFP rounding-mode bits in the FPC register. The final quotient is rounded according to the final-quotient-rounding method. The final-quotient-rounding method affects only the final quotient; partial quotients are rounded toward zero.

Since the partial quotient is rounded toward zero, the partial remainder is always exact. For the final-quotient-rounding methods of round toward 0, round to nearest with ties to even, and round to nearest with ties away from 0, the final remainder is exact. For the final-quotient-rounding methods of round toward +∞ and round toward -∞, the final remainder may not be exact.

The final quotient is rounded to an integer by rounding as specified by the modifier in the M_4 field:

M_4	**Final-Quotient-Rounding Method**
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

When the floating-point extension facility is installed, a modifier of 2 and 8-15 is invalid. If the floating-point extension facility is not installed, a modifier of 2-3 and 8-15 is invalid.

When the modifier field is zero, rounding of the final quotient is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Underflow is recognized only on the final remainder, not on the partial remainder.

For the final-quotient-rounding methods of round toward +∞, round toward -∞, and round to prepare for shorter precision, the final remainder may not be exact. When, in these cases, the final remainder is inexact, it is rounded according to the current BFP rounding mode specified in the FPC register.

The sign of a zero quotient is the exclusive or of the divisor and dividend signs.

A zero remainder has the sign of the dividend.

See Figure 19-21 on page 19-29 for a detailed description of the results of this instruction.

If the quotient exponent is greater than the largest exponent that can be represented in the operand format, the correct remainder or partial remainder still is produced, and the third-operand result is the correct value, but with the exponent reduced by 192 or 1536 for short or long operands, respectively. The condition code indicates this out-of-range condition.

If the M_4 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_4 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

The R_1, R_2, and R_3 fields must designate different registers; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Remainder final; normal quotient
1 Remainder final; quotient overflow or NaN
2 Remainder partial; normal quotient
3 Remainder partial; quotient overflow

IEEE Exceptions:

- Invalid operation
- Underflow
- Inexact

Explanation:

– The results do not depend on this condition or mask bit.

[1] This condition is true by virtue of the state of some condition to the left of this column. That is, when |q| < 2^P, there cannot be a quotient overflow; the cases of remainder is zero, tiny, or inexact are mutually exclusive; and when r is exact, it is not incremented.

[2] Underflow is not recognized for a partial remainder.

# Each entry of this column is derived from the entries of the two left columns, and helps determine the specific rounding method used in some columns on the right and determine the resulting condition code setting.

Ψ Scale factor. For overflow, $\Psi = 2^{+\alpha}$. For underflow, $\Psi = 2^{-\alpha}$. The unsigned scaling exponent (α) depends on the operand format and is 192 for short and 1536 for long.

|q| The absolute value of q, where q is the precise intermediate value of a÷b before rounding, assuming unbounded precision and unbounded exponent range.

cc0 Condition code is set to 0 (remainder final; normal quotient).

cc1 Condition code is set to 1 (remainder final; quotient overflow).

cc2 Condition code is set to 2 (remainder partial; normal quotient).

cc3 Condition code is set to 3 (remainder partial; quotient overflow).

n Integer quotient. n = q, rounded toward 0 for partial results and rounded according to the final-quotient-rounding method for final results. The sign of the integer quotient, including the cases of partial and final, scaled value, and zero, is the exclusive or of the signs of the dividend (a) and divisor (b).

r Remainder. r = a-b•n. A partial remainder is always exact; no rounding is necessary. The sign of a partial remainder is always the same as the sign of the dividend (a). A final remainder is rounded according to the current BFP rounding mode (if necessary) specified in the FPC register. The sign of a zero remainder is the same as the sign of the dividend (a). The sign of a nonzero final remainder is determined by the rules of algebra.

P Precision of the operand, which depends on the target format: P = 24 for short and 53 for long.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-10 on page 19-11.

SFi IEEE invalid-operation flag, FPC 1.0.

SFu IEEE underflow flag, FPC 1.3.

SFx IEEE inexact flag, FPC 1.4.

T(r,n) Results r (the remainder) and n (the integer quotient) are placed in target operands 1 and 3, respectively.

Figure 19-21. Results: DIVIDE TO INTEGER (Part 2 of 2)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

1. The Remainder operation, as defined in ANSI/IEEE Standard 754-2008, is produced by issuing DIVIDE TO INTEGER in an iterative loop, with the M_4 field set to 4.

2. The rounding specifications of round to nearest with ties to even, round toward 0, and round toward -∞ permit the instruction to be used directly to produce the Remainder, MOD, and modulo functions, respectively.

3. When DIVIDE TO INTEGER is used in an iterative loop, all quotients are produced in BFP format but may be considered as portions of a multiple-precision fixed-point number.

4. In the case when the resulting remainder is subnormal, ANSI/IEEE Standard 754-2008 requires that if traps are implemented and the underflow mask is one, then an underflow trap must occur. To accomplish this, DIVIDE TO INTEGER recognizes underflow on the final remainder but not on the partial remainder. Since in all cases when underflow exists on the partial remainder it will also exist on the final remainder, recognizing underflow on only the final remainder avoids two underflow traps to be reported for what ANSI/IEEE Standard 754-2008 considers a single Remainder operation.

LOAD AND TEST

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
LTEBR	'B302'	Short BFP
LTDBR	'B312'	Long BFP
LTXBR	'B342'	Extended BFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is placed unchanged at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LTXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LTXBR only)
- Transaction constraint

Programming Note: LOAD AND TEST signals invalid operation when the operand is an SNaN. TEST DATA CLASS may be used to test an operand if signaling is not desired.

LOAD COMPLEMENT

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
LCEBR	'B303'	Short BFP
LCDBR	'B313'	Long BFP
LCXBR	'B343'	Extended BFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is inverted for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LCXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LCXBR only)
- Transaction constraint

Programming Note: LOAD COMPLEMENT does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

LOAD FP INTEGER

Mnemonic1 R_1,M_3,R_2 [RRF-e]

Op Code	M_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
FIEBR	'B357'	Short BFP
FIDBR	'B35F'	Long BFP
FIXBR	'B347'	Extended BFP

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
FIEBRA	'B357'	Short BFP
FIDBRA	'B35F'	Long BFP
FIXBRA	'B347'	Extended BFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

In the absence of an interruption, if the second operand is an infinity or a QNaN, the result is that operand; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-22 on page 19-33 for a detailed description of the results of this instruction.

If the M_3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For FIXBR and FIXBRA, the R fields must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction

- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

1. LOAD FP INTEGER rounds a BFP number to an integer value. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.

2. If the BFP operand is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

3. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

Operand (a)	Is n Inexact (n≠a)	Inv.-Op. Mask (FPC 0.0)	IEEE Inexact Exception Control (XxC)[2]	Inexact Mask (FPC 0.4)	Is n Incremented (|n|>|a|)	Results
-∞	No[1]	–	–	–	–	T(-∞)
-Fn	No	–	–	–	–	T(n)

+Fn	Yes	–	0	0	–	T(n), SFx←1
+Fn	Yes	–	0	1	No	T(n), PIDx(08)
+Fn	Yes	–	0	1	Yes	T(n), PIDy(0C)
+∞	No[1]	–	–	–	–	T(+∞)
QNaN	No[1]	–	–	–	–	T(a)
SNaN	No[1]	0	–	–	–	T(a*), SFi←1
SNaN	No[1]	1	–	–	–	PIDi(80)

Explanation:

– The results do not depend on this condition or mask bit.
* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
[1] This condition is true by virtue of the state of some condition to the left of this column.
[2] XxC is defined only if the Floating-point extension facility is installed.
n The value derived when the source value, a, is rounded to a floating-point integer using the effective rounding mode.
Fn Finite nonzero number (includes both subnormal and normal).
PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-10 on page 19-11.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand location.

Figure 19-22. Results: LOAD FP INTEGER

LOAD LENGTHENED

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
LDEBR	'B304'	Short BFP operand 2, long BFP operand 1
LXDBR	'B305'	Long BFP operand 2, extended BFP operand 1
LXEBR	'B306'	Short BFP operand 2, extended BFP operand 1

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
LDEB	'ED04'	Short BFP operand 2, long BFP operand 1
LXDB	'ED05'	Long BFP operand 2, extended BFP operand 1
LXEB	'ED06'	Short BFP operand 2, extended BFP operand 1

The second operand is converted to a longer format, and the result is placed at the first-operand location.

When the second operand is a finite number, the value of the second operand is placed in the target format. The exponent of the second operand is converted to the corresponding exponent in the result format, and the fraction is extended by appending zeros on the right.

If the second operand is an infinity, the result is an infinity of the same sign. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LXDB, LXDBR, LXEB, and LXEBR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of LDEB, LXEB, and LXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LXEB, LXEBR, LXDB, LXDBR)
- Transaction constraint

LOAD NEGATIVE

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
LNEBR	'B301'	Short BFP
LNDBR	'B311'	Long BFP
LNXBR	'B341'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made one.

The sign bit is made one even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LNXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 --
3 Result is a NaN

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LNXBR only)
- Transaction constraint

Programming Note: LOAD NEGATIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

LOAD POSITIVE

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
LPEBR	'B300'	Short BFP
LPDBR	'B310'	Long BFP
LPXBR	'B340'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made zero.

The sign bit is made zero, and the rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LPXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 --
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LPXBR only)
- Transaction constraint

Programming Note: LOAD POSITIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

LOAD ROUNDED

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
LEDBR	'B344'	Long BFP source, short BFP target, short or long BFP result
LDXBR	'B345'	Extended BFP source, long BFP target, long or extended BFP result
LEXBR	'B346'	Extended BFP source, short BFP target, short or extended BFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
LEDBRA	'B344'	Long BFP source, short BFP target, short or long BFP result
LDXBRA	'B345'	Extended BFP source, long BFP target, long or extended BFP result
LEXBRA	'B346'	Extended BFP source, short BFP target, short or extended BFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

When the floating-point extension facility is installed, the second operand, if a finite number, is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward $+\infty$
7	Round toward $-\infty$

An M_3 modifier other than 0, 1, or 3-7 is invalid. The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the second operand is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

In the absence of IEEE-trap action for overflow or underflow, the result is in the format and length of the target. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. For LEDBR, LEDBRA, LEXBR and LEXBRA, the result has at most 23 significand fraction bits; for LDXBR and LDXBRA, the result has at most 52 significand fraction bits.

A short-format result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. A long-format result is placed in a floating-point register, and the other register of the floating-point register pair, if any, remains unchanged. An extended-format result is placed in a floating-point register pair.

The sign of the result is the same as the sign of the second operand.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bit 21 of the instruction is zero, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bit 21 of the instruction is one, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For LDXBR, LDXBRA, LEXBR, and LEXBRA, the R_1 and R_2 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

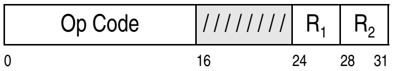
1. The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

2. The R_1 field for LDXBR, LDXBRA, LEXBR, and LEXBRA must designate a valid floating-point-register pair since in certain cases the result is in the extended format. In normal operation for LDXBR, LDXBRA, LEXBR and LEXBRA, the result format is long or short, respectively, and this result replaces the leftmost 32 bits or 64 bits of the target-register pair. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by placing a result in the extended format at the target location. Thus, the program must take into account the fact that these instructions sometimes update both registers of the pair.

3. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future

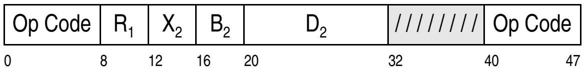
MULTIPLY

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
MEEBR	'B317'	Short BFP
MDBR	'B31C'	Long BFP
MXBR	'B34C'	Extended BFP
MDEBR	'B30C'	Short BFP multiplier and multiplicand, long BFP product
MXDBR	'B307'	Long BFP multiplier and multiplicand, extended BFP product

Mnemonic2 R_1,D_2(X_2,B_2) [RXE]



Mnemonic2	Op Code	Operands
MEEB	'ED17'	Short BFP
MDB	'ED1C'	Long BFP
MDEB	'ED0C'	Short BFP multiplier and multiplicand, long BFP product
MXDB	'ED07'	Long BFP multiplier and multiplicand, extended BFP product

The product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

The two BFP operands, if finite numbers, are multiplied, forming an intermediate product. For MDEB, MDEBR, MXDB, and MXDBR, the intermediate product is converted to the longer target format; the result cannot overflow or underflow and is exact. For MDB, MDBR, MEEB, MEEBR, and MXBR, the result is rounded to the operand format according to the current BFP rounding mode. For MEEB and MEEBR, the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

If one operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 19-23 on page 19-38 for a detailed description of the results of this instruction.

The R_1 field for MXDB, MXDBR, and MXBR, and the R_2 field for MXBR, must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Underflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Inexact (MDB, MDBR, MEEB, MEEBR, MXBR)

Program Exceptions:

- Access (fetch, operand 2 of MDEB, MEEB, MDB, and MXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (MXDB, MXDBR, MXBR)
- Transaction constraint

Programming Note: Interchanging the two operands in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

First Operand (a) Is	Results for MULTIPLY (a•b) when Second Operand (b) Is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(b)	Xi: T(b*)
-Fn	T(+∞)	R(a•b)	T(+0)	T(-0)	R(a•b)	T(-∞)	T(b)	Xi: T(b*)
-0	Xi: T(dNaN)	T(+0)	T(+0)	T(-0)	T(-0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+0	Xi: T(dNaN)	T(-0)	T(-0)	T(+0)	T(+0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+Fn	T(-∞)	R(a•b)	T(-0)	T(+0)	R(a•b)	T(+∞)	T(b)	Xi: T(b*)
+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(b)	Xi: T(b*)
QNaN	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	Xi: T(b*)
SNaN	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 19-8 on page 19-8.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

MSEB	'ED0F'	Short BFP
MSDB	'ED1F'	Long BFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$op_1 = op_3 \bullet op_2 \pm op_1$

When the operands are finite numbers, the third and second BFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

See Figure 19-24 for a detailed description of the results of MULTIPLY AND ADD. The results of MUL-

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
P(x)	The value x is passed to Part 2 of this figure.
R(v)	Rounding and range action is performed on the value v. See Figure 19-8 on page 19-8.
Rezd	Exact zero-difference result. See Figure 19-8 on page 19-8.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-24. Results: MULTIPLY AND ADD (Part 2 of 2)

TIPLY AND SUBTRACT are the same, except that the first operand, if numeric, participates in the operation with its sign bit inverted. When the first operand is a NaN, it participates in the operation with its sign bit unchanged.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of MAEB, MADB, MSEB, MSDB)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Transaction constraint

Programming Note: MULTIPLY AND ADD and MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

SQUARE ROOT

Mnemonic1 R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

SQDBR	'B315'	Long BFP
SQXBR	'B316'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
SQEB	'ED14'	Short BFP
SQDB	'ED15'	Long BFP

The square root of the second operand is placed at the first-operand location.

The result rounded according to the current BFP rounding mode is placed at the first-operand location.

If the second operand is a positive finite number, the result is the square root of that number with a plus sign. If the operand is a zero of either sign, the result is a zero of the same sign. If the operand is $+\infty$, the result is $+\infty$.

If the second operand is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 19-17 on page 19-21 for a detailed description of the results of this instruction.

For SQXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of SQEB and SQDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SQXBR only)
- Transaction constraint

SUBTRACT

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic1	Op Code	Operands
SEBR	'B30B'	Short BFP
SDBR	'B31B'	Long BFP
SXBR	'B34B'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic2	Op Code	Operands
SEB	'ED0B'	Short BFP
SDB	'ED1B'	Long BFP

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the second operand, if numeric, participates in the operation with its sign bit inverted. When the second operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 19-13 on page 19-16 for the detailed results of ADD.

For SXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of SEB and SDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SXBR only)
- Transaction constraint

TEST DATA CLASS

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]

Op Code	R_1	X_2	B_2	D_2	////////	Op Code
0	8	12	16	20	32	40 47

Mnemonic	Op Code	Operands
TCEB	'ED10'	Short BFP
TCDB	'ED11'	Long BFP
TCXB	'ED12'	Extended BFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of BFP data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 19-25, BFP operands are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

	Bit Used when Sign Is	
BFP Operand Class	**+**	**-**
Zero	52	53
Normal number	54	55
Subnormal number	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 19-25. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TCXB, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (TCXB only)
- Transaction constraint

Programming Notes:

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, DFP TEST DATA CLASS uses bits 54 and 55 for subnormal number, and bits 56 and 57 for normal number.

Decimal-Floating-Point Facility

The decimal-floating-point (DFP) facility provides instructions to operate on decimal (radix-10) floating-point data. The facility was designed in cooperation with the IEEE floating-point working group.

Additionally, this facility was designed to support a common library for various systems. This facility in both the z/architecture and Power architectures supports the same data formats, the same rounding methods, the same functions, and the same exceptions.

DFP has a number of important characteristics:

- It produces results consistent with decimal arithmetic as taught in elementary school.
- It recognizes the quantum of a finite number, maintains quantum information through arithmetic operations, and provides special operations to extract, compare, and adjust the quantum.
- It provides greater exponent range than hexadecimal-floating-point (HFP) and binary-floating-point (BFP) while maintaining comparable precision.
- It provides greater precision and better space efficiency than provided by the decimal-arithmetic instructions and the packed-decimal format as described in Chapter 8, “Decimal Instructions.”
- It supports IEEE flags, exceptions, and special entities of “infinity” and “Not-a-Number” (NaN).
- It supports eight automatic rounding methods. For DFP computational instructions, an explicit rounding method can be specified in a modifier field in the instruction.
- It facilitates production of DFP results with a precision other than any supported format precision and with the effect of single rounding.
- It provides operations for conversion between fixed-point and DFP formats.
- It provides operations for conversion between packed-decimal and DFP formats.
- It provides three-operand nondestructive arithmetic operations by permitting different target-operand registers from source-operand registers.

The DFP facility uses the same 16 floating-point registers as those used by HFP and BFP. A set of radix-independent floating-point-support instructions can be used to load, store, or change the sign of a DFP operand. These instructions are defined in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP facility uses the same floating-point-control (FPC) register as that used by BFP. The bits of the FPC register are often referred to as, for example, FPC1.0, meaning bit 0 of byte 1 of the register. The description of the FPC register, including the DFP-rounding-mode field, and the instructions that operate on the FPC register are provided in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP computational model, a high-level overview of the computational steps, is described in the section “IEEE Computational Operations” of Chapter 9, “Floating-Point Overview and Support Instructions.” Detailed definitions of rounding methods and IEEE exceptions supported by DFP are also described in the section.

DFP Arithmetic

Finite Floating-Point Number

A finite floating-point number has three components: a sign, an exponent, and a significand. The magnitude of a finite number is the product of significand multiplied by the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

Cohort

Finite decimal-floating-point (DFP) numbers are not necessarily normalized; that is, the leftmost significand digit may be zero. This allows some values to have multiple representations; each with a different combination of the significand and the exponent. The set of different representations for a value of the same sign is called a cohort; and each representation in a cohort is called a cohort member. A positive zero and a negative zero have the same value but are in different cohorts.

Quantum

For a DFP finite number, the magnitude of a value of one in the rightmost digit position of the significand is called the quantum. Each cohort member of a cohort uses a different quantum to represent the same value. Regardless of whether the left-units view or right-units view is taken, the quantum of a cohort member is the same.

Preferred Quantum

For operations that produce a DFP result, when, in the absence of a trap overflow or a trap underflow, the delivered value is a finite number, a value, called the preferred quantum, is defined to select a cohort member to represent the delivered value. The preferred quantum for each of these operations is shown in Figure 20-4 on page 20-10. When the delivered value is exact, the preferred quantum depends on the operation. When the delivered value is inexact, the preferred quantum is the smallest quantum of the cohort members, unless otherwise stated.

Scaled Preferred Quantum

For operations that produce a DFP result, when a trap overflow or a trap underflow occurs, a scaled preferred quantum is used to select a cohort member to represent the delivered value. The scaled preferred quantum is obtained by scaling the preferred quantum using the same scale factor as that used to obtain the delivered value.

Delivered Quantum

Normally, when the delivered value is a finite number, the result is selected from the cohort for the delivered value in the target format. However, in case of a trap overflow or trap underflow for LOAD ROUNDED, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format.

In the absence of a trap overflow or trap underflow, if the delivered value is a finite number, the cohort member with the quantum closest to the preferred quantum is selected.

In case of a trap overflow or trap underflow, the cohort member with the quantum closest to the scaled preferred quantum is selected.

Special Quantum-Handling Operations

Special operations are provided to handle the quantum: COMPARE BIASED EXPONENT can be used to compare two quanta; EXTRACT BIASED EXPONENT can be used to determine the quantum of a finite number; and QUANTIZE can be used to adjust the quantum of a finite number.

Programming Notes:

1. Many financial applications and commercial databases use scaled integer representation of decimal data. Calculations are carried out by using integer arithmetic and scaling factors are tracked separately; the scaling factor is often an attribute of a column in the database.

   This computational model can be supported by DFP by allowing the integer part of decimal data to map into the significand with a right-units view and the scaling factor to map into the quantum.

2. The term coefficient is used in some other documents to mean an integer value in significand; that is, significand in right-units view.

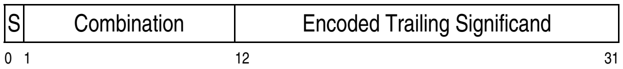
DFP Data Formats

Decimal-floating-point data may be represented in any of three data formats: short, long, or extended.

The contents of each data format represent encoded information. Special codes are assigned to distinguish finite numbers from NaNs and infinities.

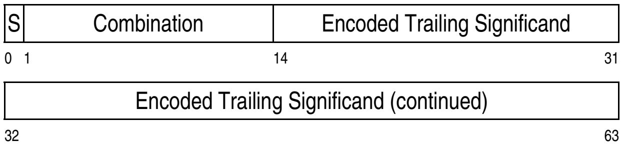
For finite numbers, a biased exponent is used in the format. For each format, a different bias is used for right-units-view (RUV) exponents from that for left-units-view (LUV) exponents. The biased exponents are unsigned numbers and all biases are shown in Figure 20-3 on page 20-6. The biased exponent is encoded with the leftmost digit (LMD) of the significand in the combination field. The remaining digits of the significand are encoded in the encoded trailing-significand field.

DFP Short Format



When an operand in the DFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

DFP Long Format



S
Combination
Encoded Trailing Significand
0
1
14
31
Encoded Trailing Significand (continued)
32
63

When an operand in the DFP long format is loaded into a floating-point register, it occupies the entire register.

DFP Extended Format

S	Combination	Encoded Trailing Significand
0	18	31

Encoded Trailing Significand (continued)
32 63

Encoded Trailing Significand (continued)
64 95

Encoded Trailing Significand (continued)
96 127

An operand in the DFP extended format occupies a register pair. The leftmost 64 bits occupy the entire lower-numbered register of the pair and the rightmost 64 bits occupy the entire higher-numbered register.

The properties of the three formats are tabulated in Figure 20-3 on page 20-6.

Sign

The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

Combination

For finite numbers, this field contains the biased exponent and the leftmost digit of the significand; for NaNs and infinities, this field contains codes to identify them.

When bits 1-5 of the format are in the range of 00000 - 11101, the operand is a finite number. The two leftmost bits of the biased exponent and the leftmost digit of the significand are encoded in bits 1-5 of the format. Bit 6 through the end of the combination field contain the rest of the biased exponent.

When bits 1-5 of the format field are 11110, the operand is an infinity. All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity. A nonzero value in the reserved field is accepted in a source infinity; the reserved field is set to zero in a resultant infinity.

When bits 1-5 of the format are 11111, the operand is a NaN and bit 6, called the SNaN bit, further distinguishes QNaN from SNaN. If bit 6 is zero, then it is QNaN; otherwise, it is SNaN. All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN. A nonzero value in the reserved field is accepted in a source NaN; the reserved field is set to zero in a resultant NaN.

Figure 20-1 summarizes the encoding and layout of the combination field. In the figure, the biased exponent of a finite number is the concatenation of two parts: (1) two leftmost bits are derived from bits 1-5 of the format, and (2) the remaining bits in the combination field. For example, if the combination field of the DFP short format contains 10101010101 binary, it represents a biased exponent of 10010101 binary and a leftmost significand digit of 5.

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD

Figure 20-1. The Combination Field

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD
11111	1	SNaN[2]	--	--

Explanation:

--	Not applicable.
|	Concatenation.
[1]	All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity.
[2]	All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN.
LMD	Leftmost digit of the significand.
m	Bit 6 is a part of the remaining biased exponent.
RBE	Remaining biased exponent. It includes all bits in the combination field to the right of bit 5 of the format.
r	Bit 6 is a reserved bit for infinity.

Figure 20-1. The Combination Field (Continued)

Encoded Trailing Significand

This field contains an encoded decimal number, which represents digits in the trailing significand. The trailing significand contains all significand digits, except the leftmost digit. For infinities, nonzero trailing-significand digits are accepted in a source infinity; all trailing-significand digits in a resultant infinity are set to zeros, unless otherwise stated. For NaNs, this field contains diagnostic information called the payload.

The encoded trailing-significand field is a multiple of 10-bit blocks called declets. The number of declets depends on the format. Each declet represents three decimal digits in a 10-bit value. This is described in the section, “Densely Packed Decimal (DPD)” on page 20-58.

Values of Finite Numbers

The values of finite numbers in the various formats are shown in Figure 20-2.

Format	Value	
	Left-Units View	Right-Units View
Short	$\pm 10^{e-95} \times (d_0.d_1d_2...d_6)$	$\pm 10^{e-101} \times (d_0d_1d_2...d_6)$
Long	$\pm 10^{e-383} \times (d_0.d_1d_2...d_{15})$	$\pm 10^{e-398} \times (d_0d_1d_2...d_{15})$
Extended	$\pm 10^{e-6143} \times (d_0.d_1d_2...d_{33})$	$\pm 10^{e-6176} \times (d_0d_1d_2...d_{33})$

Explanation:

$d_0.d_1d_2\ldots d_{p-1}$	Significand in left-units view. The decimal point is to the immediate right of the leftmost digit and d_i is a decimal digit, where $0 \le i \le (p - 1)$ and p is the format precision.
$d_0d_1d_2\ldots d_{p-1}$	Significand in right-units view. The decimal point is to the right of the rightmost digit and d_i is a decimal digit, where $0 \le i \le (p - 1)$ and p is the format precision.
e	Biased exponent.

Figure 20-2. Values of Finite Numbers

Programming Note: The RUV exponent, Q, is related to the LUV exponent, E, as follows: Q = E - p + 1, where p is the format precision.

Significand

Hereafter, the term significand is used to mean the following:

1. For finite numbers, the significand contains all trailing significand digits padded on the left with the leftmost digit of significand derived from the combination field.
2. For infinities and NaNs, the significand contains all trailing significand digits padded on the left with a zero digit.

DFP Significant Digits

For a finite number, the DFP significant digits begin with the leftmost nonzero significand digit and end with the rightmost significand digit.

For a finite number, the number of DFP significant digits is the difference of subtracting the number of leading zeros from the format precision. The number of leading zeros is the number of zeros in the significand to the left of the leftmost nonzero digit.

Programming Note: The number of DFP significant digits of the value zero is zero.

Property	Format		
	Short	Long	Extended
Format length (bits)	32	64	128
Combination length (bits)	11	13	17
Encoded Trailing significand length (bits)	20	50	110
Precision (p)	7	16	34
Maximum left-units-view (LUV) exponent (Emax)	96	384	6144
Minimum left-units-view (LUV) exponent (Emin)	-95	-383	-6143
Left-units-view (LUV) bias	95	383	6143
Maximum right-units-view (RUV) exponent (Qmax)	90	369	6111
Minimum right-units-view (RUV) exponent (Qmin)	-101	-398	-6176
Right-units-view (RUV) bias	101	398	6176
Maximum biased exponent	191	767	12,287
Nmax	$(10^{7} - 1) \times 10^{90}$	$(10^{16} - 1) \times 10^{369}$	$(10^{34} - 1) \times 10^{6111}$
Nmin	1×10^{-95}	1×10^{-383}	1×10^{-6143}
Dmin	1×10^{-101}	1×10^{-398}	1×10^{-6176}

Explanation:

Dmin	Smallest (in magnitude) subnormal number.
Nmax	Largest (in magnitude) normal number.
Nmin	Smallest (in magnitude) normal number,

Figure 20-3. Summary of DFP Formats

Canonical Declets

The trailing significand digits in a DFP data format are encoded by representing three decimal digits with a 10-bit declet. Of the 1024 possible declets, 1000 canonical declets are produced in resultant DFP operands, and 24 noncanonical declets are not produced as DFP results. Both canonical and noncanonical declets are accepted in source DFP operands. The encoding of a canonical declet or noncanonical declet is described in the section, “Densely Packed Decimal (DPD)” on page 20-58.

DFP Canonical Data

A finite number is canonical when all declets are canonical declets.

An infinity is canonical when the reserved field is zero and all digits in the trailing significand are zeros.

A NaN is canonical when the reserved field is zero and all declets are canonical declets.

Programming Note: To ensure compatibility with future extensions and interchangeability between software routines, only DFP canonical data should be used.

Classes of DFP Data

There are six classes of DFP data: zero, subnormal number, normal number, infinity, signaling NaN, and quiet NaN. The zero, subnormal number, and normal number data classes are collectively called finite numbers. The instruction TEST DATA CLASS may be used to determine the class of a DFP operand.

Zeros

Zeros have a zero significand and any representable value in the biased exponent. A +0 is distinct from a -0 and zeros with different biased exponents are distinct, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers are numbers which are smaller than Nmin and larger than zero in magnitude.

Normal Numbers

Normal numbers are numbers whose magnitude is between Nmin and Nmax inclusively.

Infinities

An infinity is represented by 11110 binary in bits 1-5 of the data format. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, +∞ compares greater than any finite number, and -∞ compares less than any finite number. All +∞ are compared equal and all -∞ are compared equal.

Signaling and Quiet NaNs

A NaN (Not-a-Number) is represented by 11111 binary in bits 1-5 of the data format. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from a quiet NaN (QNaN) by bit 6, the SNaN bit, of the data format: zero for the QNaN and one for the SNaN. A special QNaN, called the default QNaN, is supplied as the nontrap result for an IEEE-invalid-operation exception; it has a plus sign, and the SNaN bit, the reserved field, and the payload are set to zeros.

Normally, source QNaNs are canonicalized to become the resultant QNaN that has the same sign and payload as the source during operations so that they will remain visible at the end. (See the section “Canonicalization” on page 20-7 for details.) An SNaN operand causes an IEEE invalid-operation exception, unless otherwise stated. When the exception is recognized for a SNaN, the nontrap result is the corresponding QNaN**,** which is produced by setting the SNaN bit in the source SNaN to zero and then the converted QNaN is canonicalized, and the IEEE-invalid-operation flag (FPC 1.0) is set to one.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Canonicalization

For operations that are defined to produce a DFP result, the result placed at the target operand location is canonical, unless otherwise stated.

Programming Notes:

1. The following instructions may produce a noncanonical infinity as the result:

   - INSERT BIASED EXPONENT
   - LOAD LENGTHENED
   - LOAD ROUNDED
   - SHIFT SIGNIFICAND LEFT
   - SHIFT SIGNIFICAND RIGHT

   Infinities produced as a DFP result have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. However, the infinity produced by the above instructions does not necessarily have zeros in all digits in the trailing significand. Such an infinity is not canonical.

2. Only canonical operands should be used, as it is possible that some libraries or software routines reject noncanonical operands.

3. Except for INSERT BIASED EXPONENT, if only canonical source operands are used, the result is canonical. INSERT BIASED EXPONENT may produce a noncanonical result even if all source operands are canonical. Special precautions should be taken to avoid producing a noncanonical result from INSERT BIASED EXPONENT.

DFP-Format Conversion

DFP format conversion is described in the section “IEEE Same-Radix Format Conversion” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Rounding

DFP rounding is described in the section “IEEE DFP Rounding” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Comparison

DFP comparison is described in the section “IEEE Comparison” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Formatting Instructions

A set of instructions are provided to compose and decompose DFP data. These instructions do not recognize any IEEE exceptions. They are:

- CONVERT FROM PACKED
- CONVERT FROM SIGNED PACKED
- CONVERT FROM UNSIGNED PACKED
- CONVERT FROM ZONED
- CONVERT TO PACKED
- CONVERT TO SIGNED PACKED
- CONVERT TO UNSIGNED PACKED
- CONVERT TO ZONED
- EXTRACT BIASED EXPONENT
- INSERT BIASED EXPONENT
- SHIFT SIGNIFICAND LEFT
- SHIFT SIGNIFICAND RIGHT

Conversion of data between character strings in an external format and the DFP format may be performed in several steps. At certain steps, for finite numbers, the significand is kept in the packed-decimal format and the biased exponent in the fixed-point format. See Chapter 8, “Decimal Instructions,” for a detailed description of the zoned and packed-decimal formats.

It takes 17 packed-decimal digits to hold the 16 significand digits and one sign of a long DFP format; it takes 35 packed-decimal digits for an extended DFP format. To facilitate the conversion, the significand is divided into pieces and only one piece contains the sign. Each piece fits into a register or a register pair, and each piece is converted separately. To support this piecemeal conversion, two formats, signed-packed-decimal and unsigned-packed-decimal, are used to hold the pieces.

To facilitate the conversion between packed-decimal format data in memory and the DFP format, the CONVERT FROM PACKED and CONVERT TO PACKED instructions are provided. It takes up to 9 bytes to hold the 16 significand digits and one sign digit of a long DFP format. It takes up to 18 bytes to hold the 34 significand digits and one sign digit for an extended DFP format. Any unused digits in a packed-decimal format operand of CONVERT FROM PACKED must be zero.

For a zoned-decimal format, it takes 16 bytes to hold the 16 significand digits and one sign digit of a long DFP format; it takes 34 bytes for an extended DFP format. To facilitate the conversion, the CONVERT FROM ZONED and CONVERT TO ZONED instructions are provided.

Signed-Packed-Decimal Format

In the signed-packed-decimal format, each byte contains two 4-bit decimal digits (D), except for the rightmost byte, which contains a 4-bit sign (S) to the right of a 4-bit decimal digit.

When a signed-packed-decimal operand resides in a general register (GR), the operand is 64 bits (15 digits and sign), as shown below.

GR	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	S
	0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60 63

When a signed-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.

GR_{even}	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D
	0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60 63
GR_{odd}	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	S
	64	68	72	76	80	84	88	92	96	100	104	108	112	116	120	127

Unsigned-Packed-Decimal Format

In the unsigned-packed-decimal format, each byte contains two 4-bit decimal digits (D) and there is no sign.

When an unsigned-packed-decimal operand resides in a general register, the operand is 64 bits (16 digits), as shown below.

GR	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D
	0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60 63

When an unsigned-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.

GR_{even}	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D
	0	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60 63
GR_{odd}	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D
	64	68	72	76	80	84	88	92	96	100	104	108	112	116	120	127

Zoned-Decimal Format

In the unsigned zoned-decimal format, each byte contains two fields, a zone field in the leftmost four bit positions and a decimal digit in the rightmost four bit positions. The signed zoned-decimal format is similar to the unsigned zoned-decimal format except that the zone field of the rightmost byte instead contains a 4-bit sign. A zoned-decimal operand is a storage operand. See “Zoned Format” on page 8-1 for more details.

IEEE Exceptions

The IEEE exceptions for the DFP instructions are described in the section “IEEE Exceptions” on page 9-18. This also includes the quantum exception.

Summary of Preferred Quantum

Figure 20-4 summarizes all preferred quanta.

Operations	Delivered value	Preferred Quantum
ADD	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members
CONVERT FROM FIXED	Exact	One†
	Inexact	The smallest quantum of cohort members
CONVERT FROM LOGICAL	Exact	One†
	Inexact	The smallest quantum of cohort members
CONVERT FROM PACKED	—	One
CONVERT FROM SIGNED PACKED	—	One
CONVERT FROM UNSIGNED PACKED	—	One
CONVERT FROM ZONED	—	One
DIVIDE	Exact	The quantum of the dividend divided by the quantum of the divisor†
	Inexact	The smallest quantum of cohort members
INSERT BIASED EXPONENT	—	The quantum corresponds to the requested biased exponent
LOAD AND TEST	—	The quantum of the source operand
LOAD FP INTEGER	Exact	The larger value of one and the quantum of the source operand
	Inexact	One
LOAD LENGTHENED	Exact*	The quantum of the source operand
LOAD ROUNDED	Exact	The quantum of the source operand†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=0)‡	Exact	The largest quantum of cohort members†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=1)‡	Exact	One†
	Inexact	The smallest quantum of cohort members
MULTIPLY	Exact	The product of the quanta of the two source operands†
	Inexact	The smallest quantum of cohort members
QUANTIZE	Exact	The requested quantum
	Inexact	The requested quantum
REROUND	Exact	See the instruction description
	Inexact	The quantum that corresponds to the requested significance
SHIFT SIGNIFICAND LEFT	—	The quantum of the source operand
SHIFT SIGNIFICAND RIGHT	—	The quantum of the source operand
SUBTRACT	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members

Explanation:

*	This is true due to a condition to the left of the column.
—	For these operations, the concept of exact result or inexact result does not apply.
†	If the delivered value cannot be represented with the preferred quantum, it is represented with the quantum closest to the preferred quantum.
‡	Applicable only when the operation-type code is 01 hex (PFPO Convert Floating-Point Radix).
DPQC	DFP preferred quantum control.

Figure 20-4. Summary of Preferred Quantum

Summary of Rounding And Range Actions

Figure 20-5 on page 20-11 and Figure 20-6 on page 20-12 summarizes rounding and range actions.

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is							
		RNTE	RNTZ	RNTA	RA	RM	RFS	RP	RZ
v < -Nmax, g < -Nmax	Overflow	-∞[1]	-∞[1]	-∞[1]	-∞[1]	-∞[1]	-Nmax	-Nmax	-Nmax
v < -Nmax, g = -Nmax	Normal	-Nmax	-Nmax	-Nmax	—	—	-Nmax	-Nmax	-Nmax
-Nmax ≤ v ≤ -Nmin	Normal	g	g	g	g	g	g	g	g
-Nmin < v ≤ -Dmin	Tiny	d*	d*	d*	d*	d*	d*	d	d
-Dmin < v < -Dmin/2	Tiny	-Dmin	-Dmin	-Dmin	-Dmin	-Dmin	-Dmin	-0	-0
v = -Dmin/2	Tiny	-0	-0	-Dmin	-Dmin	-Dmin	-Dmin	-0	-0
-Dmin/2 < v < 0	Tiny	-0	-0	-0	-Dmin	-Dmin	-Dmin	-0	-0
v = 0	EZD	+0	+0	+0	+0	-0	+0	+0	+0
0 < v < +Dmin/2	Tiny	+0	+0	+0	+Dmin	+0	+Dmin	+Dmin	+0
v = +Dmin/2	Tiny	+0	+0	+Dmin	+Dmin	+0	+Dmin	+Dmin	+0

+Nmax < v, +Nmax < g	Overflow	+∞[1]	+∞[1]	+∞[1]	+∞[1]	+Nmax	+Nmax	+∞[1]	+Nmax

Explanation:

— This situation cannot occur.
* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
[1] The nontrap result r is considered to have been incremented.
d The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.
g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value.
EZD Exact zero difference. The case applies only to ADD and SUBTRACT. For all other DFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.
Dmin Smallest (in magnitude) representable subnormal number in the target format.
Nmax Largest (in magnitude) representable finite number in the target format.
Nmin Smallest (in magnitude) representable normal number in the target format.
RNTA Round to nearest with ties away from 0.
RNTE Round to nearest with ties to even.
RNTZ Round to nearest with ties toward 0.
RA Round away from 0.
RFS Round to prepare for shorter precision.
RM Round toward -∞.
RP Round toward +∞.
RZ Round toward 0.

Explanation:

—	The results do not depend on this condition or mask bit.
[1]	This condition is true by virtue of the state of some condition to the left of this column.
[2]	The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.
[3]	This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.
Ψ	Scale factor. For overflow, $\Psi=2^{+\alpha}$. For underflow, $\Psi=2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, α depends on the source format and is 192 for long and 3072 for extended.
g	The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
r	Nontrap result as defined in Part 1 of this figure.
v	Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.
PIDq(04)	DXC 04 is defined only when the floating-point extension facility is installed.
QX	Quantum exception. This exception is defined only when the floating-point extension facility is installed.
SFo	IEEE overflow flag, FPC 1.2.
SFq	Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed
SFu	IEEE underflow flag, FPC 1.3.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand location.
Tw(x)	The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Explanation:

— The results do not depend on this condition or mask bit.

[1] This condition is true by virtue of the state of some condition to the left of this column.

[2] The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.

[3] This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.

Ψ Scale factor. For overflow, $\Psi=2^{+\alpha}$. For underflow, $\Psi=2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, α depends on the source format and is 192 for long and 3072 for extended.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

r Nontrap result as defined in Part 1 of this figure.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.

PIDq(04) DXC 04 is defined only when the floating-point extension facility is installed.

QX Quantum exception. This exception is defined only when the floating-point extension facility is installed.

SFo IEEE overflow flag, FPC 1.2.

SFq Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed

SFu IEEE underflow flag, FPC 1.3.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

Tw(x) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 20-6. (Part 3 of 3) Rounding and Range Actions

Result Figures

Concise descriptions of the results produced by many of the DFP instructions are made by means of figures which contain columns and rows representing all possible combinations of DFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross-reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 20-8 on page 20-16.

Data-Exception Codes (DXC) and Abbreviations

Figure 20-7 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols "Xi:" and "Xz:" that are used in the figures. Bits 0-4 (i,z,o,u,x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 (y) of byte 2 is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

When the floating-point extension facility is installed, bit 5 of DXC also has a second meaning. When DXC bits 0-4 are zero, DXC bit 5 is the quantum-exception trap flag and corresponds to the quantum-exception mask IMq and its status flag SFq.

Figure 20-8 on page 20-16 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation "PID" stands for "program interruption for a data exception.")

Exception		FPC IEEE Mask bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx
Quantum-exception	Xq	0.5	1.5	SFq

Explanation:

[1] The symbol "Xi:" followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

[2] The symbol "Xz:" followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 20-7. IEEE Exception and Flag Abbreviations

Abbr.	DXC (hex)	Data-Exception-Code Name	Instruction Ending
PIDq	04	Quantum exception	Complete
PIDx	08	IEEE inexact and truncated	Complete
PIDy	0C	IEEE inexact and incremented	Complete
PIDu	10	IEEE underflow, exact	Complete, wrap exponent
PIDux	18	IEEE underflow, inexact and truncated	Complete, wrap exponent
PIDuy	1C	IEEE underflow, inexact and incremented	Complete, wrap exponent
PIDo	20	IEEE overflow, exact	Complete, wrap exponent
PIDox	28	IEEE overflow, inexact and truncated	Complete, wrap exponent
PIDoy	2C	IEEE overflow, inexact and incremented	Complete, wrap exponent
PIDz	40	IEEE division by zero	Suppress
PIDi	80	IEEE invalid operation	Suppress

Figure 20-8. IEEE Data-Exception Codes (DXC) and Abbreviations

Instructions

The Decimal-Floating-Point (DFP) instructions and their mnemonics and operation codes are listed in Figure 20-9 on page 20-17.

The figure indicates, in the column labeled “Characteristics,” the instruction format, when the condition code is set, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All DFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the DFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a DFP-instruction data exception, DXC 3, is recognized.

Mnemonics for the DFP instructions are distinguished from corresponding HFP or BFP instructions by a T in the mnemonic. Mnemonics for the DFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the DFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for DFP instructions to represent operand format and operand-format length, as follows:

E	Short
F	Thirty-two-bit fixed point
G	Sixty-four-bit fixed point
D	Long
P	Packed
X	Extended
Z	Zoned

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (long), for example, CDTR is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The floating-point extension facility includes the following:
   - The following new DFP instructions:
     - CONVERT FROM FIXED (CXFTR, CDFTR)
     - CONVERT FROM LOGICAL (CXLGTR, CDLGTR, CXLFTR, CDLFTR)
     - CONVERT TO FIXED (CFXTR, CFDTR)
     - CONVERT TO LOGICAL (CLGXTR, CLGDTR, CLFXTR, CLFDTR)
   - All reserved values in the effective rounding method field and a quantum-exception control (XqC) are assigned for LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND.
   - All reserved values in the effective rounding method field are assigned for CONVERT TO FIXED.
   - An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD ROUNDED.
   - An effective rounding method field and a quantum-exception control (XqC) are added to ADD, DIVIDE, MULTIPLY, and SUBTRACT.
   - An effective rounding method field, an IEEE-inexact-exception control (XxC), and a quantum-exception control (XqC) are added to CONVERT FROM FIXED.

2. The following instructions are available when the DFP-zoned-conversion facility is installed:
   - CONVERT FROM ZONED (CDZT, CXZT)
   - CONVERT TO ZONED (CZDT, CZXT)

3. The following instructions are available when the DFP-packed-conversion facility is installed:
   - CONVERT FROM PACKED (CDPT, CXPT)
   - CONVERT TO PACKED (CPDT, CPXT)

Figure 20-9. Summary of Decimal Instructions (Part 2 of 3)

Name	Mne- monic	Characteristics	Op Code	Page

Explanation:

¤^{7}	Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
¤^{9}	Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
A	Access exceptions for logical addresses.
B_2	B_2 field designates an access register in the access-register mode.
C	Condition code is set.
Dg	General-operand data exception.
Dt	DFP-instruction data exception.
F	Floating-point extension facility.
PC	DFP packed-conversion facility .
RRE	RRE instruction format.
RRF	RRF instruction format.
RSL	RSL instruction format.
RXE	RXE instruction format.
RXF	RXF instruction format.
S	S instruction format.
SP	Specification exception.
ST	PER storage-alteration event.
TF	Decimal-Floating-Point facility.
Xi	IEEE invalid-operation data exception.
Xo	IEEE overflow data exception.
Xq	Quantum data exception (if the floating-point extension facility is installed).
Xu	IEEE underflow data exception.
Xx	IEEE inexact data exception.
Xz	IEEE division-by-zero data exception.
ZF	DFP zoned-conversion facility.

Figure 20-9. Summary of Decimal Instructions (Part 3 of 3)

ADD

Mnemonic1 R_1,R_2,R_3 [RRF-a]

Op Code	R_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
ADTR	'B3D2'	Long DFP
AXTR	'B3DA'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
ADTRA	'B3D2'	Long DFP
AXTRA	'B3DA'	Extended DFP

The third operand is added to the second operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format and the rounded value is then placed at the result location.

When the floating-point extension facility is installed, the intermediate sum is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision

M_4	Effective Rounding Method
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate sum is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero, as follows:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward -∞, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand is an infinity and the other is a finite number, the result is an infinity with the sign of the source infinity. If both operands are infinities of the same sign, the result is an infinity with the same sign. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-11 on page 20-21 for a detailed description of the results of this instruction. (Figure 20-10 is referred to by Figure 20-11.)

For AXTR and AXTRA, the R fields designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (AXTR and AXTRA only)
- Transaction constraint

Value of Result (r)	Condition code
r = 0	0
r < 0	1
r > 0	2

Figure 20-10. Condition Code for Resultant Sum

Programming Notes:

1. Interchanging the two operands in a DFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs; or when both operands are SNaNs and the IEEE invalid-operation mask bit in the FPC register is zero, in these cases, the result is the canonical QNaN derived from the second operand.

2. For ADD or SUBTRACT, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the smaller quantum of the two source operands.

COMPARE

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
CDTR	'B3E4'	Long DFP
CXTR	'B3EC'	Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for DFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 20-12 on page 20-22 for a detailed description of the results of this instruction.

For CXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

CONVERT FROM FIXED

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
CDGTR	'B3F1'	64-bit binary-integer source, long DFP result
CXGTR	'B3F9'	64-bit binary-integer source, extended DFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
CDGTRA	'B3F1'	64-bit binary-integer source, long DFP result
CXGTRA	'B3F9'	64-bit binary-integer source, extended DFP result
CDFTR	'B951'	32-bit binary-integer source, long DFP result
CXFTR	'B959'	32-bit binary-integer source, extended DFP result

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded and then the rounded value is placed at the first-operand location.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0

M_3	**Effective Rounding Method**
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current DFP rounding mode; if bits 16-19 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

For CXGTR, CXGTRA, and CXFTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CDFTR and CXFTR, the operation exception is also recognized if the floating-point extension facility is not installed.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CDGTR and CDGTRA only)
- Quantum (CDGTR and CDGTRA only, if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXGTR, CXGTRA, and CXFTR only)
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

CONVERT FROM LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CDLGTR	'B952'	64-bit binary-integer source, long DFP result
CXLGTR	'B95A'	64-bit binary-integer source, extended DFP result
CDLFTR	'B953'	32-bit binary-integer source, long DFP result
CXLFTR	'B95B'	32-bit binary-integer source, extended DFP result

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

The result always has a plus sign.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For CXLGTR and CXLFTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CDLGTR only)
- Quantum (CDLGTR only)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification (CXLGTR and CXLFTR only)
- Transaction constraint

Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

2. Using either the round toward 0 or the round toward -∞ rounding method produces the same result; using either the round away from 0 or the round toward +∞ rounding method produces the same result.

CONVERT FROM PACKED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]

OpCode	L_2	B_2	D_2	R_1	M_3	OpCode
0	8	16	20	32	36	40 47

Mnemonic	Op Code	Operands
CDPT	'EDAE'	Packed source, long DFP result
CXPT	'EDAF'	Packed source, extended DFP result

The second operand in the packed-decimal format is converted to the DFP format, and the result is placed at the first-operand location.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

For CXPT the length in bytes of the second operand is 1-18, corresponding to a length code in L_2 of 0-17. For CDPT the length in bytes of the second operand is 1-9, corresponding to a length code in L_2 of 0-8. See Figure 20-17 for valid L_2 values along with the corresponding number of digits converted.

The M_3 field has the following format:

S	/	/	I
0	1	2	3

The bits of the M_3 field are defined as follows:

- **Sign-Control (S):** Bit 0 of the M_3 field is the sign control (S). When the S bit is zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero.

  When the S bit is one, the second operand contains a sign field in the rightmost four bit positions of the rightmost byte. The sign bit of the DFP first-operand result is set to zero when the sign field of the second operand indicates a positive value, or when the ignore-sign-digit control is one. The sign bit of the DFP first-operand result is set to one when the sign field of the second operand indicates a negative value and the ignore-sign-digit control is zero.
- **Reserved:** Bits 1-2 of the M_3 field are reserved.
- **Ignore-Sign-Digit Control (I):** Bit 3 of the M_3 field is the ignore-sign-digit control (I). When the I bit is zero, no special action is taken. When the I bit is one, the sign field of the second operand is ignored, it is not checked for invalid digits, and the sign bit of the DFP first-operand result is set to zero. When the S-bit is zero, the I bit is ignored.

Special Conditions

When an invalid digit or sign code is detected in the second operand, or an unused digit is not zero, a general-operand data exception is recognized. If the sign control and the ignore-sign-digit control are one, no sign code checking is performed on the sign digit.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CDPT, the L_2 field is greater than 8
- For CXPT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than 17

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (Fetch operand 2)
- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP packed-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Depending on the model, for CXPT, when the L_2 field specifies 16 or 17 (meaning 32-34 digits), performance may be significantly worse than if shorter lengths are specified.
2. When trying to convert 16 packed digits and a sign digit for CDPT, a L_2 value of 8 should be used and the S bit in the M_3 field should be set to one. When trying to convert 34 packed digits and a sign digit for CXPT an L_2 value of 17 should be used and the S bit in the M_3 field should be set to one. In both of these cases, bits 0-3 of the first byte of the second operand should be zero; otherwise, a general-operand data exception will occur.

CONVERT FROM SIGNED PACKED

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
CDSTR	'B3F3'	64-bit signed-packed-decimal source in GR, long DFP result
CXSTR	'B3FB'	128-bit signed-packed-decimal source in GRs, extended DFP result

The second operand in the signed-packed-decimal format is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R_2.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit or sign code is detected in the second operand, a general-operand data exception is recognized.

For CXSTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CXSTR only)
- Transaction constraint

CONVERT FROM UNSIGNED PACKED

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2

Mnemonic	Op Code	Operands
CDUTR	'B3F2'	64-bit unsigned-packed-decimal source in GR, long DFP result
CXUTR	'B3FA'	128-bit unsigned-packed-decimal source in GRs, extended DFP result

The second operand in the unsigned-packed-decimal format is converted to the DFP format with a positive sign, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R_2.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit code is detected in the second operand, a general-operand data exception is recognized.

For CXUTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction

- Operation (if the DFP facility is not installed)
- Specification (CXUTR only)
- Transaction constraint

CONVERT FROM ZONED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]

Op Code	L_2	B_2	D_2	R_1	M_3	Op Code
0	8	16	20	32	36	40 47

Mnemonic	Op Code	Operands
CDZT	'EDAA'	Zoned source, long DFP result
CXZT	'EDAB'	Zoned source, extended DFP result

The second operand in the zoned format is converted to the DFP format, and the result is placed at the first-operand location.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

The length in bytes of the second operand is 1-34 for CXZT, corresponding to a length code in L_2 of 0-33. The length in bytes of the second operand is 1-16 for CDZT, corresponding to a length code in L_2 of 0-15.

The M_3 field has the following format:

S	/	/	/
0	1	2	3

The bits of the M_3 field are defined as follows:

- **Sign-Control (S):** Bit 0 of the M_3 field is the sign control (S). When zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero. When one, the second operand is signed. That is, the leftmost four bit positions of the rightmost byte are a sign. The sign bit of the DFP first-operand result is set to zero when the sign field indicates a positive value and one when the sign field indicates a negative value.
- **Reserved:** Bits 1-3 of the M_3 field are ignored.

Special Conditions:

When an invalid digit or sign code is detected in the second operand, a general-operand data exception is recognized.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CDZT, the L_2 field is greater than or equal to 16.
- For CXZT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than or equal to 34.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (Fetch operand 2)
- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP zoned-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When an ASCII second operand is specified, bit 0 of the M_3 field must be zero, otherwise a general-operand data exception is recognized. That is, a sign value of 0011 binary is not a valid sign.
2. Depending on the model, for CXZT, when the L_2 field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.
3. Bits 1-3 of the M_3 field should be set to zeros, otherwise the program may not operate compatibly in the future.

CONVERT TO FIXED

Mnemonic1 R_1,M_3,R_2 [RRF-e]

Op Code	M_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
CGDTR	'B3E1'	Long DFP source, 64-bit binary-integer result
CGXTR	'B3E9'	Extended DFP source, 64-bit binary-integer result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
CGDTRA	'B3E1'	Long DFP source, 64-bit binary-integer result
CGXTRA	'B3E9'	Extended DFP source, 64-bit binary-integer result
CFDTR	'B941'	Long DFP source, 32-bit binary-integer result
CFXTR	'B949'	Extended DFP source, 32-bit binary-integer result

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is not installed, and if the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 20-18 for a detailed description of the results of this instruction.

For CGXTR, CGXTRA, and CFXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CFDTR, CFXTR, CGDTRA, and CGXTRA, the operation exception is also recognized if the floating-point extension facility is not installed.

Resulting Condition Code:

0	Source was zero
1	Source was less than zero
2	Source was greater than zero
3	Special case

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation
- Specification (CGXTR, CGXTRA, and CFXTR only)
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

Explanation:

—	The results do not depend on this condition or mask bit.
1	This condition is true by virtue of the state of some condition to the left of this column.
2	XxC is defined only when the floating-point extension facility is installed.
ccn	Condition code is set to n.
†	Result differs from BFP CONVERT TO FIXED. The BFP instruction recognizes inexact for this case and takes different actions depending on the inexact mask. The DFP implementation is intended to be more in keeping with the spirit of the IEEE standard.
f	The value n converted to a fixed-point result.
n	The value derived when the source value (b) is rounded to a floating-point integer using the effective rounding method.
MN	Maximum negative number representable in the target fixed-point format.
MP	Maximum positive number representable in the target fixed-point format.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. Figure 20-8 on page 20-16
SFi	IEEE invalid-operation flag, FPC 1.0.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand location

Figure 20-18. Results: CONVERT TO FIXED

CONVERT TO LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CLGDTR	'B942'	Long DFP source, 64-bit binary-integer result
CLGXTR	'B94A'	Extended DFP source, 64-bit binary-integer result
CLFDTR	'B943'	Long DFP source, 32-bit binary-integer result
CLFXTR	'B94B'	Extended DFP source, 32-bit binary-integer result

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R_1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

See Figure 20-19 for a detailed description of the results of this instruction.

For CLGXTR and CLFXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed.)
- Specification (CLGXTR and CLFXTR only)
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

Figure 20-19. Results: CONVERT TO LOGICAL

CONVERT TO PACKED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]

OpCode	L_2	B_2	D_2	R_1	M_3	OpCode
0	8	16	20	32	36	40 47

Mnemonic	Op Code	Operands
CPDT	'EDAC'	Long DFP source, packed result
CPXT	‘EDAD’	Extended DFP source, packed result

The significand digits of the DFP first operand and the sign bit of the first operand are converted to the packed format. The exponent in the combination field is ignored. The specified number of rightmost bytes of packed digits are placed at the second-operand location.

If there are not enough significand digits to fill all of the packed bytes, zero digits are appended to the significand as leftmost digits.

The number of bytes containing rightmost significand digits of the converted first operand is specified by L_2. The length in bytes of the second operand is 1-18 for

CPXT, corresponding to a length code in L_2 of 0-17. The length in bytes of the second operand is 1-9 for CPDT, corresponding to a length code in L_2 of 0-8.

The M_3 field has the following format:

S	/	P	F
0	1	2	3

The bits of the M_3 field are defined as follows:

- **Sign Control (S):** Bit 0 of the M_3 field is the sign control (S). When S is zero, the second operand does not have a sign field. When S is one, the second operand has a sign field. That is, the rightmost four bit positions of the rightmost byte are a sign.
- **Reserved:** Bit 1 of the M_3 field is reserved and should be zero.
- **Plus-Sign-Code Control (P):** Bit 2 of the M_3 field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary. When the S bit is zero, the P bit is ignored.
- **Force-Plus-Zero Control (F)**: Bit 3 of the M_3 field is the force-plus-zero control (F). When F is zero and a signed value of negative zero results, no action is taken. When F is one and the absolute value of the result placed in the second operand location is zero, the result is set to indicate a positive zero with the sign code specified by the P bit. When the S bit is zero, the F bit is ignored.

Special Conditions

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is appended as the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective significand digits and the sign bit are converted to the packed format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity and a NAN, when one or more leftmost nonzero digits of the significand are lost because the second operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CPDT, the L_2 field is greater than 8.
- For CPXT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than 17.

Resulting Condition Code:

0 Source is zero
1 Source is not special and is less than zero
2 Source is not special and is greater than zero
3 Source is special which is infinity, QNaN, SNaN, or a partial result

Program Exceptions:

- Access (Store operand 2)
- Data with DXC 3, DFP instruction
- Decimal overflow
- Operation (if the DFP packed-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored except for the detection of a decimal overflow exception.
2. A completion with condition code 0 indicates that the absolute value of the first operand is zero.

CONVERT TO SIGNED PACKED

Mnemonic R$_1$,R$_2$,M$_4$ [RRF-d]

Op Code	////	M$_4$	R$_1$	R$_2$
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CSDTR	'B3E3'	Long DFP source, 64-bit signed packed-decimal result in GR
CSXTR	'B3EB'	Extended DFP source, 128-bit signed-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the signed-packed-decimal format, and the result is placed at the first-operand location.

For CSDTR, the rightmost 15 digits in the trailing significand and the sign bit of the second operand are converted to a 64-bit result (15 4-bit decimal digits and a 4-bit sign); for CSXTR, the rightmost 31 digits in the trailing significand and the sign bit of the second operand are converted to a 128-bit result (31 4-bit decimal digits and a 4-bit sign). The sign of the result is the sign of the second operand.

Bit 3 of the M$_4$ field is the plus sign-code selection bit. When the bit is zero, the plus sign is encoded as 1100; when the bit is one, the plus sign is encoded as 1111. Bits 0-2 are ignored.

The result is placed in the general register or general-register pair designated by R$_1$.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CSXTR, the R$_2$ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R$_1$ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CSXTR only)
- Transaction constraint

Programming Notes:

1. See also the programming note under CONVERT FROM FIXED.
2. The sign code 1100 is the preferred plus sign in IBM z Systems products, and 1111 is the preferred plus sign in IBM System i products.

CONVERT TO UNSIGNED PACKED

Mnemonic R$_1$,R$_2$ [RRE]

Op Code	////////	R$_1$	R$_2$
0	16	24	28 31

Mnemonic	Op Code	Operands
CUDTR	'B3E2'	Long DFP source, 64-bit unsigned-packed-decimal result in GR
CUXTR	'B3EA'	Extended DFP source, 128-bit unsigned-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the unsigned-packed-decimal format, and the result is placed at the first-operand location.

For CUDTR, 16 significand digits of the second operand are converted to a 64-bit result (16 4-bit decimal digits). If the second operand is an infinity or NaN, the 15 digits in the trailing significand are padded with a zero digit on the left to form a 16 significand digits.

For CUXTR, the rightmost 32 digits in the trailing significand of the second operand are converted to a 128-bit result (32 4-bit decimal digits).

The result is placed in the general register or general-register pair designated by R$_1$.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CUXTR, the R$_2$ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R$_1$ field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CUXTR only)
- Transaction constraint

CONVERT TO ZONED

Mnemonic R$_1$,D$_2$(L$_2$,B$_2$),M$_3$ [RSL-b]

Op Code	L_2	B_2	D_2	R_1	M_3	Op Code	
0	8	16	20	32	36	40	47

Mnemonic	Op Code	Operands
CZDT	'EDA8'	Long DFP source, zoned result
CZXT	‘EDA9’	Extended DFP source, zoned result

The specified number of rightmost significand digits of the DFP first operand and the sign bit of the first operand are converted to the zoned format, and the result is placed at the second-operand location. The exponent in the combination field is ignored.

The number of rightmost significand digits of the first operand to be converted is specified by L_2. The length in bytes of the second operand is 1-34 for CZXT, corresponding to a length code in L_2 of 0-33, meaning 1-34 digits. The length in bytes of the second operand is 1-16 for CZDT, corresponding to a length code in L_2 of 0-15, meaning 1-16 digits.

The M_3 field has the following format:

S	Z	P	F
0	1	2	3

The bits of the M_3 field are defined as follows:

- **Sign Control (S):** Bit 0 of the M_3 field is the sign control (S). When S is zero, the second operand does not have a sign field, and the zone field is set as determined by the Z bit. When S is one, the second operand has a sign field. That is, the leftmost four bit positions of the rightmost byte are a sign.

- **Zone Control (Z):** Bit 1 of the M_3 field is the zone control (Z). When Z is zero, each zone field of the second operand is stored as 1111 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one. When Z is one, each zone field of the second operand is stored as 0011 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one.

- **Plus-Sign-Code Control (P):** Bit 2 of the M_3 field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary.

  When the S bit is zero, the P bit is ignored and assumed to be zero. The zone of the rightmost digit is set as determined by the Z bit.

- **Force-Plus-Zero Control (F)**: Bit 3 of the M_3 field is the force-plus-zero control (F). When F is zero, no action is taken. When F is one and the absolute value of the result placed at the second-operand location is zero, the sign of the result is set to indicate a plus value with the sign code specified by the P bit.

  When the S bit is zero, the F bit is ignored and assumed to be zero.

Special Conditions

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is assumed to be the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective-significand digits and the sign bit are converted to the zoned format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity, and a NaN, when one or more leftmost nonzero digits of the significand are lost because the second-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true:

- For CZDT, the L_2 field is greater than or equal to 16, meaning 17 or more digits.
- For CZXT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than or equal to 34, meaning 35 or more digits.

Resulting Condition Code:

0 Source is zero
1 Source is less than zero
2 Source is greater than zero
3 Infinity, QNaN, SNaN, Partial result

Program Exceptions:

- Access (Store operand 2)
- Data with DXC 3, DFP instruction
- Decimal overflow
- Operation (if the DFP zoned-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. An ASCII zoned-decimal operand may be stored as signed when the S bit is one. This is entirely up to the program as ASCII representations are usually unsigned and positive with no concept of a rightmost zone being used as a sign.
2. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored.
3. Depending on the model, for CZXT, when the L_2 field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.
4. A completion with condition code 0 indicates that the absolute value of the first operand is zero.

DIVIDE

Mnemonic1 R_1,R_2,R_3 [RRF-a]

Op Code	R_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
DDTR	'B3D1'	Long DFP
DXTR	'B3D9'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
DDTRA	'B3D1'	Long DFP
DXTRA	'B3D9'	Extended DFP

The second operand (the dividend) is divided by the third operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If divisor is nonzero and both the dividend and divisor are finite numbers, the second operand is divided by the third operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate quotient is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-

7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate quotient is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the dividend is a finite number and the divisor is infinity, then a value of zero with zero significand and zero biased exponent is produced.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

When the delivered value is exact, the preferred quantum is the quantum of the dividend divided by the quantum of the divisor; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

If the divisor is zero but the dividend is nonzero and finite, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinite, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 20-20 on page 20-38 for a detailed description of the results of this instruction.

For DXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (DXTR and DXTRA only)
- Transaction constraint

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Nonzero finite number (includes both subnormal and normal numbers).
R(x)	Rounding and range action is performed on the value x. See Figure 20-5 on page 20-11. The result is canonical.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
Xz:	IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.
zt	A value of zero with zero significand and zero biased exponent.

Figure 20-20. Results: DIVIDE

Programming Note: For DIVIDE, when the delivered value is inexact, the preferred quantum is the smallest quantum which is not always the same quantum as that closest to the quantum of the dividend divided by the quantum of the divisor.

For example, with the short data format, when 5000001×10^{-7} is divided by 400×10^{0}, the smallest quantum for the delivered value is 1×10^{-9}. However, the quantum that is closest to the quantum of the dividend divided by the quantum of the divisor is 1×10^{-7}.

EXTRACT BIASED EXPONENT

Mnemonic R_1,R_2 [RRE]

Op Code	////////	R_1	R_2
0	16	24	28 31

Mnemonic	Op Code	Operands
EEDTR	'B3E5'	Long DFP source, 64-bit binary-integer result
EEXTR	'B3ED'	Extended DFP source, 64-bit binary-integer result

The biased exponent of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the biased exponent of the second operand is placed at the first-operand location. When the second operand is an infinity, QNaN, or SNaN, a special value is placed at the first-operand location.

The result is a 64-bit signed binary integer that is placed in the general register designated by R_1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-21 for a detailed description of the results of this instruction.

Second-operand data	First-operand value
Finite number	e
Infinity	-1
QNaN	-2
SNaN	-3
Explanation: e Biased exponent	

Figure 20-21. Results: EXTRACT BIASED EXPONENT

For EEXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

INSERT BIASED EXPONENT

Mnemonic R_1,R_3,R_2 [RRF-b]

Op Code	R_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
IEDTR	'B3F6'	Long DFP
IEXTR	'B3FE'	Extended DFP

A DFP operand is produced by combining the requested biased exponent with the sign bit and the significand of the DFP third operand, and the result is placed in the first-operand location.

The value of the requested biased exponent is a 64-bit signed binary integer and is located in the general register designated by R_2.

When the value of the requested biased exponent is in the range between zero and the maximum biased exponent, inclusively, for the target format, the result is a finite number. The biased exponent of the result is set to the value of the requested biased exponent; the significand of the result is set to the significand of the third operand. If the third operand is an infinity or NaN, the significand of the third operand contains the digits in the trailing significand of the third operand padded with a zero digit on the left.

When the value of the requested biased exponent is -1, the result is an infinity. The reserved field of the result is set to zero; the trailing significand of the result is set to the trailing significand of the third operand.

When the value of the requested biased exponent is equal to -2, less than -3, or greater than the maximum biased exponent for the target format, the result is a QNaN; when the value of the requested biased exponent is -3, the result is an SNaN. When a NaN is produced as the result, the reserved field of the result is set to zero, and the trailing significand of the result is set to the trailing significand of the third operand.

The sign of the result is the same as the sign of the third operand.

The preferred quantum is the quantum that corresponds to the requested biased exponent. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the third operand are zeros, then the result is a canonical infinity; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

See Figure 20-23 for a detailed description of the results of this instruction.

This operation is performed for any requested biased exponent and any third operand without causing an IEEE exception.

For IEXTR, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (IEXTR only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand

Value (b) in second operand	Results[1] for INSERT BIASED EXPONENT when third operand (c) is			
	F	∞	QNaN	SNaN
b > MBE	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
MBE ≥ b ≥ 0	T(F)	T(F[2])	T(F[2])	T(F[2])
b = -1	N(∞)	N(∞)	N(∞)	N(∞)
b = -2	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
b = -3	T(SNaN)	T(SNaN)	T(SNaN)	T(SNaN)
b ≤ -4	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)

Explanation:

[1] The sign of the result is the same as the sign of the third operand.

[2] The leftmost digit of the significand is zero.

F All finite numbers, including zeros.

MBE Maximum biased exponent for the target format.

N(∞) The result is a canonical infinity if all digits in the trailing significand of the third operand are zeros; otherwise, the resultant infinity has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

T(x) The canonical result x is placed at the target operand location.

Figure 20-23. Results: INSERT BIASED EXPONENT

field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

LOAD AND TEST

Mnemonic R$_1$,R$_2$ [RRE]

Op Code	////////	R$_1$	R$_2$
0	16	24	28 31

Mnemonic	Op Code	Operands
LTDTR	'B3D6'	Long DFP
LTXTR	'B3DE'	Extended DFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is canonicalized before it is placed at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN**.**

The preferred quantum is the quantum of the second operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 for a detailed description of the results of this instruction.

For LTXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LTXTR only)
- Transaction constraint

Instruction	Results for some instructions with a single operand (b) when second operand (b) is

Explanation:

— The results do not depend on this condition.
* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
[1] The operand is extended to the longer format by appending zeros on the left before it is placed at the target operand location.
[2] The operand is shortened to the target format by truncating the leftmost digits.
Fn Nonzero finite number (includes both subnormal and normal).
N(±∞) The resultant infinity has the reserved field set to zero and has canonical declets in the encoded trailing-significand field. The result is not considered canonical unless all digits in the trailing significand are zeros.
R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-11. The result is canonical.
Rf(b) The value b is converted to the exact floating-point number v, and then action R(v) is performed. The result is canonical.
T(x) The canonical result x is placed at the target operand location.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
XiC IEEE-invalid-operation-exception control, bit 0 of the M_4 field.

Figure 20-24. Results: Some Single-Operand Instructions

LOAD FP INTEGER

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
FIDTR	'B3D7'	Long DFP
FIXTR	'B3DF'	Extended DFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

In the absence of an interruption, if the second operand is an infinity, the result is the canonical infinity; if the second operand is a QNaN, the result is the canonicalized source QNaN that has the same sign and payload as the source; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored.

When the result differs in value from the second operand, if XxC is zero, an IEEE-inexact exception is recognized. If XxC one, then no IEEE-inexact exception is recognized.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the delivered value is exact, the preferred quantum is the larger value of one and the quantum of the second operand; when the delivered value is inexact, the preferred quantum is one. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-25 on page 20-43 for a detailed description of the results of FIDTR and FIXTR.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the second operand and if XqC is zero, then a quantum exception is recognized.

For FIXTR, the R fields must designate valid floating-point-register fields; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Explanation:

— The results do not depend on this condition or mask bit.

* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.

[1] This condition is true by virtue of the state of some condition to the left of this column.

[2] XqC is defined only if the floating-point extension facility is installed.

n The value derived when the source value, b, is rounded to an integer using the effective rounding method.

Fn Finite nonzero number (includes both subnormal and normal).

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.

PIDq(04) Program interruption for data exception, quantum-exception condition q, with DXC of 04 in hex. It is defined only if the floating-point extension facility is installed.

Q Quantum of the second operand.

SFi IEEE invalid-operation flag, FPC 1.0.

SFq Quantum exception flag, FPC 1.5. The flag is defined only if the floating-point extension facility is installed.

SFx IEEE inexact flag, FPC 1.4.

T(x) The canonical result x is placed at the target operand location. The result, when it is a finite number, is always represented with the preferred quantum.

Figure 20-25. Results: LOAD FP INTEGER

Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

2. If the DFP source operand is numeric with a quantum of at least one so that it is already an integer, the result value and quantum remain the same. Other numeric DFP source operands that are integers with a quantum less than one are

converted to the same value with a quantum of one.

LOAD LENGTHENED

Mnemonic R$_1$,R$_2$,M$_4$ [RRF-d]

Op Code	////	M$_4$	R$_1$	R$_2$
0	16	24	28	31

Mnemonic	Op Code	Operands
LDETR	'B3D4'	Short DFP source, long DFP result
LXDTR	'B3DC'	Long DFP source, extended DFP result

The second operand is converted to a longer format, and the result is placed at the first-operand location.

Bit 0 of the M$_4$ field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). Bits 1-3 are ignored. When XiC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XiC is one, recognition of the exception is suppressed.

When the second operand is a finite number, the value of the second operand is placed in the target format.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being extended by appending zeros on the left, and all declets in the encoded trailing-significand field being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload extended by appending zeros on the left.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload extended by appending zeros on the left; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload extended by appending zeros on the left.

The sign of the result is the same as the sign of the second operand.

The delivered value is always exact and the preferred quantum is the quantum of the second operand.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For LXDTR, the R$_1$ field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LXDTR only)
- Transaction constraint

Programming Notes:

1. Unassigned bits in the M$_4$ field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

2. The equivalent operations of LOAD LENGTHENED (short to long) in the Power architecture do not recognize the invalid-operation exception for both BFP and DFP. The equivalent operations of LOAD LENGTHENED in z/Architecture do recognize the exception for BFP. The IEEE-invalid-operation-exception control (XiC) is provided for compatibility.

3. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

LOAD ROUNDED

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]

Op Code	M_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
LEDTR	'B3D5'	Long DFP source, short DFP target, short or long DFP result
LDXTR	'B3DD'	Extended DFP source, long DFP target, long or extended DFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

The second operand, if it is a finite number, is rounded as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

Bit 0 of the M_4 field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). When XiC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XiC is one, recognition of IEEE-invalid-operation exception is suppressed.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 2-3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 21-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 21-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

In the absence of a trap overflow or trap underflow, the result is in the format and length of the target. However, when a trap overflow or trap underflow occurs, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. In this case, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format. For LEDTR, the result has at most seven DFP significant digits; for LDXTR, the result has at most 16 DFP significant digits.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being shortened by removing leftmost digits, and declets corresponding to the shortened trailing significand being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload shortened by removing leftmost digits.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload shortened by removing leftmost digits; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload shortened by removing leftmost digits.

The sign of the result is the same as the sign of the second operand.

When the delivered value is exact, the preferred quantum is the quantum of the second operand; when the delivered value is inexact, the preferred quantum is the smallest quantum.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For LDXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

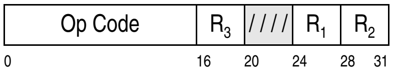
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LDXTR only)
- Transaction constraint

Programming Notes:

1. LOAD ROUNDED and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with the precision of a shorter format and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable rounding method is used by the subsequent LOAD ROUNDED instruction.
2. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.
3. The equivalent operation of LOAD ROUNDED (long to short) in the Power architecture does not recognize the invalid-operation exception. IEEE-invalid-operation-exception control (XiC) is provided for compatibility.
4. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
5. In case of a trap overflow or a trap underflow, the number of DFP significand digits of the delivered result is limited to the precision of the target format. For example, when the source operand is 75958100 X 10^{369} and is represented with the quantum of 10^{369}, execution of LEDTR using the round-away-from-0 rounding method produces a value of 7595810 X 10^{178} with the delivered quantum of 10^{178} as the trap overflow result.

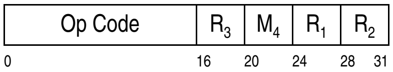
MULTIPLY

Mnemonic1 R_1,R_2,R_3 [RRF-a]



Mnemonic2	Op Code	Operands
MDTR	'B3D0'	Long DFP
MXTR	'B3D8'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]



Mnemonic2	Op Code	Operands
MDTRA	'B3D0'	Long DFP
MXTRA	'B3D8'	Extended DFP

The product of the second operand (the multiplicand) and the third operand (the multiplier) is placed at the first-operand location.

If both source operands are finite numbers, they are multiplied to form an intermediate product. The intermediate product is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate product is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate product is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

When the delivered value is exact, the preferred quantum is the product of the quanta of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-26 on page 20-49 for a detailed description of the results of this instruction.

If one source operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized

For MXTR and MXTRA, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (MXTR and MXTRA only)
- Transaction constraint

Programming Notes:

1. Interchanging the two operands in a DFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs. in which case the result is the canonical QNaN derived from the second operand; or when both operands are SNaNs and the IEEE invalid-operation

Multiplicand (b) is	Results for MULTIPLY (b • c) when multiplier (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(c)	Xi: T(c*)
-Fn	T(+∞)	R(b • c)	T(+0)	T(-0)	R(b • c)	T(-∞)	T(c)	Xi: T(c*)
-0	Xi: T(dNaN)	T(+0)	T(+0)	T(-0)	T(-0)	Xi: T(dNaN)	T(c)	Xi: T(c*)
+0	Xi: T(dNaN)	T(-0)	T(-0)	T(+0)	T(+0)	Xi: T(dNaN)	T(c)	Xi: T(c*)
+Fn	T(-∞)	R(b • c)	T(-0)	T(+0)	R(b • c)	T(+∞)	T(c)	Xi: T(c*)
+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(c)	Xi: T(c*)
QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Nonzero finite number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 20-5 on page 20-11. The result is canonical.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-26. Results: MULTIPLY

mask bit in the FPC register is zero, in which case the result is the canonical QNaN derived from the second operand.

2. For MULTIPLY, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the product of the quanta of the two source operands.

QUANTIZE

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
QADTR	'B3F5'	Long DFP
QAXTR	'B3FD'	Extended DFP

The third operand is rounded to a requested quantum, and the result is placed at the first-operand location.

The requested quantum is the quantum of the second operand.

When both the second and third operands are finite numbers, if the quantum of the third operand is equal to or larger than the requested quantum, the value of the third operand with the requested quantum is placed at the first-operand location. If the quantum of the third operand is smaller than the requested quantum, the third operand is rounded to the requested quantum by rounding as specified by the modifier in the M_4 field, and the result with the requested quantum is placed at the first-operand location.

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_4 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

The preferred quantum is the requested quantum. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-27 on page 20-51 for a detailed description of the results of this instruction.

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested quantum. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

An IEEE inexact exception is recognized when the result differs in value from the third operand,

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For QAXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged***.***

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (QAXTR only)
- Transaction constraint

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
E(0)	The value zero with the quantum of operand b is placed at the target operand location.
Fn	Finite nonzero number (includes both subnormal and normal).
Q(b:c)	See Figure 20-28.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-27. Results: QUANTIZE

Relation[1]	Is $\lvert Vc \rvert > (10^p - 1) \times 10^{Qb}$?	Result for Q(b:c)
$10^{Qb} < 10^{Qc}$	Yes	Xi: T(dNaN)
	No	L(c)
$10^{Qb} = 10^{Qc}$		T(c)
$10^{Qb} > 10^{Qc}$		Rq(c)

Explanation:

1	The quantum of the second operand and the third operand is 10^{Qb} and 10^{Qc}, respectively.
dNaN	Default NaN.
p	Format precision.
Qb	The right-units-view exponent of the second operand (b).
Qc	The right-units-view exponent of the third operand (c).
|Vc|	The absolute value of the third operand (c).
L(c)	The third operand (c) is represented with the requested quantum. The result is represented with the preferred quantum and is canonical.
Rq(c)	The third operand (c) is rounded to the requested quantum. The result is represented with the preferred quantum and is canonical.
T(x)	The canonical result x is placed at the target operand location. The result, when it is a finite number, is represented with the preferred quantum and is canonical.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-28. Results: Q(b:c)

Programming Notes:

1. When the third operand is larger than $(10^p - 1) \times 10^{Qb}$ in magnitude, an invalid-operation exception is recognized, where p is the format precision and 10^{Qb} is the requested quantum.

   The expression, $(10^p - 1) \times 10^{Qb}$, specifies the largest magnitude that can be represented with the requested quantum in the format. A value larger than $(10^p - 1) \times 10^{Qb}$ in magnitude will have more than p digits when the value is represented with the requested quantum.

2. When both source operands are finite numbers, an invalid-operation exception can occur only if the requested quantum is smaller than the quantum of the third operand; and an inexact exception can occur only if the requested quantum is larger than the quantum of the third operand.

REROUND

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic	Op Code	Operands
RRDTR	'B3F7'	Long DFP
RRXTR	'B3FF'	Extended DFP

The third operand is rounded to the requested significance, and the result is placed at the first-operand location.

The requested significance, which specifies a number of DFP significant digits, is an unsigned binary integer and is in bit positions 58-63 of general register R_2. The contents of bit positions 0-57 of general register R_2 are ignored.

When the third operand is a finite number, if the requested significance is zero, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is greater than the requested significance, then the third operand is rounded to the requested significance, and the result with the requested significance is placed at the first-operand location.

The third operand is rounded to the requested significance by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_4 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

When the delivered value is exact, if the requested significance is zero, or if the requested significance is nonzero and the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the preferred quantum is the quantum of the third operand. When the delivered value is exact, if the requested significance is nonzero and the number of DFP significant digits of the third operand is greater than the requested significance, then the preferred quantum is the quantum that corresponds to the requested significance.

When the delivered value is inexact, the preferred quantum is the quantum that corresponds to the requested significance.

If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-29 for a detailed description of the results of this instruction.

Significance Comparison	Is $\lvert Rp(c)\rvert > (10^k-1) \times 10^{Qmax}$?	Results for REROUND when the Third Operand (c) is							
		-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
k = 0	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k > m	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k = m	--	T(-∞)	T(c)	--	--	T(c)	T(+∞)	T(c)	Xi: T(c*)

	Yes	T(-∞)	Xi:T(dNaN)	--	--	Xi:T(dNaN)	T(+∞)	T(c)	Xi: T(c*)

Explanation:

-- Not applicable.
* The SNaN is converted to the corresponding QNaN and placed at the target operand location.
dNaN Default NaN.
Fn Nonzero finite numbers (includes both subnormal and normal).
k The requested significance.
m Number of DFP significant digits in the third operand (c).
Qmax Maximum right-units-view exponent.
Rp(c) The third operand (c) is rounded to the requested significance. The result is canonical and is represented with the preferred quantum.
|Rp(c)| The absolute value of Rp(c).
T(x) The canonical result x is placed at the target operand location. The result is canonical and, when it is a finite number, is represented with the preferred quantum.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-29. Results: REROUND

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested significance. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

When an invalid-operation exception is recognized, the IEEE inexact exception is not recognized.

In the absence of an invalid-operation exception, if the result differs in value from the third operand, an IEEE inexact exception is recognized.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For RRXTR, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (RRXTR only)
- Transaction constraint

Programming Notes:

1. REROUND and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with a precision other than any supported format precision and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable round-

ing method is used by the subsequent REROUND instruction.

2. When the rounded intermediate value is larger than $(10^k - 1) \times 10^{Qmax}$ in magnitude, an invalid-operation exception is recognized, where k is the requested significance and 10^{Qmax} is the largest quantum for the format.

   The expression, $(10^k - 1) \times 10^{Qmax}$, specifies the largest magnitude that can be represented with the requested significance in the format. A value larger than $(10^p - 1) \times 10^{Qb}$ in magnitude will have a quantum larger than 10^{Qmax} when the value is represented with the requested significance.

SHIFT SIGNIFICAND LEFT

Mnemonic $R_1,R_3,D_2(X_2,B_2)$ [RXF]

OpCode	R_3	X_2	B_2	D_2	R_1	////	OpCode
0	8	12	16	20	32	36	40 47

Mnemonic	Op Code	Operands
SLDT	'ED40'	Long DFP
SLXT	'ED48'	Extended DFP

The significand of the third operand is shifted left the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNAN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SLXT, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SLXT only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

SHIFT SIGNIFICAND RIGHT

Mnemonic $R_1,R_3,D_2(X_2,B_2)$ [RXF]

OpCode	R_3	X_2	B_2	D_2	R_1	////	OpCode
0	8	12	16	20	32	36	40 47

Mnemonic	Op Code	Operands
SRDT	'ED41'	Long DFP
SRXT	'ED49'	Extended DFP

The significand of the third operand is shifted right the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the rightmost digit are lost. Zeros are supplied to the vacated positions on the left. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SRXT, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SRXT only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

SUBTRACT

Mnemonic1 R_1,R_2,R_3 [RRF-a]

Op Code	R_3	////	R_1	R_2
0	16	20	24	28 31

Mnemonic1	Op Code	Operands
SDTR	'B3D3'	Long DFP
SXTR	'B3DB'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]

Op Code	R_3	M_4	R_1	R_2
0	16	20	24	28 31

Mnemonic2	Op Code	Operands
SDTRA	'B3D3'	Long DFP
SXTRA	'B3DB'	Extended DFP

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the third operand, if numeric, participates in the operation with its sign bit inverted. When the third operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 20-11 on page 20-21 for the detailed results of ADD.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

For SXTR and SXTRA, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero

3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (SXTR and SXTRA only)
- Transaction constraint

Programming Note: See the programming notes for ADD.

TEST DATA CLASS

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]

OpCode	R_1	X_2	B_2	D_2	////////	OpCode
0	8	12	16	20	32	40 47

Mnemonic	***Op Code***	***Operands***
TDCET	'ED50'	Short DFP
TDCDT	'ED54'	Long DFP
TDCXT	'ED58'	Extended DFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 20-30, DFP operands are divided into six classes: zero, subnormal, normal, infinity, quiet NaN, and signaling NaN:

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

	Bit used when sign is	
DFP data class	**+**	**-**
Zero	52	53
Subnormal	54	55
Normal	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 20-30. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDCXT, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDCXT only)
- Transaction constraint

Programming Notes:

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, BFP TEST DATA CLASS uses bits 54 and 55 for normal number, and bits 56 and 57 for subnormal number.

TEST DATA GROUP

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]

OpCode	R_1	X_2	B_2	D_2	////////	OpCode
0	8	12	16	20	32	40 47

Mnemonic	Op Code	Operands
TDGET	'ED51'	Short DFP
TDGDT	'ED55'	Long DFP
TDGXT	'ED59'	Extended DFP

The group and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data group and sign. Bits 0-51 of the second-operand address are ignored.

TEST DATA GROUP is used to determine whether a finite number is safe. A finite number is safe if the exponent is neither maximum nor minimum, and the leftmost significand digit is zero.

Figure 20-31 on page 20-58 shows the data groups and the bit assignment. There are six data groups: safe zero, zero with extreme exponent, nonzero with extreme exponent, safe nonzero, nonzero leftmost significand digit with nonextreme exponent, and special. The special group is defined for infinity and NaN. Depending on the model, subnormal with nonextreme exponent may be placed in the nonzero-with-extreme-exponent group or the safe-nonzero group.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the group and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDGXT, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDGXT only)
- Transaction constraint

Programming Notes:

1. TEST DATA GROUP provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. TEST DATA GROUP can be issued after an operation that produces a DFP result to quickly determine if the result is safe. For DFP results that are finite numbers, the result is safe if using a wider data format by the operation would have produced the same value and quantum. A safe result has two important characteristics: (1) the exponent is neither the maximum exponent nor the minimum exponent, and (2) the leftmost significand digit is zero.

3. TEST DATA GROUP may be used to test whether a nonzero finite number is safe by setting bits 58 and 59 of the second-operand address to ones.

4. TEST DATA GROUP may be used to test whether a nonzero finite number has reached the limit of the format precision but not the limit of the format range by setting bits 60 and 61 of the second-operand address to ones.

5. Subnormal with nonextreme exponent may be grouped with either the nonzero-with-extreme-exponent group or the safe-nonzero group. The

program shouldn't depend on which group subnormal with nonextreme exponent is in.

DFP Operand	Exponent	LMD	Data Group	Bit used when sign is	
				+	−
Zero	Nonextreme	z[1]	Safe zero	52	53
	Extreme	z[1]	Zero with extreme exponent	54	55
Nonzero finite	Extreme	--	Nonzero with extreme exponent	56	57
	Nonextreme	z	Safe nonzero	58	59
	Nonextreme	nz	Nonzero leftmost significand digit with nonextreme exponent	60	61
Infinity or NaN	na	na	Special	62	63

Explanation:

--	The result does not depend on this condition.
[1]	This condition is true by virtue of the condition to the left of this column.
Extreme	Maximum right-units-view (RUV) exponent, Qmax, or minimum right-units-view (RUV) exponent, Qmin.
Nonextreme	Qmax < right-units-view (RUV) exponent < Qmin.
LMD	Leftmost significand digit.
na	Not applicable.
nz	Nonzero.
z	Zero.

Figure 20-31. Second-Operand-Address Bits for TEST DATA GROUP

Densely Packed Decimal (DPD)

Decimal-to-DPD Mapping

The mapping of a 3-digit decimal number (000 - 999) to a 10-bit value, called a declet is shown in Figure 20-32 on page 20-59. The DPD entries are shown in hexadecimal. The first two digits of the decimal number are shown in the leftmost column and the third digit along the top row. The table is split into two halves, with the right half being a continuation of the left half.

DPD-to-Decimal Mapping

The mapping of the 10-bit declet to a 3-digit decimal number is shown in Figure 20-33 on page 20-60. The 10-bit declet value is split into a 6-bit index shown in the left column and a 4-bit index shown along the top row, both represented in hexadecimal. The values marked with an asterisk are results mapped from noncanonical declets and are explained further in the following section.

Overview

The vector facility provided in the z/Architecture architectural mode provides fixed-sized vectors ranging from one to sixteen elements. For most instructions, all of the data contained in a vector is operated on by the instructions defined in this facility. Some instructions only operate on a subset of the elements within a vector. If a vector is made up of multiple elements, each element is processed in parallel with the others. Instruction completion does not occur until processing of all elements is complete.

Figure 21-1. Vector Register Element Representations

Vector Enablement Control

The vector instructions should only be used if both the vector enablement control (bit 46) and the AFP-register-control (bit 45) in control register zero are set to one. If the vector facility for z/Architecture is installed and a vector instruction is executed without the vector enablement control set, a data exception with DXC FE hex is recognized. If bit 45 of control register zero is not also set to one, it is unpredictable if a data exception is recognized. If the vector facility for z/Architecture is not installed, an operation exception is recognized.

Programming Note: When a control program initially enables the vector facility for z/Architecture for a task, which may occur in response to a data exception with DXC FE, it should ensure that newly enabled full vector registers as well as the rightmost portions of vector registers that overlap with any enabled floating-point registers are zeroed.

Vector Storage Accesses

All vector data appears in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also “Storage Addressing” on page 3-2.)

Saturating Arithmetic

Some vector operations perform saturating operations. Saturation for signed binary integers means that if there is an overflow, the result is set to the largest positive number; if there is an underflow, the result is set to the largest negative number. Saturation for unsigned binary integers means that if there is an overflow, the result is set to the largest representable number; if there is an underflow, the result is set to zero.

Instructions

All vector instructions, defined in chapters 21-25, have a field in bits 36-39 of the instruction labeled as RXB. This field contains the most significant bit for each of the vector register designated operands. Bits for register designations not specified by the instruction are reserved and should be set to zero; otherwise the program may not operate compatibly in the future.

The bits are defined as follows:

Bit	MSB of Vector Register in Instruction Bits
36	8-11
37	12-15
38	16-19
39	32-35

Programming Note: It is assumed that the assembler will set these bits whenever a vector register designation greater than 15 is specified.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Each instruction has an extended-mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax.

Programming Note: The vector-enhancements facility 2 includes the following new instructions to handle load and store of elements or arrays of elements in the little endian format:

- VECTOR LOAD BYTE REVERSED ELEMENTS (VLBR), VECTOR LOAD ELEMENTS REVERSED (VLER), VECTOR LOAD BYTE REVERSED ELEMENT AND ZERO (VLLEBRZ), VECTOR LOAD BYTE REVERSED ELEMENT (VLEBRH, VLEBRF, VLEBRG), VECTOR LOAD BYTE REVERSED ELEMENT AND REPLI-

CATE (VLBRREP), VECTOR STORE BYTE REVERSED ELEMENTS (VSTBR), VECTOR STORE ELEMENTS REVERSED (VSTER), and VECTOR STORE BYTE REVERSED ELEMENT (VSTEBRH, VSTEBRF, VSTEBRG)

Explanation:

¤^{7}	Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
¤^{9}	Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
A	Access exceptions for logical addresses.
B_2	B_2 field designates an access register in the access-register mode.
C*	Condition code optionally set.
Dv	Vector-instruction data exception
SP	Specification exception.
ST	PER storage-alteration event.
V1	Vector-enhancements facility 1
V2	Vector-enhancements facility 2
VD	Vector packed-decimal facility
VF	Vector facility for z/Architecture
VRI	VRI instruction format
VRR	VRR instruction format
VRS	VRS instruction format
VRX	VRX instruction format
VRV	VRV instruction format
VSI	VSI instruction format

Figure 21-2. Summary of Vector Support Instructions (Part 2 of 2)

VECTOR BIT PERMUTE

VBPERM V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	////////////////	RXB	'85'
0	8	12	16	20	36	40 47

A source vector is created from the concatenation of the second operand followed by 128 binary zeros. The byte sized elements of the third operand contain unsigned integers which are used to select bits from the source vector to create a halfword result which is placed in bits 48 to 63 of the first operand, other halfwords are set to zero. Each bit of the halfword result is selected from the source vector by the corresponding byte in the third operand.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 1 is not installed)
- Transaction constraint

Programming Note: The fact that the source vector contains 128 bits of zeros following the second operand permits the permuted bits to be selected from a 256-bit quantity using a single index register. Assume the 256-bit quantity is in vector registers 0 and 1, the indicies are in vector register 2, and each byte of vector register 3 contains the value 128. The following code sequence selects sixteen bits from the 256-bit quantity.

```
VBPERM   v4,v0,v2
VX       v2,v2,v3
VBPERM   v5,v1,v2
VO       v4,v4,v5
```

VECTOR GATHER ELEMENT

VGEF V_1,D_2(V_2,B_2),M_3 [VRV]

‘E7’	V_1	V_2	B_2	D_2	M_3	RXB	‘13’
0	8	12	16	20	32	36	40 47

VGEG V_1,D_2(V_2,B_2),M_3 [VRV]

‘E7’	V_1	V_2	B_2	D_2	M_3	RXB	‘12’
0	8	12	16	20	32	36	40 47

The element-sized second operand replaces the specified element of the first operand indexed by the M_3 field. The remaining elements are left unchanged. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VGEF the elements in all operands are 4-bytes in size; for VGEG the elements in all operands are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register V_2 indexed by the M_3 field with the address in the B_2 register along with the D_2 value.

The displacement for VECTOR GATHER ELEMENT is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The VECTOR GATHER ELEMENT instruction can be used to perform a load when doing scalar computation in vector registers and the address resides in a vector register. However, depending on the model, performance may be better if address computations are done in general registers.

2. For VGEF care must be taken to ensure that the values in the second operand elements are unsigned. Otherwise, when running in 64-bit addressing mode program behavior might not be as expected.

VECTOR GENERATE BYTE MASK

VGBM V_1,I_2 [VRI-a]

‘E7’	V_1	////	I_2	////	RXB	‘44’
0	8	12	16	32	36	40 47

For each bit in the second operand, if the bit is one, all bit positions in the corresponding byte element of the first operand are set to ones. If the bit is zero, all bit positions in the corresponding byte element of the first operand are set to zeros.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VZERO V_1	VGBM V_1,0

Extended Mnemonic		Base Mnemonic	
VONE	V_1	VGBM	V_1,X'FFFF'

Programming Note: VECTOR GENERATE BYTE MASK is the preferred method for setting a vector register to all zeros or ones.

VECTOR GENERATE MASK

VGM V_1,I_2,I_3,M_4 [VRI-b]

'E7'	V_1	////	I_2	I_3	M_4	RXB	'46'
0	8	12	16	24	32	36	40 47

For each element in the first operand a bit mask is generated. The mask consists of bits set to one starting at the bit position specified by the unsigned integer value in I_2 and ending with the bit position specified by the unsigned integer value in I_3 all other bit positions are set to zero. Only the number of bits needed to represent all of the bit positions for the specified element size are used from the I_2 and I_3 fields, other bits are ignored. If the bit position in the I_2 field is greater than the bit position in the I_3 field, the range of bits wraps at the maximum bit position for the specified element size.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VGMB	V_1,I_2,I_3	VGM	V_1,I_2,I_3,0
VGMH	V_1,I_2,I_3	VGM	V_1,I_2,I_3,1
VGMF	V_1,I_2,I_3	VGM	V_1,I_2,I_3,2
VGMG	V_1,I_2,I_3	VGM	V_1,I_2,I_3,3

VECTOR LOAD

VL $V_1,D_2(X_2,B_2)[,M_3]$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'06'
0	8	12	16	20	32	36	40 47

VLR V_1,V_2 [VRR-a]

'E7'	V_1	V_2	///////////////////	RXB	'56'
0	8	12	16	36	40 47

The 128-bit second operand is placed unchanged in the first-operand location.

The displacement for VL is treated as a 12-bit unsigned integer.

For VL the M_3 field contains a 4-bit unsigned binary integer specifying the alignment of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_3	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 for VL)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. If the alignment of the address specified by the second operand is known to be either on a dou-

bleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.

2. Setting the alignment hint to a non-zero value that doesn’t correspond to the alignment of the second operand may reduce performance on some models.

VECTOR LOAD AND REPLICATE

VLREP $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘05’
0	8	12	16	20	32	36	40 47

The element-sized second operand is replicated into all elements of the first operand.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLREPB	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),0$
VLREPH	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),1$
VLREPF	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),2$
VLREPG	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),3$

VECTOR LOAD BYTE REVERSED ELEMENT

VLEBRH $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘01’
0	8	12	16	20	32	36	40 47

VLEBRF $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘03’
0	8	12	16	20	32	36	40 47

VLEBRG $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘02’
0	8	12	16	20	32	36	40 47

The element-sized second operand replaces the first-operand element, indexed by the M_3 field, with the left-to-right sequence of bytes reversed. The remaining elements are left unchanged. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR LOAD BYTE REVERSED ELEMENT is treated as a 12-bit unsigned integer.

For VLEBRH the elements are halfword sized. For VLEBRF the elements are word sized. For VLEBRG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Programming Note: No byte-sized element are supported by this instruction as the result would be same as VLEB.

VECTOR LOAD BYTE REVERSED ELEMENT AND REPLICATE

VLBRREP V_1,D_2(X_2,B_2),M_3 [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘05’
0	8	12	16	20	32	36	40 47

The element-sized second operand is loaded and replicated into all elements of the first operand with the left-to-right sequence of bytes reversed within the elements.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VLBRREPH V_1,D_2(X_2,B_2)	VLBRREP V_1,D_2(X_2,B_2),1
VLBRREPF V_1,D_2(X_2,B_2)	VLBRREP V_1,D_2(X_2,B_2),2
VLBRREPG V_1,D_2(X_2,B_2)	VLBRREP V_1,D_2(X_2,B_2),3

VECTOR LOAD BYTE REVERSED ELEMENT AND ZERO

VLLEBRZ V_1,D_2(X_2,B_2),M_3 [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘04’
0	8	12	16	20	32	36	40 47

An element, of the size specified by the M_3 field, is loaded from the second-operand location in storage and placed into an element in the first-operand vector register, with the left-to-right sequence of bytes reversed within that element. When the M_3 value is in the range 1-3, the unsigned element-sized second operand is placed in the rightmost sub-element or element of the leftmost doubleword element of the vector-register specified first operand with the left-to-right sequence of the bytes reversed. When the M_3 value is 6 the unsigned 4-byte second operand is placed in word 0 of the vector-register specified first operand, with its byte order reversed.

The displacement for VLLEBRZ is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-5	Reserved
6	Word - Left Aligned
7-15	Reserved

The illustration below shows the resulting register content of this instruction:

Operand 2[a]	0	1	[2]	[3]	[[4]]	[[5]]	[[6]]	[[7]]								
Operand 1[b]																
M_3=3	7	6	5	4	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=2	Z	Z	Z	Z	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=1	Z	Z	Z	Z	Z	Z	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=6	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z

a. only the number of bytes corresponding to the element size specified by M_3 are accessed.

b. a ‘Z’ in the table denotes a byte with the value of zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification

- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VLLEBRZH	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),1
VLLEBRZF	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),2
VLLEBRZG	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),3
VLLEBRZE	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),6
LDRV	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),3
LERV	V_1,D_2(X_2,B_2)	VLLEBRZ	V_1,D_2(X_2,B_2),6

Programming Note: This instruction is similar to the VECTOR LOAD LOGICAL ELEMENT AND ZERO but is useful for operating on data in storage in the little endian format

VECTOR LOAD BYTE REVERSED ELEMENTS

VLBR V_1,D_2(X_2,B_2),M_3 [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘06’

0 8 12 16 20 32 36 40 47

The 16-byte second operand is loaded into the first-operand location. For each element of the second operand, the left-to-right sequence of the bytes is reversed and placed into the corresponding first-operand element location.

The displacement for VLBR is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The illustration below shows the resulting byte position of this instruction:

Operand 2	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Operand 1																
M_3=4	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M_3=3	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
M_3=2	3	2	1	0	7	6	5	4	11	10	9	8	15	14	13	12
M_3=1	1	0	3	2	5	4	7	6	9	8	11	10	13	12	15	14

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VLBRH	V_1,D_2(X_2,B_2)	VLBR	V_1,D_2(X_2,B_2),1
VLBRF	V_1,D_2(X_2,B_2)	VLBR	V_1,D_2(X_2,B_2),2
VLBRG	V_1,D_2(X_2,B_2)	VLBR	V_1,D_2(X_2,B_2),3
VLBRQ	V_1,D_2(X_2,B_2)	VLBR	V_1,D_2(X_2,B_2),4

Programming Note: This instruction is similar to the VECTOR LOAD but is useful for operating on data in storage in the little endian format.

VECTOR LOAD ELEMENT

VLEB V_1,D_2(X_2,B_2),M_3 [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘00’

0 8 12 16 20 32 36 40 47

VLEH V_1,D_2(X_2,B_2),M_3 [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘01’

0 8 12 16 20 32 36 40 47

VLEF V_1,D_2(X_2,B_2),M_3 [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘03’

0 8 12 16 20 32 36 40 47

VLEG V_1,D_2(X_2,B_2),M_3 [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘02’

0 8 12 16 20 32 36 40 47

The element-sized second operand replaces the specified element of the first operand indexed by the

M_3 field. The remaining elements are left unchanged. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR LOAD ELEMENT is treated as a 12-bit unsigned integer.

For VLEB the elements are byte sized. For VLEH the elements are halfword sized. For VLEF the elements are word sized. For VLEG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: For VLEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

VECTOR LOAD ELEMENT IMMEDIATE

VLEIB V_1,I_2,M_3 [VRI-a]

‘E7’	V_1	////	I_2	M_3	RXB	‘40’
0	8	12	16	32	36	40 47

VLEIH V_1,I_2,M_3 [VRI-a]

‘E7’	V_1	////	I_2	M_3	RXB	‘41’
0	8	12	16	32	36	40 47

VLEIF V_1,I_2,M_3 [VRI-a]

‘E7’	V_1	////	I_2	M_3	RXB	‘43’
0	8	12	16	32	36	40 47

VLEIG V_1,I_2,M_3 [VRI-a]

‘E7’	V_1	////	I_2	M_3	RXB	‘42’
0	8	12	16	32	36	40 47

The signed binary integer second operand is sign extended, if necessary, and replaces the specified element of the first operand. The remaining elements are left unchanged. The M_3 field specifies the element index of the first operand for the second operand to replace. For VLEIB, only bits 8-15 of the second operand are placed into the byte element; bits 0-7 are ignored. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VLEIB the elements are byte sized. For VLEIH the elements are halfword sized. For VLEIF the elements are word sized. For VLEIG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: For VLEIB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

VECTOR LOAD ELEMENTS REVERSED

VLER $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘07’
0	8	12	16	20	32	36	40 47

The 16-byte second operand is loaded into the first-operand location. The left-to-right sequence of the elements is reversed when loading into the vector register. The bytes within the elements themselves are not reversed.

The displacement for VLER is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The illustration below shows the resulting byte position of this instruction:

Operand 2	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Operand 1																
M_3=3	8	9	10	11	12	13	14	15	0	1	2	3	4	5	6	7
M_3=2	12	13	14	15	8	9	10	11	4	5	6	7	0	1	2	3
M_3=1	14	15	12	13	10	11	8	9	6	7	4	5	2	3	0	1

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLERH	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),1$
VLERF	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),2$
VLERG	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),3$

Programming Notes:

1. VECTOR LOAD BYTE REVERSED ELEMENTS with an M_3 value of 4 can be used to reverse the elements when the elements are byte-sized.
2. This instruction is useful in the context of large precision arithmetic.

VECTOR LOAD GR FROM VR ELEMENT

VLGV $R_1,V_3,D_2(B_2),M_4$ [VRS-c]

'E7'	R_1	V_3	B_2	D_2	M_4	RXB	'21'
0	8	12	16	20	32	36	40 47

The element of the third operand indexed by the second-operand address is placed in the first-operand location. The third operand is a vector register. The first operand is a general register. If the index specified by the second-operand address is greater than the highest numbered element in the third operand, of the specified element size, the result in the first operand is unpredictable.

If the vector register element is smaller than a doubleword, the element is right aligned in the 64-bit general register and zeros fill the remaining bits.

The second-operand address is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the third operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic

VLGVH	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2)$,1
VLGVF	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2)$,2
VLGVG	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2)$,3

VECTOR LOAD LOGICAL ELEMENT AND ZERO

VLLEZ $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E7’	V_1	X_2	B_2	D_2	M_3	RXB	‘04’	
0	8	12	16	20	32	36	40	47

When the M_3 value is in the range of 0-3, the unsigned element-sized second operand is placed in the rightmost sub-element or element of the leftmost doubleword element of the vector-register specified first operand. When the vector-enhancements facility 1 is installed and the M_3 value is 6 the unsigned element-sized second operand is placed in the leftmost sub-element of the leftmost doubleword element of the vector-register specified first operand. The bit positions of all other elements are set to zero. The element size is determined by the ES value in the M_3 field.

The displacement for VLLEZ is treated as a 12-bit unsigned binary integer.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 1 is not installed the M_3 value of 6 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-5	Reserved
6	Word - Left Aligned
7-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLLEZB	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2)$,0
VLLEZH	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2)$,1
VLLEZF	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2)$,2
VLLEZG	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2)$,3
VLLEZLF	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2)$,6

Programming Note: This instruction can be used for loading scalar values into vector registers.

VECTOR LOAD MULTIPLE

VLM $V_1,V_3,D_2(B_2)[,M_4]$ [VRS-a]

‘E7’	V_1	V_3	B_2	D_2	M_4	RXB	‘36’	
0	8	12	16	20	32	36	40	47

The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are loaded from storage beginning at the location specified by the second-operand address and continuing through as many locations as needed.

The vector registers are loaded in ascending order of their register numbers starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized. The number of registers to be loaded is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VLM is treated as a 12-bit unsigned binary number.

The M_4 field contains a 4-bit unsigned binary integer specifying the alignment of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_4	**Alignment Hint**
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are loaded.
2. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.
3. Setting the alignment hint to a non-zero value that doesn’t correspond to the alignment of the second operand may reduce performance on some models.

VECTOR LOAD RIGHTMOST WITH LENGTH

VLRLR $V_1,R_3,D_2(B_2)$ [VRS-d]

'E6'	////	R_3	B_2	D_2	V_1	RXB	‘37’
0	8	12	16	20	32	36	40 47

VLRL $V_1,D_2(B_2),I_3$ [VSI]

'E6'	I_3	B_2	D_2	V_1	RXB	'35'
0	8	16	20	32	36	40 47

Proceeding from left to right, the specified number of bytes from the second-operand location are placed in the first operand location.

For VLRLR, bits 32-63 of the general-register specified third operand contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to load. If the third operand contains a value greater than or equal to fifteen, all bytes of the first operand are loaded. Bits 0-31 of the third operand are ignored.

For VLRL, the I_3 field has the following format:

/	/	/	/	L_2
0	1	2	3	4 7

The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-3 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code(L2):*** Bits 4-7 contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to load. If the L_2 field contains a value equal to fifteen, all bytes of the first operand are loaded.

Zeros are placed in any bytes of the first operand that are not loaded from the second operand. Access exceptions are only recognized for the bytes of the second operand that are loaded from storage.

The displacement is a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification (VLRL only)
- Transaction constraint

VECTOR LOAD TO BLOCK BOUNDARY

VLBB V$_1$,D$_2$(X$_2$,B$_2$),M$_3$ [VRX]

‘E7’	V$_1$	X$_2$	B$_2$	D$_2$	M$_3$	RXB	‘07’
0	8	12	16	20	32	36	40 47

The single vector-register first operand is loaded starting at the zero indexed byte element with bytes from the second operand. If a boundary condition is encountered, the rest of the first operand is unpredictable . Access exceptions are not recognized for second-operand locations beyond the specified boundary. If no boundary is encountered, all byte elements of the first operand are loaded with data from storage.

The displacement for VLBB is treated as a 12-bit unsigned integer.

The M$_3$ field specifies a code indicating the boundary at which the second operand ends. If a reserved value is specified, a specification exception is recognized.

Code	Boundary
0	64 Byte
1	128 Byte
2	256 Byte
3	512 Byte
4	1 K-byte
5	2 K-Byte
6	4 K-Byte
7-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. In certain circumstances, data may be loaded past the block boundary. However, this will only occur if there are no access exceptions on that data. The program should not depend on the unpredictable data being loaded by a particular model.
2. This instruction can be used for loading null-terminated character data without crossing a page, segment, or region boundary unnecessarily.
3. If a block size code equal to the cache line size of the processor is specified, performance may be improved due to the fact that subsequent accesses will be aligned.
4. The LOAD COUNT TO BLOCK BOUNDARY instruction may be used with the same specified boundary to obtain a count of the number of bytes loaded.

VECTOR LOAD VR ELEMENT FROM GR

VLVG V$_1$,R$_3$,D$_2$(B$_2$),M$_4$ [VRS-b]

‘E7’	V$_1$	R$_3$	B$_2$	D$_2$	M$_4$	RXB	‘22’
0	8	12	16	20	32	36	40 47

The third operand of size specified by the ES value in the M$_4$ field is placed into the element of the first operand indexed by the second-operand address. The third operand is a general register. The first operand is a vector register. If the index, specified by the second-operand address, is greater than the highest numbered element in the first operand, of the specified element size, it is unpredictable which element, if any, is replaced.

For element sizes less than doubleword the rightmost bits of the third operand are used.

The second operand is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the first operand.

The M$_4$ field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M$_4$	Element Size
0	Byte
1	Halfword
2	Word

M_4	Element Size
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR LOAD VR FROM GRS DISJOINT

VLVGP V_1,R_2,R_3 [VRR-f]

'E7'	V_1	R_2	R_3	/////////////////	RXB	'62'
0	8	12	16	20	36	40 47

The general register specified second operand placed unchanged into bit positions 0-63 of the first operand. The general register specified third operand is placed unchanged into bit positions 64-127 of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR LOAD WITH LENGTH

VLL $V_1,R_3,D_2(B_2)$ [VRS-b]

'E7'	V_1	R_3	B_2	D_2	////	RXB	'37'
0	8	12	16	20	32	36	40 47

Proceeding from left to right, bytes of the first operand are loaded from the second-operand location. The third operand (in general register R_3) contains a 32-bit unsigned integer that represents the highest indexed byte to load. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are loaded. Zeros are placed in any bytes that are not loaded.

Access exceptions are only recognized for the bytes of the second operand that are loaded from storage.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR MERGE HIGH

VECTOR PACK

VPK V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘94’
0	8	12	16	20	32	36	40 47

A source vector is created from the concatenation of the vector register-specified second operand followed by the vector-register-specified third operand. In a left to right fashion, each element in the source vector is reduced in size by half. The rightmost half of each element of the source vector is placed into the corresponding element of the vector-register-specified first operand.

If the same register is used to designate the first operand as either the second or third operands the source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Reserved

0	8	12	16	20	24	28	32	36	40 47

A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion each signed element in the source vector is reduced in size by half and placed in the corresponding element of the first operand. If the element in the source vector is outside of the allowable range of the target element, the target element is set to the maximum value in the target format in the direction of the overflow.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:

/	/	/	CS
0			3

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When bit 3 of the M_5 field is one, the condition code is set as follows:

0 No saturation
1 At least one but not all elements saturated
2 --
3 Saturation on all elements

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VPKSH	V_1,V_2,V_3	VPKS	V_1,V_2,V_3,1,0
VPKSF	V_1,V_2,V_3	VPKS	V_1,V_2,V_3,2,0

VPKSFS	V_1,V_2,V_3	VPKS	V_1,V_2,V_3,2,1
VPKSGS	V_1,V_2,V_3	VPKS	V_1,V_2,V_3,3,1

VECTOR PACK LOGICAL SATURATE

VPKLS V_1V_2,V_3,M_4,M_5 [VRR-b]

'E7'	V_1	V_2	V_3	////	M_5	////	M_4	RXB	'95'
0	8	12	16	20	24	28	32	36	40 47

A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion, each unsigned integer element in the source vector is reduced in size by half and placed in the corresponding element in the first operand. If the magnitude of the element in the source vector is greater than the largest magnitude representable in the target element, the target element is set to the largest representable magnitude value.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:

/	/	/	CS
0			3

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When bit 3 of the M_5 field is one, the condition code is set as follows:

0 No saturation
1 At least one but not all elements saturated
2 --
3 Saturation on all elements

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VPKLSH	V_1,V_2,V_3	VPKLS	V_1,V_2,V_3,1,0

VECTOR PERMUTE

VPERM V_1,V_2,V_3,V_4 [VRR-e]

'E7'	V_1	V_2	V_3	////////////	V_4	RXB	'8C'
0	8	12	16	20	32	36	40 47

A source vector is created from the concatenation of the second operand followed by the third operand. The byte element of the source vector indexed by the five least significant bits of each byte element of the fourth operand is placed into the byte element of the first operand corresponding to the byte element in the fourth operand.

If the same register is used to designate the first operand as either the second, third, or fourth operands the original source value is used throughout the operation with no intermediate updates.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR PERMUTE DOUBLEWORD IMMEDIATE

VPDI V_1,V_2,V_3,M_4 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////	M_4	RXB	'84'
0	8	12	16	20	32	36	40 47

The first, second and third operands consist of double word elements. Bit 1 of the M_4 field is the index which selects which doubleword of the second operand is placed into the zero indexed doubleword of the first operand. Bit 3 of the M_4 field is the index which selects which doubleword of the third operand is placed in the doubleword element with index one of the first operand.

The M_4 field has the following format:

/	I 2	/	I 3
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0 and 2 are reserved and should be zeros; otherwise, the program may not operate compatibly in the future.
- ***Second Operand Index (I2):*** Bit 1 provides the index of the doubleword in the second operand to be placed in the first operand.
- ***Third operand index (I3):*** Bit 3 provides the index of the doubleword in the third operand to be placed in the first operand.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR REPLICATE

VREP V_1,V_3,I_2,M_4 [VRI-c]

'E7'	V_1	V_3	I_2	M_4	RXB	'4D'
0	8	12	16	32	36	40 47

The element of the third operand indexed by the unsigned integer in I_2 is replicated across all elements of the first operand. If the value of the unsigned integer in I_2 is greater than the highest element number in the third operand, of the specified element size, a specification exception is recognized.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VREPB V_1,V_3,I_2	VREP V_1,V_3,I_2,0

Extended Mnemonic		Base Mnemonic	
VREPH	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,1$
VREPF	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,2$
VREPG	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,3$

VECTOR REPLICATE IMMEDIATE

VREPI V_1,I_2,M_3 [VRI-a]

‘E7’	V_1	////	I_2	M_3	RXB	‘45’	
0	8	12	16	32	36	40	47

The signed integer immediate value in I_2 is sign extended, if necessary, and replicated across all elements of the first operand. If the element size is less than a halfword, only bits 8 through 15 of the I_2 field are used; bits zero through seven are ignored.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VREPIB	V_1,I_2	VREPI	$V_1,I_2,0$
VREPIH	V_1,I_2	VREPI	$V_1,I_2,1$
VREPIF	V_1,I_2	VREPI	$V_1,I_2,2$
VREPIG	V_1,I_2	VREPI	$V_1,I_2,3$

VECTOR SCATTER ELEMENT

VSCEF $V_1,D_2(V_2,B_2),M_3$ [VRV]

‘E7’	V_1	V_2	B_2	D_2	M_3	RXB	‘1B’	
0	8	12	16	20	32	36	40	47

VSCEG $V_1,D_2(V_2,B_2),M_3$ [VRV]

‘E7’	V_1	V_2	B_2	D_2	M_3	RXB	‘1A’	
0	8	12	16	20	32	36	40	47

The element of the first operand designated by the M_3 field is placed unchanged into the second-operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VSCEF the elements are 4-bytes in size; for VSCEG the elements are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register V_2 indexed by the M_3 field with the address in the B_2 register along with the D_2 value.

The displacement for VECTOR SCATTER ELEMENT is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The VECTOR SCATTER ELEMENT instruction can be used to perform a store when doing scalar computation in vector registers and the address resides in a vector register. However, depending on the model, performance may be better if address computations are done in general registers.

2. For VSCEF care must be taken to ensure that the values in the second operand elements are unsigned. Otherwise, when running in 64-bit

addressing mode program behavior might not be as expected.

VECTOR SELECT

VSEL V_1,V_2,V_3,V_4 [VRR-e]

'E7'	V_1	V_2	V_3	////////////	V_4	RXB	'8D'
0	8	12	16	20	32		40 47

For each bit in the fourth operand that contains a zero, the corresponding bit from the third operand is placed in the corresponding bit of the first operand. For each bit in the fourth operand that contains a one, the corresponding bit from the second operand is placed in the corresponding bit of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SIGN EXTEND TO DOUBLEWORD

VSEG V_1,V_2,M_3 [VRR-a]

'E7'	V_1	V_2	////////////////	M_3	RXB	'5F'
0	8	12	16	32	36	40 47

The leftmost bit of the rightmost element-sized subelement of each doubleword of the second operand is replicated across all bit positions of all other elements in the doubleword. The result is placed in the corresponding doubleword of the first operand.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in each doubleword of the second operand. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSEGB	V_1,V_2	VSEG	$V_1,V_2,0$
VSEGH	V_1,V_2	VSEG	$V_1,V_2,1$
VSEGF	V_1,V_2	VSEG	$V_1,V_2,2$

Programming Notes:

1. This instruction allows for a value to be sign extended after being loaded with VECTOR LOAD LOGICAL ELEMENT AND ZERO.
2. To sign extend to smaller element sizes the VECTOR UNPACK instructions can be used.

VECTOR STORE

VST $V_1,D_2(X_2,B_2)[,M_3]$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'0E'
0	8	12	16	20	32	36	40 47

The 128-bit value in the first operand is stored to the storage location specified by the second operand.

The displacement for VST is treated as a 12-bit unsigned integer.

The M_3 field specifies an alignment hint (AH). The AH control specifies the alignment of the first byte of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_3	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.

2. Setting the alignment hint to a non-zero value that doesn’t correspond to the alignment of the second operand may reduce performance on some models.

VECTOR STORE BYTE REVERSED ELEMENT

VSTEBRH $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘09’
0	8	12	16	20	32	36	40 47

VSTEBRF $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘0B’
0	8	12	16	20	32	36	40 47

VSTEBRG $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘0A’
0	8	12	16	20	32	36	40 47

The first-operand element, indexed by the M_3 field, is stored into the element-sized second-operand. The left-to-right sequence of bytes within the elements is reversed when storing into the storage location. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR STORE BYTE REVERSED ELEMENT is treated as a 12-bit unsigned integer.

For VSTEBRH the elements are halfword sized. For VSTEBRF the elements are word sized. For VSTEBRG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
STERV	$V_1,D_2(X_2,B_2)$	VSTEBRF	$V_1,D_2(X_2,B_2)$,0
STDRV	$V_1,D_2(X_2,B_2)$	VSTEBRG	$V_1,D_2(X_2,B_2)$,0

Programming Note: No byte-sized element version of this instruction exists as it would deliver the same result as VSTEB.

VECTOR STORE BYTE REVERSED ELEMENTS

VSTBR $V_1,D_2(X_2,B_2),M_3$ [VRX]

‘E6’	V_1	X_2	B_2	D_2	M_3	RXB	‘0E’
0	8	12	16	20	32	36	40 47

The first operand is stored into the 16-bytes second operand. For each element of the first operand, the left-to-right sequence of bytes is reversed as that element is placed into the corresponding element of the 16-byte storage.

The displacement for VSTBR is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be stored. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The illustration below shows the resulting byte position of this instruction:

Operand 1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Operand 2																
M_3=4	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M_3=3	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
M_3=2	3	2	1	0	7	6	5	4	11	10	9	8	15	14	13	12
M_3=1	1	0	3	2	5	4	7	6	9	8	11	10	13	12	15	14

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSTBRH	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2)$,1
VSTBRF	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2)$,2
VSTBRG	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2)$,3
VSTBRQ	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2)$,4

Programming Note: This instruction is similar to the VECTOR STORE but is useful for operating on data in storage in the little endian format.

VECTOR STORE ELEMENT

VSTEB $V_1,D_2(X_2,B_2),M_3$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'08'
0	8	12	16	20	32	36	40 47

VSTEH $V_1,D_2(X_2,B_2),M_3$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'09'
0	8	12	16	20	32	36	40 47

VSTEF $V_1,D_2(X_2,B_2),M_3$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'0B'
0	8	12	16	20	32	36	40 47

VSTEG $V_1,D_2(X_2,B_2),M_3$ [VRX]

'E7'	V_1	X_2	B_2	D_2	M_3	RXB	'0A'
0	8	12	16	20	32	36	40 47

The element of the first operand designated by the M_3 field is placed unchanged into the second-operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized. For VSTEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

The displacement for VECTOR STORE ELEMENT is treated as a 12-bit unsigned integer.

For VSTEB the elements are byte sized. For VSTEH the elements are halfword sized. For VSTEF the elements are word sized. For VSTEG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR STORE ELEMENTS REVERSED

VSTER $V_1,D_2(X_2,B_2),M_3$ [VRX]

'E6'	V_1	X_2	B_2	D_2	M_3	RXB	'0F'
0	8	12	16	20	32	36	40 47

The first operand is stored into the 16-bytes second operand. The left-to-right sequence of the elements is reversed when storing into the storage location.

The displacement for VSTER is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be stored. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The illustration below shows the resulting byte position of this instruction:

Operand 1	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Operand 2																
M_3=3	8	9	10	11	12	13	14	15	0	1	2	3	4	5	6	7
M_3=2	12	13	14	15	8	9	10	11	4	5	6	7	0	1	2	3
M_3=1	14	15	12	13	10	11	8	9	6	7	4	5	2	3	0	1

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VSTERH	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2)$,1
VSTERF	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2)$,2
VSTERG	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2)$,3

Programming Notes:

1. VECTOR STORE BYTE REVERSED ELEMENTS with an M_3 value of 4 can be used to reverse the elements when the elements are byte-sized.
2. This instruction is useful in the context of large precision arithmetic.

VECTOR STORE MULTIPLE

VSTM $V_1,V_3,D_2(B_2)[,M_4]$ [VRS-a]

'E7'	V_1	V_3	B_2	D_2	M_4	RXB	'3E'
0	8	12	16	20	32	36	40 47

The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are placed in the storage area beginning at the location specified by the second-operand address and continuing through as many locations as needed.

The contents of bit positions 0-127 of the vector registers are stored in successive 16-byte fields beginning at the second-operand address.

The vector registers are stored in the ascending order of their register numbers, starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized. The number of registers to be stored is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VSTM is treated as a 12-bit unsigned binary number.

The M_4 field specifies an alignment hint (AH). The AH control specifies the alignment of the first byte of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_4	**Alignment Hint**
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are stored.

2. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.

3. Setting the alignment hint to a non-zero value that doesn't correspond to the alignment of the second operand may reduce performance on some models.

VECTOR STORE RIGHTMOST WITH LENGTH

VSTRLR $V_1,R_3,D_2(B_2)$ [VRS-d]

'E6'	////	R_3	B_2	D_2	V_1	RXB	'3F'
0	8	12	16	20	32	36	40 47

VSTRL $V_1,D_2(B_2),I_3$ [VSI]

'E6'	I_3	B_2	D_2	V_1	RXB	'3D'
0	8	16	20	32	36	40 47

Proceeding from left to right, the specified number of rightmost bytes from the first operand are stored at the second-operand location.

For VSTRLR, bits 32-63 of the general register specified third operand contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to store. If the third operand contains a value greater than or equal to fifteen, all bytes of the first operand are stored. Bits 0-31 of the third operand are ignored.

For VSTRL, the I_3 field has the following format:

/	/	/	/	L_2
0	1	2	3	4 7

The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-3 are reserved and must contain zeros. Otherwise, a specification exception is recognized.

- ***Operand 2 Length Code(L2):*** Bits 4-7 contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to store. If the L_2 field contains a value equal to fifteen, all bytes of the first operand are stored.

Access exceptions are only recognized on bytes stored.

The displacement is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification (VSTRL only)
- Transaction constraint

VECTOR STORE WITH LENGTH

VSTL $V_1,R_3,D_2(B_2)$ [VRS-b]

‘E7’	V_1	R_3	B_2	D_2	////	RXB	‘3F’
0	8	12	16	20	32	36	40 47

Proceeding from left to right, bytes from the first operand are stored at the second-operand location. The general register specified third operand contains a 32-bit unsigned integer containing a value that represents the highest indexed byte to store. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are stored.

Access exceptions are only recognized on bytes stored.

The displacement for VECTOR STORE WITH LENGTH is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR UNPACK HIGH

VUPH V_1V_2,M_3 [VRR-a]

‘E7’	V_1	V_2	////////////////	M_3	RXB	‘D7’
0	8	12	16	32	36	40 47

The elements of the left-most half of the vector-register second operand are sign extended and placed into double-sized elements in the first operand. The right-most half of the second operand are ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the second operand. The first operand contains elements twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

Instructions

Many instructions have an extended mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.

Unless otherwise specified all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Programming Note: The vector-enhancements facility 2 includes the following shift features:

- The following new instructions are added:
  – VECTOR SHIFT LEFT/RIGHT DOUBLE BY BIT (VSLD, VSRD)
- The behavior for different per byte element shift amount has been defined:
  – VECTOR SHIFT LEFT (VSL), VECTOR SHIFT RIGHT LOGICAL (VSRL)

VRI	VRI instruction format
VRR	VRR instruction format
VRS	VRS instruction format

Figure 22-1. Summary of Vector Integer Instructions (Part 2 of 2)

VECTOR ADD

VA V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘F3’
0	8	12	16	20	32	36	40 47

The contents of each element of the second operand are added to the contents of each corresponding element of the third operand and the resulting sum or sums are placed in the first operand. Each element is treated as a signed binary integer of size specified by the element size control in the M_4 field.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position.

No fixed point overflow exceptions are recognized.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VAB	V_1,V_2,V_3	VA	V_1,V_2,V_3,0
VAH	V_1,V_2,V_3	VA	V_1,V_2,V_3,1
VAF	V_1,V_2,V_3	VA	V_1,V_2,V_3,2
VAG	V_1,V_2,V_3	VA	V_1,V_2,V_3,3
VAQ	V_1,V_2,V_3	VA	V_1,V_2,V_3,4

Programming Note: The same results are obtained if the contents of each element contain unsigned binary integers.

VECTOR ADD COMPUTE CARRY

VACC V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘F1’
0	8	12	16	20	32	36	40 47

The contents of each element of the second operand are added to the contents of each corresponding element of the third operand. If the addition of two elements results in a carry out of bit zero, a value of one is placed in the corresponding element of the first operand. If there is no carry out of bit zero, a value of zero is placed in the corresponding element of the first operand. Each element is treated as an unsigned binary integer of size specified by the element size in the M_4 field.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACCB	V_1,V_2,V_3	VACC	V_1,V_2,V_3,0
VACCH	V_1,V_2,V_3	VACC	V_1,V_2,V_3,1
VACCF	V_1,V_2,V_3	VACC	V_1,V_2,V_3,2
VACCG	V_1,V_2,V_3	VACC	V_1,V_2,V_3,3
VACCQ	V_1,V_2,V_3	VACC	V_1,V_2,V_3,4

VECTOR ADD WITH CARRY

VAC V_1,V_2,V_3,V_4,M_5 [VRR-d]

‘E7’	V_1	V_2	V_3	M_5	/////////	V_4	RXB	‘BB’
0	8	12	16	20	24	32	36	40 47

The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand concatenated with 127 bits of zero on its left are added to the intermediate sum and the resulting sum is placed in the first operand. All bits except for the rightmost bit position of the fourth operand are ignored. Each operand is treated as a 128-bit unsigned binary integer.

When there is an overflow, the result is obtained by allowing any carry into the leftmost-bit position and ignoring any carry out of the leftmost-bit position.

No fixed point overflow exceptions are recognized.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACQ	V_1,V_2,V_3,V_4	VAC	$V_1,V_2,V_3,V_4,4$

VECTOR ADD WITH CARRY COMPUTE CARRY

VACCC V_1,V_2,V_3,V_4,M_5 [VRR-d]

'E7'	V_1	V_2	V_3	M_5	/////////	V_4	RXB	'B9'
0	8	12	16	20	24	32	36	40 47

The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand concatenated with 127 bits of zero on its left are added to the intermediate sum. All bits except for the rightmost bit position of the fourth operand are ignored. If the addition results in a carry out of the leftmost bit, a value of one is placed in the first operand. If there is no carry out of the leftmost bit, a value of zero is placed in the first operand. Each operand is treated as a 128-bit unsigned binary integer.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACCCQ	V_1,V_2,V_3,V_4	VACCC	$V_1,V_2,V_3,V_4,4$

VECTOR AND

VN V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	////////////////	RXB	'68'
0	8	12	16	20	36	40 47

The AND of the second and third operands is placed in the first operand.

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operand contain ones; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR AND WITH COMPLEMENT

VNC V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	////////////////	RXB	'69'
0	8	12	16	20	36	40 47

The AND of the second operand and the bit-wise complement of the third operand is placed in the first operand.

The connective AND is applied to the second operand and bit-wise complemented third operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in the second operand contains a one and the third operand contains a zero; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Note: This instruction is useful for zeroing out bits under a mask.

VECTOR AVERAGE

VAVG V_1,V_2,V_3,M_4 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////	M_4	RXB	'F2'
0	8	12	16	20	32	36	40 47

VECTOR AVERAGE LOGICAL

VAVGL V_1,V_2,V_3,M_4 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////	M_4	RXB	'F0'
0	8	12	16	20	32	36	40 47

The average of the corresponding elements of the second and third operands is placed in the corresponding element of the first operand.

For VECTOR AVERAGE, each element of the second operand and the corresponding element of the third operand are sign extended by one bit. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

For VECTOR AVERAGE LOGICAL, each element of the second operand and the corresponding element of the third operand are extended by one bit by appending a zero on the left. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VAVGB	V_1,V_2,V_3	VAVG	V_1,V_2,V_3,0
VAVGH	V_1,V_2,V_3	VAVG	V_1,V_2,V_3,1
VAVGF	V_1,V_2,V_3	VAVG	V_1,V_2,V_3,2
VAVGG	V_1,V_2,V_3	VAVG	V_1,V_2,V_3,3
VAVGLB	V_1,V_2,V_3	VAVGL	V_1,V_2,V_3,0
VAVGLH	V_1,V_2,V_3	VAVGL	V_1,V_2,V_3,1
VAVGLF	V_1,V_2,V_3	VAVGL	V_1,V_2,V_3,2

VECTOR CHECKSUM

VCKSM V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	//////////////////	RXB	'66'
0	8	12	16	20	36	40 47

The word-sized elements from the second operand are added together one-by-one along with the element in word one of the third operand. The sum is placed in word one of the first operand. Zeros are placed in word elements 0, and 2-3 of the first operand. The word-sized elements are all treated as 32-bit unsigned binary integers. After each addition of an element, a carry out of bit position 0 of the sum is added to bit position 31 of the result in word element one of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. The contents of the third operand should contain zero at the start of a checksum computation algorithm.
2. A16-bit checksum is used in, for example, the TCP/IP application. The following program can be executed after a 32-bit checksum has been computed:

   ```
   VERLLF V2,V1,16(0)
   VAF V2,V1,V2
   ```

   The halfword in element 2 will contain the 16-bit checksum.

VECTOR ELEMENT COMPARE

VEC V_1,V_2,M_3 [VRR-a]

'E7'	V_1	V_2	/////////////////	M_3	RXB	'DB'
0	8	12	16	32	36	40 47

VECTOR ELEMENT COMPARE LOGICAL

VECL V_1,V_2,M_3 [VRR-a]

'E7'	V_1	V_2	/////////////////	M_3	RXB	'D9'
0	8	12	16	32	36	40 47

The single element of specified size of the first and second operands are compared and the result is indicated in the condition code.

The elements compared are treated as signed binary integers for VEC and unsigned binary integers for VECL.

The index of the element that is being compared is dependent on the size of the element being compared. Figure 22-2 specifies what element is compared for each element size.

Element Size	Element Index
Byte	7
Halfword	3
Word	1
Doubleword	0

Figure 22-2. Element Sizes and Indexes

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Resulting Condition Code:

0 Operand elements equal
1 First operand element low
2 First operand element high
3 --

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

0	8	12	16	20	24	28	32	36	40 47

The unsigned binary integer elements of the second operand are compared with the corresponding unsigned binary integer elements of the third operand. If the element in the second operand is equal to the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise they are all set to zeros.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:

/	/	/	CS
0			3

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code:

When bit 3 of the M_5 field is one, the condition code is set as follows:

0	All elements equal
1	At least one, but not all elements equal
2	--
3	No element equal

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic

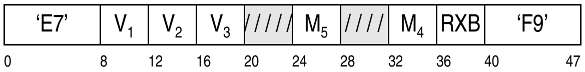
VCHGS	V_1,V_2,V_3	VCH	$V_1,V_2,V_3,3,1$

Programming Notes:

1. Depending on the model, setting the condition code may result in reduced performance.
2. To do a COMPARE NOT HIGH, reverse the second and third operands.

VECTOR COMPARE HIGH LOGICAL

VCHL V_1,V_2,V_3,M_4,M_5 [VRR-b]

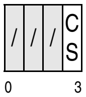


The unsigned elements of the second operand are compared to the corresponding unsigned elements of the third operand. If the element in the second operand is greater than the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise, they are all set to zeros.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code:

When bit 3 of the M_5 field is one, the condition code is set as follows:

0 All elements high
1 Some elements high
2 --
3 No element high

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VCHLB	V_1,V_2,V_3	VCHL	$V_1,V_2,V_3,0,0$

VECTOR EXCLUSIVE OR

VX V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////////	RXB	'6D'
0	8	12	16	20	36	40 47

The EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR GALOIS FIELD MULTIPLY SUM

VGFM V_1,V_2,V_3,M_4 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////	M_4	RXB	'B4'
0	8	12	16	20	32	36	40 47

Each element of the second operand is multiplied in a Galois field with the corresponding element of the third operand. The Galois field has an order of two. This multiplication is similar to standard binary multiplication, but instead of adding the shifted multiplicand it is exclusive ORed. The resulting even-odd pairs of double element-sized products are exclusive ORed with each other and placed in the corresponding double-wide element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘FC’
0	8	12	16	20	32	36	40 47

Each element of the second operand is compared to the corresponding element of the third operand. The smaller of the two values is placed into the corresponding element of the first operand. If the operands are equal the value of both elements is placed in the corresponding element of the first operand.

For VECTOR MINIMUM the operands contain signed integer elements, for VECTOR MINIMUM LOGICAL the operands contain unsigned integer elements.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR MULTIPLY SUM LOGICAL

VMSL V_1,V_2,V_3,V_4,M_5,M_6 [VRR-d]

‘E7’	V_1	V_2	V_3	M_5	M_6	////	V_4	RXB	‘B8’

0 8 12 16 20 24 28 32 36 40 47

The even indexed unsigned integer elements of the second and third operands are multiplied to create a double element wide first intermediate result. The odd indexed elements of the second and third operands are multiplied together to create a double element wide second intermediate result. The first and second double-element-wide intermediate results are each shifted to the left by the values specified in the M_6 field and then added together along with the corresponding double-wide even-odd element pair value in the fourth operand and the corresponding even-odd element pair sums are placed in the first operand. Any carry outs or overflows from the additions are ignored.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0-2	Reserved
3	Doubleword
4-15	Reserved

The M_6 field has the following format:

E S	O S	/	/
0	1	2	3

The bits of the M_6 field are defined as follows:

- ***Even Shift Indication (ES):*** When bit 0 is one, the first intermediate result is shifted left one bit before the addition; when bit 0 is zero shifting of the first intermediate result is not performed.

- ***Odd Shift Indication (OS):*** When bit 1 is one, the second intermediate result is shifted left one bit before the addition; when bit 1 is zero shifting of the second intermediate result is not performed.

- ***Reserved:*** Bits 2 and 3 are reserved and should be zeros; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (vector-enhancements facility 1 not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VMSLG	V_1,V_2,V_3,V_4,M_6	VMSL	V_1,V_2,V_3,V_4,3,M_6

Programming Notes:

1. On some models when a doubleword element size is specified, if the most significant eight bits of the elements in the second and third operands are non-zero performance may be significantly reduced.

2. The primary intended use of this instruction is as a building block for software implementation of larger multiplications.

3. The shift controls in the M_6 field may be used for software implementations of squaring of large binary numbers.

VECTOR NAND

VNN V_1,V_2,V_3 [VRR-c]

'E7'	V_1	V_2	V_3	/////////////////	RXB	'6E'

0 8 12 16 20 36 40 47

The NAND of the second and third operands is placed in the first operand.

The connective NAND is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in both source operands contain ones; otherwise, the result bit is set to one.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (vector-enhancements facility 1 not installed)
- Transaction constraint

VECTOR NOR

VNO V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////////	RXB	‘6B’

0 8 12 16 20 36 40 47

The NOR of the second and third operands is placed at the first-operand location.

The connective NOR is applied to the operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit in both operands contains zero; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Note: VNO can be used to provide the functionality of a bit-wise NOT operation by specifying the same vector-register for V_2 and V_3.

Extended Mnemonics:

VPOPCTG V_1,V_2	VPOPCT V_1,V_2,3

Programming Note: To count all of the ones in a vector register, a VECTOR SUM ACROSS instruction may be used.

VECTOR ELEMENT ROTATE LEFT LOGICAL

VERLLV V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘73’
0	8	12	16	20	32	36	40 47

VERLL $V_1,V_3,D_2(B_2),M_4$ [VRS-a]

‘E7’	V_1	V_3	B_2	D_2	M_4	RXB	‘33’
0	8	12	16	20	32	36	40 47

For VERLLV, each element in the second operand is rotated left by the number of bits specified in the corresponding element of the third operand modulo the element size in bits. For VERLL, each element in the third operand is rotated left by the number of bits specified by the second-operand address, modulo the number of bits in the specified element size.

Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The result is placed in the corresponding element in the first operand.

For VERLL, The displacement is treated as a 12-bit unsigned integer.

For VERLL, The second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: Although the rotate amount is defined to be an unsigned integer of the number of bits necessary to specify a full rotate left amount for an element, a negative value may be encoded which effectively specifies a rotate-right amount.

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VERLLVB	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,0$
VERLLVH	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,1$

VECTOR ELEMENT ROTATE AND INSERT UNDER MASK

VERIM V_1,V_2,V_3,I_4,M_5 [VRI-d]

‘E7’	V_1	V_2	V_3	////	I_4	M_5	RXB	‘72’

0 8 12 16 20 24 32 36 40 47

Each element of the second operand is rotated left by the number of bits specified by the fourth operand. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The third operand contains a mask in each element. For each bit in the third operand that is one, the corresponding bit of the rotated elements in the second operand replaces the corresponding bit in the first operand. For each bit in the third operand that is zero, the corresponding bit of the first operand remains unchanged. Except for the case when the first operand is the same as either the second or third operand, the second and third operands remain unchanged.

The fourth operand is an unsigned binary integer specifying the number of bits to rotate each element in the second operand by. If the value is larger than the number of bits in the specified element size, the value is reduced modulo the number of bits in the element.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VERIMB	V_1,V_2,V_3,I_4	VERIM	V_1,V_2,V_3,I_4,0
VERIMH	V_1,V_2,V_3,I_4	VERIM	V_1,V_2,V_3,I_4,1
VERIMF	V_1,V_2,V_3,I_4	VERIM	V_1,V_2,V_3,I_4,2
VERIMG	V_1,V_2,V_3,I_4	VERIM	V_1,V_2,V_3,I_4,3

Programming Notes:

1. A combination of VERIM and VGM may be used to accomplish the full functionality of ROTATE AND INSERT SELECTED BITS in Chapter 7.
2. Although the bits of the I_4 field are defined to contain an unsigned binary integer specifying the number of bits to rotate each element left, a negative value may be coded which effectively specifies a rotate-right amount.

VECTOR ELEMENT SHIFT LEFT

VESLV V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘70’
0	8	12	16	20	32	36	40 47

VESL $V_1,V_3,D_2(B_2),M_4$ [VRS-a]

‘E7’	V_1	V_3	B_2	D_2	M_4	RXB	‘30’
0	8	12	16	20	32	36	40 47

For VESLV, each element in the second operand is shifted left by the number of bits specified in the corresponding element in the third operand modulo the number of bits in an element. For VESL, each element in the third operand is shifted left by the number of bits specified by the second-operand address modulo the number of bits in the specified element size. Bits shifted out of bit 0 of each element are lost and zeros are supplied to the vacated bit positions to the right of each element. The result is placed in the first operand.

For VESL, the displacement is treated as a 12-bit unsigned integer.

For VESL, the second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be shifted. The leftmost bits of the address are ignored.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: The same results are obtained if the second operand contains either signed or unsigned binary integers.

Extended Mnemonics:

VECTOR SHIFT LEFT

VSL V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////////	RXB	‘74’
0	8	12	16	20	36	40 47

Each byte elements of the second operand are shifted left by the number of bits specified by an unsigned binary integer in bits 5-7 of the corresponding byte element of the third operand. If the vector-enhancements facility 2 is not installed and all bytes of the third operand are not equal, then the result is unpredictable. Bits shifted out of bit 0 of each byte are lost and the leftmost bits of the byte element located right of each byte element are supplied to the vacated bit positions to the right. For the rightmost byte element of the second operand, zeros are supplied to the vacated bit positions to the right. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Engineering Notes:

VECTOR SHIFT LEFT BY BYTE

VSLB V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////////	RXB	‘75’
0	8	12	16	20	36	40 47

The second operand is shifted left by the number of bytes specified by the unsigned integer in bits 1-4 of byte element seven of the third operand. Bits shifted out of bit 0 are lost and zeros are supplied to the vacated bit positions to the right. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT LEFT DOUBLE BY BIT

VSLD V_1,V_2,V_3,I_4 [VRI-d]

‘E7’	V_1	V_2	V_3	////	I_4	////	RXB	‘86’
0	8	12	16	20	24	32	36	40 47

A double-wide source vector is created by concatenating the second operand followed by the third operand. Bits 5-7 of the fourth operand contain an unsigned binary integer that specifies the start index of the 128 consecutive bits from the source vector which are placed into the first operand vector register.

If bits 0-4 of the fourth operand are non zero, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 2 is not installed)
- Transaction constraint

- Specification

Programming Note: The illustration below shows an example:

Operand 2	01	23	45	67	89	AB	CD	EF	FE	DC	BA	98	76	54	32	1 0
Operand 3	F0	E1	D2	C3	B4	A5	96	87	78	69	5A	4B	3C	2D	1E	0 A

Operand 4 = 4

Operand 1	12	34	56	78	9A	BC	DE	FF	ED	CB	A9	87	65	43	21	0 F

VECTOR SHIFT LEFT DOUBLE BY BYTE

VSLDB V_1,V_2,V_3,I_4 [VRI-d]

‘E7’	V_1	V_2	V_3	////	I_4	////	RXB	‘77’
0	8	12	16	20	24	32	36	40 47

A double-wide source vector of byte elements is created by concatenating the second operand followed by the third operand. Bits 4-7 of the fourth operand contain an unsigned binary integer that specifies the starting index of sixteen consecutive bytes from the source vector which are placed into vector register V_1. Bits 0-3 of the fourth operand should contain zeros; otherwise the results are unpredictable.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT ARITHMETIC

VSRA V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	////////////////	RXB	‘7E’
0	8	12	16	20	36	40 47

Each byte elements of the second operand is shifted right by the number of bits specified by an unsigned binary integer in bits 5-7 of each byte of the third operand. If the vector-enhancements facility 2 is not installed and all bytes of the third operand are not equal, then the result is unpredictable. Bits shifted out of bit 7 of each byte are lost and the rightmost bits of the byte element located left of each byte element are supplied to the vacated bit positions to the left. For the byte element zero of the second operand, bits equal to bit zero of byte element zero are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Engineering Notes:

VECTOR SHIFT RIGHT ARITHMETIC BY BYTE

VSRAB V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	////////////////	RXB	‘7F’
0	8	12	16	20	36	40 47

The second operand is shifted right by the number of bytes specified by the unsigned integer in bits 1-4 of byte seven of the third operand. Bits shifted out of bit 127 are lost, and bits equal to bit zero are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT DOUBLE BY BIT

VSRD V_1,V_2,V_3,I_4 [VRI-d]

‘E7’	V_1	V_2	V_3	////	I_4	////	RXB	‘87’
0	8	12	16	20	24	32	36	40 47

A double-wide source vector is created by concatenating the second operand followed by the third operand. Bits 5-7 of the fourth operand contain an unsigned binary integer that subtracted from 128 specifies the start index of the 128 consecutive bits from the source vector which are placed into the first operand vector register.

If bits 0-4 of the fourth operand are non zero, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 2 is not installed)
- Transaction constraint
- Specification

Programming Note: This instruction is intended to extract arbitrary length data elements not on a byte boundary into SIMD elements for parallel processing.

VECTOR SHIFT RIGHT LOGICAL

VSRL V_1,V_2,V_3 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////////	RXB	‘7C’
0	8	12	16	20	36	40 47

Each byte elements of the second operand are shifted right by the number of bits specified by an unsigned binary integer in bits 5-7 of the corresponding byte element of the third operand. If the vector-enhancements facility 2 is not installed and all bytes of the third operand are not equal, then the result is unpredictable. Bits shifted out of bit 7 of each byte are lost and the rightmost bits of the byte element located left of each byte element are supplied to the vacated bit positions to the left. For the byte element zero of the second operand, zeros are supplied to the vacated bit positions to the left. The result is placed in the first operand.

Programming Note: VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION in conjunction with VECTOR SUBTRACT WITH BORROW INDICATION can be used to perform subtractions on values with a precision greater than a quadword.

VECTOR SUM ACROSS DOUBLEWORD

VSUMG V_1,V_2,V_3,M_4 [VRR-c]

'E7'	V_1	V_2	V_3	////////////	M_4	RXB	'65'
0	8	12	16	20	32	36	40 47

The four halfword or two word sub-elements in each of the doubleword elements of the second operand are summed and then added to the corresponding rightmost sub-element of the corresponding doubleword of the third operand. The full-precision intermediate-sum is extended on the left with zeros to a doubleword and the results are placed in the corresponding doubleword of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VSUMGH	V_1,V_2,V_3	VSUMG	$V_1,V_2,V_3,1$
VSUMGF	V_1,V_2,V_3	VSUMG	$V_1,V_2,V_3,2$

VECTOR SUM ACROSS QUADWORD

VSUMQ V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘67’
0	8	12	16	20	32	36	40 47

The two doubleword elements or four word elements of the second operand are added together along with the corresponding right-most word or doubleword element of the third operand. The full-precision intermediate-sum is extended on the left with zeros to a quadword and the result is placed in the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0-1	Reserved
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VSUMQF	V_1,V_2,V_3	VSUMQ	$V_1,V_2,V_3,2$
VSUMQG	V_1,V_2,V_3	VSUMQ	$V_1,V_2,V_3,3$

VECTOR SUM ACROSS WORD

VSUM V_1,V_2,V_3,M_4 [VRR-c]

‘E7’	V_1	V_2	V_3	/////////////	M_4	RXB	‘64’
0	8	12	16	20	32	36	40 47

The two halfword elements or four byte elements of each word element of the second operand are added together along with the corresponding right-most sub-element of each word in the third operand. The full-precision intermediate-sum is extended on the left with zeros to a word and the result is placed in the corresponding word element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operand. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VSUMB	V_1,V_2,V_3	VSUM	$V_1,V_2,V_3,0$
VSUMH	V_1,V_2,V_3	VSUM	$V_1,V_2,V_3,1$

VECTOR TEST UNDER MASK

VTM V_1,V_2 [VRR-a]

‘E7’	V_1	V_2	////////////////////	RXB	‘D8’
0	8	12	16	36	40 47

The second operand contains a mask. The bits in the mask correspond one for one with the bits of the first operand. A mask bit of one indicates that the first-operand bit is to be tested. When a mask bit is zero, the first operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

Resulting Condition Code:

0 Selected bits all zeros; or all mask bits zero
1 Selected bits a mix of zeros and ones
2 --
3 Selected bits all ones

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Chapter 23. Vector String Instructions

Vector String Facility 23-1
Instructions 23-1
VECTOR FIND ANY ELEMENT EQUAL. . . . 23-2
VECTOR FIND ELEMENT EQUAL 23-3
VECTOR FIND ELEMENT NOT EQUAL 23-4
VECTOR ISOLATE STRING 23-5
VECTOR STRING RANGE COMPARE 23-6
VECTOR STRING SEARCH 23-8

Vector String Facility

The vector string facility provides instructions to accelerate the processing of strings of character data.

Instructions

All of the instructions except for VECTOR ISOLATE STRING have the ability to produce an index to a character element within a vector. This index is always placed in the rightmost bits of the leftmost doubleword of the vector. This index will often be used in scalar computation for address generation and will need to be transferred to a general register. If an element index is needed the index will have to be shifted right by the appropriate number of bits.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Each instruction has an Extended Mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.

Programming Notes:

1. For all instructions that optionally set the condition code, performance may be degraded if the condition code is set.

2. The following additional instruction is available when the vector-enhancements facility 2 is installed:

   - VECTOR STRING SEARCH (VSTRS)

Name	Mne-monic	Characteristics					Op-code	Page
VECTOR FIND ANY ELEMENT EQUAL	VFAE	VRR-b C* VF	¤^{7,9} SP	Dv			E782	23-2
VECTOR FIND ELEMENT EQUAL	VFEE	VRR-b C* VF	¤^{7,9} SP	Dv			E780	23-3
VECTOR FIND ELEMENT NOT EQUAL	VFENE	VRR-b C* VF	¤^{7,9} SP	Dv			E781	23-4

VF	Vector facility for z/Architecture
VRR	VRR instruction format

Figure 23-1. Summary of Vector String Instructions

VECTOR FIND ANY ELEMENT EQUAL

VFAE V_1,V_2,V_3,M_4[,M_5] [VRR-b]

'E7'	V_1	V_2	V_3	////	M_5	////	M_4	RXB	'82'
0	8	12	16	20	24	28	32	36	40 47

Proceeding from left to right, each element of the second operand is compared for equality with every element of the third operand. A first intermediate result is created from this comparison with an indication for each element in the second operand if the element was equal to any element in the third operand.

If the invert-result (IN) flag in the M_5 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M_5 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero, the second intermediate result contains all false indications.

If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

If the RT flag in the M_5 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

IN	RT	ZS	CS
0	1	2	3

The bits of the M_5 field are defined as follows:

- ***Invert Result (IN):*** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.
- ***Result Type (RT):*** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.

1 At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at

least one match in the second operand and, if the ZS-bit is one, no zero matches.

2 If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.

3 All indications in the first intermediate and second intermediate results are false.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**
VFAEB	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,0[,M_5]$
VFAEH	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,1[,M_5]$
VFAEF	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,2[,M_5]$
VFAEBS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,0,([M_5 \mid] X'1')$
VFAEHS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,1,([M_5 \mid] X'1')$
VFAEFS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,2,([M_5 \mid] X'1')$
VFAEZB	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,0,([M_5 \mid] X'2')$
VFAEZH	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,1,([M_5 \mid] X'2')$
VFAEZF	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,2,([M_5 \mid] X'2')$
VFAEZBS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,0,([M_5 \mid] X'3')$
VFAEZHS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,1,([M_5 \mid] X'3')$
VFAEZFS	$V_1,V_2,V_3[,M_5]$	VFAE $V_1,V_2,V_3,2,([M_5 \mid] X'3')$

Programming Notes:

1. If the RT flag is zero, a byte index is always stored into the first operand for any element size. For example, if the specified element size is halfword and the 2nd indexed halfword compared equal, a byte index of 4 would be stored.

2. If the CS bit is one, conditions codes 0 and 2 can only be set if the ZS-bit is one.

VECTOR FIND ELEMENT EQUAL

VFEE $V_1,V_2,V_3,M_4[,M_5]$ [VRR-b]

'E7'	V_1	V_2	V_3	////	M_5	////	M_4	RXB	'80'
0	8	12	16	20	24	28	32	36	40 47

Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zero.

If two elements are equal, the byte index of the first byte of the left-most equal element is placed in byte seven of the first operand. Zeros are stored in the remaining bytes of the first operand. If no bytes are found to be equal, or are equal to zero if the zero search (ZS) bit is one, an index equal to the number of bytes in the vector is stored in byte seven of the first operand. Zeros are stored in the remaining bytes.

If the ZS bit is one in the M_5 field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand before any other elements of the second and third operands are found to be equal, the byte index of the first byte of the element found to be zero is stored in byte seven the first operand and zeros are stored in all other byte locations. If the condition-code-set (CS) flag is one, the condition code is set to zero.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

/	/	ZS	CS
0	1	2	3

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0-1 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.

- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, in the second operand there were no equal comparisons in an element with an index less than an element whose contents are zero.
1 Comparison detected a match between the second and third operands in some element. If the ZS-bit is one, there were no zero comparisons in the second operand.
2 If the ZS-bit is one, there was a match between the second and third operands with a lower index than a match with zero in the second operand.
3 No elements compared equal. Additionally, if the ZS-bit is one, no elements contain zero.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VFEEB	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,0[,M_5]$
VFEEH	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,1[,M_5]$
VFEEF	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,2[,M_5]$
VFEEBS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,1$
VFEEHS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,1$
VFEEFS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,1$
VFEEZB	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,2$
VFEEZH	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,2$
VFEEZF	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,2$
VFEEZBS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,3$
VFEEZHS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,3$
VFEEZFS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,3$

Programming Notes:

1. A byte index is always stored into the first operand for any element size. For example, if the specified element size is halfword and the 2nd indexed halfword compared equal, a byte index of 4 would be stored.

2. Depending on the model, VECTOR FIND ELEMENT EQUAL may have better performance than VECTOR FIND ANY EQUAL when searching for a single character by replicating the character across all elements of the third operand.

VECTOR FIND ELEMENT NOT EQUAL

VFENE $V_1,V_2,V_3,M_4[,M_5]$ [VRR-b]

'E7'	V_1	V_2	V_3	////	M_5	////	M_4	RXB	'81'
0	8	12	16	20	24	28	32	36	40 47

Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zeros. The elements of the second and third operands are treated as unsigned binary integers.

If two elements are not equal, the byte index of the leftmost not-equal element is placed in byte seven of the first operand and zeros are stored to all other bytes. If the condition code set (CS) bit in the M_5 field is one, the condition code is set to indicate which operand was greater. If all elements were equal, a byte index equal to the vector size is placed in byte seven of the first operand and zeros are placed in all other byte locations and if the CS bit is one, condition code 3 is set.

If the zero search (ZS) bit is one in the M_5 field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand with a lower index than any other element of the second operand found to be unequal, the byte index of the first byte of the element found to be zero is stored in byte seven of the first operand. Zeros are stored in all other bytes and condition code 0 is set.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

/	/	ZS	CS
0	1	2	3

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0 and 1 are reserved and must be zero, otherwise a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, comparison detected a zero element in both operands in a lower indexed element than any unequal compares.
1 An element mismatch was detected and the element in the second operand is less than the element in the third operand.
2 An element mismatch was detected and the element in the second operand is greater than the element in the third operand.
3 All elements compared equal, and if the ZS-bit is one, no zero elements were found in the second operand.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VISTRFS	V_1,V_2	VISTR	$V_1,V_2,2,1$

VECTOR STRING RANGE COMPARE

VSTRC $V_1,V_2,V_3,V_4,M_5[,M_6]$ [VRR-d]

'E7'	V_1	V_2	V_3	M_5	M_6	////	V_4	RXB	'8A'
0	8	12	16	20	24	28	32	36	40 47

Proceeding from left to right, the elements of the second operand are compared to ranges specified by values in even-odd element pairs of the third and fourth operands and, optionally, against an element containing zero. The element in the second and third operand are treated as unsigned binary integers.

The elements of the third and fourth operands form range comparisons to which are applied to elements of the second operand. The even-odd pairs of elements in the third operand define values for the limits of the ranges. The corresponding even-odd pair of elements in the fourth operand contain control information to specify the comparison to be done with each value in the third operand. A range comparison is said to be true if the comparisons on both elements in the even-odd pair are true.

Each element in the second operand is compared against every range specified by the even-odd element pairs in the third and fourth operands. A first intermediate result is created from this comparison with an indication for each element in the second operand if the element was contained in any of the specified ranges.

If the invert-result (IN) flag in the M_6 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M_6 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero the second intermediate result contains all false indications.

If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

If the RT flag in the M_6 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The fourth operand elements have the following format:

If ES equals 0:

E	L	H	/	/	/	/	/
0	1	2					7

If ES equals 1:

E	L	H	/	/	/	/	/	/	/	/	/	/	/	/	/
0	1	2													15

If ES equals 2:

E	L	H	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/	/
0	1	2						8								16								24							31

The bits in the fourth operand elements are defined as follows:

- ***Equal (E):*** When one, a comparison for equality is made.
- ***Low (L):*** When one, a less than comparison is performed.
- ***High (H):*** When one, a greater than comparison is performed.
- All other bits are reserved and should be zero to ensure future compatibility.

The control bits may be used in any combination. If none of the bits are set, the comparison will always produce a false result. If all of the bits are set, the comparison will always produce a true result.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_6 field has the following format:

IN	RT	ZS	CS
0	1	2	3

The bits of the M_6 field are defined as follows:

- ***Invert Result (IN):*** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.
- ***Result Type (RT):*** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.

1 At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at

least one match in the second operand and, if the ZS-bit is one, no zero matches.

2 If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.

3 All indications in the first intermediate and second intermediate results are false.

Programming Notes:

1. To create a comparison that is a range with only one bound, either place that comparison in both the even and odd elements of the pair in the third and fourth operands or place the operand in a single element of the pair with the comparison needed in the corresponding element of the fourth operand, and set the other element in the fourth operand to have all three control bits set.

2. To create a comparison for equality place the same value in the even-odd pair in the third operand. The corresponding even-odd element pair in the fourth operand should contain elements with only a one in the EQ bit.

3. If all available ranges are not needed, the control bits in the fourth operand should all be zero for the elements in the unneeded range. The corresponding elements in the third operand are ignored.

VECTOR STRING SEARCH

VSTRS $V_1,V_2,V_3,V_4,M_5,[M_6]$ [VRR-d]

‘E7’	V_1	V_2	V_3	M_5	M_6	////	V_4	RXB	‘8B’
0	8	12	16	20	24	28	32	36	40 47

The substring specified in the third operand is searched for in the second operand. The length of the substring in the third operand is dependent on the zero-search (ZS) flag in the M_6 field. When the ZS flag is zero, the length in bytes is specified as an unsigned binary integer in bits 56-63 of the fourth operand. When the ZS flag is one, the length in bytes is specified by the smaller of, the unsigned binary integer in bits 56-63 of the fourth operand, or the number of leftmost bytes of the third operand that contain nonzero values (from 0 to 16). See Figure 23-2 and Figure 23-3 for the dataflow of the instruction.

If the zero search (ZS) flag in the M_6 field is one and a zero element is contained in the third operand at a position less than the length specified by the fourth operand, then the position of the leftmost byte of the zero element is used as the length of the substring. If the ZS flag is zero, then the length specified in the fourth operand is used.

A first intermediate result is computed as the leftmost byte position in the second operand where the elements, left to right, of the substring are matching the elements in the second operand for the length of the substring. If such a position exists, then a full match exists. Otherwise, the longest partial string, left to right, of the substring matching the rightmost elements of the second operand is computed as the intermediate result. If such a match is found, it is called a partial match. Otherwise, there is no match and the intermediate result is 16.

If the zero search (ZS) flag in the M_6 is one and the index of the first substring matching position is greater than the position of the leftmost byte of the leftmost zero element in the second operand then the match is ignored.

If a non-ignored match is found then the starting position in bytes of the match in the second operand is stored in byte element seven of the first operand else a value of 16 is stored. All other bytes of the first operand are set to zero.

Byte element seven of the fourth operand specifies the length of the substring in bytes and must be in the range of 0-16. Other values will result in an unpredictable result.

The M_5 field specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

If the M_5 field specifies a halfword or word element size and the length of the substring in bytes is not a multiple of this element size, then results are unpredictable .

The M_6 field has the following format:

/	/	ZS	/
0	1	2	3

The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0,1,3 are reserved and must be zero, otherwise a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, the position of the leftmost zero byte element marks the string length.

Resulting Condition Code:

0 No match or partial match of the substring was found, and either the ZS flag is zero or no zero byte was detected in the second operand.
1 No match of the substring was found, and the ZS flag is one and a zero byte was detected in the second operand.
2 A full match was found.
3 A partial match was found but no full match.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 for the z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VSTRSB	$V_1,V_2,V_3,V_4[,M_6]$	VSTRS	$V_1,V_2,V_3,V_4,0\ [,M_6]$
VSTRSH	$V_1,V_2,V_3,V_4[,M_6]$	VSTRS	$V_1,V_2,V_3,V_4,1\ [,M_6]$

VSTRSZF	V_1,V_2,V_3,V_4	VSTRS	$V_1,V_2,V_3,V_4,2, 2$

Programming Notes:

1. In accordance to C11 and java programming language standard a zero length substring is recognized as a full match.
2. If the ZS flag is one and a zero byte was detected in the second operand, then there can not be a partial match as the end of the string has been reached.
3. For proper usage, if the M_5 field specifies a halfword size then bit 63 of the fourth operand must be zero, and if the M_5 field specifies a word size then bits 62 and 63 of the fourth operand must both be zero.

The vector facility for z/Architecture provides support for short-format, long-format, and extended format binary-floating-point (BFP) operations. Numerically, the results in each element are the same as would occur as if an instruction in Chapter 19 was used to compute the result. Some instructions have different result figures noting changes due to different exception handling described below.

IEEE Exception Handling

When a vector instruction is executed and a trapping IEEE exception condition is encountered, instruction execution is suppressed for all elements, except that the floating-point-control register is updated with the VXC. The index in the VXC is always the index of the source element that caused the trapping exception except for once special case in VECTOR LOAD LENGTHENED (see the programming note on page 24-27). If trapping vector-processing exception conditions exist for multiple elements, the exception of the lowest-indexed source element is recognized.

When either a trapping IEEE overflow or IEEE underflow exception occur concurrently on the same element with a trapping IEEE inexact exception, only the IEEE overflow or IEEE underflow exception is recognized.

When a vector instruction is executed, no trapping IEEE exceptions are encountered on any elements, and a non-trapping IEEE exception condition is encountered on an element, the flag bit for that exception is set in the floating-point-control (FPC) register and the IEEE defined default value is placed in the corresponding element of the target operand. If multiple elements have non-trapping IEEE exception conditions then each element sets the flag bit in the FPC register and the defined default values are placed in the corresponding elements of the target operand.

Result Figures

Concise descriptions of the results produced by many of the vector floating point instructions are made by means of figures which contain columns and rows representing all possible combinations of data class for the source operand elements of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand element data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results for an element is a program interruption. In the case of a program interruption on any element, the operation is suppressed.

Figure 24-1, “IEEE Exception and Flag Abbreviations” on page 24-2 shows IEEE exceptions and flag abbreviations that are used in the result figures.

Exception		**FPC IEEE Mask Bit**	**IEEE Flag**	
Name	**Abbr.**		**FPC Bit**	**Abbr.**
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

Explanation:

[1] The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 1 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a vector-processing exception occurs.

[2] The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 2 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a data exception occurs.

Figure 24-1. IEEE Exception and Flag Abbreviations

Instructions

Each instruction has an Extended Mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax. Not all assemblers may provide these mnemonics.

Most vector floating-point instructions have a single element control bit. If this bit is set to one, indicating only one element is to be executed, performance may be improved on some models. When the single element control bit is set the bit positions of all other elements besides the zero indexed element are unpredictable A mnemonic with the initial V replaced with a W indicates the instruction will only operate on a single element.

Programming Note: When the vector-enhancements facility 2 is installed, the following instructions are extended to provide conversion between BFP short format and word sized integer:

- VECTOR FP CONVERT FROM FIXED
- VECTOR FP CONVERT FROM LOGICAL
- VECTOR FP CONVERT TO FIXED
- VECTOR FP CONVERT TO LOGICAL

To distinguish which functions are provided, alternative names and mnemonics are assigned to these instructions.

Figure 24-2. Summary of Vector Floating-Point Instructions

VECTOR FP ADD

VFA V_1,V_2,V_3,M_4,M_5 [VRR-c]

‘E7’	V_1	V_2	V_3	////////	M_5	M_4	RXB	‘E3’
0	8	12	16	20	28	32	36	40 47

The floating-point element or elements of the third operand are added to the corresponding floating-point element or elements of the second operand. The results are placed in the corresponding elements of the first operand. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements all are treated as BFP numbers of the specified format.

If the corresponding elements of both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operand elements with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward -∞, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand element is an infinity and the other is a finite number, the result is that infinity. If both operand elements are infinities of the same sign, the result is the same infinity. If the two operand elements are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 24-3 on page 24-5 for detailed information on the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	/	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid Operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Explanation:

* The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
dNaN Default NaN.
Dn Subnormal number.
Nn Normal number.
R(v) Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
Rezd Exact zero-difference result. See Figure 24-4 on page 24-6.
T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 24-3. Results: VECTOR FP ADD

Explanation:

– This situation cannot occur.

* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.

[1] The nontrap result r is considered to have been incremented.

[2] The exact-zero-difference case applies only to VECTOR FP ADD, VECTOR FP SUBTRACT, VECTOR FP MULTIPLY AND ADD, and VECTOR FP MULTIPLY AND SUBTRACT. For all other vector BFP operations, a zero result is detected by inspection of the source operand elements without use of the R(v) function.

d The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For VECTOR LOAD ROUNDED, v is the source value (a).

Dmin Smallest (in magnitude) representable subnormal number in the target format.

Nmax Largest (in magnitude) representable finite number in the target format.

Nmin Smallest (in magnitude) representable normal number in the target format.

Figure 24-4. Action for R(v): Rounding and Range Function (Part 1 of 2)

Case	Is r Inexact (r≠v)	Overflow Mask (FPC 0.2)	Underflow Mask (FPC 0.3)	IEEE Inexact Exception Control (XxC)[2]	Inexact Mask (FPC 0.4)	Results
Overflow	Yes[1]	0	–	1	–	T(r), SFo←1
Overflow	Yes[1]	0	–	0	0	T(r), SFo←1, SFx←1
Overflow	Yes[1]	0	–	0	1	PIV(5)
Overflow	Yes[1]	1	–	–	–	PIV(3)
Normal	No	–	–	–	–	T(r)
Normal	Yes	–	–	1	–	T(r)
Normal	Yes	–	–	0	0	T(r), SFx←1
Normal	Yes	–	–	0	1	PIV(5)
Tiny	No	–	0	–	–	T(r)
Tiny	No	–	1	–	–	PIV(4)
Tiny	Yes	–	0	1	–	T(r), SFu←1
Tiny	Yes	–	0	0	0	T(r), SFu←1, SFx←1
Tiny	Yes	–	0	0	1	PIV(5)
Tiny	Yes	–	1	–	–	PIV(4)

Explanation:

–	The results do not depend on this condition or mask bit.
[1]	This condition is true by virtue of the state of some condition to the left of this column.
[2]	If no XxC is defined for an instruction it is assumed to be zero.
r	Nontrap result as defined in Part 1 of this figure.
v	Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
PIV(h)	Program interruption for vector-processing exception, with VXC containing the element index and a VIC of h in hex.
SFo	IEEE overflow flag, FPC 1.2.
SFu	IEEE underflow flag, FPC 1.3.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand element location.

Figure 24-4. Action for R(v): Rounding and Range Function (Part 2 of 2)

VECTOR FP COMPARE SCALAR

WFC V_1,V_2,M_3,M_4 [VRR-a]

‘E7’	V_1	V_2	////////////	M_4	M_3	RXB	‘CB’
0	8	12	16	28	32	36	40 47

The zero-indexed floating-point element of the first operand is compared with the zero-indexed floating-point element of the second operand, and the condition code is set to indicate the result. The operand elements are all treated as BFP numbers of the specified format.

If both operand elements are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operand elements remain unchanged. If the difference is exactly zero with either sign, the operand elements are equal; this includes zero operand elements (so +0 equals -0). If a nonzero difference is positive or negative, the first operand element is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operand elements of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operand elements as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operand elements are QNaNs and neither operand element is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operand elements are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a vector-processing exception with a VXC indicating an IEEE invalid-operation occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-14, “Results: COMPARE” on page 19-18 for a detailed description of the results of this instruction substituting the first operand element for (a) and the second operand element for (b).

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field must be zero otherwise a specification exception is recognized.

Resulting Condition Code:

0	Operand elements equal
1	First operand element low
2	First operand element high
3	Operand elements unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
WFCSB	V_1,V_2	WFC	$V_1,V_2,2,0$
WFCDB	V_1,V_2	WFC	$V_1,V_2,3,0$
WFCXB	V_1,V_2	WFC	$V_1,V_2,4,0$

Programming Notes:

1. VECTOR FP COMPARE SCALAR may be used to set a condition code to be used by a subsequent branch for program control flow.
2. VECTOR FP COMPARE SCALAR may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to not recognize an exception when the result is unordered due to a QNaN.

VECTOR FP COMPARE AND SIGNAL SCALAR

WFK V_1,V_2,M_3,M_4 [VRR-a]

‘E7’	V_1	V_2	////////////	M_4	M_3	RXB	‘CA’
0	8	12	16	28	32	36	40 47

The zero-indexed first operand floating-point element is compared with the zero-indexed second operand floating-point element, and the condition code is set to indicate the result. The operand elements are all treated as BFP numbers of the specified format. The operation is the same as for VECTOR FP COMPARE SCALAR except that QNaN operand elements cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operand elements are treated as if they were SNaNs.

See Figure 19-16, “Results: COMPARE AND SIGNAL” on page 19-19 for a detailed description of the results of this instruction substituting the first operand element for (a) and the second operand element for (b).

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	**Floating-Point Format**
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field must be zero otherwise a specification exception is recognized.

Resulting Condition Code:

0	Operand elements equal
1	First operand element low
2	First operand element high
3	Operand elements unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
WFKSB	V_1,V_2	WFK	V_1,V_2,2,0
WFKDB	V_1,V_2	WFK	V_1,V_2,3,0
WFKXB	V_1,V_2	WFK	V_1,V_2,4,0

Programming Notes:

1. VECTOR FP COMPARE AND SIGNAL SCALAR may be used to set a condition code to be used by a subsequent branch for program control flow.

2. VECTOR FP COMPARE AND SIGNAL SCALAR may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.

VECTOR FP COMPARE EQUAL

VFCE V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]

'E7'	V_1	V_2	V_3	////	M_6	M_5	M_4	RXB	'E8'
0	8	12	16	20	24	28	32	36	40 47

The floating-point element or elements of the second operand are compared for equality with the corresponding element or elements of the third operand. If equal, the bits of the corresponding element in the first operand are set to all ones, otherwise the bits are set to all zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-5 on page 24-11 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	**Floating-Point Format**
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	SQ	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.

- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:

/	/	/	CS
0		2	3

The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.

- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements equal (All T results in Figure 24-5)
1 Mix of equal, and unequal or unordered elements (A mix of T and F results in Figure 24-5)
2 --
3 All elements not equal or unordered (All F results in Figure 24-5)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid Operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
CXi:	IEEE invalid-operation exception if the vector-enhancements facility 1 is installed and the SQ control in M_5 is one. The results shown are produced only when FPC 0.0 is zero.

Figure 24-5. Results: VECTOR FP COMPARE EQUAL

VECTOR FP COMPARE HIGH

VFCH V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]

'E7'	V_1	V_2	V_3	////	M_6	M_5	M_4	RXB	'EB'
0	8	12	16	20	24	28	32	36	40 47

The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise, the bit positions in the corresponding element of the first operand are set to zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized.If the IEEE invalid-operation mask bit is one, a program interruption with a VXC indicating and IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-6 on page 24-13 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved

M_4	**Floating-Point Format**
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	SQ	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.
- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:

/	/	/	CS
0		2	3

The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements greater than (All T results in Figure 24-6)
1 Mix of greater than, and non-greater than or unordered elements (A mix of T and F results in Figure 24-6)
2 --
3 All elements not greater than, or unordered (All F results in Figure 24-6)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

‘E7’	V_1	V_2	V_3	////	M_6	M_5	M_4	RXB	‘EA’
0	8	12	16	20	24	28	32	36	40 47

The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than or equal to the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise the bit positions in the corresponding element of the first operand are set to zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

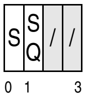
If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-7 on page 24-15 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	**Floating-Point Format**
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:



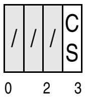
The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.

- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:



The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.

- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements greater than or equal (All T results in Figure 24-7)

1 Mix of greater than or equal and less than or unordered elements (A mix of T and F results in Figure 24-7)

2 --

3 All elements less than or unordered (All F results in Figure 24-7)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
CXi:	IEEE invalid-operation exception if the vector-enhancements facility 1 is installed and the SQ control in M_5 is one. The results shown are produced only when FPC 0.0 is zero.

Figure 24-7. Results: VECTOR FP COMPARE HIGH OR EQUAL

VECTOR FP CONVERT FROM FIXED

VCFPS V_1,V_2,M_3,M_4,M_5 [VRR-a]

VCDG V_1,V_2,M_3,M_4,M_5 [VRR-a]

'E7'	V_1	V_2	////////	M_5	M_4	M_3	RXB	'C3'
0	8	12	16	24	28	32	36	40 47

The signed binary integer element or elements of the second operand are converted to binary floating-point numbers. The results are placed in the corresponding element or elements of the first-operand location. The first operand elements are treated as BFP numbers.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

$\mathbf{M_3}$	**Floating-Point Format**
0-1	Reserved
2	Word to BFP short format
3	Doubleword to BFP long format
4-15	Reserved

The M_4 field has the following format:

S	X x C	/	/
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

VCDLG V_1,V_2,M_3,M_4,M_5 [VRR-a]

'E7'	V_1	V_2	////////	M_5	M_4	M_3	RXB	'C1'

0 8 12 16 24 28 32 36 40 47

The unsigned binary integer element or elements in the second operand are converted to binary floating-point numbers. The results are placed in the corresponding element or elements of the first-operand location. The first operand elements are treated as BFP numbers.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	Word to BFP short format
3	Doubleword to BFP long format
4-15	Reserved

The M_4 field has the following format:

S	XxC	/	/

0 1 2 3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

VECTOR FP CONVERT TO FIXED

VCSFP V_1,V_2,M_3,M_4,M_5 [VRR-a]

VCGD V_1,V_2,M_3,M_4,M_5 [VRR-a]

'E7'	V_1	V_2	////////	M_5	M_4	M_3	RXB	'C2'
0	8	12	16	24	28	32	36	40 47

The BFP floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The signed binary integer result is placed in the corresponding element of the first-operand location. The second operand elements are treated as BFP numbers.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand element, except that a zero result has a plus sign.

See Figure 24-9 on page 24-19 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	BFP short format to word
3	BFP long format to doubleword
4-15	Reserved

The M_4 field has the following format:

S	XxC	/	/
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 of the M_4 field is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact
- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Explanation:

– The results do not depend on this condition or mask bit.
[1] This condition is true by virtue of the state of some condition to the left of this column.
f The value n converted to a fixed-point result.
n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MN Maximum negative number representable in the target fixed-point format.
MP Maximum positive number representable in the target fixed-point format.
PIV(h) Program interruption for vector-processing exception with VXC containing the element index and a VIC of h in hex.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

Figure 24-9. Results: VECTOR FP CONVERT TO FIXED 64 (Continued)

VECTOR FP CONVERT TO LOGICAL

VCLFP V_1,V_2,M_3,M_4,M_5 [VRR-a

VCLGD V_1,V_2,M_3,M_4,M_5 [VRR-a]

'E7'	V_1	V_2	////////	M_5	M_4	M_3	RXB	'C0'
0	8	12	16	24	28	32	36	40 47

The BFP floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The unsigned binary integer result is placed in the corresponding element of the first-operand location. The second operand elements are treated as BFP numbers.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M_5 field:

M_5	**Effective Rounding Method**
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-10 on page 24-22 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of 2 is also invalid and a specification exception is recognized.

M_3	**Floating-Point Format**
0-1	Reserved
2	BFP short format to word
3	BFP long format to doubleword
4-15	Reserved

The M_4 field has the following format:

S	XxC	/	/
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact
- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Explanation:

– The results do not depend on this condition or mask bit.
[1] This condition is true by virtue of the state of some condition to the left of this column.
f The value n converted to a fixed-point result.
n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MU Maximum unsigned number representable in the target fixed-point format.
PIV(h) Program interruption for vector-processing exception with VXC containing the element index and a VIC of h in hex.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

Figure 24-10. Results: VECTOR FP CONVERT TO LOGICAL 64-BIT

VECTOR FP DIVIDE

VFD V_1,V_2,V_3,M_4,M_5 [VRR-c]

'E7'	V_1	V_2	V_3	////////	M_5	M_4	RXB	'E5'
0	8	12	16	20	28	32	36	40 47

The floating-point element or elements of the second operand (the dividend) are divided by the corresponding floating-point element or elements in the third operand (the divisor), and the quotient or quotients are placed at the corresponding elements in first-operand location. No remainder is preserved.

The operand elements are all treated as BFP numbers of the specified format.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the second operand element is divided by the third operand element to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the corresponding operand element signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 24-11 on page 24-24 for a detailed description of the results of each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	/	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

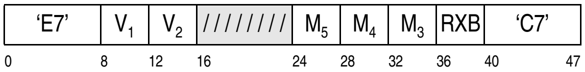
Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
T(x)	The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
Xz:	IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

Figure 24-11. Results: DIVIDE

VECTOR LOAD FP INTEGER

VFI V_1,V_2,M_3,M_4,M_5 [VRR-a]



The floating-point element or elements of the second operand are rounded to integer values in the same floating-point format, and the results are placed in the corresponding elements of the first-operand. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The first and second operands are treated as BFP numbers.

The second operand elements, if finite numbers, are rounded to an integer value by the rounding method specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

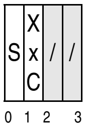
In the absence of an interruption, if the second operand element is an infinity or a QNaN, the result is that operand element; if the second operand element is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand element, even when the result is zero.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	**Floating-Point Format**
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

See Figure 24-12 on page 24-26 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Notes:

1. VECTOR LOAD FP INTEGER rounds BFP numbers to an integer values. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.
2. If the BFP operand element is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

VECTOR FP LOAD LENGTHENED

VFLL V_1,V_2,M_3,M_4 [VRR-a]

‘E7’	V_1	V_2	////////////	M_4	M_3	RXB	‘C4’
0	8	12	16	28	32	36	40 47

The even indexed floating-point element or elements of the second operand are converted to the next largest format floating point numbers, and the results are placed in the even-odd pair of elements in the first operand. The operand elements are all treated as BFP numbers of the specified format.

When the second operand element is numeric, the value of the second operand element is placed in the target format.

If the second operand element is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the second operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the value 3 is reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4-15	Reserved

The M_4 field has the following format:

S	/	/	/
0	1		3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLDE	V_1,V_2,M_3,M_4	VFLL	V_1,V_2,M_3,M_4
VLDEB	V_1,V_2	VFLL	$V_1,V_2,2,0$
WLDEB	V_1,V_2	VFLL	$V_1,V_2,2,8$
VFLLS	V_1,V_2	VFLL	$V_1,V_2,2,0$
WFLLS	V_1,V_2	VFLL	$V_1,V_2,2,8$
WFLLD	V_1,V_2	VFLL	$V_1,V_2,3,8$

Programming Note: If a trapping IEEE exception is encountered during execution of VECTOR LOAD LENGTHENED it is model dependent if the VIX in the VXC field is the index of the source or target element unless the The z/Architecture CPU Architecture is installed in which case it is always the index of the source element.

VECTOR FP LOAD ROUNDED

VFLR V_1,V_2,M_3,M_4,M_5 [VRR-a]

‘E7’	V_1	V_2	////////	M_5	M_4	M_3	RXB	‘C5’
0	8	12	16	24	28	32	36	40 47

The floating-point element or elements of the second operand, are rounded to the precision of the next smallest element size, and the result is placed at the corresponding even elements in the first-operand location. The data in the odd elements of the first operand is unpredictable. The size of the second operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The sign of the resulting element or elements is the same as the corresponding element of the second operand.

The second operand element, if a finite number, is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the second operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the value 4 is reserved.

M_3	Floating-Point Format
0-2	Reserved
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:

S	XxC	/	/
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: The sign of the rounded result is the same as the sign of the operand element, even when the result is zero.

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic

VECTOR FP MAXIMUM

VFMAX V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]

'E7'	V_1	V_2	V_3	////	M_6	M_5	M_4	RXB	'EF'
0	8	12	16	20	24	28	32	36	40 47

The floating point element or elements of the second operand are compared to the corresponding floating-point element or elements of the third operand. The greater of the two values is placed in the corresponding element of the first operand. The operand elements are all treated as BFP numbers of the specified format.

Depending on the maximum function performed, if any of the floating-point elements in the second or third operand are NaNs, an IEEE invalid-operation exception may be recognized as specified in the action figures. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed.

The M_6 field specifies the handling of special cases for the comparison, see Figure 24-13 to Figure 24-22 for detailed descriptions of the results for each element. If a reserved value is specified, a specification exception is recognized.

M_6	Maximum Function Performed
0	IEEE MaxNum
1	Java Math.Max()
2	C-Style Max Macro
3	C++ Algorithm.max()
4	fmax()
5-7	Reserved

Figure 24-22. Results: VECTOR FP MAXIMUM with M_6=12 (“fmax() of absolute values”)

VECTOR FP MINIMUM

VFMIN V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]

‘E7’	V_1	V_2	V_3	////	M_6	M_5	M_4	RXB	‘EE’
0	8	12	16	20	24	28	32	36	40 47

The floating-point element or elements of the second operand are compared to the corresponding floating-point element or elements of the third operand. The lesser of the two values is placed in the corresponding element of the first operand. The operand elements are all treated as BFP numbers of the specified format.

Depending on the minimum function performed, if any of the floating-point elements in the second or third operand are NaNs, an IEEE invalid-operation exception may be recognized as specified in the action figures. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed.

The M_6 field specifies the handling of special cases for the comparison, see Figure 24-23 to Figure 24-32 for detailed descriptions of the results for each element. If a reserved value is specified, a specification exception is recognized.

M_6	Minimum Function Performed
0	IEEE MinNum
1	Java Math.Min()
2	C-Style Min Macro
3	C++ algorithm.min()
4	fmin()
5-7	Reserved
8	IEEE MinNum of absolute values
9	Java Math.Min() of absolute values
10	C-Style Min Macro of absolute values
11	C++ algorithm.min() of absolute values
12	fmin() of absolute values
13-15	Reserved

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	///
0	1 3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***Reserved:*** Bits 1, 2, and 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 1 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Figure 24-32. Results: VECTOR FP MINIMUM with M_6=12 (“fmin() of absolute values”)

VECTOR FP MULTIPLY

VFM V_1,V_2,V_3,M_4,M_5 [VRR-c]

‘E7’	V_1	V_2	V_3	////////	M_5	M_4	RXB	‘E7’
0	8	12	16	20	28	32	36	40 47

The product of the floating-point element or elements of the second operand (the multiplier) and the corresponding floating-point element or elements of the third operand (the multiplicand) are placed in the corresponding element or elements of the first-operand.

The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements are all treated as BFP numbers.

The two corresponding operand elements, if finite numbers, are multiplied, forming an intermediate product. The result is rounded to the operand format according to the current BFP rounding mode.

The sign of the product, if the product is numeric, is the exclusive OR of the operand element signs. This includes the sign of a zero or infinite product.

If one operand element is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 24-33 on page 24-42 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	/	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VFMSB	V_1,V_2,V_3	VFM	V_1,V_2,V_3,2,0
VFMDB	V_1,V_2,V_3	VFM	V_1,V_2,V_3,3,0
WFMSB	V_1,V_2,V_3	VFM	V_1,V_2,V_3,2,8
WFMDB	V_1,V_2,V_3	VFM	V_1,V_2,V_3,3,8
WFMXB	V_1,V_2,V_3	VFM	V_1,V_2,V_3,4,8

Programming Note: Interchanging the two operand elements in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operand elements are QNaNs, in which case the result is the second operand element; or when both operand elements are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the second operand element.

‘E7’	V_1	V_2	V_3	M_6	////	M_5	V_4	RXB	‘9F’

0 8 12 16 20 24 28 32 36 40 47

VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT

VFNMS V_1,V_2,V_3,V_4,M_5,M_6 [VRR-e]

‘E7’	V_1	V_2	V_3	M_6	////	M_5	V_4	RXB	‘9E’

0 8 12 16 20 24 28 32 36 40 47

The floating-point element or elements of the third operand are multiplied by the corresponding floating-point element or elements of the second operand, and then the corresponding floating-point element or elements of the fourth operand are added to or subtracted from the products. The sum or differences are placed at the corresponding first-operand element locations.The size of the operand elements is determined by the floating-point-format control in the M_6 field. The operand elements are all treated as BFP numbers.

The VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT operations may be summarized below, where “(i)” represents the “i”th indexed element of the operand:

$op_1(i) = op_3(i) \bullet op_2(i) \pm op_4(i)$

The VECTOR FP NEGATIVE MULTIPLY AND ADD and VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT operations may be summarized as below where “(i)” represents the “i”th indexed element of the operand:

$op_1(i) = -(op_3(i) \bullet op_2(i) \pm op_4(i))$

When all of the corresponding operand elements are finite numbers, the third and second BFP operand elements are multiplied, forming an intermediate product, and the corresponding fourth operand element is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the corresponding element of the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

See Figure 24-34 for a detailed description of the results for each element of VECTOR FP MULTIPLY AND ADD. The results for each element of VECTOR FP MULTIPLY AND SUBTRACT are the same, except that the fourth operand element, if numeric, participates in the operation with its sign bit inverted. When the fourth operand element is a NaN, it participates in the operation with its sign bit unchanged.

The results for each element of VECTOR FP NEGATIVE MULTIPLY AND ADD and VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT are the same as for VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT, respectively, except the sign bit of numeric results are inverted. When the result is a NaN it's sign bit is unchanged.

The M_6 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. For VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT, if the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_6	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	/	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (VFMA and VFMS, if the vector facility for z/Architecture is not installed; VFNMA and VFNMS, if the vector-enhancements facility 1 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: VECTOR FP MULTIPLY AND ADD, VECTOR FP MULTIPLY AND SUBTRACT, VECTOR FP NEGATIVE MULTIPLY AND ADD, and VECTOR NEGATIVE MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

0	8	12	16	24	28	32	36	40 47

The sign of the floating-point element or elements of the second operand are modified in a manner specified by the value of the M_5 field. The modified sign bit and the rest of the unchanged second operand element are placed into the corresponding element in the first operand. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The sign operation is performed even if the element contains zero. If the element contains a QNaN or SNaN, the sign is still set without causing an IEEE exception.

The M_5 field indicates the operation to perform on the sign bit.

M_5	**Sign Operation Performed**
0	The sign bit is inverted (complement)
1	The sign bit is set to one (negative)
2	The sign bit is set to zero (positive)

If any other M_5 values are specified, a specification exception is recognized.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	**Floating-Point Format**
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:

S	/	/	/
0	1		3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR FP SQUARE ROOT

VFSQ V_1,V_2,M_3,M_4 [VRR-a]

'E7'	V_1	V_2	////////////	M_4	M_3	RXB	'CE'
0	8	12	16	28	32	36	40 47

The square roots of the floating-point element or elements of the second operand are placed in the corresponding elements of the first-operand location. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The result rounded according to the current BFP rounding mode is placed at the first operand element location.

If the second operand element is a positive finite number, the result is the square root of that number with a plus sign. If the operand element is a zero of either sign, the result is a zero of the same sign. If the operand element is $+\infty$, the result is $+\infty$.

If the second operand element is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:

S	/	/	/
0	1		3

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

VECTOR FP SUBTRACT

VFS V_1,V_2,V_3,M_4,M_5 [VRR-c]

'E7'	V_1	V_2	V_3	////////	M_5	M_4	RXB	'E2'	
0	8	12	16	20	28	32	36	40	47

The floating-point element or elements in the third operand are subtracted from the floating-point element or elements of the second operand, and the difference is placed in the floating-point element or elements at the first-operand location. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements are all treated as BFP numbers.

The execution of VECTOR FP SUBTRACT is identical to that of VECTOR FP ADD, except that the third operand element, if numeric, participates in the operation with its sign bit inverted. When the third operand contains an element that is a NaN, it participates in the operation with its sign bit unchanged. See Figure 24-3 on page 24-5 for the detailed results for each element of VECTOR FP ADD.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format

The class and sign of the floating-point element or elements of the second operand are examined to select one bit from the third-operand. If the selected bit is set, all bit positions of the corresponding element in the first operand are set to ones, otherwise they are set to zero. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second operand elements are treated as BFP numbers.

The 12 bits of the third operand, bits 16-27 of the instruction text, are used to specify 12 combinations of BFP data class and sign.

As shown in Figure 24-35, BFP operand elements are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

	Bit Used when Sign Is	
BFP Element Class	+	-
Zero	0	1
Normal number	2	3
Subnormal number	4	5
Infinity	6	7
Quiet NaN	8	9
Signaling NaN	10	11

Figure 24-35. Third-Operand Bits for VECTOR FP TEST DATA CLASS

One or more of the third-operand bits may be set to one.

Operand elements, including SNaNs and QNaNs, are examined without causing an IEEE exception.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

S	/	/	/
0	1		3

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 1 for all elements (match)
1 Selected bit is 1 for at least one but not all elements (when S-bit is zero)
2 --
3 Selected bit is 0 for all elements (no match)

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Vector-Packed-Decimal Facility

The vector-packed-decimal facility provides instructions to operate on signed-packed-decimal format data in register operands. Decimal numbers and decimal instructions are introduced in Chapter 8, “Decimal Instructions.” The decimal-arithmetic instructions described in Chapter 8 operate on decimal data in storage operands. Since the delay between instructions encountered to ensure sequential order of operand accesses is likely less between register accesses than between storage accesses, a sequence of vector decimal instructions referencing operands in registers may achieve better performance than a comparable sequence of decimal instructions referencing operands in storage. Additionally, a program performing sign manipulation can use the force operand positive controls of the vector decimal-arithmetic instructions described in this chapter to reduce the program instruction count.

Vector Decimal Control

The vector decimal instructions described in this chapter are available to use when the vector-packed-decimal facility for z/Architecture is installed (which requires the vector facility for z/Architecture to also be installed), the vector enablement control (bit 46) in control register zero is one, and the AFP-register control (bit 45) in control register zero is one. If the vector-packed-decimal facility for z/Architecture is not installed and a vector decimal instruction is executed, then an operation exception is recognized. If the vector-packed-decimal facility for z/Architecture is installed, the vector enablement control (bit 46) in control register zero is zero, and a vector decimal instruction is executed, a data exception with DXC FE hex is recognized. When the vector-packed-decimal facility for z/Architecture is installed, and the AFP-register control (bit 45) in control register zero is zero, and a vector decimal instruction is executed, it is unpredictable whether a data exception is recognized.

Vector Decimal Registers

The vector-packed-decimal facility uses the same 32 vector registers as the vector facility. When a decimal operand occupies a vector register, the operand is in the signed-packed-decimal format and occupies all 16 bytes (31 digits and a sign), as illustrated in Figure 25-1 on page 25-2. Decimal numbers with fewer than 31 significant digits are right-aligned with zeros supplied in the remaining leftmost digits. Several vector decimal-arithmetic instructions described in this chapter provide a result digits count (RDC) control to specify the number of rightmost digits of an operation to place in the result register.

The vector registers are used by the vector-packed-decimal facility to support decimal operand lengths up to 16 bytes. The vector-packed-decimal facility does not support multiple elements within a vector register for the purpose of parallel processing.

D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D
0		8		16		24		32		40		48		56	63

Figure 25-1. Signed-Packed-Decimal Format Number in Vector Registers

Decimal Digits and Signs

Decimal digits 0-9 have codes 0000-1001 binary.

The preferred positive sign has code 1100 binary (C hex). The preferred negative sign has code 1101 binary (D hex). The vector decimal-arithmetic instructions and VECTOR CONVERT TO DECIMAL instructions generate a preferred sign code when the force operand 1 positive control (P1) is zero and generate alternate positive sign code 1111 binary (F hex) when the P1 control is one. VECTOR LOAD IMMEDIATE generates a preferred sign code. The VECTOR PACK ZONED and VECTOR UNPACK ZONED instructions move the source sign to the result sign unchanged.

The vector decimal-arithmetic instructions provide the option to treat source sign codes as positive and ignore source sign codes during operation and validity checks. The force operand positive (P) controls enable this option.

The vector decimal-arithmetic instructions and VECTOR CONVERT TO DECIMAL instructions generate a positive sign when the resulting magnitude is zero. VECTOR LOAD IMMEDIATE can produce a zero magnitude with a negative sign code. The VECTOR PACK ZONED and VECTOR UNPACK ZONED instructions move the source sign to the result sign unchanged.

Instructions

The vector decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison and shifting. The set of vector decimal instructions includes the vector decimal-arithmetic instructions, VECTOR CONVERT TO BINARY, VECTOR CONVERT TO DECIMAL, VECTOR PACK ZONED, VECTOR UNPACK ZONED, VECTOR LOAD IMMEDIATE DECIMAL, and VECTOR TEST DECIMAL instructions.

Programming Note: The vector-packed-decimal-enhancement facility provides the following enhancements:

- Support for negative zero and digit code validity check for VECTOR PERFORM SIGN OPERATION DECIMAL (VPSOP).
- Support on the following instructions to suppress a decimal overflow exception: VECTOR ADD DECIMAL (VAP), VECTOR CONVERT TO BINARY (VCVB, VCVBG), VECTOR CONVERT TO DECIMAL (VCVD, VCVDG), VECTOR [SHIFT AND] DIVIDE DECIMAL (VDP, VSDP), VECTOR MULTIPLY [AND SHIFT] DECIMAL (VMSP, VMP), VECTOR REMAINDER DECIMAL (VRP), VECTOR SHIFT AND ROUND DECIMAL (VSRP), VECTOR SUBTRACT DECIMAL (VSP).

SP	Specification exception.
ST	PER storage-alteration event.
VD	Vector-packed-decimal facility.
VRI	VRI instruction format.
VRR	VRR instruction format.
VSI	VSI instruction format.

Figure 25-2. Summary of Vector Decimal Instructions (Part 2 of 2)

VECTOR ADD DECIMAL

VAP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'71'
0	8	12	16	20	24	28	36	40 47

The second operand is added to the third operand. The sign and specified number of rightmost digits of the sum are placed in the first operand location with other digits set to zero. The operands are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the add operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

Addition is algebraic, taking into account the signs and all digits of the second and third operands.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

If the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_4 field has the following format:

IOM	/ /	RDC
0		3 7

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the sum to be placed in the first operand. If the magnitude of the sum is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

P2	P3	P1	CS
0	1	2	3

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the sum.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand

- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR COMPARE DECIMAL

VCP V_1,V_2,M_3 [VRR-h]

'E6'	////	V_1	V_2	////	M_3	////////	RXB	'77'

0 8 12 16 20 24 28 36 40 47

The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

The sign codes of the first and second operands may be modified for use in the compare operation by the force operand one positive (P1) and force operand two positive (P2) controls respectively.

Comparison is algebraic and follows the procedure for decimal subtraction with operand two subtracted from operand one. When the difference is zero the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand one positive (P1) or force operand two positive (P2) controls.

Overflow cannot occur because the difference is discarded.

The M_3 field has the following format:

P1	P2	/ /

0 1 2 3

The bits of the M_3 field are defined as follows:

- ***Force Operand 1 Positive (P1):*** When bit 0 is one, the first operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the first operand sign is used in the operation and is checked for validity.
- ***Force Operand 2 Positive (P2):*** When bit 1 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Reserved:*** Bits 2-3 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

Resulting Condition Code:

The condition code is set as follows:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.
2. A negative zero and positive zero compare equal.

VECTOR CONVERT TO BINARY

VCVB $R_1,V_2,M_3[,M_4]$ [VRR-i]

'E6'	R_1	V_2	////////	M_3	M_4	////	RXB	'50'

0 8 12 16 24 28 36 40 47

VCVBG $R_1,V_2,M_3[,M_4]$ [VRR-i]

'E6'	R_1	V_2	////////	M_3	M_4	////	RXB	'52

0 8 12 16 24 28 36 40 47

The second operand is changed from decimal to binary, and the result is placed at the first-operand location. The second operand is in a vector register, and the first operand is in a general register.

The second operand has the format of signed-packed-decimal data. The sign of the second operand may be modified for use before conversion by the force operand 2 positive (P2) control or the logical binary (LB) control. All digit codes of the second operand are checked for validity. The sign code of the second operand is checked for validity unless overridden by the force operand 2 positive (P2) control.

For VECTOR CONVERT TO BINARY (VCVB) when the LB control is zero, the result of the conversion is a 32-bit signed binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged. The maximum positive number that can be converted and still be contained in 32 bit positions is 2,147,483,647; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -2,147,483,648.

For VECTOR CONVERT TO BINARY (VCVB) when the LB control is one, the second operand sign is treated as a positive sign, and the result of the conversion is a 32-bit unsigned binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged. The maximum number that can be converted and still be contained in 32 bit positions is 4,294,967,295.

For VECTOR CONVERT TO BINARY (VCVBG) when the LB control is zero, the result of the conversion is a 64-bit signed binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 9,223,372,036,854,775,807; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -9,223,372,036,854,775,808.

For VECTOR CONVERT TO BINARY (VCVBG) when the LB control is one, the second operand sign is treated as a positive sign, and the result of the conversion is a 64-bit unsigned binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 18,446,744,073,709,551,615.

For any decimal number outside these ranges (overflow case), the 32 or 64 rightmost bits of the binary result are placed in the register. Condition code three is optionally set depending on the value of the condition code set (CS) control. If the fixed-point-overflow mask is one and the instruction-overflow mask (IOM) is zero a program interruption for fixed-point overflow occurs.

The M_3 field has the following format:

P2	/	LB	CS
0	1	2	3

The bits of the M_3 field are defined as follows:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign code is checked for validity, and is used in the operation if the LB control is zero.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Logical Binary (LB):*** When bit 2 is one, the first operand result is an unsigned binary integer, which is considered positive. When bit 2 is zero, the first operand result is a signed binary integer. When the LB control is one and the P2 control is zero, the sign code of the second operand is checked for validity but is treated as a positive sign code in the conversion.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

The M_4 field has the following format:

IOM	/	/	/
0	1		3

The bits of the M_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a fixed-point overflow program interrupt is suppressed.

- ***Reserved:*** Bits 1-3 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0	No overflow
1	--
2	--
3	Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Fixed-point overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. When the second operand is negative and the LB bit is zero, the result is in two's-complement notation.

2. VECTOR CONVERT TO BINARY (VCVB, VCVBG) differs from CONVERT TO BINARY (CVB, CVBY, CVBG) when the converted value is larger than the first operand can represent. For VECTOR CONVERT TO BINARY, in the overflow case, the operation is completed and results in a program interrupt for fixed-point-overflow if the fixed-point-overflow mask is one. For CONVERT TO BINARY, in the overflow case, the operation is suppressed and results in a program interrupt for fixed-point-divide.

VECTOR CONVERT TO DECIMAL

VCVD V_1,R_2,I_3,M_4 [VRI-i]

'E6'	V_1	R_2	////////	M_4	I_3	RXB	'58'
0	8	12	16	24	28	36	40 47

VCVDG V_1,R_2,I_3,M_4 [VRI-i]

'E6'	V_1	R_2	////////	M_4	I_3	RXB	'5A'
0	8	12	16	24	28	36	40 47

The second operand is changed from binary to decimal, and the result is placed at the first-operand location. The second operand is in a general register, and the first operand is in a vector register.

For VECTOR CONVERT TO DECIMAL (VCVD), the second operand is treated as a 32-bit binary integer that is either signed or unsigned depending on the logical binary (LB) control. For VECTOR CONVERT TO DECIMAL (VCVDG), the second operand is treated as a 64-bit binary integer that is either signed or unsigned depending on the logical binary (LB) control.

The result is in the format for signed-packed-decimal data, as described in Chapter 8, "Decimal Instructions." The number of rightmost digits of the conversion, as specified by the result digits count (RDC) control, is placed in the first-operand location.

If the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the conversion, decimal overflow occurs. The operation is completed, the specified number of digits are placed in the first-operand location, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The rightmost four bits of the result represent the sign. When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the result is the preferred sign code corresponding to the sign of the second operand. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_3 field has the following format:

IOM	/ /	RDC
0		3 7

The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.

- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.

- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the conversion to be placed in the first operand. If the magnitude of the conversion is larger than the largest decimal number that can be represented with the specified number of digits decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_4 field has the following format:

LB	/	P1	CS
0	1	2	3

The bits of the M_4 field are defined as follows:

- ***Logical Binary (LB):*** When bit 0 is one, the second operand contains an unsigned binary integer. When bit 0 is zero, the second operand contains a signed binary integer.

- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.

- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand and is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the conversion.

- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 No overflow
1 --
2 --
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR DIVIDE DECIMAL

VDP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'7A'
0	8	12	16	20	24	28	36	40 47

The second operand (the dividend) is divided by the third operand (the divisor). The sign and specified number of rightmost digits of the quotient are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the quotient, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_4 field has the following format:

I O M	/ /	RDC
0		3 7

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the quotient to be placed in the first operand. If the magnitude of the quotient is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

P 2	P 3	P 1	C S
0	1	2	3

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the quotient.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Unlike DIVIDE DECIMAL, VECTOR DIVIDE DECIMAL will recognize a decimal-overflow exception instead of a decimal-divide exception if the first operand is too short to contain all of the quotient digits.

2. VECTOR DIVIDE DECIMAL may recognize a decimal-divide exception when the divisor is zero, depending on the divisor sign code used, unlike DIVIDE DECIMAL, which may recognize a decimal-divide exception when the divisor is zero, depending on all sign and digit codes of both divisor and dividend. Also note, if the divisor is zero, all divisor digits are valid.

VECTOR LOAD IMMEDIATE DECIMAL

VLIP V_1,I_2,I_3 [VRI-h]

'E6'	V_1	////	I_2	I_3	RXB	'49'
0	8	12	16	32	36	40 47

The four decimal digits of the second operand, shifted left by the specified number of digits, and concatenated on the right with the specified sign form a signed-packed-decimal format number placed at the first-operand location.

The four digit second operand is shifted left the number of digit positions specified by the shift amount (SHAMT) control. Zeros are supplied for vacated digit positions. The shifted value is placed in the magnitude of the signed-packed-decimal format first operand. Zeros are placed in the remaining leftmost digits of the first operand.

The sign code of the result placed at the first-operand is determined by the sign control (SC) bit.

All digits of the second operand are checked for validity.

The I_3 field has the following format:

SC	SHAMT
0	1 3

The bits of the I_3 field are:

- ***Sign Control (SC):*** When bit 0 is zero, the result is positive with a sign code of 1100. When bit 0 is one, the result is negative with a sign code of 1101.

- ***Shift Amount (SHAMT):*** Bits 1-3 specify a three bit unsigned binary number specifying the number of digits to shift the second operand left.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Programming Note: VECTOR LOAD IMMEDIATE DECIMAL can produce a negative zero, a zero value with a negative sign, which is a valid operand.

VECTOR MULTIPLY DECIMAL

VMP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'78'
0	8	12	16	20	24	28	36	40 47

The second operand (the multiplicand) is multiplied by the third operand (the multiplier). The sign and specified number of rightmost digits of the product are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

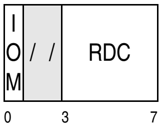
All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra from the multiplier and multiplicand signs determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the product, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

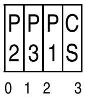
The I_4 field has the following format



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the product to be placed in the first operand. If the magnitude of the product is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the product.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR MULTIPLY AND SHIFT DECIMAL

VMSP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'79'
0	8	12	16	20	24	28	36	40 47

The product of the second operand (the multiplicand) and the third operand (the multiplier) is shifted right by the number of digits specified in the fourth operand and is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity, including digits with no effect on the result due to the shift amount. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after being shifted, is nonzero and the force operand one positive (P1) control is zero, rules of algebra from the multiplier and multiplicand signs determine the sign of the result and a preferred sign code is used. When the result, after being shifted, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_4 field has the following format:

IOM	/ /	SHAMT
0		3 7

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Shift Amount (SHAMT):*** Bits 3-7 contain an unsigned binary number specifying the number of digits the product is shifted right before the rightmost thirty one digits are placed in the first operand. The sign position does not participate in the shift.

If the first operand does not contain all leftmost nonzero digits of the shifted product, decimal overflow occurs. The operation is completed. Condition code 3 is set if the Condition Code Set (CS) bit is one. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interrupt for decimal overflow occurs.

The M_5 field has the following format:

P2	P3	P1	CS
0	1	2	3

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.

- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the product.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0	Result zero; no overflow
1	Result less than zero; no overflow
2	Result greater than zero; no overflow
3	Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR PACK ZONED

VPKZ $V_1,D_2(B_2),I_3$ [VSI]

'E6'	I_3	B_2	D_2	V_1	RXB	'34'

0 8 16 20 32 36 40 47

The format of the second operand is changed from the zoned format to the signed-packed-decimal format and placed in the first operand. The zoned and signed-packed-decimal formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the zoned format. The numeric bits of each byte are treated as a digit. The zone bits are ignored, except the zone bits in the rightmost byte, which are treated as a sign.

The sign and digits are moved unchanged to the first operand and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the first operand, and the digits are placed adjacent to the sign and to each other in the remainder of the result field. The number of bytes the second operand occupies in storage is specified by the operand 2 length code (L2) control. When necessary, the second operand is considered to be extended on the left with zeros.

The I_3 field has the following format:

/ / /	L2

0 3 7

The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code (L2):*** Bits 3-7 contain the length code of the second-operand. The length of the second-operand is 1-31 bytes, corresponding to a length code in L2 of 0-30. The second-operand length must not exceed 31 bytes (L2 must be less than or equal to 30); otherwise, a specification exception is recognized.

Special Conditions:

If the L2 field is larger than 30 a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)

- Specification
- Transaction constraint

VECTOR PERFORM SIGN OPERATION DECIMAL

VPSOP V_1,V_2,I_3,I_4,M_5 [VRI-g]

'E6'	V_1	V_2	I_4	M_5	I_3	RXB	'5B'
0	8	12	16	24	28	36	40 47

The modified sign and specified number of rightmost digits of the second operand are placed in the first operand location with other digits set to zero. The operand and result are in the signed-packed-decimal format.

All digit codes of the second operand are checked for validity, unless the operand 2 no validation (NV) control is one. The sign code of the second operand is checked for validity based on the SO control, the operand 2 sign validation (SV) control, and the operand 2 no validation (NV) control, as specified in Figure 25-3.

The result sign code is a function of the SO control, the second operand sign, the second operand digits, the result digits count (RDC) control, the positive sign code (PC) control, and the negative zero (NZ) control, as specified in Figure 25-3.

Sign Operation (SO)	Result Magnitude (after RDC applied)	V_2 Sign	Positive Sign Code (PC)	Negative Zero (NZ)	V2 Sign Code Validity Check	V2 Digit Code Validity Check perform if...	Result Sign Code (hex)	Condi-tion Code[d]

Explanation:

– Results do not depend on this value
a A result magnitude is considered nonzero if any bits of the result are nonzero
b A sign code between 0-9 is considered invalid
c Produces a suppressing data exception
d Table is showing the condition code for the non-overflow case. Overflow case will deliver a CC3.

Figure 25-3. Operation of VECTOR PERFORM SIGN OPERATION DECIMAL (Part 2 of 2)

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_3 field has the following format:

IOM	/ /	RDC
0		3 7

The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the second operand to be placed in the first operand. If the magnitude of the second operand is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The I_4 field has the following format:

NV	NZ	/ /	SO	PC	SV
0	1		4	6	7

The bits of the I_4 field are defined as follows:

- ***No Validation (NV):*** When bit 0 is zero or the vector-packed-decimal-enhancement facility is not installed, the second operand digits are checked for validity; if the SO control specifies maintain sign, then the second operand sign code is also checked for validity. Sign code validity is always checked when the SO control specifies complement sign and dependent on SV control if the SO control specifies force positive or force negative. If the validity check fails, a data exception is recognized. If bit 0 is one, then the second operand digits are not checked for validity; and if the SO control specifies maintain sign, then the second operand sign code is also not checked.

- ***Negative Zero (NZ):*** When bit 1 is zero or the vector-packed-decimal-enhancement facility is not installed, a zero result after applying the RDC will result in a positive sign. If bit 1 is one, then the sign of a zero result after applying the RDC will be dependent of the second operand sign if the SO control does not specify force positive or force negative.
- ***Reserved:*** Bits 2-3 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Sign Operation (SO):*** Bits 4-5 specify the sign operation used in determining the result sign code. The result sign code is a function of the SO control, the second operand sign, the second operand digits, the RDC control, and the PC bit, as specified in Figure 25-3.
- ***Positive Sign Code (PC):*** When bit 6 is one, sign code 1111 is used when the result is positive. When bit 6 is zero, sign code 1100 is used when the result is positive.
- ***Operand 2 Sign Validation (SV):*** If bit 7 is one and the SO control specifies force positive or force negative, then the second operand sign code is checked for validity. If bit 7 is zero and the SO control specifies force positive or force negative, then the second operand sign code is not checked for validity. When the SO control specifies maintain or complement sign, the second operand sign code is checked for validity, based on the NV bit value. If the validity check fails, a data exception is recognized.

The M_5 field has the following format:

/ / /	C S

0 1 2 3

The bits of the M_5 field are:

- ***Reserved:*** Bits 0-2 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero, or nonzero result and invalid sign code; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: A zero result after applying the RDC will always result in setting condition code 0 if the CS bit is one, independent of the positive or negative sign of the zero.

VECTOR REMAINDER DECIMAL

VRP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'7B'

0 8 12 16 20 24 28 36 40 47

The second operand (the dividend) is divided by the third operand (the divisor). The sign and specified number of rightmost digits of the remainder are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

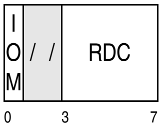
When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the dividend after P2 is applied is the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the remainder, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

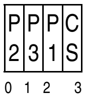
The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the remainder to be placed in the first operand. If the magnitude of the remainder is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the remainder.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow

1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SHIFT AND DIVIDE DECIMAL

VSDP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'7E'
0	8	12	16	20	24	28	36	40 47

The second operand, shifted left (the dividend) by the number of digits specified in the fourth operand, is divided by the third operand (the divisor), and the rightmost thirty one digits of the quotient are placed in the first-operand location. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

If the first operand can not contain all leftmost nonzero digits of the quotient, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interrupt for decimal overflow occurs.

When the rightmost thirty one digits of the quotient are nonzero and the force operand one positive (P1) control is zero, rules of algebra from the dividend and divisor signs determine the sign of the result and a preferred sign code is used. When the rightmost thirty one digits of the quotient are zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

The I_4 field has the following format:

IOM	/ /	SHAMT
0		3 7

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.

- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.

- ***Shift Amount (SHAMT):*** Bits 3-7 contain an unsigned binary number specifying the number of digits the second operand is shifted left to form the dividend. The second operand sign position does not participate in the shift. Zeros are supplied for the vacated digit positions.

The M_5 field has the following format:

P2	P3	P1	CS
0	1	2	3

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the quotient.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SHIFT AND ROUND DECIMAL

VSRP V_1,V_2,I_3,I_4,M_5 [VRI-g]

'E6'	V_1	V_2	I_4	M_5	I_3	RXB	'59'
0	8	12	16	24	28	36	40 47

The second operand is shifted in the direction and for the number of decimal-digit positions specified by the fourth operand, and, when shifting to the right is specified, the absolute value of the second operand is rounded by the rounding digit, and the result is placed at the first-operand location. The first and second operands are in the signed-packed-decimal format.

The sign code of the second operand may be modified for use in the operation by the force operand two positive control (P2).

All digit codes are checked for validity, including digits with no effect on the result due to the shift amount. The sign code is checked for validity unless overridden by the force operand two positive control (P2).

Only the digit portion of the second operand is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result is stored in the first operand.

The shift amount (SHAMT) control specifies a 7-bit signed binary integer, indicating the direction and number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two’s complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

SHAMT (binary)	amount and direction
0011111	31 digits to the left
0000001	1 digit to the left
0000000	No shift
1111111	1 digit to the right
1100000	32 digits to the right

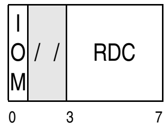
For a right shift, the second operand is rounded by treating the second operand as positive, regardless of the sign, and decimally adding the rounding digit, as specified by the decimal rounding digit control (DRD), to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The sum is then shifted to the right. Except for validity checking and participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, or if the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the shifted value, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for a decimal overflow occurs.

When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the second operand after P2 is applied determines the sign of the result and a preferred sign code is used. When the result, after being shifted, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

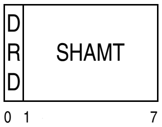
The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the shifted value to be placed in the first operand. If the magnitude of the shifted value is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

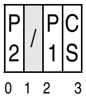
The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Decimal Rounding Digit (DRD):*** When bit 0 is zero, the rounding digit is zero, when bit 0 is one, the rounding digit is 5.
- ***Shift Amount: (SHAMT):*** Bits 1-7 specify a signed binary integer representing the shift amount and direction. Bit 1 must equal bit 2 or results are unpredictable.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the shifted value.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition

code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SUBTRACT DECIMAL

VSP V_1,V_2,V_3,I_4,M_5 [VRI-f]

'E6'	V_1	V_2	V_3	////	M_5	I_4	RXB	'73'	
0	8	12	16	20	24	28	36	40	47

The third operand is subtracted from the second operand. The sign and specified number of rightmost digits of the difference are placed in the first operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

VECTOR SUBTRACT DECIMAL is executed the same as VECTOR ADD DECIMAL, except that the third operand is considered to have a sign opposite to the sign in the potentially modified operand.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the difference, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_4 field has the following format:

IOM	/ /	RDC	
0		3	7

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.

- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.

- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the difference to be placed in the first operand. If the magnitude of the difference is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

P2	P3	P1	CS
0	1	2	3

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.

- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.

- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the difference.

- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR TEST DECIMAL

VTP V_1 [VRR-g]

'E6'	////	V_1	///////////////////	RXB	'5F'
0	8	12	16	36	40 47

The first operand is tested for valid decimal digits and a valid sign code, and the result is indicated in the condition code. The operand is in the signed-packed-decimal format.

Resulting Condition Code:

0 All digit codes and the sign valid
1 All digit codes valid and sign invalid
2 At least one digit code invalid and sign valid
3 At least one digit code invalid and sign invalid

Program Exceptions:

- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

VECTOR UNPACK ZONED

VUPKZ V_1,D_2(B_2),I_3 [VSI]

'E6'	I_3	B_2	D_2	V_1	RXB	'3C'
0	8	16	20	32	36	40 47

The format of the first operand is changed from the signed-packed-decimal format to the zoned format and placed in the second-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, “Decimal Instructions.”

The first operand is treated as having the signed-packed-decimal format. Its digits and sign are placed unchanged in the second-operand location, using the zoned format. Zone bits with coding of 1111 binary are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the first operand. The sign and digits are not checked for valid codes.

The number of bytes the second operand occupies in storage is specified by the operand 2 length code (L2) control. If the second-operand field is too short to contain all digits of the first operand, the remaining leftmost portion of the first operand is ignored.

The I_3 field has the following format:

/ / /	L2
0	3 7

The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code (L2):*** Bits 3-7 contain the length code of the second-operand. The length of the second-operand is 1-31 bytes, corresponding to a length code in L2 of 0-30. The second-operand length must not exceed 31 bytes (L2 must be less than or equal to 30); otherwise, a specification exception is recognized.

Special Conditions:

If the L2 field is larger than 30 a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Chapter 26. Specialized-Function-Assist Instructions

Instructions 26-1
COMPUTE DIGITAL SIGNATURE AUTHENTICATION 26-2
DEFLATE CONVERSION CALL. 26-16

The specialized-function-assist instructions described in this chapter are intended to provide performance improvements for specific operations used in software libraries, utilities, and operating system services. The facilities and instructions described in this chapter may be replaced or removed in the future. As a result, it is recommended that when a software library, utility, or operating system service provides an implementation using one or more of the specialized-function-assist instructions in this chapter, the software library also provides an alternate implementation which does not rely on any specialized-function-assist instruction in case the corresponding facility is not available to the program. It is also recommended that application programs use provided software libraries, utilities, or operating system services rather than use specialized-function-assist instructions directly.

The description for each instruction in this chapter specifies whether the instruction is a privileged or unprivileged instruction.

Instructions

The instructions described in this chapter are summarized in Figure 26-1 on page 26-1. The figure lists each instruction and indicates the instruction name, mnemonic, operation code, format, and other noteworthy characteristics.

Programming Notes:

1. The COMPUTE DIGITAL SIGNATURE AUTHENTICATION instruction is available when the message-security-assist extension 9 is installed.
2. The DEFLATE CONVERSION CALL instruction is available when the DEFLATE-conversion facility is installed.

Name	Mnemonic	Characteristics												Op-code	Page
COMPUTE DIGITAL SIGNATURE AUTHENTICATION	KDSA	RRE	C	M9	¤^{5,9}	A	SP	IC	GM	I1	ST		R_2	B93A	26-2
DEFLATE CONVERSION CALL	DFLTCC	RRF-a	C	GZ	¤^{5,9}	A	SP	IC	GM	I1	ST	R_1	R_2 R_3	B939	26-16

Explanation:

¤^{5} Model dependent whether the instruction is restricted from transactional execution.

¤^{9} Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized. For PFD and PFDRL, the instruction is restricted only when the code in the M_1 field is 6 or 7; for STCMH, the instruction is restricted only when the M_3 field is zero and the code in the R_1 field is 6 or 7.

A Access exceptions for logical addresses.

C Condition code is set.

Dg General-operand data exception.

GM Instruction execution includes the implied use of multiple general registers:

- General registers 0 and 1 for COMPUTE DIGITAL SIGNATURE AUTHENTICATION and DEFLATE CONVERSION CALL.

GZ DEFLATE-conversion facility.

I1 Access register 1 is implicitly designated in the access-register mode.

IC Condition code alternative to interruptible instruction

M9 Message-security-assist extension 9.

R_1 R_1 field designates an access register in the access-register mode.

Figure 26-1. Summary of Specialized-Function-Assist Instructions (Part 1 of 2)

Name	Mne- monic	Characteristics	Op- code	Page

R_2 R_2 field designates an access register in the access-register mode.

R_3 R_3 field designates an access register in the access-register mode.

RRE RRE instruction format.

RRF RRF instruction format.

SP Specification exception.

ST PER storage-alteration event.

COMPUTE DIGITAL SIGNATURE AUTHENTICATION

KDSA R_1, R_2 [RRE]

'B93A'	////////	R_1	R_2
0	16	24	28 31

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R_1 field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 0 contains various controls affecting the operation of the instruction, as follows:

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 26-2 shows the assigned function codes for COMPUTE DIGITAL SIGNATURE AUTHENTICATION. All other function codes are unassigned. A specification exception is recognized if an unassigned or uninstalled function code is specified.

Code	Function	Param. Block Size (bytes)	Data Block Size (bytes)
0	KDSA-Query	16	—
1	KDSA-ECDSA-Verify-P256	4096	—
2	KDSA-ECDSA-Verify-P384	4096	—

Figure 26-2. Function Codes for COMPUTE DIGITAL SIGNATURE AUTHENTICATION

Deterministic (D): Bit position 56 of general register 0 contains the deterministic bit which effects the KDSA-ECDSA-Sign-P256, KDSA-ECDSA-Sign-P384, and KDSA-ECDSA-Sign-P521 function codes. When the deterministic bit is equal to zero the source random number is used to generate a secret random number within the execution of the instruction, hidden to the user. This adds security to the signature process and the signature will vary with each execution. When the deterministic bit is equal to a one the source random number is used directly and will provide the same signature for each execution with the same input. Other function codes are unaffected by the deterministic bit.

Bits 0-31 of general register 0 are ignored. Bits 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

Figure 26-3 on page 26-3 shows the contents of the general registers just described.

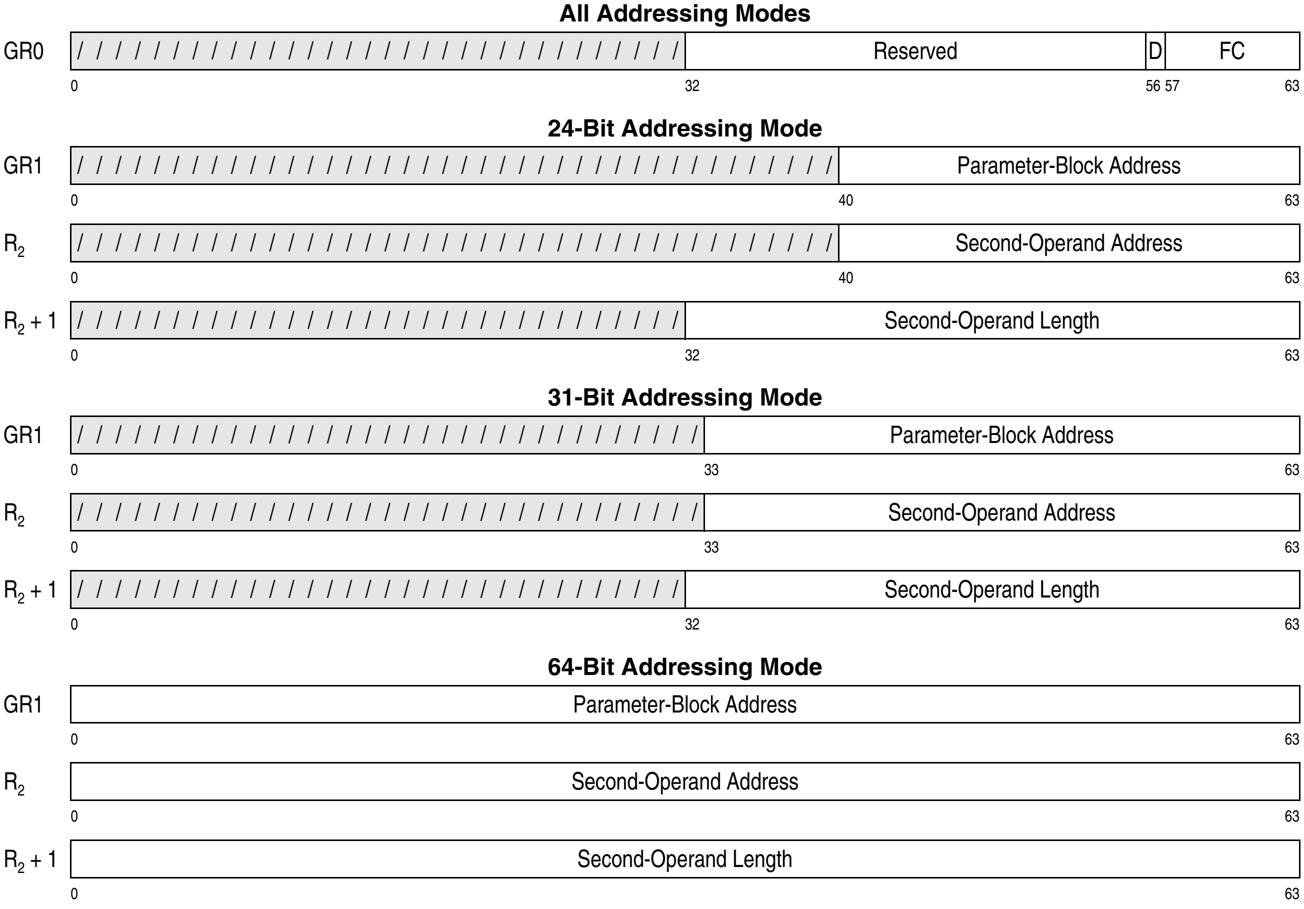

Figure 26-3. General Register Assignment for COMPUTE DIGITAL SIGNATURE AUTHENTICATION

In the access-register mode, access register 1 specifies the address space containing the parameter block.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and R_2 + 1 are ignored for the query function.

The verify functions check the validity of the signature of the hashed message and reports whether the credentials are valid via the condition code. The sign functions create a signature for the hashed message.

Note: The description of the COMPUTE DIGITAL SIGNATURE AUTHENTICATION (KDSA) instruction assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxx and in the Edwards-curve Digital Signature Algorithm (EdDSA) described in Reference [25.] on page xxx.

In the case of ECDSA, three Weierstrass curves over prime fields are supported: NIST P256, P384, and P521. In Reference [24.] on page xxx these curves are actually referred to as P-256, P-384, and P-521, respectively. In Reference [32.] on page xxxi and Reference [33.] on page xxxi they are referred to as secp256r1, secp384r1, and secp521r1, respectively. Also see Reference [27.] on page xxx section 5.4 p.17-18 for algorithm details and see D.1.2.3-5 in Reference [24.] on page xxx p.100 for the curve parameter values including the prime modulus, the order, the coefficient, the base point x coordinate, and the base point y coordinate used by these function codes. Two other prime fields are supported which use the EdDSA algorithm in Reference [25.] on page xxx and Reference [26.] on page xxx referred to as Ed25519 and Ed448 though they use the curve Curve255-19 and Curve448, respectively. Also see Reference [25.] on page xxx for algorithm details and curve parameter values, section 5.1.7 and 5.2.7 describe the verify function and 5.1 and 5.2 describe the curve parameters for Ed25519 and Ed448 respectively which are used by these function codes. The following is the definition of the moduli of these fields:

- P256 = $2^{256} - 2^{224} + 2^{192} + 2^{96} - 1$
- P384 = $2^{384} - 2^{128} - 2^{96} + 2^{32} - 1$
- P521 = $2^{521} - 1$
- Ed25519 = $2^{255} - 19$
- Ed448 = $2^{448} - 2^{224} - 1$

The sign and verify function codes (1, 2, 3, 9, 10, 11, 17, 18, and 19), which use the ECDSA algorithm on NIST curves, ignore the contents of general registers R_2 and R_2 + 1. These functions utilize a hashed message of fixed size which is contained in the parameter block.

The Edwards curve functions: KDSA-EdDSA-Verify, KDSA-EdDSA-Sign, and KDSA-Encrypted-EdDSA-Sign (function codes 32, 36, 40, 44, 48, and 52), use the EdDSA algorithm, and the message is not prehashed Reference [25.] on page xxx. The second operand is the message. The PureEdDSA variant is supported for the curves Ed25519 and Ed448. Other variants such as the HashEdDSA variants Ed25519ph and Ed448ph and the context variant Ed25519ctx are not supported. The context is assumed to be null and the prehash function is the identity function and the flag is 0.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register R_2 + 1. Note the second-operand can have a length of zero bytes.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register R_2 + 1 form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register R_2 + 1. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 + 1 form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register R_2 + 1.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and R_2 + 1, always remain unchanged. In the access register mode, access register R_2 specifies the address space for the second operand.

These functions will be described in more detail along with their parameter blocks.

KDSA-Query (Function Code 0)

The location of the operands and addresses used by the instruction are shown in Figure 26-3 on page 26-3.

The parameter block used for the function has the following format shown in Figure 26-4:

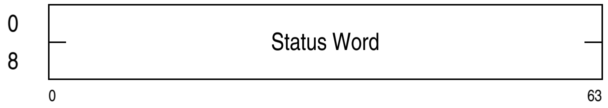

Figure 26-4. Parameter Block for KDSA-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE DIGITAL SIGNATURE AUTHENTICATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KDSA-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

KDSA-ECDSA-Verify Functions

This section describes the function codes for three KDSA-ECDSA-Verify functions for Weierstrass curves with NIST primes:

- KDSA-ECDSA-Verify-P256 (function code 1)
- KDSA-ECDSA-Verify-P384 (function code 2)
- KDSA-ECDSA-Verify-P521 (function code 3)

The locations of the operands and addresses used by each of these functions are as shown in Figure 26-3 on page 26-3. The parameter block contains the operands used by the KDSA-ECDSA-Verify functions and is addressed by general register 1.

The KDSA-ECDSA-Verify function checks the validity of a signed message. The originator of the message has a public key that can be used to see if the signature matches the hashed message. The signature consists of two integers in the prime field designated by R and S. The originator and receiver agree on a hashing scheme for creating the signature. The KDSA-ECDSA-Verify function operates on the already hashed message represented as H(msg) in the parameter block. The hashed message is reduced to be less than the order of the curve by modulo reduction by the order of the curve. The originator's public key is represented by K. An elliptic curve public key is actually a point on the curve and has X and Y coordinates (represented by Xk and Yk) within the prime field making it twice as big as other parameters. These operands are supplied to the function in the parameter block. The operation results in a true or false validity indication which is represented by a condition code equal to zero versus two respectively.

The parameter block used for KDSA-ECDSA-Verify-P256 function has the format as shown in Figure 26-5, below.

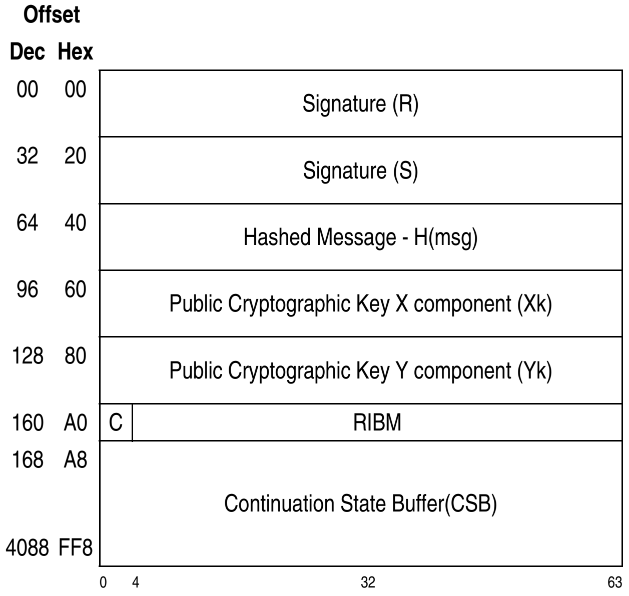

Figure 26-5. Parameter Block for KDSA-ECDSA-Verify-P256 Function

The parameter block for KDSA-ECDSA-Verify-P384 is shown in Figure 26-6, below. Each field is 48 bytes or 384 bits wide.

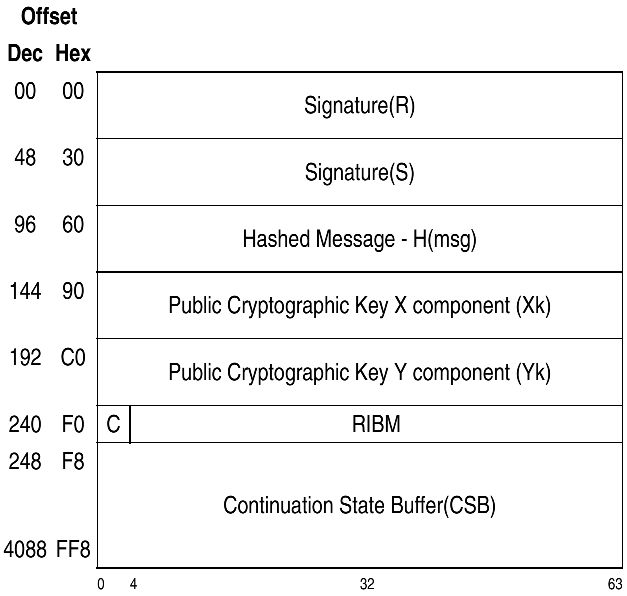

Figure 26-6. Parameter Block for KDSA-ECDSA-Verify-P384 Function

The parameter block for KDSA-ECDSA-Verify-P521 is shown in Figure 26-7, below. The NIST standard defines data to be passed in “octets” which are 8 bits wide. 521-bit operands need to be padded on the leftmost significant bits with 7 zeros to form 528 bits or 66 bytes (octets). Each parameter is 66 bytes which is right-aligned in the 80-byte field. The 14 remaining bytes are ignored and not updated. The hashed message is 66 bytes wide and upper bits can be non-zero which may require the function to perform modulo reduction by the order of the curve.

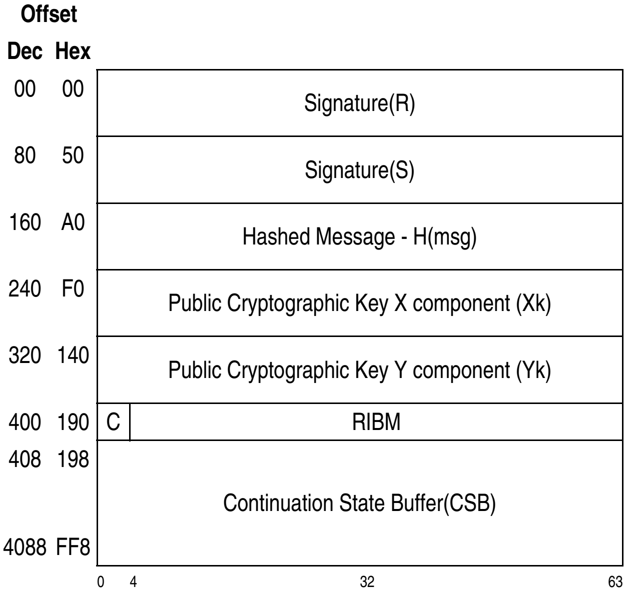

Figure 26-7. Parameter Block for KDSA-ECDSA-Verify-P521 Function

The reserved for IBM use (RIBM) field is 60 bits and the information code (C) is 4 bits for a total of 8 bytes, and must be initialized to zero prior to the first invocation of the instruction. The RIBM holds status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the programmer after partial completion and before subsequent invocation. Corruption of the CSB is handled by the CPU clearing the intermediate results and status in the CSB and ending in partial completion which will allow a clean re-execution of the instruction. Also the CSB is cleared by the CPU of any intermediate state if the KDSA instruction ends with neither a condition code 3 nor an access exception. The information code is utilized by the KDSA Encrypted Sign functions to distinguish between different condition code one cases and is reserved for future use on other function codes.

Condition code 1 is set when the public key is invalid due to a coordinate not being greater than or equal to zero and less than the prime of the curve, or the point not on the curve. Condition code 2 is set if the signature is invalid, and condition code 0 is set if the signature is valid. Condition code 3 is set if the operation ends in partial completion.

KDSA-ECDSA-Sign Functions

Note: The description of the KDSA-ECDSA-Sign function assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxx.

This section illustrates the operation for three KDSA-ECDSA-Sign and three KDSA-Encrypted-ECDSA-Sign functions:

- KDSA-ECDSA-Sign-P256 (function code 9)
- KDSA-ECDSA-Sign-P384 (function code 10)
- KDSA-ECDSA-Sign-P521 (function code 11)
- KDSA-Encrypted-ECDSA-Sign-P256 (function code 17)
- KDSA-Encrypted-ECDSA-Sign-P384 (function code 18)

- KDSA-Encrypted-ECDSA-Sign-P521 (function code 19)

The KDSA-ECDSA-Sign function uses a cryptographic key (K) that is a plain text key for the author's private key. The KDSA-Encrypted-ECDSA-Sign function uses an encrypted key to hold the author's private key and has a corresponding Wrapping Key Verification Pattern (WK$_e$VP) to test the key.

The ECDSA algorithm uses a random number to randomize the signature. KDSA-ECDSA-Sign and KDSA-Encrypted-ECDSA-Sign functions for NIST curves (P256, P384, and P521) utilize a user specified random number, RN, in the parameter block. For KDSA-ECDSA-Sign with the deterministic bit equal to zero and for KDSA-Encrypted-ECDSA-Sign, the specified random number is hashed with a CPU-generated random number that varies on each invocation. For KDSA-ECDSA-Sign with the deterministic bit equal to one the user specified random number is used directly, which makes every execution with the same input produce the same signature. The EdDSA algorithm does not use a random number.

The result of the sign function is a signature which is represented by two integers, R and S, which are between a value of zero and the order of the curve for the particular function and is stored in the designated location in the parameter block.

The parameter block for KDSA-ECDSA-Sign-P256 function with plain text key is shown in Figure 26-8, below.

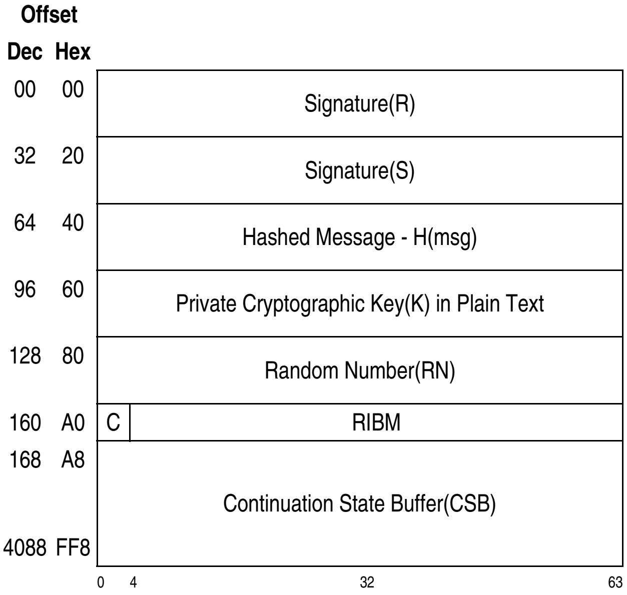

Figure 26-8. Parameter Block for KDSA-ECDSA-Sign-P256 Function

The parameter block for KDSA-ECDSA-Sign-P384 function with plain text key is shown in Figure 26-9, below.

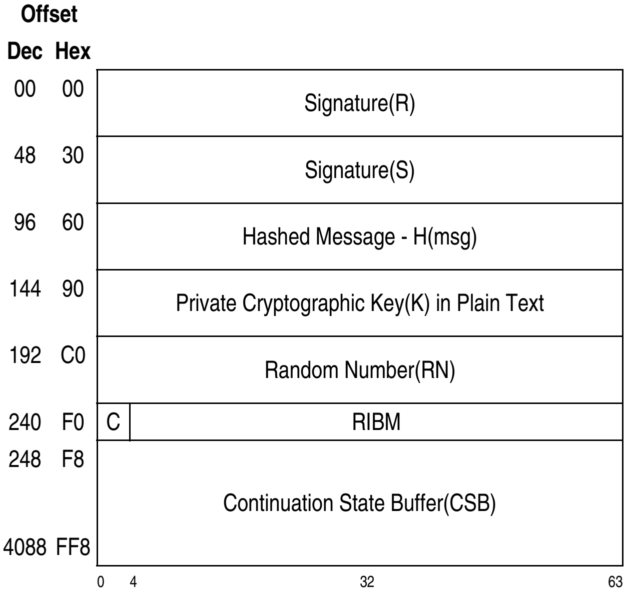

Figure 26-9. Parameter Block for KDSA-ECDSA-Sign-P384 Function

The parameter block for KDSA-ECDSA-Sign-P521 function for with plain text key is shown in Figure 26-10. The NIST standard defines data to be passed in “octets” which are 8 bits wide. 521-bit operands need to be padded on the leftmost significant bits with 7 zeros to form 528 bits or 66 bytes (octets). Each parameter is 66 bytes which is right-aligned in the 80-byte field. The 14 remaining bytes are ignored and not updated. The hashed message is 66 bytes wide and leftmost bits can be non-zero which may require the function to perform modulo reduction by the order of the curve.

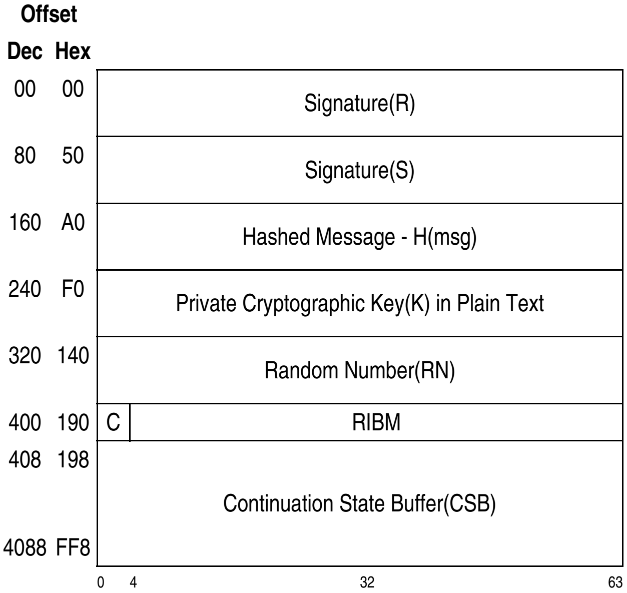

Figure 26-10. Parameter Block for KDSA-ECDSA-Sign-P521 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P256 which uses an encrypted key is shown in Figure 26-11, below.

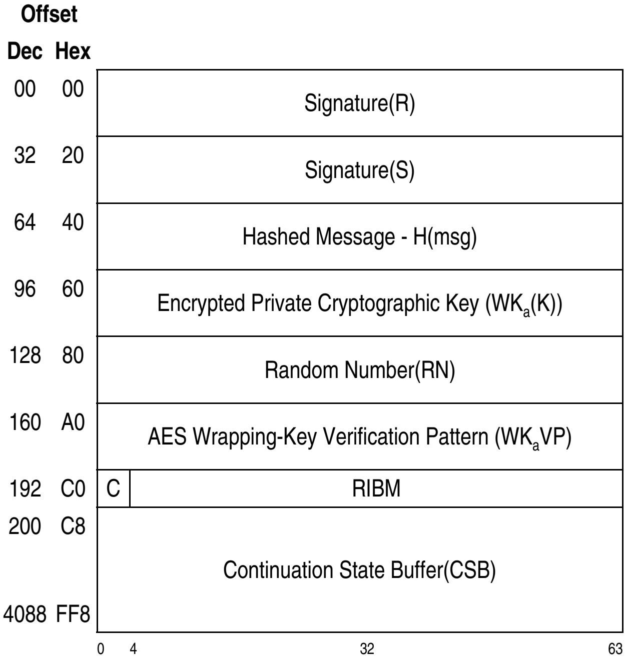

Figure 26-11. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P256 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P384 function is shown in Figure 26-12, below.

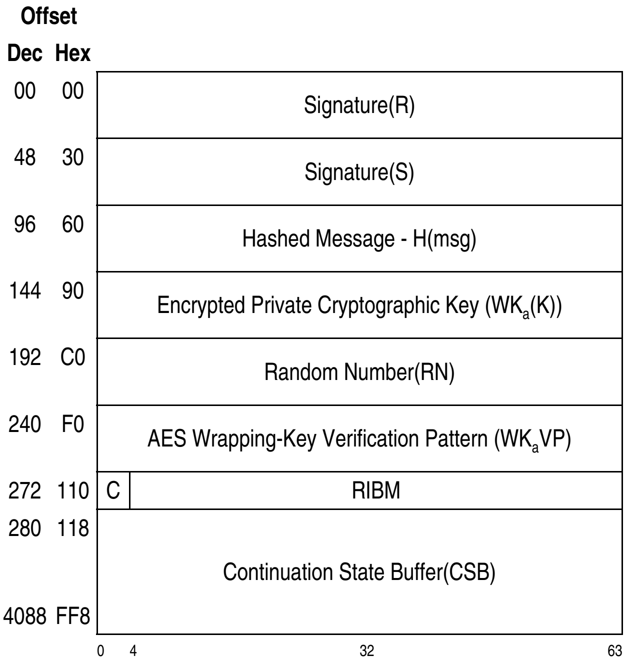

Figure 26-12. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P384 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P521 function is shown in Figure 26-13, below.

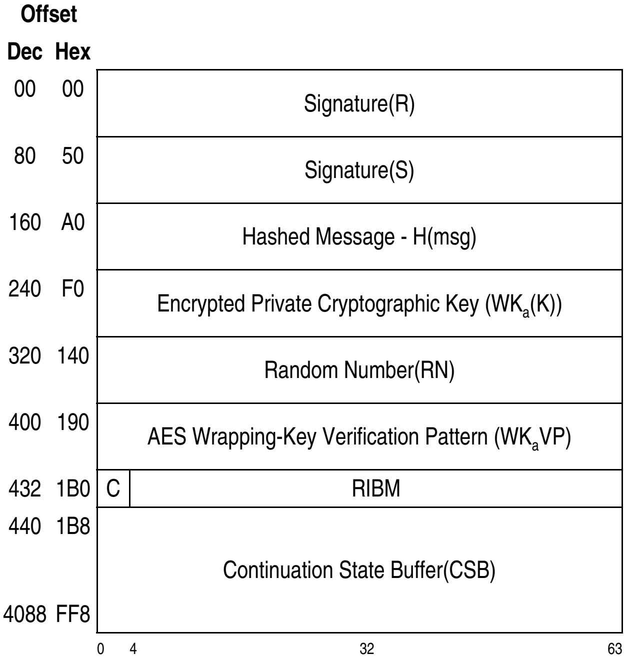

Figure 26-13. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P521 Function

P521 format has 521 bits with an additional most significant 7 bits of zeros for R, S, and operands for 66 bytes which are right aligned within the 80 byte field. The remaining 14 bytes of the R and S fields are unchanged. The hashed message is the width of the whole 80-byte field.

Condition code 1 is set and C is set to 0001 binary if the verification pattern mismatches. The condition code is set to 1 and C is set to 0000 binary if the private key is zero or greater than or equal to the order of the curve. Condition code 2 is set if the random number is not invertible for ECDSA-Sign with the deterministic bit set to one but not when the deterministic bit is zero or for Encrypted-ECDSA-Sign. For ECDSA-Sign with the deterministic bit set to zero and for Encrypted-ECDSA-Sign the CPU generated random number will be invertible. Condition code 0 is set if signature generation is successful. Condition code 3 is set if the operation ends in partial completion.

KDSA-EdDSA-Verify Functions

This section illustrates the operation for two KDSA-EdDSA-Verify functions for Edwards curves:

- KDSA-EdDSA-Verify-Ed25519 (function code 32)
- KDSA-EdDSA-Verify-Ed448 (function code 36)

The locations of the operands and addresses used by each of these functions are as shown in Figure 26-3 on page 26-3. The parameter block contains the operands used by the KDSA-EdDSA-Verify functions and is addressed by general register 1.

Note that EdDSA is defined in RFC-8032 Reference [25.] on page xxx to have integers encoded in little-endian form as opposed to most cryptographic algorithms. Transformation from little-endian to big-endian can be accomplished by a MOVE INVERSE (MVCIN) instruction and KDSA is assumed to have operands in big-endian form.

For Ed25519 the most significant bit of the most significant byte is not needed for 255 bit format though the standard requires this bit to be a zero. For compressed points the y-coordinate is placed in the 255 least significant bits and the x-coordinate least significant bit is placed in the remaining most significant bit. Ed448 encodes a compressed point with the 56 byte y-coordinate in the least significant 56 bytes of the 57 bytes and the x-coordinate least significant bit is placed in the most significant bit of the most significant byte and the remaining bits of the byte are filled with zeros. Note that the integer representation of a compressed point can not take on all values, and there are some values which are invalid and can not be decompressed. In the case of input that can not be decompressed, such as the signature R or the public key, a condition code is produced indicating the input is invalid.

The KDSA-EdDSA-Verify function checks the validity of a signed message. The originator of the message has a public key that can be used to see if the signature matches the hashed message. The signature consists of two integers in the prime field designated by R and S. The originator and receiver agree on a hashing scheme for creating the signature. The KDSA-EdDSA-Verify function operates on full message which is addressed by operand 2. The originator's public key is represented by K in the parameter block and it is in compressed format where the least significant bit of the x coordinate is concatenated to all the bits of the y coordinate. Therefore the public key is slightly wider than the prime of the curve taking 57 bytes for the Ed448 curve. The operation results in a true or false validity indication in the condition code represented by condition code equal to zero or two respectively.

Note the public key and signature R are compressed points that are represented in big-endian form in the parameter block, though the RFC-8032 algorithm Reference [25.] on page xxx requires these compressed points to be hashed in little-endian format in compressed format. This requires byte reversing the public key and signature R.

The parameter block used for KDSA-EdDSA-Verify-Ed25519 function has the format as shown in Figure 26-14, below. R, S, and K are represented as 32 bytes or 256 bits wide.

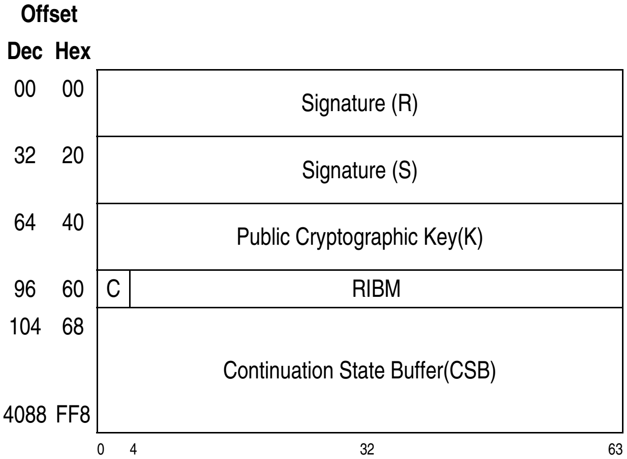

Figure 26-14. Parameter Block for KDSA-EdDSA-Verify-Ed25519 Function

The parameter block for KDSA-EdDSA-Verify-Ed448 is shown in Figure 26-15, below. R, S, and K fields are 64 bytes or 512 bits wide. The S parameter is represented by the right most 456 bits of the 512 bit field and the R and K field which are compressed points are represented by the right most 456 bits of the 512 bit field.

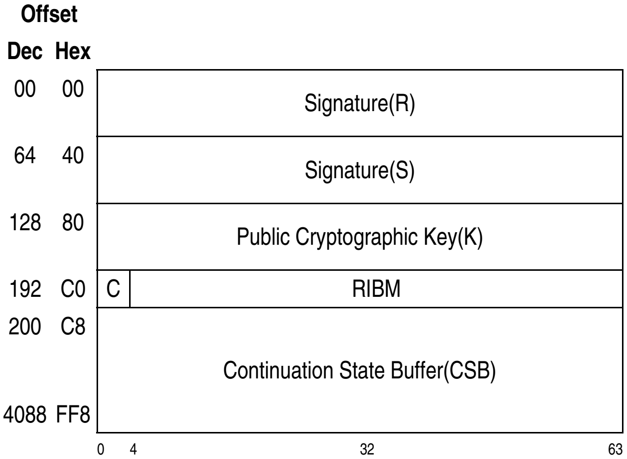

Figure 26-15. Parameter Block for KDSA-EdDSA-Verify-Ed448 Function

The second operand address in general register R_2 and the second operand length in general register R_2+1 are not updated as the message is processed.

Condition code 1 is set when the public key is invalid due to the compressed point not being decompressable or the Y coordinate not being greater than or equal to zero and less than the prime of the curve, or the point not on the curve. Condition code 2 is set if the signature is invalid and condition code 0 is set if the signature is valid. There are several cases of the signature being invalid such as the compressed point R not being decompressable or its resulting Y coordinate not greater than zero and less than the prime or the signature S not being greater than zero and less than the prime or the signature not matching. Note for Ed448 S is 57 bytes and the most significant byte must be zero otherwise condition code 2 is set. Condition code 3 is set if the operation ends with partial completion.

KDSA-EdDSA-Sign Functions

Note: The description of the KDSA-EdDSA-Sign function assumes that the reader is familiar with the Edwards-curve Digital Signature Algorithm (EdDSA) described in Reference [25.] on page xxx.

This section illustrates the operation for two KDSA-EdDSA-Sign functions and the two KDSA-Encrypted-EdDSA-Sign functions:

- KDSA-EdDSA-Sign-Ed25519 (function code 40)
- KDSA-EdDSA-Sign-Ed448 (function code 44)
- KDSA-Encrypted-EdDSA-Sign-Ed25519 (function code 48)
- KDSA-Encrypted-EdDSA-Sign-Ed448 (function code 52)

The KDSA-EdDSA-Sign function uses a cryptographic key (K) that is a plain text key for the author's private key. This key must be protected by software. The KDSA-Encrypted-EdDSA-Sign function uses an encrypted key to hold the author's private key and has a corresponding Wrapping Key Verification Pattern (WK_aVP) to test the key.

The EdDSA algorithm does not use a random number and therefore none is specified for KDSA-EdDSA-Sign functions.

The result of the KDSA-EdDSA-Sign function is a signature which is represented by two integers, R and S, where S is between a value of zero and the order of the curve for the particular function and is stored in the designated location in the parameter block.

Note that for EdDSA the private key is not checked for range since it is directly hashed and does not need to be in a certain range.

Note the public key and signature R are compressed points that are created internal to the sign operation in big-endian form, though the RFC-8032 algorithm Reference [25.] on page xxx requires these compressed points to be hashed in little-endian format in compressed format. This requires byte reversing the public key and signature R.

The parameter block for KDSA-EdDSA-Sign-Ed25519 with plain text key is shown in Figure 26-16, below. The R, S, and K parameters are 32 byte fields. Note that the S parameter has the most significant bit of the field forced to zero. No random number is specified since EdDSA algorithm does not require one.

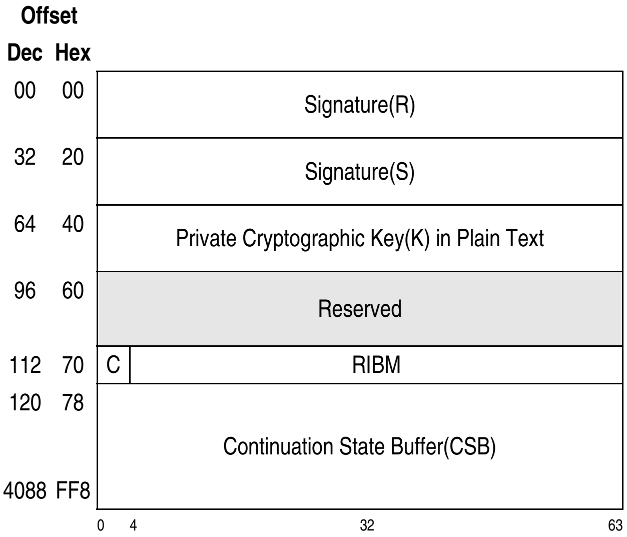

Figure 26-16. Parameter Block for KDSA-EdDSA-Sign-Ed25519 Functions

The parameter block for KDSA-EdDSA-Sign-Ed448 function with plain text key is shown in Figure 26-17, below. The R, S, and the K parameters are 456 bits or 57 bytes and are right aligned. The remaining bytes of the R and S fields are unchanged. The Ed448 format also uses the EdDSA algorithm which does not utilize a random number.

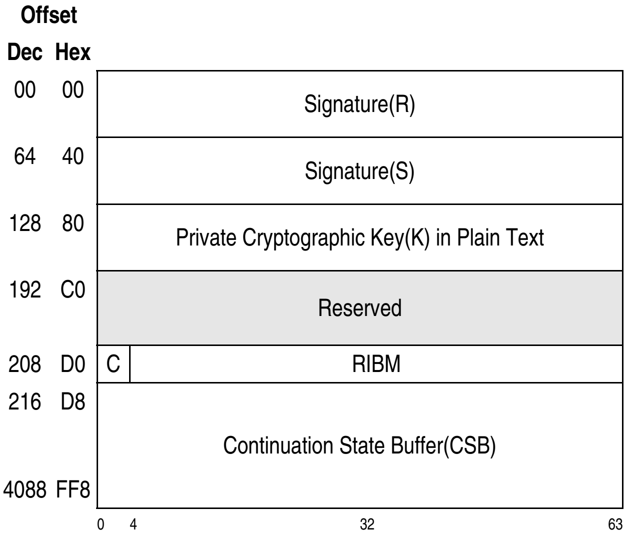

Figure 26-17. Parameter Block for KDSA-EdDSA-Sign-Ed448 Function

The reserved for IBM use (RIBM) field is 60 bits and the information code (C) is 4 bits for a total of 8 bytes, and must be initialized to zero prior to the first invocation of the instruction. The RIBM holds status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the programmer after partial completion and before subsequent invocation. Corruption of the CSB is handled by the CPU clearing the intermediate results and status in the CSB and ending in partial completion which will allow a clean re-execution of the instruction. Also the CSB is cleared by the CPU of any intermediate state if the KDSA instruction ends with neither a condition code 3 nor an access exception. The information code is utilized by the KDSA Encrypted Sign functions to distinguish between different condition code one cases and is reserved for future use on other function codes.

The parameter block for KDSA-Encrypted-ECDSA-Sign-Ed25519 for encrypted key is shown in Figure 26-18, below. Note the Ed25519 format utilizes 32 bytes for each parameter including the S field which has a zero for the most significant bit.

Figure 26-19. Parameter Block for KDSA-EdDSA-Sign-Ed448 Function

The second operand address in general register R_2 and the second operand length in general register $R_2 + 1$ are not updated as the message is processed which is twice for the KDSA-EdDSA-Sign and KDSA-Encrypted-EdDSA-Sign functions.

Condition code 1 is set and C is set to 0001 binary, if the verification pattern mismatches. The condition code is set to 1 and C is set to 0000 binary, if the private key is zero or greater than or equal to the order of the curve. And condition code 0 is set if signature generation is successful. Condition code 3 is set if the operation ends with partial completion.

Operand Field Description

The fields of the parameter block for all KDSA-Verify and KDSA-Sign functions are as follows where each parameter is right aligned in the field and extracted to byte boundaries (P521 parameters are 66 bytes or 528 bits with the most significant 7 bits equal to zeros, except for the hashed message which allows these 7 bits to be non-zero):

Signature (R): The first part of the signature is represented by R. For ECDSA, R is an unsigned integer which is greater than zero and less than the order of the curve, otherwise it is considered an invalid signature and for the ECDSA Verify function results in a condition code equal to 2. For EdDSA functions, R is a compressed point where the least significant bit of X is concatenated with the Y. R must be decompressable or the condition code is set to 2. For Ed25519, R is 256 bits consisting of 1 bit of X concatenated on the left of 255 bits of Y and for Ed448 an extra byte is added on the left with 1 bit X concatenated with 7 zeros, followed by 448 bits of Y. The Y coordinate must be greater than or equal to zero and less than the prime otherwise it is considered an invalid signature resulting in a condition code equal to 2.

Signature (S): The second part of the signature is represented by S. S is an unsigned integer for both ECDSA and EdDSA functions and is greater than zero and less than the order of the curve, otherwise for the Verify functions it is considered an invalid signature resulting in a condition code equal to 2.

Hashed Message - H(msg): The sign and verify operation utilize a hashed version of the author's message for ECDSA curves. Hashing for ECDSA is performed prior to the KDSA instruction to allow greater flexibility in supported encryption. The hashed message is an unsigned integer and can be any value including zero or greater than the prime. The hashed message is reduced by the function modulo the order of the curve to be greater than or equal to zero and less than the order of the curve. This parameter is not available on EdDSA curves, since they do not prehash the message, and instead operand 2 addresses the encrypted message.

Cryptographic Key (K): The cryptographic key used in the sign and verify operations begins at various bytes of the parameter block. The size of the key field and its offset in the parameter block are dependent on the function code, as shown in Figure 26-20.

Function Code	Function	Key Length (bytes)	Key Offset (bytes)
1	KDSA-ECDSA-Verify-P256	32x2	96-159
2	KDSA-ECDSA-Verify-P384	48x2	144-239
3	KDSA-ECDSA-Verify-P521	66x2	254-319, 334-399
9	KDSA-ECDSA-Sign-P256	32	96-127
10	KDSA-ECDSA-Sign-P384	48	144-191

36	KDSA-EdDSA-Verify-Ed448	57	135-191
40	KDSA-EdDSA-Sign-Ed25519	32	64-95
44	KDSA-EdDSA-Sign-Ed448	57	135-191
48	KDSA-Encrypted-EdDSA-Sign-Ed25519	32	64-95
52	KDSA-Encrypted-EdDSA-Sign-Ed448	64	128-191

Figure 26-20. Summary of Key Lengths and Offsets for KDSA Functions

The key used for KDSA-EdDSA-Verify functions is a compressed point whereas the other functions use an integer key. If the compressed point public key can not be decompressed or if the Y coordinate is greater than or equal to the prime the condition code is set to 1. Note that Ed25519 requires 255 least significant bits of the 256-bit, 32-byte field. The KDSA-Sign for P521 and Ed448 require different key widths for encrypted key and plain text functions. The encrypted key is encoded into blocks of 128 bits. The P521 plain text key for sign and for verify are 521 bits which is 65 bytes and 1 bit, which is aligned in the right most bits of the 66 byte key and the 66 byte key is aligned in the right most bytes of the 80 byte field in the parameter block.

For KDSA-ECDSA-Sign the key must be greater than zero and less than the order of the curve or the condition code is set to 1. For KDSA-ECDSA-Verify the public key point has to be on the curve and the coordinates must be less than the order of the curve or the condition code is set to 1.

AES Wrapping-Key Verification Pattern (WK_aVP): For the KDSA-Encrypted-Sign functions (codes 17-19, 48, and 52), the 32 bytes immediately following the key in the parameter block contain the AES wrapping-key verification pattern (WK_aVP).

For the KDSA-Verify functions and the plain text key KDSA-Sign functions, the WK_aVP field is not present in the parameter block.

Wrapping-Key Verification: For the KDSA-Sign with encrypted key functions (function codes 17-19, 48, and 52), the contents of the 32-byte WK_aVP field are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of the key field of the parameter block are deciphered using the AES wrapping key to obtain the cryptographic key, K. (See the “Protection of Cryptographic Keys” on page 7-431 for details.) Note encrypted ECC keys are protected by AES-256 encryption.

For the KDSA functions that do not use encrypted keys, wrapping-key verification is not performed.

Random Number (RN): The KDSA-ECDSA-Sign and KDSA-Encrypted-Sign functions have an input random number. For KDSA-ECDSA-Sign functions with the deterministic bit set equal to one the random number must be greater than zero. Bits more significant than number bits in the prime number are forced to zero and if not less than the order of the curve of the function, the order of curve is subtracted from the random number. The random number must be invertible by the order of curve otherwise the parameter-block location remains unchanged, and the operation is completed by setting condition code 2.

For KDSA-ECDSA-Sign with the deterministic bit equal to zero and for KDSA-Encrypted-ECDSA-Sign functions the random number can be any value including zero, since it is not used directly but instead is used as a seed to create an invertible, hidden, random number.

RIBM, C, and Continuation State Buffer (CSB):

The RIBM and C must be initialized to zero prior to the first invocation of the instruction. This reserved area and continuation state buffer (CSB) are provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the programmer after partial completion and before subsequent invocation. If corruption is detected in the RIBM and CSB the CPU clears the CSB intermediate state and status and ends the instruction in partial completion which will allow a clean re-execution of the instruction. Also, the CSB is cleared by the CPU of any intermediate state when the ends in neither partial completion nor an access exception. The C field is an information code field defined for the KDSA Encrypted Sign functions to distinguish the condition code one cases of private key not in range, C=0000 binary, and the WKVP mismatch, C=0001 binary and is reserved for other functions.

Reserved: As an input to an operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When an operation ends, reserved fields may be stored as zeros or may remain unchanged.

Common Operation

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the second operand when the comparison results in a mismatch.

When the contents of general register R_2 are zero, multiple PER zero-address-detection events will be detected if the instruction ends in partial completion.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4 K-bytes beyond the current location being processed. The entire parameter block may be tested for store-type accesses even though part of it may not be stored. All KDSA function codes may test for store-type accesses including KDSA-Verify since it could store to the RIBM and CSB fields on partial completion.

Special Conditions for KDSA

If the second operand overlaps the parameter block, results are unpredictable.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_2 field designates an odd-numbered register or general register 0.

Resulting Condition Code:

0 Query: function completes; Verify: signature verified for function; Sign: normal completion.
1 Verify: public key not on curve, or not decompressable, or coordinate greater than the prime of the curve; Sign: key verification-pattern mismatch, or for ECDSA-Sign the private key is equal to zero or greater than the prime of the curve.
2 Verify: signature is incorrect, or for EdDSA R not decompressable, or for non-Encrypted ECDSA sign with D=1: random number not invertible or out of range (0 < RN < order of curve).
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block fields, operand 2 (EdDSA functions only); store, parameter block fields)
- Operation (if the message-security-assist extension 9 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint.
8.	Specification exception due to invalid function code or invalid register number.
9.A.1	Access exceptions for an access to the parameter block.
9.A.2	Sign function with condition code 1 due to verification-pattern mismatch, or ECDSA private key equal to zero or greater than the order of the curve. Verification function for ECDSA with condition code 1 due to the public key not on the curve or one or more of the coordinates greater than or equal to the order. Verification function for EdDSA with condition code 1 due to the public key not decompressable, or one or more of the coordinates greater than or equal to the prime.
9.A.3	ECDSA Sign (non-encrypted) function and D = 1 with condition code 2 due to a non-invertible random number or out of range (0 < RN < order of curve). Verification function for ECDSA with condition code 2 due to the signature equal to zero or greater than or equal to the prime of the curve. Verification function for EdDSA with condition code 2 due to the signature S equal to zero or greater than or equal to the order of the curve or signature R not decompressable or the Y coordinate greater than or equal to the prime.
9.B	Access exceptions for an access to the second operand.

Figure 26-21. Priority of Execution: KDSA

10.	Condition code 3 due to partial processing.
11.	Condition code 0 due to normal completion or condition code 2 due to signature incorrect.

Figure 26-21. Priority of Execution: KDSA (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. When condition code 3 is set, the general registers containing the operand addresses and lengths, and the parameter block, are updated such that the program can simply branch back to the instruction to continue the operation.

3. The R_1 field is not used by this instruction for any function codes.

4. Software should clear fields in the parameter block that are sensitive such as the Private Key and the Random Number to limit the time exposed in storage. The CPU will zero out the CSB upon restart of the instruction and full completion.

5. The reserved field should be initialized to zero otherwise the program may not operate compatibly in the future.

DEFLATE CONVERSION CALL

DFLTCC R_1,R_2,R_3 [RRF-a]

'B939'	R_3	////	R_1	R_2
0	16	20	24	28 31

DEFLATE CONVERSION CALL performs functions related to transforming the state of data between the original (uncompressed) form of the data, and a compressed representation of the data, as specified by the standard described in Reference [23.] on page xxx. The uncompressed data is a sequence of bytes. The compressed representation of the data includes symbols. Symbols represent an individual byte of uncompressed data, referred to as a literal byte, or represent a reoccurring sequence of bytes of uncompressed data, referred to as a duplicate string. A Huffman table specifies the encoding and decoding between compressed-data symbols and uncompressed data. There are two types of Huffman tables. A fixed-Huffman table (FHT) is a predetermined specification which includes all possible codings. A dynamic-Huffman table (DHT) is a set of codings created specifically for the data to be compressed, which may be a subset of all possible codings. A compressed representation of data generated with a DHT is typically smaller than a compressed representation of the same data generated with an FHT. A portion of the most recently processed uncompressed data, referred to as history, is maintained for encoding and decoding compressed-data symbols representing duplicate strings. The history is the reference source for duplicate strings. The history is updated as data is processed during an operation.

The definition of DEFLATE CONVERSION CALL assumes knowledge of the DEFLATE compressed data format, which is described in Reference [23.] on page xxx. Noteworthy attributes of the DEFLATE standard which apply to DEFLATE CONVERSION CALL are as follows:

- A compressed-data set consists of a series of blocks. There are three types of blocks. One type consists of a 3-bit header followed by length information and uncompressed data. Two types of blocks consists of a 3-bit header followed by compressed-data elements.
- Compressed-data elements may include a compressed representation of a dynamic-Huffman table, compressed-data symbols, and an end-of-block (EOB) symbol.
- Compressed-data elements have various bit lengths.
- Compressed-data elements may begin or end between byte boundaries in storage.
- Compressed-data elements are loaded into bytes in order from the rightmost bit position to the leftmost bit position.

Refer to “Descriptions for Compressed-data Blocks” on page 26-43 for details on boundaries and orderings for bytes and bits of the various blocks encountered in a compressed-data set.

When a compressed-data element occupies part of, and not all of, a byte in storage, the entire byte in storage is accessed. Storage-operand lengths specify the number of addressable bytes, which may specify more bits than the compressed-data occupies.

DEFLATE CONVERSION CALL is an unprivileged instruction. It may be executed when the CPU is in the problem or supervisor state.

Bits 20-23 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

A function specified by the function code in bit positions 57-63 of general register 0 is performed. Figure 26-22 shows the assigned function codes for DEFLATE CONVERSION CALL. All other function codes are unassigned. When the specified function is DFLTCC-CMPR or DFLTCC-XPND, bit 56 of general register 0 specifies the history-buffer type (HBT) used during the operation. When HBT is zero, the history buffer is called an in-line history buffer. When using an in-line history buffer, the history is immediately to the left of the second operand when DFLTCC-CMPR is specified, and is immediately to the left of the first operand when DFLTCC-XPND is specified. When HBT is one, the history-buffer is called a circular history buffer. When using a circular history buffer, the history is a portion of, or all of, the third operand when either DFLTCC-CMPR or DFLTCC-XPND is specified. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, bit 56 of general register 0 is ignored. Bit positions 0-31 of general register 0 are ignored. Bit positions 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Code	Function	Parameter Block Size (bytes)
0	DFLTCC-QAF	32
1	DFLTCC-GDHT	384
2	DFLTCC-CMPR	1536
4	DFLTCC-XPND	1536

Figure 26-22. Function Codes for DEFLATE COMPRESSION CALL

When bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

The contents of general register 1 specify the logical address of the leftmost byte of the parameter block in storage. The parameter block must be designated on a doubleword boundary; otherwise a specification exception is recognized.

When the specified function is DFLTCC-CMPR or DFLTCC-XPND, the contents of general register R_1 specify the logical address of the leftmost byte of the first operand. When the specified function is DFLTCC-CMPR, the contents of general register $R_1 + 1$, in conjunction with the values of the NT and SBB fields of the parameter block, specify the length of the first operand. Figure 26-23 on page 26-17 provides examples which demonstrate the length of the first operand for the DFLTCC-CMPR function as a function of the contents of general register $R_1 + 1$, the NT field, and the SBB field. When the specified function is DFLTCC-XPND, the contents of general register $R_1 + 1$ specify the length of the first operand. When the specified function is DFLTCC-CMPR or DFLTCC-XPND the results of compressing or uncompressing data are stored at the first-operand location. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, the contents of general registers R_1 and $R_1 + 1$ are ignored. For all functions, the R_1 field designates an even-odd pair of general registers. For all functions, the R_1 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized.

contents of GR R1 + 1 (hex)	NT	SBB (binary)	length of first operand
00000000 00000002	0	001	15 bits
00000000 00000001	1	---	8 bits
00000000 00000001	0	000	8 bits
00000000 00000001	0	011	5 bits
00000000 00000001	0	111	1 bit
00000000 00000000	-	---	0 bits

Figure 26-23. Examples Illustrating how NT and SBB Apply to the length of the first operand for the DFLTCC-CMPR function

When the specified function is DFLTCC-GDHT, DFLTCC-CMPR, or DFLTCC-XPND, the contents of general register R_2 specify the logical address of the leftmost byte of the second operand. When the specified function is DFLTCC-CMPR or DFLTCC-GDHT, the contents of general register $R_2 + 1$ specify the length of the second operand. When the specified function is DFLTCC-XPND, the contents of general register $R_2 + 1$, in conjunction with the values of the NT and SBB fields of the parameter block, specify the length of the second operand. When the second-operand length is referenced and has a non-zero value at the beginning of the execution of the instruction, data is fetched from the second-operand location. When the second-operand length is referenced, has a value of zero at the beginning of the execution of the instruction, and the continuation flag (CF) field of the parameter block is one at the beginning of the execution of the instruction, the second operand is not accessed. Refer to page 26-50 and page 26-57 for additional details. When the DFLTCC-QAF function is specified, the contents of general registers R_2 and $R_2 + 1$ are ignored. When the DFLTCC-GDHT function is specified and the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed. When the DFLTCC-CMPR or DFLTCC-XPND function is specified, the continuation flag (CF) field of the parameter block is zero at the beginning of the execution of the instruction, and the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed. For all functions, the R_2 field designates an even-odd pair of general registers. For all functions, the R_2 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized.

When the specified function is DFLTCC-CMPR or DFLTCC-XPND and the history-buffer type (HBT) is circular, the contents of general register R_3 specify the logical address of the leftmost byte of the third operand, and must designate a 4 K-byte boundary; otherwise a specification exception is recognized. The circular history buffer is a 32 K-byte buffer located at the third-operand location. When the specified function is DFLTCC-CMPR or DFLTCC-XPND and the HBT is zero, the contents of general register R_3 are ignored. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, the contents of general register R_3 are ignored. For all functions, the R_3 field must not designate general register 0 or general register 1; otherwise, a specification exception is recognized.

As part of the operation when the specified function is DFLTCC-CMPR, the address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit position 0, and the length in general register $R_1 + 1$ is decremented by the same number; the address in general register R_2 is incremented by the number of bytes processed of the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit position 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight. The formation and updating of the addresses and lengths are dependent on the addressing mode.

As part of the operation when the specified function is DFLTCC-XPND, the address in general register R_1 is incremented by the number of bytes processed of the first operand, and the length in general register $R_1 + 1$ is decremented by the same number; the address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit position 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit position 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight. The formation and updating of the addresses and lengths are dependent on the addressing mode.

For all functions, the contents of general registers 0, 1, and R_3 are not modified.

In the 24-bit addressing mode, the following apply:

- The contents of bit positions 40-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively, and the contents of bit positions 0-39 are ignored.
- Bits 40-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 40 of the updated addresses are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged. When the instruction ends with partial or normal completion, and an updated operand address equals the operand address at the beginning of the execution of the

instruction, bit positions 32-39 of the corresponding general register are set to zeros.

- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 31-bit addressing mode, the following apply:

- The contents of bit positions 33-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively, and the contents of bit positions 0-32 are ignored.
- Bits 33-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 33 of the updated addresses are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged. When the instruction ends with partial or normal completion, and an updated operand address equals the operand address at the beginning of the execution of the instruction, bit position 32 of the corresponding general register are set to zero.
- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 64-bit addressing mode, the following apply:

- The contents of bit positions 0-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively.
- Bits 0-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 0 of the updated addresses are ignored.
- The contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 64-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively.
- Bits 0-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively.

In the access-register mode, access registers 1, R_1, R_2, and R_3 specify the address spaces containing the parameter block, first operand, second operand, and circular history buffer, respectively. When DFTCC-CMPR with an in-line history buffer is specified in the access-register mode, access register R_2 specifies the address space containing the in-line history. When DFTCC-XPND with an in-line history buffer is specified in the access-register mode, access register R_1 specifies the address space containing the in-line history.

Figure 26-24 on page 26-19 shows the contents of the general registers just described.

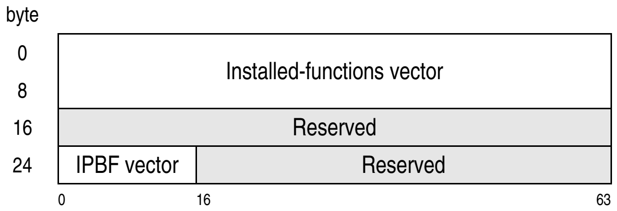
Function Code 0: DFLTCC-QAF (Query Available Functions)

The DFLTCC-QAF (query) function provides the means of indicating the availability of all installed functions and installed parameter block formats.

The parameter block for the query function has the following format:



Explanation

IPBF Installed-parameter-block-formats

Figure 26-25. Parameter Block for DFLTCC-QAF

An installed-functions vector and an installed-parameter-block-formats vector are stored to bytes 0-15 and bytes 24-25, respectively, of the parameter block, as illustrated in Figure 26-25.

Bits 0-127 of the installed-functions vector correspond to function codes 0-127, respectively, of the DEFLATE CONVERSION CALL instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Bits 0-15 of the installed-parameter-block-formats vector correspond to parameter-block formats 0-15, respectively, for the DFLTCC-GDHT, DFLTCC-CMPR, and DFLTCC-XPND functions. When a bit is one, the corresponding parameter-block format is installed; otherwise, the parameter-block format is not installed.

Zeros are stored to reserved bytes 16-23 and 26-31 of the parameter block.

The contents of general registers R_1, $R_1 + 1$, R_2, $R_2 + 1$, and R_3 are ignored when the DFLTCC-QAF function is specified.

A PER storage-alteration event is recognized, when applicable, for the parameter block. A PER zero-address-detection event is recognized, when applicable, for the parameter block.

Condition code 0 is set when execution of the DFLTCC-QAF function completes; condition codes 1, 2, and 3 are not applicable to the query function.

Function Code 1: DFLTCC-GDHT (Generate Dynamic-Huffman Table)

When the DFLTCC-GDHT function is specified, the second operand is used as a source to generate a compressed representation of a dynamic-Huffman table (DHT), as specified by the DEFLATE standard. Aspects of DHT generation are specified by the program to the machine using the DHTGC field of the parameter block. It is intended that the source contains uncompressed data and subsequent to completing the operation, the generated result is specified with the DFLTCC-CMPR function to compress the same source.

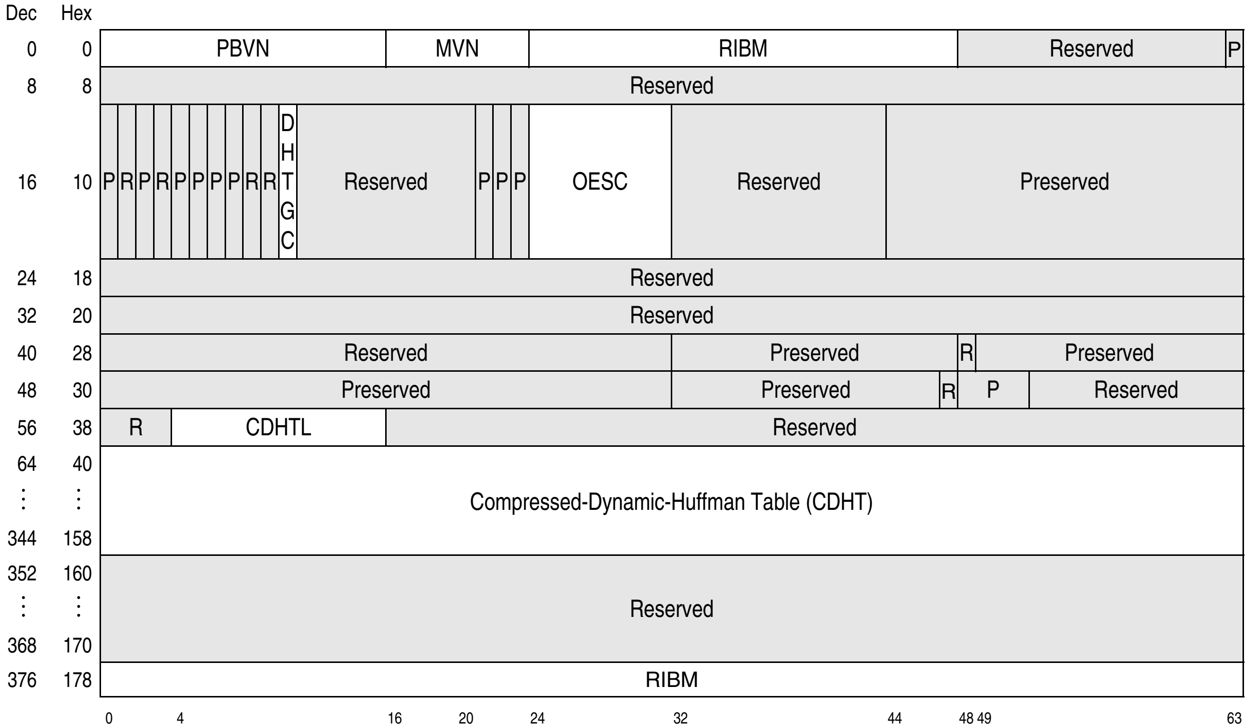
There is no history to reference from prior operations while processing the current operation.

When the contents of general register $R_2 + 1$ specify a length greater than 32 K-bytes, the following applies:

- Only the first 32 K-bytes of the second operand are used to generate the DHT.
- Access exceptions are not recognized for locations beyond the first 32 K-bytes of the second operand.

When the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed.

The parameter block for the DFLTCC-GDHT function is shown in Figure 26-26 on page 26-22. The fields of the parameter block are described in section ”Parameter Block for Data Conversion” on page 26-33. Fields of the parameter block designated as preserved are not modified by the DFLTCC-GDHT function. Preserved fields are distinguished from reserved fields to enable a program to initialize a single storage location, use that storage location for the parameter block of a DFLTCC-GDHT function, and subsequently use the same storage location for the parameter block of a DFLTCC-CMPR function.



Explanation:

CDHTL	Compressed-Dynamic-Huffman Table Length
DHTGC	Dynamic-Huffman-Table Generation Control
MVN	Model-Version Number
OESC	Operation-Ending-Supplemental Code
P	Preserved
PBVN	Parameter-Block-Version Number
R	Reserved
RIBM	Reserved for IBM use

Figure 26-26. Parameter Block (format 0 hex) for the DFLTCC-GDHT function

An invalid-input condition exists when the DFLTCC-GDHT function is specified and the following occurs:

- The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.

When an invalid-input condition is encountered, a dynamic-Huffman table (DHT) is not generated, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to 01 hex.
- Condition code 2 is set.

Normal completion occurs when a dynamic-Huffman table (DHT) is generated. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- A compressed format of the generated DHT is stored to the CDHT field of the parameter block. The resulting compressed format of the DHT includes a Huffman code representing an end-of-block (EOB) symbol.
- The length of the compressed format of the generated DHT is stored to the CDHTL field of the parameter block.

- The operation-ending-supplemental code (OESC) field of the parameter block is set to 00 hex.
- Condition code 0 is set.

Condition codes 1 and 3 are not applicable to the DFLTCC-GDHT function.

General registers R_2 and $R_2 + 1$ are not modified by the operation.

The contents of general registers R_1, $R_1 + 1$, and R_3 are ignored when the DFLTCC-GDHT function is specified.

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block.

Function Code 2: DFLTCC-CMPR (Compress)

When the DFLTCC-CMPR function is specified, a compressing operation is performed. The operation consists of encoding data from the second-operand location into compressed-data symbols, which are stored to the first-operand location.

The operation proceeds as described in section “Compressing Data” on page 26-49.

Normal completion occurs when the entire second operand is compressed and stored to the first-operand location. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 0 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When normal completion occurs, the NT and CSB fields of the parameter block are undefined, but may be modified.

When a CPU-determined number of bytes have been processed and an invalid-input condition, as defined on page 26-25, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero when the CPU-determined number of bytes processed is greater than zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.

- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 3 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

The CPU-determined number of bytes depends on the model, and may be a different number each time the instruction is executed.

Subsequent to the instruction ending with condition code 3 set, it is expected the program does not modify any input or output specification for the instruction and branches back to reexecute the instruction to resume the operation.

In certain unusual situations, despite ending the instruction with condition code 3 set, the parameter block and general registers are not updated. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL. In these cases, the CPU-determined number of bytes processed is zero, data may have been stored to the first-operand location, data may have been stored to the third-operand location, when applicable, and corresponding change bits have been set.

The first-operand length is insufficient to complete the operation when any of the following conditions apply:

- The first-operand length, as specified by the contents of general register $R_1 + 1$, is zero at the beginning of the execution of the instruction.
- The first-operand length becomes equal to zero during the execution of the instruction and normal completion does not occur.

Note: The first-operand length is zero when the content of general register $R_1 + 1$ is zero, regardless of the values in the NT and SBB fields of the parameter block.

When the first-operand length becomes equal to zero during the execution of the instruction and an invalid-input condition, as defined on page 26-25, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that

included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When the first-operand length is zero at the beginning of the execution of the instruction and an invalid-input condition, as defined on page 26-25, has not been encountered, the operation ends and the following occurs:

- Condition code 1 is set.

Subsequent to the instruction ending with condition code 1 set, it is expected the program modifies the first-operand length, first-operand address, or both and reexecute the instruction to resume the operation.

An invalid-input condition exists when the DFLTCC-CMPR function is specified and any of the following occurs:

1. The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
2. NT is zero and HL is greater than 32,768.
3. The HTT is one and the CDHTL is less than 42 or greater than 2283.
4. The HTT is one and the CDHTL does not equal the length of the compressed format of the DHT specified in the CDHT field.
5. The HTT is one and the HLIT sub-element of the compressed format of the DHT is greater than 29 (invalid DHT).
6. The HTT is one and the HDIST sub-element of the compressed format of the DHT is greater than 29 (invalid DHT).
7. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).
8. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).
9. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
10. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).
11. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
12. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18 (invalid DHT).
13. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

14. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

15. The HTT is one and the CPU attempts to generate a compressed-data symbol to represent a literal byte in the second operand, and the DHT derived from the contents of the CDHT field is non-universal and does not specify a Huffman code corresponding to that literal byte.

16. The HTT is one and the CPU attempts to generate a compressed-data symbol to represent a duplicate-string in the second operand, and the DHT derived from the contents of the CDHT field is non-universal and does not specify a Huffman code corresponding to that duplicate-string length or pointer distance.

When an invalid-input condition is encountered while attempting to generate a compressed-data symbol to represent a literal byte or duplicate-string in the second operand, no results associated with that literal byte or duplicate-string are generated, and the length of the second operand is not reduced by the size of that literal byte or duplicate-string.

When an invalid-input condition is encountered and neither the first-operand length (specified by the contents of general register $R_1 + 1$, NT, and SBB) nor the second-operand length is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- Condition code 2 is set.

When an invalid-input condition is encountered and the first-operand length (specified by the contents of general register $R_1 + 1$, NT, and SBB) or second-operand length is reduced during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes which are successfully encoded to compressed-data symbols, and the length in general register $R_2 + 1$ is decremented by the same number. Source bytes causing the invalid-input condition cannot be encoded and do not contribute to the update of general registers R_2 and $R_2 + 1$.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to processing any portion of the first or second operand, and invalid-input condition 15 or 16 is due to be recognized, the result is that either the invalid-data condition is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the invalid-data condition will be recognized when the instruction is executed again, to continue processing the same operands, and the invalid-data condition still exists.

A PER storage-alteration event is recognized, when applicable, for the following:

- Stores to the parameter block, as described below.
- Stores to the first-operand location.
- Stores to the third-operand location, which only occur when the history-buffer type (HBT) is one (circular).

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the parameter block, first-operand location, second-operand location, and third-operand location when the HBT is one (circular).

When the instruction ends with a nonzero condition code set, input data referenced from the second-operand location may be completely, or only partially, processed. When input data is only partially processed, results in the first-operand location, first-operand address, first-operand length, and SBB field of the parameter block do not represent a state consistent with the updated second-operand address and length. In these cases, partially processed data and internal-state information may be placed in the CSB field of the parameter block. The amount of partially processed data depends on conditions existing at the time the operation ends and the model. Although some data may only be partially processed, results stored to the left of the location designated by the updated first-operand address are complete and will not be modified when the operation resumes. Furthermore, when the instruction ends with condition code 1 or 3 set, it is expected the program subsequently reexecutes the instruction to resume the operation, at which time the contents of the CSB field are referenced prior to resuming the operation. When the instruction ends with condition code 0 set, all data is completely processed and all results associated with input and output data represent a consistent state.

Subsequent to the instruction ending with a nonzero condition code set, and without encountering an invalid-input condition, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

Function Code 4: DFLTCC-XPND (Expand)

When the DFLTCC-XPND function is specified, an uncompressing operation is performed. The operation consists of decoding compressed-data symbols from the second-operand location into uncompressed data, which is stored to the first-operand location.

The operation proceeds as described in section “Uncompressing Data” on page 26-54.

Normal completion occurs when all elements of the final block of the compressed-data set in the second operand are decoded and all uncompressed data is stored to the first-operand location. The last block of the compressed-data set is identified when the BFINAL bit of the block header is one. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is set to zeros.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.

- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are set to zeros.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 0 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When normal completion occurs, the NT and CSB fields of the parameter block are undefined, but may be modified.

When a CPU-determined amount of data has been processed and an invalid-input condition, as defined on page 26-30, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero when the CPU-determined amount of data processed is greater than zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 3 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

The CPU-determined amount of data depends on the model, and may be a different number each time the instruction is executed.

Subsequent to the instruction ending with condition code 3 set, it is expected the program does not modify any input or output specification for the instruction and branches back to reexecute the instruction to resume the operation.

In certain unusual situations, despite ending the instruction with condition code 3 set, the parameter block and general registers are not updated. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL. In these cases, the CPU-determined amount of data processed is zero, data may have been stored to the first-operand location, data may have been stored to the third-operand location, when applicable, and corresponding change bits have been set.

The second-operand length is insufficient to complete the operation when the following applies:

- The last element of a compressed-data block with BFINAL equal to one has not been decoded during the operation, and the number of bits in the second operand, as designated by the second-operand length and SBB, is less than the number of bits of the next element to decode, and all results from decoding data from the second-operand location have been placed at the first-operand location.

When the second-operand length is insufficient to complete the operation, the operation has been partially completed, and an invalid-input condition, as defined on page 26-30, has not been encountered, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to the instruction ending with condition code 2 set and the OESC field of the parameter block set to zeros, it is expected the program modifies the second-operand length, second-operand address, or both and reexecute the instruction to resume the operation.

The first-operand length is insufficient to complete the operation when the following applies:

- Results from decoding data from the second-operand location can not be placed at the first-operand location due to the first-operand length being equal to zero.

Note: Since decoding data from the second-operand location may not generate result data to place at the first-operand location, an updated first-operand length being equal to zero is not the only criteria which defines when condition code 1 is set. It is possible for some operations to proceed with a first-operand length being equal to zero.

When the first-operand length is insufficient to complete the operation, the operation has been partially completed, and an invalid-input condition, as defined on page 26-30, has not been encountered, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.

- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to the instruction ending with condition code 1 set, it is expected the program modifies the first-operand length, first-operand address, or both and reexecute the instruction to resume the operation.

An invalid-input condition exists when the DFLTCC-XPND function is specified and any of the following occurs:

1. The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.

2. NT is zero and HL is greater than 32,768.

3. A compressed-data block with BTYPE equal 11 binary is encountered.

4. A compressed-data block with BTYPE equal 00 binary and NLEN not equal to the one's complement of LEN is encountered.

5. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered and the HLIT sub-element of the compressed DHT is greater than 29 (invalid DHT).

6. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered and the HDIST sub-element of the compressed DHT is greater than 29 (invalid DHT).

7. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).

8. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).

9. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as spec-

ified earlier in the compressed DHT (invalid DHT).

10. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).

11. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).

12. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18 (invalid DHT).

13. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

14. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

15. A compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 10 binary, specifies a Huffman code which is not defined by the non-universal DHT derived from the compressed format of the DHT in the same block. In this case, the number of bits of the second operand which must be available to process, for the purpose of recognizing the invalid-input condition, is model-dependent. More specifically, a model attempting to decode an undefined code may process 15 bits prior to recognizing the exception, even though the exception could be determined after processing less bits.

16. A compressed-data symbol is encountered which is a duplicate-string pointer and specifies a distance greater than the length of history available at the point of processing the symbol.

17. A compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code (a code of 11000110 or 11000111 binary for a duplicate-string length, or a code of 11110 or 11111 binary for a duplicate-string-pointer distance). In this case, the number of bits of the second operand which must be available to process, for the purpose of recognizing the invalid-input condition, is model-dependent. More specifically, a model attempting to decode an invalid code may process 8 bits, in the case of a duplicate-string length, or 5 bits, in the case of a duplicate-string-pointer distance, prior to recognizing the exception, even though the exception could be determined after processing less bits.

When an invalid-input condition is encountered while attempting to decode an element of a compressed-data block, no results associated with that element are generated, and the length of the second operand (specified by the contents of general register $R_2 + 1$, NT, and SBB) is not reduced by the size of that element. However, it is possible a prior execution of the instruction ended with partially processing only a fraction of an element of input data. In that case, during the prior execution of the instruction, it had not yet been determined as to whether or not an invalid-input condition may exist with that element and the length of the second operand was reduced by the fraction of that element.

When an invalid-input condition is encountered and neither the first-operand length nor the second-operand length (specified by the contents of general register $R_2 + 1$, NT, and SBB) is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.

- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- Condition code 2 is set.

When an invalid-input condition is encountered and the first-operand length or the second-operand length (specified by the contents of general register $R_2 + 1$, NT, and SBB) is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields. An invalid DHT is not successfully processed and does not get placed into the CDHT field.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes of the second operand that were successfully processed (decoded) and included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight. Source data causing the invalid-input condition cannot be decoded successfully and does not contribute to the update of general registers R_2 and $R_2 + 1$.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to processing any portion of the first or second operand, and any of the invalid-input conditions 3-17 is due to be recognized, the result is that either the invalid-data condition is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the invalid-data condition will be recognized when the instruction is executed again, to continue processing the same operands, and the invalid-data condition still exists.

A PER storage-alteration event is recognized, when applicable, for the following:

- Stores to the parameter block, as described below.
- Stores to the first-operand location.
- Stores to the third-operand location, which only occur when the history-buffer type (HBT) is one (circular).

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

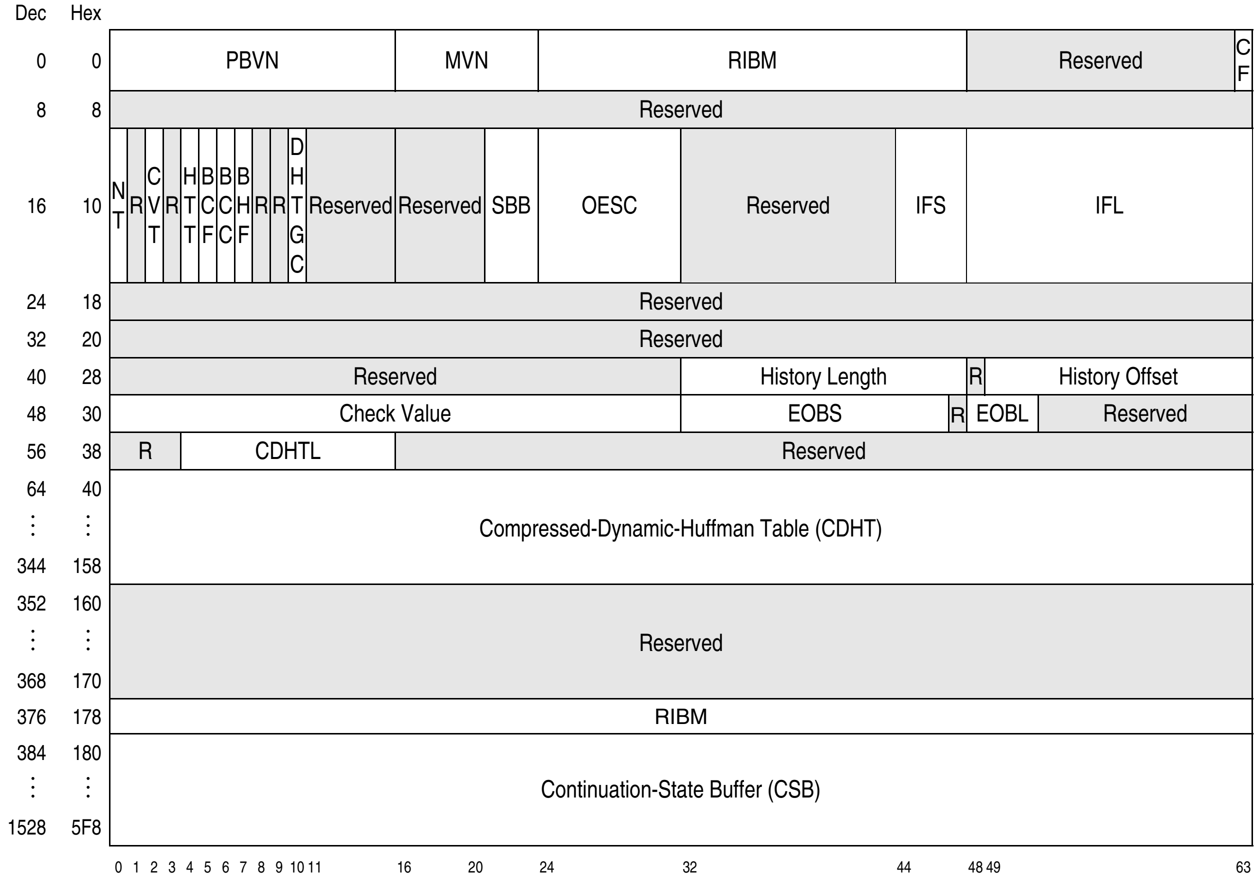
A PER zero-address-detection event is recognized, when applicable, for the parameter block, first-operand location, second-operand location, and third-operand location when the HBT is one (circular).

When the instruction ends with a nonzero condition code set, input data referenced from the second-operand location may be completely, or only partially, processed. When input data is only partially processed, results in the first-operand location, first-operand address, first-operand length, SBB field of the parameter block, check value field of the parameter block, HL field of the parameter block, IFS field of the parameter block, and when applicable, the third-operand location and HO field of the parameter block, do not represent a state consistent with the updated second-operand address and length. In these cases, partially processed data and internal-state information may be placed in the CSB field of the parameter block. The amount of partially processed data depends on conditions existing at the time the operation ends and the model. Although some data may only be partially processed, results stored to the left of the location designated by the updated first-operand address are complete and will not be modified when the operation resumes. Furthermore, when the instruction ends with a nonzero condition code set and without encountering an invalid-input condition, it is expected the program subsequently reexecutes the instruction to resume the operation, at which time the contents of the CSB field are referenced prior to resuming the operation. When the operation ends with condition code 0 set, all data is completely processed and all results associated with input and output data represent a consistent state.

Subsequent to the instruction ending with a nonzero condition code set, and without encountering an invalid-input condition, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

Parameter Block for Data Conversion

The parameter block with format 0 hex for the DFLTCC-CMPR and DFLTCC-XPND functions is shown in Figure 26-27 on page 26-34.



Explanation:

BCC	Block-Closing Control
BCF	Block-Continuation Flag
BHF	Block-Header Final bit
CDHTL	Compressed-Dynamic-Huffman Table Length
CF	Continuation Flag
CVT	Check Value Type
DHTGC	Dynamic-Huffman Table Generation Control
EOBL	End-of-block Length
EOBS	End-of-block Symbol
HTT	Huffman-Table Type
IFL	Incomplete-Function Length
IFS	Incomplete-Function Status
MVN	Model-Version Number
NT	New Task
OESC	Operation-Ending-Supplemental Code
PBVN	Parameter-Block-Version Number
R	Reserved
RIBM	Reserved for IBM use
SBB	Sub-Byte Boundary

Figure 26-27. Parameter Block (format 0 hex) for the DFLTCC-CMPR and DFLTCC-XPND functions

The fields of the parameter block are defined as follows:

Reserved: As an input to an operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When an operation ends, reserved fields may be stored as zeros or may remain unchanged.

Parameter-Block-Version Number (PBVN): Bytes 0-1 of the parameter block specify the version of the parameter block. Bits 0-11 of the PBVN are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 12-15 of the PBVN contain an unsigned binary integer specifying the format of the parameter block. The DFLTCC-QAF function provides the means of indicating the parameter block formats available. When the format of the parameter block specified is not supported by the model, an invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field). The PBVN is specified by the program and is not modified during the execution of the instruction.

Model-Version Number (MVN): Byte 2 of the parameter block is an unsigned binary integer identifying the model which executed the instruction. The program is not required to initialize the MVN. The MVN is updated during the execution of the instruction. The value stored in the MVN is model-dependent.

When the continuation flag (CF) is one, the MVN may be an input to the operation for the purpose of interpreting the contents of the CSB field of the parameter block to resume the operation.

Reserved for IBM use (RIBM): Bytes 3-5 and 376-383 of the parameter block are reserved for IBM use and must contain zeros; otherwise results are unpredictable. The RIBM field is not modified during the execution of the instruction.

Continuation Flag (CF): Bit 63 of the parameter block, when one, indicates the operation is partially complete and the contents of the continuation-state buffer may be used to resume the operation. It is required for the program to initialize the continuation flag (CF) to zero and not modify CF in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

New Task (NT): Bit 0 of byte 16 of the parameter block, when one, indicates the operation applies to the beginning of a compressed-data set. Therefore, no history and no check value from a prior operation applies to the current operation. When NT is one at the beginning of the operation, and the operation ends after partial completion, zero is stored to the NT field. When NT is zero, history and a check value from a prior operation apply to the current operation.

When the specified function is DFLTCC-CMPR, the meaning for each combination of values of the NT and CF fields is as follows:

NT	CF	meaning
1	0	Generate an individual block of a compressed-data set, which is the first block of the set.
0	0	Generate an individual block of a compressed-data set, which is not the first block of the set.
0	1	Continue to generate a block which is currently partially generated.
1	1	Invalid combination.

Check Value Type (CVT): Bit 2 of byte 16 of the parameter block specifies the type of check value contained in the check value field of the parameter block. When CVT is zero, the check value type is a 32-bit cyclic-redundancy-check (CRC-32). When CVT is one, the check value type is a 32-bit Adler checksum (Adler-32). The CVT bit is not modified during the execution of the instruction.

Huffman-Table Type (HTT): Bit 4 of byte 16 of the parameter block, when zero, specifies a table containing fixed-Huffman codes (FHT), as defined by the DEFLATE standard, is used during a compression operation. When the HTT is one, a table containing dynamic-Huffman codes (DHT), as specified in the CDHT field of the parameter block, is used during a compression operation. The HTT does not apply to uncompressing operations. The HTT bit is not modified during the execution of the instruction.

Block-Continuation Flag (BCF): Bit 5 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified. When zero, a 3-bit block header, and when applicable, the compressed format of a dynamic-Huffman table, as specified in the CDHT field of the parameter block, is stored to the first-operand location prior to storing any compressed-data elements. When one, neither a block header nor a compressed format of a DHT is stored to the first-operand location. When NT is one, BCF is treated as equal to zero. The BCF bit is not modified during the execution of the instruction.

Block Closing Control (BCC): Bit 6 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified. When one, subsequent to storing all compressed-data symbols, an end-of-block (EOB) symbol is stored to the first-operand location. When the HTT specifies using an FHT, Huffman code 0000000 binary (which corresponds to the intermediate integer representation of 256 in the table specifying codes for literal bytes, an EOB symbol, and duplicate-string lengths) is used for the EOB symbol. When the HTT specifies using a DHT, the Huffman code for the EOB symbol is specified in the DHT. When the BCC bit is zero, an EOB symbol is not stored to the first-operand location.

The BCC bit is not modified during the execution of the instruction.

Block Header Final (BHF): Bit 7 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified and either BCF is zero or NT is one; otherwise the BHF does not apply. When applicable and one, the first bit of the block header (BFINAL) is set to one before storing the block header to the first-operand location. When applicable and zero, the first bit of the block header (BFINAL) is set to zero before storing the block header to the first-operand location. The BHF bit is not modified during the execution of the instruction.

DHT Generation Control (DHTGC): Bit 2 of byte 17 of the parameter block applies to generating a dynamic-Huffman table (DHT). The DHT specifies Huffman codes for symbols representing literal bytes, duplicate-string lengths, an EOB symbol, and duplicate-string-pointer distances. The value of a Huffman code for a particular symbol is a function of the count of occurrences for the entity, which the symbol represents, in the uncompressed form of the data. When the count for a symbol is zero, there is no Huffman code in the DHT for the symbol. The DHTGC specifies counts equal to zero will be treated as follows:

DHTGC	meaning
0	Treat counts of literal bytes, duplicate-string lengths, and pointer distances equal to zero as equal to one (generate a universal DHT).
1	Treat counts of duplicate-string lengths and pointer distances equal to zero as equal to one.

A DHT which specifies a Huffman code for every possible value of literal bytes, an EOB symbol, duplicate-string lengths, and duplicate-string-pointer distances is called a universal DHT. A DHT which does not specify Huffman codes for values of literal bytes, duplicate-string lengths, or duplicate-string-pointer distances which do not occur in the uncompressed form of the data is called a non-universal DHT.

For all values of the DHTGC, the resulting DHT specifies Huffman codes for all possible duplicate-string lengths and pointer distances, as defined by the DEFLATE standard. Therefore, the HLIT and HDIST sub-elements of the resulting compressed form of the DHT each contain the value of 29. For definitions of the HLIT and HDIST sub-elements, refer to section “Descriptions for Compressed-data Blocks”, beginning on page 26-43.

The DHTGC is an input to the operation when the DFLTCC-GDHT function is specified. The DHTGC does not apply to the operation when the DFLTCC-CMPR or DFLTCC-XPND function is specified. The DHTGC is not modified during the execution of the instruction.

Sub-Byte Boundary (SBB): Bits 5-7 of byte 18 of the parameter block contain an unsigned binary integer specifying the boundary between processed and unprocessed bits within a byte of the compressed-data stream. The byte of the stream referenced is the last byte referenced, meaning the rightmost byte, when an operation ends, and is the first byte to be referenced, meaning the leftmost byte, when an operation begins or resumes. When the DFLTCC-CMPR function is specified, the SBB applies to the byte designated by the first-operand address. When the DFLTCC-XPND function is specified, the SBB applies to the byte designated by the second-operand address. The SBB specifies the number of rightmost bits that have been processed. The SBB is an input to the operation and an output of the operation. Figure 26-28 on page 26-42 illustrates a compressed-data stream when SBB has the value of 011 binary. Figure 26-29 on page 26-42 provides examples which demonstrate how the SBB applies to the DFLTCC-CMPR function. When NT is one, SBB is treated as equal to 000 binary.

Operation-Ending-Supplemental Code (OESC): When execution of DEFLATE CONVERSION CALL ends, a code is stored to byte 19 of the parameter block. The code conveys information about invalid-input conditions encountered during execution. When an invalid-input condition is not encountered, zeros are stored to the OESC field. When an invalid-input condition is encountered, a nonzero value is stored to the OESC field, which indicates the cause of the invalid-input condition recognized during execution. The codes stored to the OESC field are defined as follows:

OESC (hex)	**meaning**
00	An invalid-input condition was not encountered.
01	The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
02	The DFLTCC-CMPR or DFLTCC-XPND function is specified, the history length field is greater than 32,768, and the new task field is zero.
11	A compressed-data block with BTYPE equal to 11 binary is encountered.
12	A compressed-data block with BTYPE equal to 00 binary and NLEN not equal to the one's complement of LEN is encountered.
21	The CDHTL field applies and is less than 42 or greater than 2283.
22	The HLIT sub-element of a compressed DHT used during the operation is greater than 29 (invalid DHT).
23	The HDIST sub-element of a compressed DHT used during the operation is greater than 29 (invalid DHT).
24	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).
26	A compressed DHT used during the operation specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).
27	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
28	A compressed DHT used during the operation specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).
29	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
2A	A compressed DHT used during the operation specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18. (invalid DHT).
2B	A compressed DHT used during the operation specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).
2D	A compressed DHT used during the operation specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).
2F	The CDHTL field applies and does not equal the length of the compressed DHT in the CDHT field used during the operation.

OESC (hex)	meaning
31	A compressed DHT used during the operation does not specify a Huffman code corresponding to a literal byte or a duplicate-string length processed during the operation (deficient non-universal DHT), or the DFLTCC-XPND function is specified and a compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code for a duplicate-string length (11000110 or 11000111 binary).
32	A compressed DHT used during the operation does not specify a Huffman code corresponding to a duplicate-string-pointer distance processed during the operation (deficient non-universal DHT), or the DFLTCC-XPND function is specified and a compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code for a duplicate-string-pointer distance (11110 or 11111 binary).
40	A compressed-data symbol is encountered which is a duplicate-string pointer and specifies a distance greater than the length of history available at the point of processing the symbol.
FF	No additional information is provided.

Support for codes other than zero and FF hex is model-dependent. When multiple invalid-input conditions exist, it is model-dependent which code is reported in the OESC field.

Incomplete-Function Status (IFS): Bits 4-7 of byte 21 of the parameter block contain status information when certain operations end. When an uncompressing operation ends, the IFS conveys information about the second operand as follows:

IFS (binary)	meaning
0000	The operation ended after decoding the last element of a block with BFINAL equal to one.
1000	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 00 binary and BFINAL equal to zero.
1001	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 00 binary and BFINAL equal to one.
1010	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 01 binary and BFINAL equal to zero.
1011	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 01 binary and BFINAL equal to one.
1100	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 10 binary and BFINAL equal to zero.
1101	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 10 binary and BFINAL equal to one.
1110	The operation ended at a block boundary, the last element of a block with BFINAL equal to one has not been decoded, and the first element of the subsequent block has not yet been processed.

Note: An uncompressing operation may end with IFS equal 0000 binary and not satisfy normal completion. In such cases, the operation ends with condition code 1 or 3 set.

When a compressing operation ends, the IFS field is undefined, but may be modified.

The IFS is not an input to the operation.

Incomplete-Function Length (IFL): Bytes 22-23 of the parameter block contain length information when certain operations end. For an uncompressing operation, the IFL applies to the second operand. When an uncompressing operation ends after decoding some, but not all of a block with BTYPE equal 00 binary, the IFL contains an unsigned binary integer specifying the number of bytes of the block in the second operand, which have not yet been processed. Bytes 22-23 contain the IFL in big-endian byte order, unlike the LEN field of a block with BTYPE equal 00 binary, which is in little-endian byte order.

When an uncompressing operation ends after decoding a complete block with BTYPE equal 00 binary and BFINAL equal to one, zeros are stored to the IFL field. When an uncompressing operation ends after decoding some, but not all of a block with a non-zero BTYPE, or ends at a block boundary, the IFL field is undefined, but may be modified.

When a compressing operation ends, the IFL field is undefined, but may be modified.

The IFL is not an input to the operation.

History Length (HL): Bytes 44-45 of the parameter block contain an unsigned binary integer specifying the number of bytes of history in the history buffer which can be referenced during an operation. The HL applies to in-line and circular history buffers. When new task (NT) equals one, no history applies to the beginning of the operation and the history length is treated as zero as an input to the operation.

An invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field) when the history length is greater than 32,768 and NT equals zero.

The history length is modified during compressing and uncompressing operations. When the sum of the original HL and the number of uncompressed data bytes processed during the operation is less than, or equal to 32,768, the updated HL is equal to the sum of the original HL and the number of uncompressed data bytes processed during the operation; otherwise the updated HL is equal to the value of 32,768.

History Offset (HO): Fifteen bits, starting with bit 1 of byte 46, through bit 7 of byte 47, of the parameter block, contain an unsigned binary integer specifying an offset in the third operand when the history-buffer type is circular. The sum of the contents of R_3 and the history offset designates the location of the first byte of history within the circular-history buffer, which is the least recently processed byte of uncompressed data in the buffer. When the history-buffer type is circular, history offset is an input to the operation and is updated at the end of the operation. When the sum of the original HL and the number of uncompressed data bytes processed during the operation is less than, or equal to 32,768, the updated HO is equal to the original HO; otherwise, the updated HO is equal to the sum of the original HO, the original HL, and the number of uncompressed data bytes processed during the operation, modulo 32,768.

When the history-buffer type is in-line, the HO field of the parameter block is undefined, but may be modified.

Check Value: Bytes 48-51 of the parameter block contain a check value. As part of the operation, a check value is generated. The check value applies to the uncompressed data operand. That is, the check value applies to the second operand for the DFLTCC-CMPR function and applies to the first operand for the DFLTCC-XPND function. When the CVT bit is zero, a 32-bit cyclic-redundancy-check check value (CRC-32) is generated. When the CVT bit is one, a 32-bit Adler checksum check value (Adler-32) is generated.

The inputs to generating a check value are a 4 byte base and the uncompressed data processed during the operation. The base input provides the means to compute a single and consistent check value for a set of compressed-data blocks, regardless of the number of times the DFLTCC instruction is executed to process the complete set of compressed-data blocks. When the NT bit is zero, the original value in the check value field is used for the base input in generating a check value.

When an Adler-32 check value is generated, the following apply:

- When the NT bit is one, a value of one is used for the 4 byte base input.
- The sums defined in the Adler-32 check value generation are modulo 65,521.
- The result is stored to the check value field in big-endian byte order. That is, the most significant byte of the check value is located in byte 48 and the least significant byte of the check value is located in byte 51.

When a CRC-32 check value is generated, the following apply:

- When the NT bit is one, a value of zero is used for the 4 byte base input.
- The polynomial used as the divisor in generating a CRC-32 check value is

$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + x^{0}$, which is represented as 104C11DB7 hex. In this representation, the leftmost bit corresponds to the most significant bit.

- The first and final stages of generating the check value are computing the one's complement of the base input and computing the one's complement of the result, prior to storing the result, respectively.
- The result is stored to the check value field in little-endian byte order. That is, the least significant byte of the check value is located in byte 48 and the most significant byte of the check value is located in byte 51.

The check value is only meaningful to the program when the operation ends with condition code 0 set; otherwise, the check value is only an intermediate result and only meaningful to resume the operation. When the DFLTCC-CMPR function is specified and the operation ends with condition code 1, 2, or 3 set, some bytes to the left of the byte designated by the second-operand address may not be included in the computation of the resulting check value. When the DFLTCC-XPND function is specified and the operation ends with condition code 1, 2, or 3 set, some result bytes not yet stored to the right of the byte designated by the first-operand address may already be included in the computation of the resulting check value.

End-Of-Block Symbol (EOBS): Fifteen bits, starting with bit 0 of byte 52, through bit 6 of byte 53, of the parameter block, contain an end-of-block (EOB) symbol. The EOBL field of the parameter block specifies the length of the EOB symbol in the EOBS field. The EOB symbol is left justified in the EOBS field. Bits of the EOBS field not occupied by the EOB symbol are stored as zeros. The EOBS field is an output of the operation when compressing data, regardless which type of Huffman table applies. The EOBS field is not used as an input to the operation.

Bit 0 of byte 52 contains the most significant bit of the EOB symbol. When the length of the EOB symbol is 7 bits, bit 6 of byte 52 contains the least significant bit of the EOB symbol. When the length of the EOB symbol is 15 bits, bit 6 of byte 53 contains the least significant bit of the EOB symbol.

For blocks using a FHT, the EOB symbol is 0000000 binary, as defined by the DEFLATE standard. For blocks using a DHT, the EOB symbol is defined by the DHT. The EOB symbol is conveyed in order to provide the capability for the program to close a block.

The EOBS field is undefined when the DFLTCC-XPND function is specified, but may be modified.

End-Of-Block Length (EOBL): Bits 0-3 of byte 54 of the parameter block contain an unsigned binary integer specifying the length of the end-of-block (EOB) symbol in the EOBS field of the parameter block. The length specifies the number of bits which the EOB symbol occupies in the EOBS field. The EOBL field is an output of the operation when compressing data, regardless which type of Huffman table applies. The EOBL field is not used as an input to the operation.

The EOBL field is undefined when the DFLTCC-XPND function is specified, but may be modified.

Compressed Dynamic-Huffman-Table Length (CDHTL): Twelve bits, starting with bit 4 of byte 56, through bit 7 of byte 57, of the parameter block contain an unsigned binary integer which specifies the length, as a bit count, of the compressed format of the DHT in the CDHT field of the parameter block.

The CDHTL is an output from the operation when the DFLTCC-GDHT function is specified.

The CDHTL is an input to the operation when the DFLTCC-CMPR function is specified and HTT is one. When the CDHTL does not specify an appropriate length for the CDHT, an invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field). The CDHTL is not modified when the DFLTCC-CMPR function is specified.

When the DFLTCC-XPND function is specified and the operation ends after decoding only a portion of a block with BTYPE 10 binary, the length of the compressed representation of the DHT in the block is stored to this field. When the DFLTCC-XPND function is specified and the operation ends at a block boundary or after decoding only a portion of a block with BTYPE 00 or 01 binary, zeros are stored to this field. When an uncompressing operation is resumed within a block with BTYPE 10 binary (that is when CF equals one and IFS equals C or D hex), this field is an input to the operation.

Compressed Dynamic-Huffman Table (CDHT): Bytes 64-351 of the parameter block contain a compressed format of a dynamic-Huffman table (DHT).

The DHT specifies Huffman codes (bit sequences) to represent two sets of elements. The elements for one set include literal bytes, an EOB symbol, and duplicate-string lengths. The elements for the other set include duplicate-string pointer distances. The compressed representation of the DHT defines a set of code lengths and specifies a code length (CL) for each element of each set. The Huffman code for an element expected to be referenced during an operation is derived from the CL specified for that element and the number of elements in the same set with the same specified CL. Specifically, the compressed representation of the DHT includes the following:

- An HLIT field to specify the number of Huffman codes representing literal bytes, an EOB symbol, and duplicate-string lengths.
- An HDIST field to specify the number of Huffman codes representing and duplicate-string pointer distances.
- An HCLEN field to specify the number of Huffman codes representing code lengths.
- A sequence of codes specifying a bit length for each of the 19 code lengths defined for the compressed DHT.
- A sequence of codes specifying a code length for each of the elements of the set consisting of literal bytes, an EOB symbol, and duplicate-string lengths.
- A sequence of codes specifying a code length for each of the elements of the set consisting of duplicate-string pointer distances.

Refer to the description of a compressed-data block with block type 10 binary, starting on page 26-45 for a detailed description of the compressed representation of a DHT.

The compressed representation of the DHT is left justified in the CDHT field. That is, the rightmost bit of byte 64 contains the least-significant bit of the HLIT sub-element of the compressed representation of the DHT.

The compressed representation of a DHT is an output from the operation when the DFLTCC-GDHT function is specified.

The compressed representation of a DHT is an input to the operation when the DFLTCC-CMPR function is specified and HTT is one. The CDHT field is not modified by the DFLTCC-CMPR function.

When the DFLTCC-XPND function is specified and the operation ends after decoding only a portion of a block with BTYPE 10 binary, the compressed representation of the DHT in the block is stored to this field. When the DFLTCC-XPND function is specified and the operation ends at a block boundary or after decoding only a portion of a block with BTYPE 00 or 01 binary, zeros are stored to this field. When an uncompressing operation is resumed within a block with BTYPE 10 binary (that is when CF equals one and IFS equals C or D hex), this field is an input to the operation.

When the CDHT is modified, bits of the field not required to represent the compressed representation of the DHT are stored as zeros.

Continuation-State Buffer (CSB): When conditions cause a value of one to be stored in the CF field, internal-state data is stored to bytes 384-1535 of the parameter block; otherwise bytes 384-1535 of the parameter block are undefined and may be modified. The internal-state data stored is model-dependent and may be used subsequently to resume the operation. It is expected, but not required, for the program to initialize the continuation-state buffer to contain all zeros. Subsequent to the instruction ending with a nonzero condition code set, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify the continuation-state buffer; otherwise results are unpredictable.

Descriptions for Compressed-data Blocks

The bytes of a compressed-data block in storage are processed from left to right. Compressed-data blocks are not required to start or end on byte boundaries. A compressed-data block is a bit stream. Elements of the block are loaded into storage one bit at a time. The bit stream is loaded from right to left within each byte of storage and in byte order from left to right. When the element is a Huffman code, the bits are stored in order from most significant bit to least significant bit of the element. When the element is not a Huffman code, the bits are stored in order from least significant bit to most significant bit of the element.

Figure 26-30. Block Type 00 (no compression) Example

Figure 26-30 illustrates an example of a block with block type 00 binary, which contains no compressed-data symbols. The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identified as b_0, and ends with bit 0 of byte 7, identified as b_{60}.
- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 00 binary.
- Bits to the left of the BTYPE and to the right of a byte boundary are ignored when the BTYPE is 00 binary, which is bits 0-1 of byte 0 in this example.
- The third element encountered in the bit stream is the least significant byte of the LEN field, which is followed by the most significant byte of the LEN field. Bytes 1-2 contain the LEN field in little-endian byte order. The LEN field specifies the number of bytes in the block with literal data. Literal data is uncompressed data. The bytes with literal data follow the NLEN field in the bit stream.
- The elements encountered in the bit stream following the LEN field are the least significant byte of the NLEN field, followed by the most significant byte of the NLEN field, respectively. Bytes 3-4 contain the NLEN field in little-endian byte order. The NLEN field is the one's complement of the LEN field.
- Elements encountered in the bit stream following the NLEN field are uncompressed data, identified as literal bytes. Bytes 5-7 contain uncompressed data, which is unchanged from the source data used to generate this block.
- None of the elements contained in this block are Huffman codes. Every element in this block is stored to the bit stream order in order from least significant bit to most significant bit of the element, as defined by the DEFLATE standard. Since the LEN, NLEN, and literal elements are each an integral number of bytes aligned on byte boundaries, these elements may be processed as units of bytes, and not necessarily as units of bits.

Figure 26-31 on page 26-44 illustrates an example of a block with block type 01 binary, which contains compressed-data symbols generated using a fixed-Huffman table (FHT). The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identified as b_0, and ends with bit 3 of byte 11, identified as b_{89}.

- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 01 binary.
- The fixed-Huffman table (FHT) is not a component of the block.
- The third element encountered in the bit stream is the first compressed-data symbol, which begins in bit 1 of byte 0. A compressed-data symbol consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

  1. A Huffman code of variable length. The most significant bits of the code designate the length of the code. The code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the code. When the code represents a literal value or the end-of-block symbol, the code is the only sub-element of the compressed-data symbol. When the code represents a length of a pointer to the history buffer, the code is followed by subsequent sub-elements of the compressed-data symbol.

  2. When applicable, as specified by the DEFLATE standard, extra length bits may follow the Huffman code representing a pointer length. Extra length bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra length bits.

  3. The next sub-element encountered in the bit stream is a 5-bit distance code of a pointer to the history buffer. The distance code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the distance code.

  4. When applicable, as specified by the DEFLATE standard, extra distance bits may follow the distance code. Extra distance bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra distance bits.

- Bits 0-1 of byte 0, all bits of bytes 1 through 9, and bits 2-7 of byte 10 contain bits of compressed-data symbols.
- The last element encountered in the bit stream is a compressed-data symbol containing a single sub-element, which is the Huffman code representing the end-of-block (EOB) symbol. The EOB symbol for a block with BTYPE 01 binary is 0000000 binary. In this example, bit 1 of byte 10 contains the most significant bit of the EOB symbol and bit 3 of byte 11 contains the least significant bit of the EOB symbol.
- Bit 3 of byte 11 contains the last bit of the bit stream, which is the last bit of the compressed-data block.

t A bit of the compressed dynamic-Huffman table

Figure 26-32. Block Type 10 (compressed data using DHT) Example

Figure 26-32 on page 26-45 illustrates an example of a block with block type 10 binary, which contains compressed-data symbols generated using a dynamic-Huffman table (DHT). The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identified as b_0, and ends with bit 3 of byte 11, identified as b_{89}.
- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 10 binary.
- The third element encountered in the bit stream is the compressed representation of the dynamic-Huffman table (DHT), which begins in bit 1 of byte 0. The compressed representation of the DHT consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

  1. HLIT: The sum of the 5-bit HLIT sub-element and 257 specifies the number of Huffman codes representing literal bytes, an EOB symbol, and duplicate-string lengths. Valid values of HLIT range from 0 to 29. HLIT bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HLIT sub-element. In this example, bit 1 of byte 0, identified as b_3 is the least significant bit of the HLIT sub-element.

  2. HDIST: The sum of the 5-bit HDIST sub-element and 1 specifies the number of Huffman codes representing duplicate-string pointer distances. Valid values of HDIST range from 0 to 29. HDIST bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HDIST sub-element.

  3. HCLEN: The sum of the 4-bit HCLEN sub-element and 4 specifies the number of Huffman codes representing code lengths. Valid values of HCLEN range from 0 to 15. HCLEN bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HCLEN sub-element.

  4. A sequence of codes specifying a bit length for each of the code lengths defined for the compressed DHT. The number of codes is equal to the sum of HCLEN and 4. Each code is 3 bits.

  5. A sequence of codes specifying a code length for each of the elements of the set consisting of literal bytes, an EOB symbol, and duplicate-string lengths. The number of code lengths specified is equal to the sum of HLIT and 257.

     When the last code length (CL) for the set of literal bytes, an EOB symbol, and duplicate-string lengths is 16, 17, or 18, and the extra bits following the CL specify repeating the CL for more elements than are defined for the set, the code length also applies to the set of duplicate-string pointer distances. The sequence of codes specifying code lengths for the set of literal bytes, an EOB symbol, and duplicate-string lengths, followed by the sequence of codes specifying code lengths for duplicate-string pointer distances is a contiguous sequence for both sets.

6. A sequence of codes specifying a code length for each of the elements of the set consisting of duplicate-string pointer distances. The number of code lengths specified is equal to the sum of HDIST and 1.

- The fourth element encountered in the bit stream is the first compressed-data symbol. A compressed-data symbol consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

1. A Huffman code of variable length. The most significant bits of the code designate the length of the code. The code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the code. When the code represents a literal value or the end-of-block symbol, the code is the only sub-element of the compressed-data symbol. When the code represents a length of a pointer to the history buffer, the code is followed by subsequent sub-elements of the compressed-data symbol.

2. When applicable, as specified by the DEFLATE standard, extra length bits may follow the Huffman code representing a pointer length. Extra length bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra length bits.

3. The next sub-element encountered in the bit stream is a 5-bit distance code of a pointer to the history buffer. The distance code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the distance code.

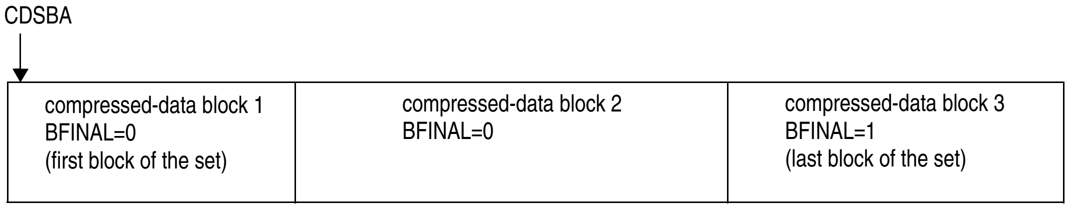
4. When applicable, as specified by the DEFLATE standard, extra distance bits may follow the distance code. Extra distance bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra distance bits.

- Subsequent bits encountered in the bit stream, up to and including bit 5 of byte 10, contain bits of compressed-data symbols.
- The last element encountered in the bit stream is a compressed-data symbol containing a single sub-element, which is the Huffman code representing the end-of-block (EOB) symbol. In this example, bit 4 of byte 10 contains the most significant bit of the EOB symbol and bit 3 of byte 11 contains the least significant bit of the EOB symbol.
- Bit 3 of byte 11 contains the last bit of the bit stream, which is the last bit of the compressed-data block.

Processing a Compressed-Data Set

This section describes examples of processing a compressed-data set to illustrate intended uses of DEFLATE CONVERSION CALL and augment the descriptions of various fields of the parameter block. The examples are simplistic and do not describe all possible scenarios, requirements, and capabilities.

The following examples and descriptions apply to a compressed-data set in storage, as illustrated in Figure 26-33 on page 26-47.



Explanation:
CDSBA: Compressed-Data Set Begin Address
BFINAL: The BFINAL element of each compressed-data block

Figure 26-33. An Example of a Compressed-Data Set in Storage.

For the examples in this section, it is intended for a program processing the compressed-data set to consider the following:

- A single parameter block may be defined and referenced by multiple usages of DEFLATE CONVERSION CALL to process the entire compressed-data set. The check value and check value type fields of the parameter block shall apply to all compressed-data blocks in the compressed-data set. The sub-byte boundary field of the parameter block shall apply to transitions between individual blocks. The history length and history offset may apply to multiple blocks. The remaining fields of the parameter block only apply to the individual compressed-data block being processed by a specific execution of a DEFLATE CONVERSION CALL instruction.
- An individual check value applies to all of the uncompressed data represented by the compressed-data set.
- There is no history for the first compressed-data symbol in block 1 to reference. Subsequent symbols in block 1 may reference history corresponding to previously encountered symbols in block 1. Symbols in block 2 may reference history corresponding to previously encountered symbols in blocks 2 and 1. Symbols in block 3 may references history corresponding to previously encountered symbols in blocks 3, 2, and 1.

Figure 26-34 on page 26-47 lists a portion of a sample program used to compress data into the compressed-data set described in Figure 26-33. Figure 26-35 lists the values for certain fields of the parameter block used during the execution of the DFLTCC instruction located at the instruction address labeled IABLK1. Figure 26-36 lists the values for certain fields of the parameter block used during the execution of the DFLTCC instruction located at the instruction address labeled IABLK2. These figures demonstrate some of the details associated with using DEFLATE CONVERSION CALL multiple times to process an entire compressed-data set.

Figure 26-37. Sample of a Program Uncompressing Data from a Compressed-Data Set

Compressing Data

The process of compressing data includes generating one or more compressed-data blocks. The compress function of DEFLATE CONVERSION CALL is used to construct a portion of an individual block. The portion may be the entire block. This function generates portions of a block with block type (BTYPE) 01 or 10 binary, and not 00 binary. When the new task bit (NT) of the parameter block is one, the first block of compressed data is generated and there is no history to reference from previously performed compressing operations.

An individual block contains the following elements in the order which they are listed:

1. Final block indication (BFINAL).
2. Block type (BTYPE).
3. Compressed format of a Dynamic-Huffman Table, when applicable.
4. Compressed-data symbols.
5. End-of-block (EOB) symbol.

The compression operation generates the elements specified in the order defined for a block. The elements may begin or end between byte boundaries in storage. The sub-byte boundary (SBB) applies to storing of the first element to the first-operand location. A compressed-data block is a bit stream. Components of the block are loaded into storage one bit at a time. The bit stream is loaded from right to left within each byte of storage and in byte order from left to right.

When the SBB is nonzero, the reference to the first byte at the first-operand location is an update reference.

Uncompressed data from the second-operand location is compressed and stored as compressed-data symbols to the first-operand location.

When the first-operand length is zero at the beginning of the execution of the instruction, the first operand is not accessed, and the first-operand address and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. This applies when the value of the CF field is zero or one at the beginning of the execution of the instruction.

When the second-operand length is zero at the beginning of the execution of the instruction, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. The second-operand length is zero at the beginning of the execution of the instruction for the following case:

- The instruction is being reexecuted to resume the operation (the CF field of the parameter block is one at the beginning of the execution of the instruction) and completing the operation can be performed with references to the CSB field of the parameter block, and without references to the second operand.

Note: The program can not use DEFLATE CONVERSION CALL to perform the following operations:

- Generate an empty compressed-data block. An empty compressed data block consists of a block header, a compressed format of a DHT when applicable, and an EOB symbol.
- Close an open compressed-data block. That is, only store an EOB symbol to the end of the compressed-data block.

The compression algorithm includes searching an updated history of recently compressed data for a string of bytes which matches data currently being compressed from the second-operand location. Before the compression operation begins or resumes, the following applies:

- When new task (NT) is one, there is no initial history available to reference.
- When NT is zero, and bit 56 of general register 0 (HBT) is zero (in-line), the initial history available to reference is located to the left of, and adjacent to, the leftmost byte of the second operand, and the length of the initial history is specified by the history length (HL) field of the parameter block.
- When NT is zero, and bit 56 of general register 0 (HBT) is one (circular), the initial history available to reference is located in the third-operand location, as specified by the history offset (HO) and history length (HL) fields of the parameter block.

During the compression operation, fetch-type references to the entire history may be made, regardless which bytes of history are required to perform the operation. Furthermore, when the history-buffer type is circular, fetch-type references to the entire 32 K-byte history buffer may be made, regardless which bytes of history are required to perform the operation.

During the compression operation, history is updated. Subsequent to encoding one or more bytes of source data into a compressed-data symbol without encountering an invalid-input condition, the source bytes are concatenated to the end of the history. The most recently processed bytes of source data, up to a maximum of 32 K-bytes, constitute the updated history available to reference while processing subsequent bytes of source data.

When the compression operation ends, the following applies to the resulting history available to subsequently resume the operation, or begin another operation:

- When the HBT is in-line, storage updates to the second-operand location are not required when the history is updated. The updated second-operand address and updated HL specify the updated location and updated length of the resulting history.
- When the HBT is circular, storage updates to the third-operand location are required when the history is updated. The third-operand address, updated HO, and updated HL specify the updated location and updated length of the resulting history.

Figure 26-38 on page 26-51 illustrates the location of in-line history with respect to the second operand before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-

CMPR function and an in-line history specified, when each execution ends with partial completion.

Figure 26-38. In-line History before and after executing DFLTCC-CMPR multiple times

When the HBT specified by bit 56 of general register 0 is circular, the history is maintained in a 32 K-byte buffer located at the third-operand location. The location of the first byte of history within the buffer (HB) is designated by the sum of the contents of general register R_3 and the history offset (HO). The first byte of history is the least recently processed byte of uncompressed data in the buffer. The location of the last byte of history within the buffer (HE) is designated by the following equation:

$$HE = R_3 + \text{modulo32K}(HO + HL - 1)$$

The last byte of history is the most recently processed byte of uncompressed data in the buffer. When the sum of the history offset (HO) and history length (HL) exceeds the size of the third operand (32 K-bytes), the history wraps from the end of the third operand to the beginning of the third operand. Figure 26-39 on page 26-52 illustrates the location of the history within a circular history buffer before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-CMPR function and a circular history buffer specified, when each execution ends with partial completion.

Figure 26-39. Circular History Buffer before and after executing DFLTCC multiple times

When the HBT is circular and the number of bytes processed from the second-operand location is less than 32,768, the following applies:

- Stores are made to a range of bytes in the third-operand location. The range of bytes includes and starts with the location designated by:

  R_3 + modulo32K(HOO + HLO)

  The range of bytes includes and ends with the location designated by:

  R_3 + modulo32K(HOO + HLO + BP -1)

  The definitions of the variables in the previous equations are:

  HOO: The history offset before the instruction executes.

  HLO: The history length before the instruction executes.

  BP: The number of bytes processed from the second-operand location during the execution of the instruction.

  Stores made to the range of bytes just described are subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

- Stores which do not modify the contents of storage locations and are not necessary, may be made to bytes in the third-operand location which are not included in the range just described. Stores to such locations are also subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the HBT is circular and the number of bytes processed from the second-operand location is more than, or equal to 32,768, stores are made to all bytes of the third-operand location and subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the block-continuation flag (BCF) is zero, a 3-bit block header, consisting of BFINAL followed by BTYPE, is stored to the first-operand location. The BFINAL bit of the block header is set equal to the block header final bit (BHF) of the parameter block. When the Huffman-table type (HTT) is zero, the BTYPE field of the block header is set to 01 binary and when the HTT is one, BTYPE field of the block header is set to 10 binary. When a block header is stored, the BFINAL bit is stored to the bit specified by the SBB in the first byte of the first operand. Subsequently, the BTYPE is stored to the first-operand location. Refer to section “Descriptions for Compressed-data Blocks” on page 26-43 for details on ordering of bits, as elements of a block are stored. When the BCF is one, a block header is not stored.

When the Huffman-table type (HTT) is one, the compressed format of the dynamic-Huffman table (DHT) specified in the parameter block is examined for invalid-input conditions. When an invalid-input condition exists for the specified compressed format of the DHT, the compressed DHT is referred to as invalid and can not be used to compress data. Refer to page 26-25 for a list of invalid-input conditions which may occur when the DFLTCC-CMPR function is specified. When the compressed format of the DHT specifies a bit length for a code length, or a code length for a literal byte, the EOB symbol, a duplicate-string length, or a duplicate-string pointer distance, which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree, the compressed DHT is still used to derive a functional DHT and compress data. When the block-continuation flag (BCF) is zero and the HTT is one, the compressed format of the DHT, as specified in the CDHT field of the parameter block is stored to the first-operand location.

During the compression operation, source data from the second-operand location is encoded into compressed-data symbols. As part of the encoding, source data is compared to the history. When no match is found, the intermediate representation of the source data is literal bytes, which is the same as the source data. When a match is found, the intermediate representation of the source data is a pointer to a location within the history which contains a duplicate copy of the source data. A pointer consists of a length and a distance. The length is the number of source data bytes which match a string in the history. The distance is the number of bytes from the end of the history to the beginning of the string which matches the source data. Two Huffman code trees from the Huffman table are used to encode the intermediate representation of the source data into compressed-data symbols. When the Huffman-table type (HTT) is zero, a fixed-Huffman table (FHT), as described by the DEFLATE standard, specifies the two Huffman code trees used for encoding intermediate results. When the HTT is one, the dynamic-Huffman table (DHT), which is derived from the compressed representation of the DHT, specified in the CDHT field of the parameter block, specifies the two Huffman code trees used for encoding intermediate results. The encoding is performed as described by the DEFLATE standard. When a non-universal DHT is used which does not specify a Huffman code required to encode the intermediate representation of the source data, an invalid-input condition is recognized. The bits of the resulting compressed-data symbol are arranged in the order specified by the DEFLATE standard before storing the result to the first-operand location.

Note: Duplicate-string lengths range from 3 to 258 bytes, as defined in Reference [23.] on page xxx.

Prior to processing further source data, the history is updated as described previously.

The process is repeated until all source bytes have been processed.

After all source bytes have been processed and the block closing control (BCC) is one, an end-of-block (EOB) symbol is stored to the first-operand location. When a fixed-Huffman table is used, Huffman code 0000000 binary is used for the EOB symbol. When a dynamic-Huffman table (DHT) is used, the Huffman code used for the EOB symbol is specified by the DHT. The bits of the EOB symbol are arranged in the order specified by the DEFLATE standard before storing the EOB symbol to the first-operand location.

When the last compressed-data symbol of the operation (including the EOB symbol), only occupies a portion of the last byte to store, the bits that do not contain a portion of the last symbol are stored as zeros.

Subsequent to processing the last compressed-data symbol, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient

resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Coincident with compressing the source data, the source data is an input to generating a 32-bit check value. Refer to "Check Value" on page 26-39 for details on generating a check value. The resulting check value is stored to the check value field of the parameter block.

Uncompressing Data

The expand function of DEFLATE CONVERSION CALL is used to decode a compressed-data set into uncompressed data. The compressed-data set in the second-operand location consists of one or more consecutive compressed-data blocks. The blocks of the compressed-data set are processed from left to right. The bytes of a block are processed from left to right. The blocks are not required to start or end on byte boundaries. Each block is decoded independent of other blocks in the compressed-data set. General register R_2 specifies the logical address of the leftmost byte of the first block in the compressed-data set. The last block in the compressed-data set is the block encountered during processing with the BFINAL bit equal to one. There are three types of blocks to process. The method of decoding the contents of a block is a function of the block type (BTYPE).

When the operation begins (when the continuation flag field of the parameter block is zero), the bit designated by general register R_2, the new task (NT) field, and the sub-byte boundary (SBB) field is interpreted as the first bit of a compressed-data block (the BFINAL bit of a block header).

The expand function includes referencing an updated history of recently decoded uncompressed data. Before the uncompressing operation begins or resumes, the following applies:

- When new task (NT) is one, there is no initial history available to reference.
- When NT is zero, and bit 56 of general register 0 (HBT) is zero (in-line), the initial history available to reference is located to the left of, and adjacent to, the leftmost byte of the first operand, and the length of the initial history is specified by the history length (HL) field of the parameter block.
- When NT is zero, and bit 56 of general register 0 (HBT) is one (circular), the initial history available to reference is located in the third-operand location, as specified by the history offset (HO) and history length (HL) fields of the parameter block.

During the operation, fetch-type references to the entire history may be made, regardless which bytes of history are required to perform the operation. Furthermore, when the history-buffer type is circular, fetch-type references to the entire 32 K-byte history buffer may be made, regardless which bytes of history are required to perform the operation.

During the uncompressing operation, history is updated. Subsequent to decoding source data without encountering an invalid-input condition, the resulting bytes of uncompressed data are concatenated to the end of the history. The most recently decoded bytes of uncompressed data, up to a maximum of 32 K-bytes, constitute the updated history available to reference while processing subsequent source data.

When the uncompressing operation ends, the following applies to the resulting history available to subsequently resume the operation, or begin another operation:

- When the HBT is in-line, storage updates to the first-operand location also constitute updates to the resulting history. The updated first-operand address and updated HL specify the updated location and updated length of the resulting history.
- When the HBT is circular, storage updates to the third-operand location are required when the history is updated. The third-operand address, updated HO, and updated HL specify the updated location and updated length of the resulting history.

Figure 26-40 on page 26-55 illustrates the location of in-line history with respect to the first operand before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-XPND function and an in-line history specified, when each execution ends with partial completion. The history length (HL) is modified during the operation.

Figure 26-40. In-line History before and after executing DFLTCC-XPND multiple times

When bit 56 of general register 0 specifies a circular history buffer, the history is maintained in a 32 K-byte buffer located at the third-operand location. The location of the first byte of history within the buffer (HB) is designated by the sum of the contents of general register R_3 and the history offset (HO). The first byte of history is the least recently processed byte of uncompressed data in the buffer. The location of the last byte of history within the buffer (HE) is designated by the following equation:

$$HE = R_3 + \text{modulo32K}(HO + HL - 1)$$

The last byte of history is the most recently processed byte of uncompressed data in the buffer. When the sum of the history offset (HO) and history length (HL) exceeds the size of the third operand (32 K-bytes), the history wraps from the end of the third operand to the beginning of the third operand. Figure 26-39 on page 26-52 illustrates the location of the history within a circular history buffer before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-XPND function and a circular history buffer specified, when each execution ends with partial completion.

When the HBT is circular and the number of bytes stored to the first-operand location is less than 32,768, the following applies:

- Stores are made to a range of bytes in the third-operand location. The range of bytes includes and starts with the location designated by:

  R_3 + modulo32K(HOO + HLO)

  The range of bytes includes and ends with the location designated by:

  R_3 + modulo32K(HOO + HLO + BP -1)

  The definitions of the variables in the previous equations are:

  HOO: The history offset before the instruction executes.

  HLO: The history length before the instruction executes.

  BP: The number of bytes stored to the first-operand location during the execution of the instruction.

  Stores made to the range of bytes just described are subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

- Stores which do not modify the contents of storage locations and are not necessary, may be made to bytes in the third-operand location which are not included in the range just described. Stores to such locations are also subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the HBT is circular and the number of bytes stored to the first-operand location is more than, or equal to 32,768, stores are made to all bytes of the third-operand location and subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the BTYPE is 00 binary, the block does not contain compressed data. Figure 26-30 on page 26-43 illustrates a block with BTYPE equal 00 binary. The LEN field specifies the number of literal bytes in the block. The byte order of the LEN field is little-endian. The LEN field may specify zero literal bytes. The literal bytes of the block are placed at the first-operand location. The history is also updated, as previously described, with each literal byte of the block.

When the BTYPE is 01 binary, the block contains compressed-data symbols that were generated using a fixed-Huffman table (FHT). The FHT is defined by the DEFLATE standard and is not part of the block. Figure 26-31 on page 26-44 illustrates a block with BTYPE equal 01 binary. Subsequent to interpreting the block header, compressed-data symbols are decoded in the order in which they appear in the block. Bytes of the block are processed from left to right. Bits within each byte of the block are processed from right to left. Each symbol is completely processed prior to processing the next symbol in the block. Each symbol which is not the end-of-block (EOB) symbol represents a literal value or a pointer to a substring previously decoded in the history buffer. A previously decoded substring is also referred to as a duplicate string. A pointer consists of codes representing the substring length and the distance from the end of the history to the beginning of the substring. When a symbol represents a substring in the history, the substring is referenced from the history buffer. The uncompressed data resulting from decoding a symbol is placed at the first-operand location.

Note: Duplicate-string lengths range from 3 to 258 bytes, as defined in Reference [23.] on page xxx.

Prior to processing further source data, the history is updated as previously described.

The updated history applies to decoding the next symbol of the block. When the EOB symbol is encountered, processing of the block is complete.

When the BTYPE is 10 binary, the block contains compressed-data symbols that were generated using a dynamic-Huffman table (DHT). A compressed format of the DHT used is an element of the compressed-data block. Figure 26-32 on page 26-45 illustrates a block with BTYPE equal 10 binary. Subsequent to interpreting the block header, the compressed format of the DHT provided within the compressed-data block is examined for invalid-input conditions. When an invalid-input condition exists for the provided compressed format of the DHT, the compressed format of the DHT is referred to as invalid and can not be used to uncompress data. Refer to page 26-30 for a list of invalid-input conditions which may occur when the DFLTCC-XPND function is specified. When the compressed format of the DHT specifies a bit length for a code length, or a code length for a literal byte, the EOB symbol, a duplicate-string length, or a duplicate-string pointer distance, which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree, the compressed DHT is still used to derive a functional DHT and compress data. Subsequent to examining the compressed format of the DHT, compressed-data symbols are decoded in the order in which they appear in the block. Bytes of the block are processed from left to right. Bits within each byte of the block are processed from right to left. Each symbol is completely processed prior to processing the next symbol in the block. The processing of symbols in a block with BTYPE 10 binary is the same as previously described for processing symbols in a block with BTYPE 01, except the former uses the DHT provided to decode symbols, and the latter uses the FHT to decode symbols. When a non-universal DHT is provided which does not specify a Huffman code required to decode a compressed-data symbol, an invalid-input condition is recognized.

Coincident with uncompressing the second operand, the uncompressed data is an input to generating a 32-bit check value. Refer to “Check Value” on page 26-39 for details on generating a check value. The resulting check value is stored to the check value field of the parameter block.

Subsequent to processing the last block of the compressed-data set, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the divi-

dend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When the first-operand length is zero at the beginning of the execution of the instruction, the first operand is not accessed, and the first-operand address and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. This applies when the value of the CF field is zero or one at the beginning of the execution of the instruction.

When the second-operand length is zero at the beginning of the execution of the instruction, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. The second-operand length is zero at the beginning of the execution of the instruction for the following case:

- The instruction is being reexecuted (the CF field of the parameter block is one at the beginning of the execution of the instruction) and the entire second operand was processed when the instruction was previously executed.

The uncompressing operation may end without storing any results to the first-operand location, even though data was processed from the second-operand location. This occurs when the data processed from the second-operand location only contains any of the following compressed-data block elements:

- A block header.
- The LEN field of a block with block type 00 binary.
- The NLEN field of a block with block type 00 binary.
- A compressed format of a dynamic-Huffman table.
- An end-of-block (EOB) symbol.

Other Conditions

When the DFLTCC-CMPR or DFLTCC-XPND function is specified, execution of the instruction ends after processing a CPU-determined amount of data. This permits interruptions to occur. When the instruction ends with partial completion, the addresses in general registers R_1 and R_2, the lengths in general registers $R_1 + 1$ and $R_2 + 1$, and specific fields of the parameter block are updated, so that the instruction, when reexecuted, resumes the operation at the point it was suspended.

When a DFLTCC-CMPR or DFLTCC-XPND function is being executed and an access exception is due to be recognized for the first or second operand, the result is that either the exception is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the exception will be recognized when the instruction is executed again to continue processing the same operands and the exception condition still exists.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block, first, second, and third operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Results are unpredictable if the DFLTCC-CMPR or DFLTCC-XPND function is specified and any of the following apply:

- The parameter block overlaps the first or second operand.
- The first operand overlaps the second operand.
- The specified history-buffer type (HBT) is circular and the third operand overlaps the first operand, the second operand, or the parameter block.
- The specified history-buffer type (HBT) is in-line, the DFLTCC-CMPR function is specified, and the history overlaps the first operand or the parameter block.
- The specified history-buffer type (HBT) is in-line, the DFLTCC-XPND function is specified, and the history overlaps the second operand or the parameter block.

In certain unusual situations, despite ending the execution of DEFLATE CONVERSION CALL with a CPU-determined amount of data processed being zero, data may have been stored to the first-operand location, data may have been stored to the third-operand location, when applicable, and corresponding change bits have been set, when applicable. In these cases, the contents of the parameter block and general registers have not been modified from original values. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL.

Resulting Condition Code:

0 Normal completion
1 The first-operand length is insufficient to complete the operation
2 The second-operand length is insufficient to complete the operation (DFLTCC-XPND) or invalid-input condition
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, operand 2, in-line history; fetch and store, parameter block, operand 1, operand 3)
- Operation (if the DEFLATE-conversion facility is not installed)
- Specification
- Transaction constraint

The priority of execution for the DEFLATE CONVERSON CALL instruction is shown in Figure 26-41 on page 26-58.

Prior to usage, the compressed format of a DHT is examined for the existence of invalid-input conditions. When the length of the compressed format of a DHT is not precisely defined due to an invalid-input condition, the interpreted length may depend on the condition, be model dependent, and does not exceed 286 bytes. As a result, when the DFLTCC-XPND function is specified, the current second-operand length is 287, or less bytes, and a compressed format of a DHT with an invalid-input condition is encountered in the second operand, it is model dependent whether the invalid-input condition (priority 14.A) or insufficient second-operand length (condition code 2 - priority 14.B) is recognized.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint.
8.A	Specification exception due to invalid function code or invalid register number.

Figure 26-41. Priority of Execution: DFLTCC (Part 1 of 2)

8.B	Specification exception due to parameter block not designated on doubleword boundary.
8.C	Specification exception due to circular history buffer not designated on 4 K-byte boundary.
9.	Access exceptions for an access to the parameter block.
10.	Condition code 2 due to specified format of the parameter block is not supported by the model.
11.	Specification exception due to second-operand length equal to zero and CF equal to zero at the beginning of the execution of the instruction.
12.	Condition code 1 due to first-operand length equal to zero at the beginning of the execution of the instruction and DFLTCC-CMPR is specified.
13.A	Condition code 2 due to the history length field greater than 32,768 and the new task field is zero when DFLTCC-CMPR or DFLTCC-XPND is specified.
13.B	Access exceptions for an access to the first operand and the first-operand length is nonzero.
13.C	Access exceptions for an access to the second operand and the second-operand length is nonzero.
13.D	Access exceptions for an access to in-line history specified at the beginning of the execution of the instruction.
13.E	Access exceptions for an access to the third operand.
14.A	Condition code 2 due to invalid-input conditions other than those included in items 10 and 13.A above.
14.B	Condition codes 1, 2, or 3 due to conditions other than those included in items 10, 12, 13.A, and 14.A above.
15.	Condition code 0.

Figure 26-41. Priority of Execution: DFLTCC (Part 2 of 2)

Programming Notes:

1. There is no partial completion for the DFLTCC-GDHT function. To complete the function, all pages designated by the second operand must be accessible.

2. When the program references the end-of-block (EOB) symbol in the parameter block to close a compressed-data block, the program is responsi-

ble for reversing the bit order of the EOB symbol, which is a Huffman code.

3. When compressing or uncompressing data, it may be significantly more efficient overall when the operation can be performed with the minimum number of times DEFLATE CONVERSION CALL (DFTLCC) is executed. In other words, executing DFLTCC with a large operand may be significantly more efficient than executing DFLTCC with small operands multiple times.

4. For the compressing and uncompressing operations, when condition code 3 is set, the general registers used by the instruction and the parameter block have been updated such that the program can simply branch back to the instruction to continue the operation.

5. When the program anticipates referencing the first or second operand of DEFLATE CONVERSION CALL (DFLTCC), subsequent to executing the instruction, there may be a performance advantage associated with the subsequent reference when DFLTCC is immediately preceded by NEXT INSTRUCTION ACCESS INTENT (NIAI) specifying an access intent corresponding to the operand of interest with an access intent code value of one or two.

6. When DFLTCC-XPND is specified and the instruction ends with condition code 2 set, the value stored to the OESC field of the parameter block distinguishes between ending due to an insufficient second-operand length (zero stored to OESC field) and ending due to an invalid-input condition (nonzero value stored to OESC field).

7. The Huffman codes of a non-universal DHT may be shorter than the Huffman codes of a universal DHT generated from the same data. As a result, compressed-data symbols generated when using a non-universal DHT may occupy less bits than those generated when using a universal DHT.

8. A program may encounter an invalid-input condition (condition code 2 set with a nonzero value stored to the OESC field of the parameter block) when using a non-universal DHT to compress data which was not the same data used as an input to generating the non-universal DHT.

9. Different compressed representations may be generated from the same uncompressed input. However, all compressed representations comply with the cited DEFLATE standard and can be decoded to the original (uncompressed) form of the data by any decoder which complies to the same standard. Varying results may be observed on the same model and between different models. Generated results may depend on the following:

   - Variations of boundaries in storage for the input data.
   - Variations of the CPU-determined amount of data processed during the execution of the instruction.
   - Variations of the algorithms implementing the functions.

   Differences to compressed-data symbols primarily include, but are not limited to, representations of duplicate strings.

10. A compressing operation may end with: the location of the last byte stored being equal to the location of first byte of the PER storage-area designation, a nonzero value in the sub-byte boundary (SBB) field of the parameter block, and a PER storage-alteration event being recognized. In this case, the address in general register R_1 is equal to the starting address of the PER storage-area designation.

11. Performance may be significantly degraded when the CPU is enabled to recognize PER storage-alteration events and the PER storage-area designation overlaps with the first-operand location or the third-operand location.

12. When the DFLTCC-CMPR function is specified and the operation ends with a nonzero value in the sub-byte boundary (SBB) field of the parameter block, the operation included storing to the byte designated by the resulting first-operand address. When the DFLTCC-XPND function is specified and the operation ends with a nonzero value in the SBB, the operation included fetching the byte designated by the resulting second-operand address.

13. When the operation ends with a nonzero condition code set and the OESC field contains zeros, the CSB field of the parameter block may contain partially processed data, and it is expected the program reexecutes the instruction to resume the operation.

14. Subsequent to an operation ending with a nonzero condition code set, and prior to reexecuting

the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

15. When the DFLTCC-GDHT function is specified, the compressed representation of a DHT generated describes three proper-full Huffman code trees, according to the Huffman algorithm. That is, no under-full Huffman code trees are described. An under-full Huffman code tree is derived from a compressed representation of a DHT which specifies a code length for an element which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree.

    When the DFLTCC-CMPR function is specified, HTT is one, and the compressed representation of the DHT includes a description of an under-full Huffman code tree, the compressed-data results can be transformed to the original uncompressed data by using the DFLTCC-XPND function, but not all decoders, which comply to the DEFLATE standard may be able to transform the results to the original uncompressed data. This may occur when the compressed representation of a DHT, specified by the program, for the DFLTCC-CMPR function was not generated as a result of performing the DFLTCC-GDHT function.

16. When the DFLTCC-CMPR function ends with condition code 1 set, the result stored to the sub-byte boundary (SBB) field of the parameter block is 000 binary. Recognizing this scenario may be relevant to a program allocating output buffers for use with DEFLATE CONVERSION CALL.

17. When the DFLTCC-XPND function is specified with a circular history buffer and two different logical addresses in the first operand translate to the same absolute address, the results stored to the circular history buffer are unpredictable. Depending on the model, the implementation for updating the circular history buffer may include fetching decoded data stored to the first-operand location.

18. Athough not explicitly stated in Reference [23.] on page xxx, two representations for the duplicate-string length of 258 bytes are possible, which are as follows:

    - Symbol code with value 284 followed by 5 extra bits with value 11111 binary.
    - Symbol code with value 285, which is the preferred representation, since it may occur frequently.

    When uncompressing data, both representations are successfully decoded.

This appendix (except for the examples for FIND LEFTMOST ONE, ROTATE THEN EXCLUSIVE OR SELECTED BITS, ROTATE THEN INSERT SELECTED BITS, ROTATE THEN OR SELECTED BITS, and changes in the terminology for signed-packed decimal and unsigned-packed decimal) is the same as in *Enterprise Systems Architecture/390 Principles of Operation*, SA22-7201; it has not been revised to show the enlargement of register sizes or the 64-bit addressing mode.

Number Representation

Binary Integers

Signed Binary Integers

Signed binary integers are most commonly represented as halfwords (16 bits) or words (32 bits). In both lengths, the leftmost bit (bit 0) is the sign of the number. The remaining bits (bits 1-15 for halfwords and 1-31 for words) are used to specify the magnitude of the number. Binary integers are also referred to as fixed-point numbers, because the radix point (binary point) is considered to be fixed at the right, and any scaling is done by the programmer.

Positive binary integers are in true binary notation with a zero sign bit. Negative binary integers are in two's-complement notation with a one bit in the sign position. In all cases, the bits between the sign bit and the leftmost significant bit of the integer are the same as the sign bit (that is, all zeros for positive numbers, all ones for negative numbers).

Negative binary integers are formed in two's-complement notation by inverting each bit of the positive binary integer and adding one. As an example using the halfword format, the binary number with the decimal value +26 is made negative (-26) in the following manner:

```
+26    0 000 0000 0001 1010
Invert 1 111 1111 1110 0101
Add 1                     1
       ____________________
-26     1 111 1111 1110 0110 (Two's complement
                                   form)
(S is the sign bit.)
```

This is equivalent to subtracting the number:

```
        00000000 00011010
from
      1 00000000 00000000
```

Negative binary integers are changed to positive in the same manner.

The following addition examples illustrate two's-complement arithmetic and overflow conditions. Only eight bit positions are used.

```
1.  +57 = 0011 1001
    +35 = 0010 0011
    ───────────────
    +92 = 0101 1100

2.  +57 = 0011 1001
    -35 = 1101 1101
    ───────────────
    +22 = 0001 0110 No overflow – carry into
                    leftmost position and
                    carry out

3.  +35 = 0010 0011
    -57 = 1100 0111
    ───────────────
    -22 = 1110 1010 Sign change only – no
                    carry into leftmost posi-
                    tion and no carry out

4.  -57 = 1100 0111
    -35 = 1101 1101
    ───────────────
    -92 = 1010 0100 No overflow – carry into
                    leftmost position and
                    carry out

5.  +57 = 0011 1001
    +92 = 0101 1100
    ───────────────
   +149 =*1001 0101 *Overflow – carry into
                    leftmost position, no
                    carry out

6.  -57 = 1100 0111
    -92 = 1010 0100
    ───────────────
   -149 =*0110 1011 *Overflow – no carry into
                    leftmost position but carry
                    out
```

The presence or absence of an overflow condition may be recognized from the carries:

- There is no overflow:
  1. If there is no carry into the leftmost bit position and no carry out (examples 1 and 3).
  2. If there is a carry into the leftmost position and also a carry out (examples 2 and 4).
- There is an overflow:
  1. If there is a carry into the leftmost position but no carry out (example 5).
  2. If there is no carry into the leftmost position but there is a carry out (example 6).

The following are 16-bit signed binary integers. The first is the maximum positive 16-bit binary integer. The last is the maximum negative 16-bit binary integer (the negative 16-bit binary integer with the greatest absolute value).

2^{15}-1=	32,767 =	0 111 1111 1111 1111
2^{0}==	1 =	0 000 0000 0000 0001
0 =	0 =	0 000 0000 0000 0000
-2^{0} =	-1 =	1 111 1111 1111 1111
-2^{15}=	-32,768 =	1 000 0000 0000 0000

Figure A-1 illustrates several 32-bit signed binary integers arranged in descending order. The first is the maximum positive binary integer that can be represented by 32 bits, and the last is the maximum negative binary integer that can be represented by 32 bits.

2^{31}-1	=	2 147 483 647	=	0 111 1111 1111 1111 1111 1111 1111 1111
2^{16}	=	65 536	=	0 000 0000 0000 0001 0000 0000 0000 0000
2^{0}	=	1	=	0 000 0000 0000 0000 0000 0000 0000 0001
0	=	0	=	0 000 0000 0000 0000 0000 0000 0000 0000
-2^{0}	=	-1	=	1 111 1111 1111 1111 1111 1111 1111 1111
-2^{1}	=	-2	=	1 111 1111 1111 1111 1111 1111 1111 1110
-2^{16}	=	-65 536	=	1 111 1111 1111 1111 0000 0000 0000 0000
-2^{31}+1	=	-2 147 483 647	=	1 000 0000 0000 0000 0000 0000 0000 0001
-2^{31}	=	-2 147 483 648	=	1 000 0000 0000 0000 0000 0000 0000 0000

Figure A-1. 32-Bit Signed Binary Integers

Unsigned Binary Integers

Certain instructions, such as ADD LOGICAL, treat binary integers as unsigned rather than signed. Unsigned binary integers have the same format as signed binary integers, except that the leftmost bit is interpreted as another numeric bit rather than a sign bit. There is no complement notation because all unsigned binary integers are considered positive.

The following examples illustrate the addition of unsigned binary integers. Only eight bit positions are used. The examples are numbered the same as the corresponding examples for signed binary integers.

```
1.   57 = 0011 1001
     35 = 0010 0011
    ---------------
     92 = 0101 1100

2.   57 = 0011 1001
    221 = 1101 1101
    ---------------
    278 =*0001 0110 *Carry out of leftmost
                     position

3.   35 = 0010 0011
    199 = 1100 0111
    ---------------
    234 = 1110 1010

4.  199 = 1100 0111
    221 = 1101 1101
    ---------------
    420 =*1010 0100 *Carry out of leftmost
                     position

5.   57 = 0011 1001
     92 = 0101 1100
    ---------------
    149 = 1001 0101

6.  199 = 1100 0111
    164 = 1010 0100
    ---------------
    363 =*0110 1011 *Carry out of leftmost
                     position
```

A carry out of the leftmost bit position may or may not imply an overflow, depending on the application.

Figure A-2 illustrates several 32-bit unsigned binary integers arranged in descending order.

$2^{32}-1$	=	4 294 967 295	=	1111 1111 1111 1111 1111 1111 1111 1111
2^{31}	=	2 147 483 648	=	1000 0000 0000 0000 0000 0000 0000 0000
$2^{31}-1$	=	2 147 483 647	=	0111 1111 1111 1111 1111 1111 1111 1111
2^{16}	=	65 536	=	0000 0000 0000 0001 0000 0000 0000 0000
2^{0}	=	1	=	0000 0000 0000 0000 0000 0000 0000 0001
0	=	0	=	0000 0000 0000 0000 0000 0000 0000 0000

Figure A-2. 32-Bit Unsigned Binary Integers

Decimal Integers

Decimal integers consist of one or more decimal digits and a sign. Each digit and the sign are represented by a 4-bit code. The decimal digits are in binary-coded decimal (BCD) form, with the values 0-9 encoded as 0000-1001. The sign is usually represented as 1100 (C hex) for plus and 1101 (D hex) for minus. These are the preferred sign codes, which are generated by the machine for the results of decimal-arithmetic operations. There are also several alternate sign codes (1010, 1110, and 1111 for plus; 1011 for minus). The alternate sign codes are accepted by the machine as valid in source operands but are not generated for results.

Decimal integers may have different lengths, from one to 16 bytes. Of the many decimal formats, only two will be considered here: signed-packed-decimal and zoned. In the signed-packed-decimal format, each byte contains two decimal digits, except for the rightmost byte, which contains the sign code in the right half. For decimal arithmetic, the number of decimal digits in the signed-packed-decimal format can vary from one to 31. Because decimal integers must consist of whole bytes and there must be a sign code on the right, the number of decimal digits in this format is always odd. If an even number of significant digits is desired, a leading zero must be inserted on the left.

In the zoned format, each byte consists of a decimal digit on the right and the zone code 1111 (F hex) on the left, except for the rightmost byte where the sign code replaces the zone code. Thus, a decimal integer in the zoned format can have from one to 16 digits. The zoned format may be used directly for input and output in the extended binary-coded-decimal interchange code (EBCDIC), except that the sign must be separated from the rightmost digit and handled as a separate character. For positive (unsigned) numbers, however, the sign can simply be represented by the zone code of the rightmost digit because the zone code is one of the acceptable alternate codes for plus.

In either format, negative decimal integers are represented in true notation with a separate sign. As for binary integers, the radix point (decimal point) of decimal integers is considered to be fixed at the right, and any scaling is done by the programmer.

The following are some examples of decimal integers shown in hexadecimal notation:

Decimal Value	Signed Packed Format	Zoned Format
+123	12 3C or 12 3F	F1 F2 C3 or F1 F2 F3
-4321	04 32 1D	F4 F3 F2 D1
+000050	00 00 05 0C or 00 00 05 0F	F0 F0 F0 F0 F5 C0 or F0 F0 F0 F0 F5 F0
-7	7D	D7
00000	00 00 0C or 00 00 0F	F0 F0 F0 F0 C0 or F0 F0 F0 F0 F0

Under some circumstances, a zero with a minus sign (negative zero) is produced. For example, the multiplicand:

```
00 12 3D   (-123)
```

times the multiplier:

```
      0C   (+0)
```

generates the product:

```
00 00 0D   (-0)
```

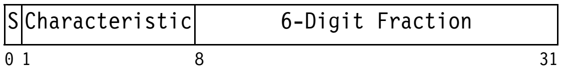
because the product sign follows the algebraic rule of signs even when the value is zero. A negative zero, however, is equivalent to a positive zero in that they compare equal in a decimal comparison.

Hexadecimal-Floating-Point Numbers

A hexadecimal-floating-point (HFP) number is expressed as a hexadecimal fraction multiplied by a separate power of 16. The term floating point indicates that the placement, of the radix (hexadecimal) point, or scaling, is automatically maintained by the machine.

The part of an HFP number which represents the significant digits of the number is called the fraction. A second part specifies the power (exponent) to which 16 is raised and indicates the location of the radix point of the number. The fraction and exponent may be represented by 32 bits (short format), 64 bits (long format), or 128 bits (extended format).

Short HFP Number



Long HFP Number

64
72
95
3
Rightmost 14 Digits of 28-Digit Fraction (continued)
96
127

An HFP number has two signs: one for the fraction and one for the exponent. The fraction sign, which is also the sign of the entire number, is the leftmost bit of each format (0 for plus, 1 for minus). The numeric part of the fraction is in true notation regardless of the sign. The numeric part is contained in bits 8-31 for the short format, in bits 8-63 for the long format, and in bits 8-63 followed by bits 72-127 for the extended format.

The exponent sign is obtained by expressing the exponent in excess-64 notation; that is, the exponent is added as a signed number to 64. The resulting number is called the characteristic. It is located in bits 1-7 for all formats. The characteristic can vary from 0 to 127, permitting the exponent to vary from -64 through 0 to +63. This provides a scale multiplier in the range of 16^{-64} to 16^{+63}. A nonzero fraction, if normalized, has a value less than one and greater than or equal to 1/16, so that the range covered by the magnitude M of a normalized floating-point number is:

$$16^{-65} \le M < 16^{63}$$

In decimal terms:

16^{-65} is approximately 5.4 x 10^{-79}

16^{63} is approximately 7.2 x 10^{75}

More precisely,

In the short format:

$$16^{-65} \le M \le (1 - 16^{-6}) \times 16^{63}$$

In the long format:

$$16^{-65} \le M \le (1 - 16^{-14}) \times 16^{63}$$

In the extended format:

$$16^{-65} \le M \le (1 - 16^{-28}) \times 16^{63}$$

Within a given fraction length (6, 14, or 28 digits), an HFP operation will provide the greatest precision if the fraction is normalized. A fraction is normalized when the leftmost digit (bit positions 8, 9, 10, and 11) is nonzero. It is unnormalized if the leftmost digit contains all zeros.

If normalization of the operand is desired, the HFP instructions that provide automatic normalization are used. This automatic normalization is accomplished by left-shifting the fraction (four bits per shift) until a nonzero digit occupies the leftmost digit position. The characteristic is reduced by one for each digit shifted.

Figure A-3 illustrates sample normalized short HFP numbers. The last two numbers represent the smallest and the largest positive normalized numbers.

1.0	= $+1/16x16^{1}$	= 0 100 0001 0001 0000 0000 0000 0000 0000_2
0.5	= $+8/16x16^{0}$	= 0 100 0000 1000 0000 0000 0000 0000 0000_2
1/64	= $+4/16x16^{-1}$	= 0 011 1111 0100 0000 0000 0000 0000 0000_2
0.0	= +0 $x16^{-64}$	= 0 000 0000 0000 0000 0000 0000 0000 0000_2
-15.0	= $-15/16x16^{1}$	= 1 100 0001 1111 0000 0000 0000 0000 0000_2
$5.4x10^{-79}$	≈ $+1/16x16^{-64}$	= 0 000 0000 0001 0000 0000 0000 0000 0000_2
$7.2x10^{75}$	≈ $(1-16^{-6})x16^{63}$	= 0 111 1111 1111 1111 1111 1111 1111 1111_2

Figure A-3. Normalized Short Hexadecimal-Floating-Point Numbers

Conversion Example

Convert the decimal number 59.25 to a short HFP number. (In another appendix are tables for the conversion of hexadecimal and decimal integers and fractions.)

1. The number is separated into a decimal integer and a decimal fraction.

   59.25 = 59 plus 0.25

2. The decimal integer is converted to its hexadecimal representation.

   $59_{10} = 3B_{16}$

3. The decimal fraction is converted to its hexadecimal representation.

   $0.25_{10} = 0.4_{16}$

4. The integral and fractional parts are combined and expressed as a fraction times a power of 16 (exponent).

$3B.4_{16} = 0.3B4_{16} \times 16^2$

5. The characteristic is developed from the exponent and converted to binary.

```
base + exponent  = characteristic
64   + 2         = 66 = 1000010
```

6. The fraction is converted to binary and grouped hexadecimally.

$.3B4_{16} = .0011\ 1011\ 0100$

7. The characteristic and the fraction are stored in the short format. The sign position contains the sign of the fraction.

```
S Char      Fraction
0 1000010   0011 1011 0100 0000 0000 0000
```

Examples of instruction sequences that may be used to convert between signed binary integers and HFP numbers are shown in “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

Instruction-Use Examples

The following examples illustrate the use of many of the unprivileged instructions. Before studying one of these examples, the reader should consult the instruction description.

The instruction-use examples are written principally for assembler-language programmers, to be used in conjunction with the appropriate assembler-language publications.

Most examples present one particular instruction, both as it is written in an assembler-language statement and as it appears when assembled in storage (machine format).

Machine Format

All machine-format values are given in hexadecimal notation unless otherwise specified. Storage addresses are also given in hexadecimal. Hexadecimal operands are shown converted into binary, decimal, or both if such conversion helps to clarify the example for the reader.

Assembler-Language Format

In assembler-language statements, registers and lengths are presented in decimal. Displacements, immediate operands, and masks may be shown in decimal, hexadecimal, or binary notation; for example, 12, X‘C’, and B‘1100’ represent the same value. Whenever the value in a register or storage location is referred to as “not significant,” this value is replaced during the execution of the instruction.

When SS-format instructions are written in the assembler language, lengths are given as the total number of bytes in the field. This differs from the machine definition, in which the length field specifies the number of bytes to be added to the field address to obtain the address of the last byte of the field. Thus, the machine length is one less than the assembler-language length. The assembler program automatically subtracts one from the length specified when the instruction is assembled.

In some of the examples, symbolic addresses are used in order to simplify the examples. In assembler-language statements, a symbolic address is represented as a mnemonic term written in all capitals, such as FLAGS, which may denote the address of a storage location containing data or program-control information. When symbolic addresses are used, the assembler supplies actual base and displacement values according to the programmer’s specifications. Therefore, the actual values for base and displacement are not shown in the assembler-language format or in the machine-language format. For assembler-language formats, in the labels that designate instruction fields, the letter “S” is used to indicate the combination of base and displacement fields for an operand address. (For example, S2 represents the combination of B2 and D2.) In the machine-language format, the base and displacement address components are shown as asterisks (****).

Addressing Mode in Examples

Except where otherwise specified, the examples assume the 24-bit addressing mode.

General Instructions

(See Chapter 7, “General Instructions” for a complete description of the general instructions.)

ADD HALFWORD (AH)

The ADD HALFWORD instruction algebraically adds the contents of a two-byte field in storage to the contents of a register. The storage operand is expanded to 32 bits after it is fetched and before it is used in the add operation. The expansion consists in propagating the leftmost (sign) bit 16 positions to the left. For example, assume that the contents of storage locations 2000-2001 are to be added to register 5. Initially:

Register 5 contains 00 00 00 19 = 25_{10}.

Storage locations 2000-2001 contain FF FE = -2_{10}.

Register 12 contains 00 00 18 00.

Register 13 contains 00 00 01 50.

The format of the required instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4A	5	D	C	6B0

Assembler Format

Op Code $R_1,D_2(X_2,B_2)$

```
   AH  5,X'6B0'(13,12)
```

After the instruction is executed, register 5 contains 00 00 00 17 = 23_{10}. Condition code 2 is set to indicate a result greater than zero.

AND (N, NC, NI, NR)

When the Boolean operator AND is applied to two bits, the result is one when both bits are one; otherwise, the result is zero. When two bytes are ANDed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ANDing two bytes:

First-operand byte: 0011 0101_2
Second-operand byte: 0101 1100_2

Result byte: 0001 0100_2

NI Example

A frequent use of the AND instruction is to set a particular bit to zero. For example, assume that storage location 4891 contains 0100 0011_2. To set the rightmost bit of this byte to zero without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

Op Code	I_2	B_1	D_1
94	FE	8	001

Assembler Format

Op Code $D_1(B_1),I_2$

```
   NI    1(8),X'FE'
```

When this instruction is executed, the byte in storage is ANDed with the immediate byte (the I_2 field of the instruction):

Location 4891: 0100 0011_2
Immediate byte: 1111 1110_2

Result: 0100 0010_2

The resulting byte, with bit 7 set to zero, is stored back in location 4891. Condition code 1 is set.

Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)

Four unprivileged instructions (BRANCH AND LINK, BRANCH AND SAVE, BRANCH AND SAVE AND SET MODE, and BRANCH AND SET MODE) are available, together with the unconditional branch (BRANCH ON CONDITION with a mask of 15), to provide linkage between subroutines. BRANCH AND LINK (BAL or BALR) is provided primarily for compatibility with programs written for System/370; BRANCH AND SAVE (BAS or BASR) is recommended instead for programs which are to be executed using ESA/370. The instructions BRANCH AND SAVE AND SET MODE (BASSM) and BRANCH AND SET MODE (BSM) provide subroutine linkage together with switching between the 24-bit and the 31-bit addressing modes. The use of these instructions is discussed in a programming note at the end of the section “Subroutine Linkage without the Linkage Stack” on page 5-14 (See also the semiprivileged instruction BRANCH AND STACK.)

The following example compares the operation of these instructions and of the unconditional-branch instruction BRANCH ON CONDITION (BC or BCR with a mask of 15). Assume that each instruction in turn is located at the current instruction address, ready to be executed next. For the first set of examples, the addressing-mode bit, PSW bit 32, is initially zero (24-bit addressing in effect). For the second set, PSW bit 32 is initially one (31-bit addressing). Assume also that general register 5 is to receive the linkage information, and that general register 6 contains the branch address.

The format of the BALR instruction is:

Machine Format

Op Code	R_1	R_2
05	5	6

Assembler Format
Op Code R_1,R_2

```
  BALR   5,6
```

The other linkage instructions in the RR format have the same format but different op codes:

```
BASR   0D
BASSM  0C
BSM    0B
```

For comparison with the RR-format instructions, the results of two RX-format instructions are also shown.

The format of the BAL instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
45	5	0	6	000

Assembler Format
Op Code R_1,D_2(X_2,B_2)

```
  BAL     5,0(0,6)
```

The BAS instruction has the same format, but the op code is 4D.

The BCR instruction specifies only one register:

Machine Format

Op Code	M_1	R_2
07	F	6

Assembler Format
Op Code M_1,R_2

```
  BCR    15,6
```

Assume that:

Register 5 contains BB BB BB BB.

Register 6 contains 82 46 8A CE.

PSW bits 32-63 contain

00 00 10 D6 (for 24-bit addressing).
80 00 10 D6 (for 31-bit addressing).

Condition code is 01_2.

Program mask is 1100_2.

The effect of executing each instruction in turn is as follows:

24-Bit Mode Initially

```
Instruction     Register 5   PSW (32-63)

Before          BB BB BB BB  00 00 10 D6

BCR  15,6       BB BB BB BB  00 46 8A CE
BAL   5,0(0,6)  9C 00 10 DA  00 46 8A CE
BAS   5,0(0,6)  00 00 10 DA  00 46 8A CE
BALR  5,6       5C 00 10 D8  00 46 8A CE
BASR  5,6       00 00 10 D8  00 46 8A CE
BASSM 5,6       00 00 10 D8  82 46 8A CE
BSM   5,6       3B BB BB BB  82 46 8A CE
```

31-Bit Mode Initially

```
Instruction     Register 5   PSW (32-63)

Before          BB BB BB BB  80 00 10 D6

BCR  15,6       BB BB BB BB  82 46 8A CE
BAL   5,0(0,6)  80 00 10 DA  82 46 8A CE
BAS   5,0(0,6)  80 00 10 DA  82 46 8A CE
BALR  5,6       80 00 10 D8  82 46 8A CE
BASR  5,6       80 00 10 D8  82 46 8A CE
BASSM 5,6       80 00 10 D8  82 46 8A CE
BSM   5,6       BB BB BB BB  82 46 8A CE
```

Note that a value of zero in the R_2 field of any of the RR-format instructions indicates that the branching function is not to be performed; it does not refer to register 0. Likewise, a value of zero in the R_1 field of the BSM instruction indicates that the old value of PSW bit 32 is not to be saved and that register 0 is to be left unchanged. Register 0 can be designated by the R_1 field of instructions BAL, BALR, BAS, BASR, and BASSM, however. In the RX-format branch instructions, branching occurs independent of whether there is a value of zero in the B_2 field or X_2 field of the instruction. However, when the field is zero, instead of using the contents of general register 0, a value of zero is used for that component of address generation.

Programming Note: It should be noted that execution of BAL in the 24-bit addressing mode results in bit 0 of register 5 being set to one. This is because the ILC for an RX-format instruction is 10. This is the only case in which bit zero of the return register does not correctly reflect the addressing mode of the caller. Thus, BSM may be used to return for BALR, BAS, BASR, and BASSM in both the 24-bit and the 31-bit addressing modes, but it cannot be used to return if the program was called by using BAL in the 24-bit addressing mode.

Other BALR and BASR Examples

The BALR or BASR instruction with the R_2 field set to zero may be used to load a register for use as a base register. For example, in the assembler language, the two statements:

```
BALR    15,0
USING   *,15
```

or

```
BASR    15,0
USING   *,15
```

indicate that the address of the next sequential instruction following the BALR or BASR instruction will be placed in register 15, and that the assembler may use register 15 as a base register until otherwise instructed. (The USING statement is an “assembler instruction” and is thus not a part of the object program.)

BRANCH AND STACK (BAKR)

The semiprivileged BRANCH AND STACK instruction facilitates linkage between subroutines by saving status in a linkage-stack state entry (sometimes called a branch state entry to distinguish it from a program-call state entry). When BRANCH AND STACK has been used, the return from the called program is made by means of the PROGRAM RETURN instruction. PROGRAM RETURN restores access registers 2-14, general registers 2-14, and the PSW with values saved in the state entry, except that it leaves the PER mask unchanged and sets the condition code to an unpredictable value. The use of BRANCH AND STACK is discussed in “Branching Using the Linkage Stack” on page 5-73.

BRANCH AND STACK can be used to perform a calling linkage, or it can be used at or near the entry point of the called program, depending on whether the R_1 field of the instruction is zero or nonzero, respectively. If the R_1 field is zero, bits 32-63 of the PSW saved in the state entry indicate the current addressing mode (24-bit or 31-bit) and the address of the next sequential instruction after the BRANCH AND STACK instruction or an EXECUTE instruction. If the R_1 field is nonzero, bits 32-63 of the PSW saved in the state entry are set with a value generated from the contents of general register R_1: bit 32 of the PSW is set equal to bit 0 of the register, and bits 1-31 of the PSW are set with an address generated from bits 1-31 of the register under the control of bit 0 of the register. Bits 32-63 of the PSW saved in the state entry are referred to in the following examples as the return value.

The branch address for the instruction is generated from the contents of general register R_2 under the control of the current addressing mode. Bit 0 of general register R_2 does not affect the operation. If the R_2 field of the instruction is zero, the operation is performed without branching.

In addition to saving a complete PSW (except with an unpredictable PER mask) in the state entry, BRANCH AND STACK saves the new value of bits 32-63 of the current PSW in the state entry. Bits 32-63 are referred to in the following examples as the branch value.

The following examples contain cases in which bit 32 of the current PSW is either zero or one (24-bit or 31-bit addressing) before BRANCH AND STACK is executed and in which bit 0 of the general register designated by a nonzero R_1 or R_2 field is either zero or one.

BAKR Example 1

This example shows BAKR used in a calling program. BAKR performs a branch, and the return is to be to the next sequential instruction.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		0	6

Assembler Format

Op Code R_1,R_2

BAKR 0,6

Assume four cases of initial values, as follows:

	PSW (32-63)	Register 6
1.	00 00 10 D6	02 46 8A CE
2.	00 00 10 D6	82 46 8A CE
3.	80 00 10 D6	02 46 8A CE
4.	80 00 10 D6	82 46 8A CE

The results in the four cases are as follows:

	Return Value	Branch Value and PSW (32-63)
1.	00 00 10 DA	00 46 8A CE
2.	00 00 10 DA	00 46 8A CE
3.	80 00 10 DA	82 46 8A CE
4.	80 00 10 DA	82 46 8A CE

BAKR Example 2

This example shows BAKR used in a called program. BAKR does not perform a branch, and the return is to be as specified in general register R_1.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		5	0

Assembler Format

Op Code R_1,R_2

BAKR 5,0

Assume four cases of initial values, as follows:

	Register 5	PSW (32-63)
1.	04 00 10 D6	00 46 8A CE
2.	04 00 10 D6	82 46 8A CE
3.	84 00 10 D6	00 46 8A CE
4.	84 00 10 D6	82 46 8A CE

The results in the four cases are as follows:

	Return Value	Branch Value and PSW (32-63)
1.	00 00 10 D6	00 46 8A D2
2.	00 00 10 D6	82 46 8A D2
3.	84 00 10 D6	00 46 8A D2
4.	84 00 10 D6	82 46 8A D2

BAKR Example 3

This example shows BAKR used in a called program. BAKR performs a branch, and the return is to be as specified in general register R_1.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		5	6

Assembler Format

Op Code R_1,R_2

BAKR 5,6

Assume eight cases of initial values, as follows:

	Register 5	Register 6	PSW (32-63)
1.	04 00 10 D6	06 99 99 00	00 46 8A CE
2.	04 00 10 D6	06 99 99 00	82 46 8A CE
3.	04 00 10 D6	86 99 99 00	00 46 8A CE
4.	04 00 10 D6	86 99 99 00	82 46 8A CE
5.	84 00 10 D6	06 99 99 00	00 46 8A CE
6.	84 00 10 D6	06 99 99 00	82 46 8A CE
7.	84 00 10 D6	86 99 99 00	00 46 8A CE
8.	84 00 10 D6	86 99 99 00	82 46 8A CE

The results in the eight cases are as follows:

	Return Value	Branch Value and PSW (32-63)
1.	00 00 10 D6	00 99 99 00
2.	00 00 10 D6	86 99 99 00
3.	00 00 10 D6	00 99 99 00
4.	00 00 10 D6	86 99 99 00

```
5. 84 00 10 D6   00 99 99 00
6. 84 00 10 D6   86 99 99 00
7. 84 00 10 D6   00 99 99 00
8. 84 00 10 D6   86 99 99 00
```

BRANCH ON CONDITION (BC, BCR)

The BRANCH ON CONDITION instruction tests the condition code to see whether a branch should or should not occur. The branch occurs only if the current condition code corresponds to a one bit in a mask specified by the instruction.

Condition Code	Instruction (Mask) Bit	Mask Value
0	8	8
1	9	4
2	10	2
3	11	1

For example, assume that an ADD (A or AR) operation has been performed and that a branch to address 6050 is desired if the sum is zero or less (condition code is 0 or 1). Also assume:

Register 10 contains 00 00 50 00.

Register 11 contains 00 00 10 00.

The RX form of the instruction performs the required test (and branch if necessary) when written as:

Machine Format

Op Code	M_1	X_2	B_2	D_2
47	C	B	A	050

Assembler Format

Op Code $M_1,D_2(X_2,B_2)$

```
   BC   12,X'50'(11,10)
```

A mask of 12_{10} means that there are ones in instruction bits 8 and 9 and zeros in bits 10 and 11, so that branching takes place when the condition code is either 0 or 1.

A mask of 15 would indicate a branch on any condition (an unconditional branch). A mask of zero would indicate that no branch is to occur (a no-operation).

(See also “Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)” on page A-8 for an example of the BCR instruction.)

BRANCH ON COUNT (BCT, BCTR)

The BRANCH ON COUNT instruction is often used to execute a program loop for a specified number of times. For example, assume that the following represents some lines of coding in an assembler-language program:

```
   ⋮
   LUPE  AR   8,1
   ⋮
   BACK  BCT  6,LUPE
   ⋮
```

where register 6 contains 00 00 00 03 and the address of LUPE is 6826. Assume that, in order to address this location, register 10 is used as a base register and contains 00 00 68 00.

The format of the BCT instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
46	6	0	A	026

Assembler Format

Op Code $R_1,D_2(X_2,B_2)$

```
  BCT    6,X'26'(0,10)
```

The effect of the coding is to execute three times the loop defined by the instructions labeled LUPE through BACK, while register 6 is decremented from three to zero.

BRANCH ON INDEX HIGH (BXH)

BXH Example 1

The BRANCH ON INDEX HIGH instruction is an index-incrementing and loop-controlling instruction that causes a branch whenever the sum of an index value and an increment value is greater than some compare value. For example, assume that:

Register 4 contains 00 00 00 8A = 138_{10} = the index.

Register 6 contains 00 00 00 02 = 2_{10} = the increment.

Register 7 contains 00 00 00 AA = 170_{10} = the compare value.

Register 10 contains 00 00 71 30 = the branch address.

The format of the BXH instruction is:

Machine Format

Op Code	R_1	R_3	B_2	D_2
86	4	6	A	000

Assembler Format

Op Code $R_1,R_3,D_2(B_2)$

```
  BXH    4,6,0(10)
```

When the instruction is executed, first the contents of register 6 are added to register 4, second the sum is compared with the contents of register 7, and third the decision whether to branch is made. After execution:

Register 4 contains 00 00 00 8C = 140_{10}.

Registers 6 and 7 are unchanged.

Since the new value in register 4 is not yet greater than the value in register 7, the branch to address 7130 is not taken. Repeated use of the instruction will eventually cause the branch to be taken when the value in register 4 reaches 172_{10}.

BXH Example 2

When the register used to contain the increment is odd, that register also becomes the compare-value register. The following assembler-language subroutine illustrates how this may be used to search a table.

Table	
2 Bytes	2 Bytes
ARG1	FUNCT1
ARG2	FUNCT2
ARG3	FUNCT3
ARG4	FUNCT4
ARG5	FUNCT5
ARG6	FUNCT6

Assume that:

Register 8 contains the search argument.

Register 9 contains the width of the table in bytes (00 00 00 04).

Register 10 contains the length of the table in bytes (00 00 00 18).

Register 11 contains the starting address of the table.

Register 14 contains the return address to the main program.

As the following subroutine is executed, the argument in register 8 is successively compared with the arguments in the table, starting with argument 6 and working backward to argument 1. If an equality is found, the corresponding function replaces the argument in register 8. If an equality is not found, zero replaces the argument in register 8.

```
SEARCH    LNR  9,9
NOTEQUAL  BXH  10,9,LOOP
NOTFOUND  SR   8,8
          BCR  15,14
LOOP      CH   8,0(10,11)
          BC   7,NOTEQUAL
          LH   8,2(10,11)
          BCR  15,14
```

The first instruction (LNR) causes the value in register 9 to be made negative. After execution of this instruction, register 9 contains FF FF FF FC = -4_{10}. Considering the case when no equality is found, the BXH instruction will be executed seven times. Each time BXH is executed, a value of -4 is added to register 10, thus reducing the value in register 10 by 4. The new value in register 10 is compared with the -4 value in register 9. The branch is taken each time until the value in register 10 is -4. Then the branch is not taken, and the SR instruction sets register 8 to zero.

BRANCH ON INDEX LOW OR EQUAL (BXLE)

The BRANCH ON INDEX LOW OR EQUAL instruction performs the same operation as BRANCH ON INDEX HIGH, except that branching occurs when the sum is lower than or equal to (instead of higher than) the compare value. As the instruction which increments and tests an index value in a program loop, BXLE is useful at the end of the loop and BXH at the beginning. The following assembler-language routines illustrate loops with BXLE.

BXLE Example 1

Assume that a group of ten 32-bit signed binary integers are stored at consecutive locations, starting at location GROUP. The integers are to be added together, and the sum is to be stored at location SUM.

```
     SR   5,5       Set sum to zero
     LA   6,GROUP   Load first address
     SR   7,7       Set index to zero
     LA   8,4       Load increment 4
     LA   9,39      Load compare value
LOOP A    5,0(7,6)  Add integer to sum
     BXLE 7,8,LOOP  Test end of loop
     ST   5,SUM     Store sum
```

The two-instruction loop contains an ADD (A) instruction which adds each integer to the contents of general register 5. The ADD instruction uses the contents of general register 7 as an index value to modify the starting address obtained from register 6. Next, BXLE increments the index value by 4, the increment previously loaded into register 8, and compares it with the compare value in register 9, the odd register of this even-odd pair. The compare value was previously set to 39, which is one less than the number of bytes in the data area; this is also the address, relative to the starting address, of the rightmost byte of the last integer to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

BXLE Example 2

The technique illustrated in Example 1 is restricted to loops containing instructions in the RX instruction format. That format allows both a base register and an index register to be specified (double indexing).

For instructions in other formats, where an index register cannot be specified, the previous technique may be modified by having the address itself serve as the index value in a BXLE instruction and by using as the compare value the address of the last byte rather than its relative address. The base register then provides the address directly at each iteration of the loop, and it is not necessary to specify a second register to hold the index value (single indexing).

In the following example, an AND (NI) instruction in the SI instruction format sets to zero the rightmost bit of each of the same group of integers as in Example 1, thus making all of them even. The I_2 field of the NI instruction contains the byte X‘FE’, which consists of seven ones and a zero. That byte is ANDed into byte 3, the rightmost byte, of each of the integers in turn.

```
     LA   6,GROUP    Load first address
     LA   8,4        Load increment 4
     LA   9,GROUP+39 Load compare value
LOOP NI   3(6),X'FE' AND immediate
     BXLE 6,8,LOOP   Test end of loop
```

The technique shown in Example 2 does not work, however, on an ESA/370 system when it is in the 31-bit addressing mode and the data is located at the rightmost end of a 31-bit address space. In this case, the compare value would be set to 2^{31}-1, which is the largest possible 32-bit signed binary value. The reason the technique does not work is that the BXLE and BXH instructions treat their operands as 32-bit signed binary integers. When the address in general register 6 reaches the value 2^{31}-4, BXLE increments it to a value that is interpreted as -2^{31}, rather than 2^{31}, and the comparison remains low, which causes looping to continue indefinitely.

This situation can be avoided by not allowing data areas to extend to the rightmost location in a 31-bit address space or by using other techniques; these may include double indexing when possible, as in Example 1, or starting at the end and stepping downward through the data area with a negative increment.

COMPARE AND FORM CODEWORD (CFC)

See “Sorting Instructions” on page A-53.

COMPARE HALFWORD (CH)

The COMPARE HALFWORD instruction compares a 16-bit signed binary integer in storage with the contents of a register. For example, assume that:

Register 4 contains FF FF 80 00 = -$32,768_{10}$.

Register 13 contains 00 01 60 50.

Storage locations 16080-16081 contain 8000 = -32,768$_{10}$.

When the instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
49	4	0	D	030

Assembler Format
Op Code $R_1,D_2(X_2,B_2)$

```
  CH     4,X'30'(0,13)
```

is executed, the contents of locations 16080-16081 are fetched, expanded to 32 bits (the sign bit is propagated to the left), and compared with the contents of register 4. Because the two numbers are equal, condition code 0 is set.

COMPARE LOGICAL (CL, CLC, CLI, CLR)

The COMPARE LOGICAL instruction differs from the signed-binary comparison instructions (C, CH, CR) in that all quantities are handled as unsigned binary integers or as unstructured data.

CLC Example

The COMPARE LOGICAL (CLC) instruction can be used to perform the byte-by-byte comparison of storage fields up to 256 bytes in length. For example, assume that the following two fields of data are in storage:

Field 1

1886											1891
D1	D6	C8	D5	E2	D6	D5	6B	C1	4B	C2	4B

Field 2

1900											190B
D1	D6	C8	D5	E2	D6	D5	6B	C1	4B	C3	4B

Also assume:

Register 9 contains 00 00 18 80.

Register 7 contains 00 00 19 00.

Execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D5	0B	9	006	7	000

Assembler Format
Op Code $D_1(L,B_1),D_2(B_2)$

```
  CLC    6(12,9),0(7)
```

sets condition code 1, indicating that the contents of field 1 are lower in value than the contents of field 2.

Because the collating sequence of the EBCDIC code is determined simply by a logical comparison of the bits in the code, the CLC instruction can be used to collate EBCDIC-coded fields. For example, in EBCDIC, the above two data fields are:

```
Field 1:  JOHNSON,A.B.
Field 2:  JOHNSON,A.C.
```

Condition code 1 indicates that JOHNSON,A.B. should precede JOHNSON,A.C. for the fields to be in alphabetic sequence.

CLI Example

The COMPARE LOGICAL (CLI) instruction compares a byte from the instruction stream with a byte from storage. For example, assume that:

Register 10 contains 00 00 17 00.

Storage location 1703 contains 7E.

Execution of the instruction:

Machine Format

Op Code	I_2	B_1	D_1
95	AF	A	003

Assembler Format
Op Code $D_1(B_1),I_2$

```
  CLI    3(10),X'AF'
```

sets condition code 1, indicating that the first operand (the quantity in main storage) is lower than the second (immediate) operand.

CLR Example

Assume that:

Register 4 contains 00 00 00 01 = 1.

Register 7 contains FF FF FF FF = 2^{32} - 1.

Execution of the instruction:

Machine Format

Op Code	R_1	R_2
15	4	7

Assembler Format

Op Code	R_1,R_2
CLR	4,7

sets condition code 1. Condition code 1 indicates that the first operand is lower than the second.

If, instead, the signed-binary comparison instruction COMPARE (CR) had been executed, the contents of register 4 would have been interpreted as +1 and the contents of register 7 as -1. Thus, the first operand would have been higher, so that condition code 2 would have been set.

COMPARE LOGICAL CHARACTERS UNDER MASK (CLM)

The COMPARE LOGICAL CHARACTERS UNDER MASK (CLM) instruction provides a means of comparing bytes selected from a general register to a contiguous field of bytes in storage. The M_3 field of the CLM instruction is a four-bit mask that selects zero to four bytes from a general register, each mask bit corresponding, left to right, to a register byte. In the comparison, the register bytes corresponding to ones in the mask are treated as a contiguous field. The operation proceeds left to right. For example, assume that:

Storage locations 10200-10202 contain F0 BC 7B.

Register 12 contains 00 01 00 00.

Register 6 contains F0 BC 5C 7B.

Execution of the instruction:

Machine Format

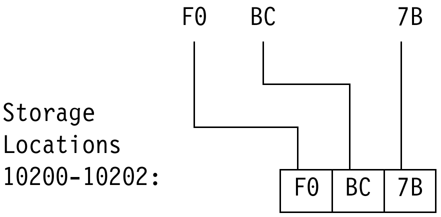
Op Code	R_1	M_3	B_2	D_2
BD	6	D	C	200

Assembler Format

Op Code	R_1,M_3,D_2(B_2)
CLM	6,B'1101',X'200'(12)

causes the following comparison:

```
Register 6:  F0   BC   5C   7B
   Mask M3:  1    1    0    1
             --   --        --
```



Because the selected bytes are equal, condition code 0 is set.

COMPARE LOGICAL LONG (CLCL)

The COMPARE LOGICAL LONG instruction is used to compare two operands in storage, byte by byte. Each operand can be of any length. Two even-odd pairs of general registers (four registers in all) are used to locate the operands and to control the execution of the CLCL instruction, as illustrated in the following diagram. The first register of each pair must be an even register, and it contains the storage address of an operand. The odd register of each pair contains the length of the operand it covers, and the leftmost byte of the second-operand odd register contains a padding byte which is used to extend the shorter operand, if any, to the same length as the longer operand.

The following illustrates the assignment of registers in the 24-bit addressing mode:

R_1	////////	First-Operand Address
(even)	0	8 31

R_1+1	////////	First-Operand Length
(odd)	0	8 31

R_2	////////	Second-Operand Address	
(even)	0	8	31

R_2+1	Pad Byte	Second-Operand Length	
(odd)	0	8	31

In the 31-bit addressing mode, the operand addresses would be in bit positions 1-31 of the even registers shown above.

Since the CLCL instruction may be interrupted during execution, the interrupting program must preserve the contents of the four registers for use when the instruction is resumed.

The following instructions set up two register pairs to control a text-string comparison. For example, assume:

Operand 1
Address: 20800_{16}
Length: 100_{10}

Operand 2
Address: $20A00_{16}$
Length: 132_{10}

Padding Byte
Address: 20003_{16}
Length: 1
Value: 40_{16}

Register 12 contains 00 02 00 00.

The setup instructions are:

LA	4,X‘800’(12)	Set register 4 to start of first operand
LA	5,100	Set register 5 to length of first operand
LA	8,X‘A00’(12)	Set register 8 to start of second operand
LA	9,132	Set register 9 to length of second operand
ICM	9,B‘1000’,3(12)	Insert padding byte in leftmost byte position of register 9

Register pair 4,5 defines the first operand. Bits 8-31 of register 4 contain the storage address of the start of an EBCDIC text string, and bits 8-31 of register 5 contain the length of the string, in this case 100 bytes.

Register pair 8,9 defines the second operand, with bits 8-31 of register 8 containing the starting location of the second operand and bits 8-31 of register 9 containing the length of the second operand, in this case 132 bytes. Bits 0-7 of register 9 contain an EBCDIC blank character (X‘40’) to pad the shorter operand. In this example, the padding byte is used in the first operand, after the 100th byte, to compare with the remaining bytes in the second operand.

With the register pairs thus set up, the format of the CLCL instruction is:

Machine Format

Op Code	R_1	R_2
0F	4	8

Assembler Format

Op Code	R_1,R_2
CLCL	4,8

When this instruction is executed, the comparison starts at the left end of each operand and proceeds to the right. The operation ends as soon as an inequality is detected or the end of the longer operand is reached.

If this CLCL instruction is interrupted after 60 bytes have compared equal, the operand lengths in registers 5 and 9 will have been decremented to 40 and 72, respectively. The operand addresses in registers 4 and 8 will have been incremented to X‘2083C’ and X‘20A3C’; the leftmost byte of registers 4 and 8 will have been set to zero. The padding byte X‘40’ remains in register 9. When the CLCL instruction is reexecuted with these register contents, the comparison resumes at the point of interruption.

Now, assume that the instruction is interrupted after 110 bytes. That is, the first 100 bytes of the second operand have compared equal to the first operand, and the next 10 bytes of the second operand have compared equal to the padding byte (blank). The residual operand lengths in registers 5 and 9 are 0 and 22, respectively, and the operand addresses in registers 4 and 8 are X‘20864’ (the value when the first operand was exhausted) and X‘20A6E’ (the current value for the second operand).

When the comparison ends, the condition code is set to 0, 1, or 2, depending on whether the first operand is equal to, less than, or greater than the second operand, respectively.

When the operands are unequal, the addresses in registers 4 and 8 indicate the bytes that caused the mismatch.

COMPARE LOGICAL STRING (CLST)

The COMPARE LOGICAL STRING instruction is used to compare a first operand designated by general register R_1 and a second operand designated by general register R_2. The comparison is made left to right, byte by byte, until unequal bytes are compared, an ending character specified in general register 0 is encountered in either operand, or a CPU-determined number of bytes have been compared. The condition code is set to 0 if the two operands are equal, to 1 if the first operand is low, to 2 if the second operand is low, or to 3 if a CPU-determined number of bytes have been compared. If the ending character is found in both operands simultaneously, the operands are equal. If it is found in only one operand, that operand is low.

When condition code 1 or 2 is set, the addresses of the last bytes processed in the first and second operands are placed in general registers R_1 and R_2, respectively. These are the addresses of unequal bytes in the two operands, or they are the address of an ending character in one operand and of the byte in the corresponding byte position in the other operand. When condition code 3 is set, the addresses of the next bytes to be processed are placed in the registers. When condition code 0 is set, the contents of the registers remain unchanged.

Following are examples of first and second operands beginning at decimal locations 1000 and 2000, respectively. The addresses in general registers R_1 and R_2 are 1000 and 2000, respectively. The ending character in general register 0 is 00 hex (as in the C programming language). The values of the operand bytes are shown in hex, and the resulting condition code and final contents of general registers R_1 and R_2 are shown.

Example 1

```
1000           2000
C1 C2 C3 00    C1 C2 C3 00
```

CC: 0; (R_1): 1000; (R_2): 2000

Example 2

```
1000           2000
40 40 40 C1    40 40 40 C2
```

CC: 1; (R_1): 1003; (R_2): 2003

Example 3

```
1000           2000
40 40 40 C2    40 40 40 C1
```

CC: 2; (R_1): 1003; (R_2): 2003

Example 4

```
1000           2000
C1 C2 C3 00    C1 C2 C3 C4
```

CC: 1; (R_1): 1003; (R_2): 2003

Example 5

```
1000           2000
C1 C2 C3 C4    C1 C2 C3 00
```

CC: 2; (R_1): 1003; (R_2): 2003

Example 6

Assuming that the CPU-determined number of bytes compared is 256:

```
1000     1256  2000     2256
40 .. 40 00    40 .. 40 00
```

CC: 3; (R_1): 1256; (R_2): 2256

Example 7

```
1000           2000
00 40 40 40    40 40 40 40
```

CC: 1; (R_1): 1000; (R_2): 2000

Example 8

```
1000           2000
40 40 40 40    00 40 40 40
```

CC: 2; (R_1): 1000; (R_2): 2000

Example 9

```
1000           2000
00 40 40 40    00 40 40 40
```

CC: 0; (R_1): 1000; (R_2): 2000

CONVERT TO BINARY (CVB)

The CONVERT TO BINARY instruction converts an eight-byte, signed-packed-decimal number into a signed binary integer and loads the result into a general register. After the conversion operation is completed, the number is in the proper form for use as an operand in signed binary arithmetic. For example, assume:

> Storage locations 7608-760F contain a decimal number in the signed-packed-decimal format: 00 00 00 00 00 25 59 4C (+25,594).
>
> The contents of register 7 are not significant.
>
> Register 13 contains 00 00 76 00.

The format of the conversion instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4F	7	0	D	008

Assembler Format

Op Code	$R_1,D_2(X_2,B_2)$
CVB	7,8(0,13)

After the instruction is executed, register 7 contains 00 00 63 FA.

CONVERT TO DECIMAL (CVD)

The CONVERT TO DECIMAL instruction is the opposite of the CONVERT TO BINARY instruction. CVD converts a signed binary integer in a register to signed-packed-decimal number and stores the eight-byte result. For example, assume:

> Register 1 contains the signed binary integer: 00 00 0F 0F.
>
> Register 13 contains 00 00 76 00.

The format of the instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4E	1	0	D	008

Assembler Format

Op Code	$R_1,D_2(X_2,B_2)$
CVD	1,8(0,13)

After the instruction is executed, storage locations 7608-760F contain 00 00 00 00 00 03 85 5C (+3855).

The plus sign generated is the preferred plus sign, 1100_2.

DIVIDE (D, DR)

The DIVIDE instruction divides the dividend in an even-odd register pair by the divisor in a register or in storage. Since the instruction assumes the dividend to be 64 bits long, it is important first to extend a 32-bit dividend on the left with bits equal to the sign bit. For example, assume that:

> Storage locations 3550-3553 contain 00 00 08 DE = 2270_{10} (the dividend).
>
> Storage locations 3554-3557 contain 00 00 00 32 = 50_{10} (the divisor).
>
> The initial contents of registers 6 and 7 are not significant.
>
> Register 8 contains 00 00 35 50.

The following assembler-language statements load the registers properly and perform the divide operation:

Statement	Comments
L 6,0(0,8)	Places 00 00 08 DE into register 6.
SRDA 6,32(0)	Shifts 00 00 08 DE into register 7. Register 6 is filled with zeros (sign bits).
D 6,4(0,8)	Performs the division.

The machine format of the above DIVIDE instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
5D	6	0	8	004

After the instructions listed above are executed:

> Register 6 contains 00 00 00 14 = 20_{10} = the remainder.
>
> Register 7 contains 00 00 00 2D = 45_{10} = the quotient.

Note that if the dividend had not been first placed in register 6 and shifted into register 7, register 6 might not have been filled with the proper dividend-sign bits (zeros in this example), and the DIVIDE instruction might not have given the expected results.

EXCLUSIVE OR (X, XC, XI, XR)

When the Boolean operator EXCLUSIVE OR is applied to two bits, the result is one when either, but not both, of the two bits is one; otherwise, the result is zero. When two bytes are EXCLUSIVE ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of the EXCLUSIVE OR of two bytes:

First-operand byte: $0011\ 0101_2$
Second-operand byte: $0101\ 1100_2$

Result byte: $0110\ 1001_2$

XC Example

The EXCLUSIVE OR (XC) instruction can be used to exchange the contents of two areas in storage without the use of an intermediate storage area. For example, assume two three-byte fields in storage:

```
         359      35B
Field 1 | 00 | 17 | 90 |

         360      362
Field 2 | 00 | 14 | 01 |
```

Execution of the instruction (assume that register 7 contains 00 00 03 58):

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	001	7	008

Assembler Format
Op Code $D_1(L,B_1),D_2(B_2)$

XC   1(3,7),8(7)

Field 1 is EXCLUSIVE ORed with field 2 as follows:

Field 1: $00000000\ 00010111\ 10010000_2$ = $00\ 17\ 90_{16}$
Field 2: $00000000\ 00010100\ 00000001_2$ = $00\ 14\ 01_{16}$

Result: $00000000\ 00000011\ 10010001_2$ = $00\ 03\ 91_{16}$

The result replaces the former contents of field 1. Condition code 1 is set to indicate a nonzero result.

Now, execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	008	7	001

Assembler Format
Op Code $D_1(L,B_1),D_2(B_2)$

XC   8(3,7),1(7)

produces the following result:

Field 1: $00000000\ 00000011\ 10010001_2$ = $00\ 03\ 91_{16}$
Field 2: $00000000\ 00010100\ 00000001_2$ = $00\ 14\ 01_{16}$

Result: $00000000\ 00010111\ 10010000_2$ = $00\ 17\ 90_{16}$

The result of this operation replaces the former contents of field 2. Field 2 now contains the original value of field 1. Condition code 1 is set to indicate a nonzero result.

Lastly, execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	001	7	008

Assembler Format
Op Code $D_1(L,B_1),D_2(B_2)$

XC   1(3,7),8(7)

produces the following result:

Field 1: $00000000\ 00000011\ 10010001_2$ = $00\ 03\ 91_{16}$
Field 2: $00000000\ 00010111\ 10010000_2$ = $00\ 17\ 90_{16}$

Result: $00000000\ 00010100\ 00000001_2$ = $00\ 14\ 01_{16}$

The result of this operation replaces the former contents of field 1. Field 1 now contains the original value of field 2. Condition code 1 is set to indicate a nonzero result.

XI Example

A frequent use of the EXCLUSIVE OR (XI) instruction is to invert a bit (change a zero bit to a one or a one bit to a zero). For example, assume that storage location 8082 contains $0110\ 1001_2$. To invert the leftmost and rightmost bits without affecting any of the other bits, the following instruction can be used (assume that register 9 contains 00 00 80 80):

Machine Format

Op Code	I_2	B_1	D_1
97	81	9	002

Assembler Format

Op Code $D_1(B_1),I_2$

```
   XI    2(9),X'81'
```

When the instruction is executed, the byte in storage is EXCLUSIVE ORed with the immediate byte (the I_2 field of the instruction):

Location 8082: $0110\ 1001_2$
Immediate byte: $1000\ 0001_2$

Result: $1110\ 1000_2$

The resulting byte is stored back in location 8082. Condition code 1 is set to indicate a nonzero result.

Notes:

1. With the XC instruction, fields up to 256 bytes in length can be exchanged.
2. With the XR instruction, the contents of two registers can be exchanged.
3. Because the X instruction operates storage to register only, an exchange cannot be made solely by the use of X.
4. A field EXCLUSIVE ORed with itself is cleared to zeros.
5. For additional examples of the use of EXCLUSIVE OR, see “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

EXECUTE (EX)

The EXECUTE instruction causes one *target instruction* in main storage to be executed out of sequence without actually branching to the target instruction. Unless the R_1 field of the EXECUTE instruction is zero, bits 8-15 of the target instruction are ORed with bits 56-63 of the R_1 register before the target instruction is executed. Thus, EXECUTE may be used to supply the length field for an SS instruction without modifying the SS instruction in storage. For example, assume that a MOVE (MVC) instruction is the target that is located at address 3820, with a format as follows:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	00	C	003	D	000

Assembler Format

Op Code $D_1(L,B_1),D_2(B_2)$

```
  MVC    3(1,12),0(13)
```

where register 12 contains 00 00 89 13 and register 13 contains 00 00 90 A0.

Further assume that at storage address 5000, the following EXECUTE instruction is located:

Machine Format

Op Code	R_1	X_2	B_2	D_2
44	1	0	A	000

Assembler Format

Op Code $R_1,D_2(X_2,B_2)$

```
   EX    1,0(0,10)
```

where register 10 contains 00 00 38 20 and register 1 contains 00 0F F0 03.

When the instruction at 5000 is executed, the rightmost byte of register 1 is ORed with the second byte of the target instruction:

Instruction byte: $0000\ 0000_2$ = 00
Register byte: $0000\ 0011_2$ = 03

Result: $0000\ 0011_2$ = 03

causing the instruction at 3820 to be executed as if it originally were:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	03	C	003	D	000

Assembler Format

Op Code $D_1(L,B_1),D_2(B_2)$

```
  MVC    3(4,12),0(13)
```

However, after execution:

Register 1 is unchanged.

The instruction at 3820 is unchanged.

The contents of the four bytes starting at location 90A0 have been moved to the four bytes starting at location 8916.

The CPU next executes the instruction at address 5004 (PSW bits 104-127 contain 00 50 04).

FIND LEFTMOST ONE (FLOGR)

FIND LEFTMOST ONE may be used to locate free objects, the availability of which is tracked in a hierarchical bit map.

In the following example, the hierarchical bit map consists of multiple levels of bits, each level having 64 times the number of bits as the next lower-numbered level. This example shows four levels, mapping a total of 16M objects, however additional levels may be added to manage larger numbers of objects.

The highest-numbered bit map level (L3 in this illustration) represents the availability of individual objects, for example, records or pages. A one bit indicates that the object is available, and a zero bit means that the object is not available.

In lower-numbered bit map levels (L0, L1, and L2 in this illustration), a bit position corresponds to a doubleword in the next higher-numbered level. When a bit in a lower-numbered bit map level is one, at least one bit of the corresponding doubleword in the higher-level is one. When a bit in a lower-number bit map level is zero, no bits in the corresponding higher-level doubleword are one.

An example of using FIND LEFTMOST ONES to quickly locate the next available lowest-numbered object, as mapped by such a hierarchical bit map, is shown below. Upon completion, at the label “FOUND”, general register 15 contains the number of the located object. If no objects are available, the code branches to the label “NOTFND”.

```
       LA    15,0           Zero accumulator
       LA    9,OFFSET       Point to table
       LA    10,4           Load increment
       LA    11,ENDOFF-1    Load compare value
FIND   LGR   7,15           Copy accum. to R7
       ALGF  7,0(,9)        Add # DWs to bits
       SLLG  7,7,3          Get byte offset
       LG    1,BITS(7)      Get DW to test
       FLOGR 0,1            Find leftmost one
       BZ    NOTFND         No one bits found
       SLLG  15,15,6        Times # bits in DW
       AGR   15,0           Add bit just found
       BXLEG 9,10,FIND      Do for each level
FOUND  STG   1,BITS(7)      Update changed bit
       ...
NOTFND [Any instruction]

OFFSET DC    A((L0-BITS)/8) Offset to level 0
       DC    A((L1-BITS)/8) Offset to level 1
       DC    A((L2-BITS)/8) Offset to level 2
       DC    A((L3-BITS)/8) Offset to level 3
ENDOFF EQU   *              End of table

BITS   DS    0D             Start of bit map
L0     DS    FD             -L0 (64 objects)
L1     DS    64FD           -L1 (4K objects)
L2     DS    (64*64)FD      -L2 (256K objects)
L3     DS    (64*64*64)FD   -L3 (16M objects)
```

This code sequence shows the zeroing of the found bit with the STORE (STG) instruction at the label “FOUND”. Proper maintenance of such a hierarchical bit map requires that when all bits of a doubleword become zeros, the corresponding bit in the next lower-numbered level is set to zeros. Similarly, when adding a free object to the highest level, the corresponding bits in lower-numbered levels must be set to one. These maintenance functions are not shown.

Note, in a multiprocessing environment, access to the bit map is assumed to be serialized for the duration of the update process.

INSERT CHARACTERS UNDER MASK (ICM)

The INSERT CHARACTERS UNDER MASK (ICM) instruction may be used to replace all or selected bytes in a general register with bytes from storage and to set the condition code to indicate the value of the inserted field.

For example, if it is desired to insert a three-byte address from FIELDA into register 5 and leave the leftmost byte of the register unchanged, assume:

Machine Format

Op Code	R_1	M_3	S_2
BF	5	7	* * * *

Assembler Format

```
Op Code  R1,M3,S2
________________________

  ICM    5,B'0111',FIELDA

FIELDA:                  FE DC BA
Register 5 (before):     12 34 56 78
Register 5 (after):      12 FE DC BA
Condition code (after):  1 (leftmost bit of
                            inserted field
                            is one)
```

As another example:

Machine Format

Op Code	R_1	M_3	S_2
BF	6	9	* * * *

Assembler Format

```
Op Code  R1,M3,S2
________________________

  ICM    6,B'1001',FIELDB

FIELDB:                 12 34
Register 6 (before):    00 00 00 00
Register 6 (after):     12 00 00 34
Condition code (after): 2 (inserted field is
                           nonzero with left-
                           most zero bit)
```

When the mask field contains 1111, the ICM instruction produces the same result as LOAD (L) (provided that the indexing capability of the RX format is not needed), except that ICM also sets the condition code. The condition-code setting is useful when an all-zero field (condition code 0) or a leftmost one bit (condition code 1) is used as a flag.

LOAD (L, LR)

The LOAD instruction takes four bytes from storage or from a general register and place them unchanged into a general register. For example, assume that the four bytes starting with location 21003 are to be loaded into register 10. Initially:

Register 5 contains 00 02 00 00.

Register 6 contains 00 00 10 03.

The contents of register 10 are not significant.

Storage locations 21003-21006 contain 00 00 AB CD.

To load register 10, the RX form of the instruction can be used:

Machine Format

Op Code	R_1	X_2	B_2	D_2
58	A	5	6	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
______________________

   L      10,0(5,6)
```

After the instruction is executed, register 10 contains 00 00 AB CD.

LOAD ADDRESS (LA)

The LOAD ADDRESS instruction provides a convenient way to place a nonnegative binary integer up to 4095_{10} in a register without first defining a constant and then using it as an operand. For example, the following instruction places the number 2048_{10} in register 1:

Machine Format

Op Code	R_1	X_2	B_2	D_2
41	1	0	0	800

Assembler Format

```
Op Code  R1,D2(X2,B2)
─────────────────────
   LA    1,2048(0,0)
```

The LOAD ADDRESS instruction can also be used to increment a register by an amount up to 4095_{10} specified in the D_2 field. Depending on the addressing mode, only the rightmost 24 or 31 bits of the sum are retained, however. The leftmost bits of the 32-bit result are set to zeros. For example, assume that register 5 contains 00 12 34 56.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
41	5	0	5	00A

Assembler Format

```
Op Code  R1,D2(X2,B2)
─────────────────────
   LA    5,10(0,5)
```

adds 10 (decimal) to the contents of register 5 as follows:

```
Register 5 (old):  00 12 34 56
D2 field:          00 00 00 0A
──────────────────────────────
Register 5 (new):  00 12 34 60
```

The register may be specified as either B_2 or X_2. Thus, the instruction LA 5,10(5,0) produces the same result.

As the most general example, the instruction LA 6,10(5,4) forms the sum of three values: the contents of register 4, the contents of register 5, and a displacement of 10 and places the 24-bit or 31-bit sum with zeros appended on the left in register 6.

LOAD HALFWORD (LH)

The LOAD HALFWORD instruction places unchanged a halfword from storage into the right half of a register. The left half of the register is loaded with zeros or ones according to the sign (leftmost bit) of the halfword.

For example, assume that the two bytes in storage locations 1803-1804 are to be loaded into register 6. Also assume:

The contents of register 6 are not significant.

Register 14 contains 00 00 18 03.

Locations 1803-1804 contain 00 20.

The instruction required to load the register is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
48	6	0	E	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
─────────────────────
   LH    6,0(0,14)
```

After the instruction is executed, register 6 contains 00 00 00 20. If locations 1803-1804 had contained a negative number, for example, A7 B6, a minus sign would have been propagated to the left, giving FF FF A7 B6 as the final result in register 6.

MOVE (MVC, MVI)

MVC Example

The MOVE (MVC) instruction can be used to move data from one storage location to another. For example, assume that the following two fields are in storage:

	2048										2052
Field 1	C1	C2	C3	C4	C5	C6	C7	C8	C9	CA	CB

	3840								3848
Field 2	F1	F2	F3	F4	F5	F6	F7	F8	F9

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	07	1	000	2	000

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
MVC	0(8,1),0(2)

After the instruction is executed, field 1 becomes:

	2048										2052
Field 1	F1	F2	F3	F4	F5	F6	F7	F8	C9	CA	CB

Field 2 is unchanged.

MVC can also be used to propagate a byte through a field by starting the first-operand field one byte location to the right of the second-operand field. For example, suppose that an area in storage starting with address 358 contains the following data:

358								360
00	F1	F2	F3	F4	F5	F6	F7	F8

With the following MVC instruction, the zeros in location 358 can be propagated throughout the entire field (assume that register 11 contains 00 00 03 58):

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	07	B	001	B	000

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
MVC	1(8,11),0(11)

Because MVC is executed as if one byte were processed at a time, the above instruction, in effect, takes the byte at address 358 and stores it at 359 (359 now contains 00), takes the byte at 359 and stores it at 35A, and so on, until the entire field is filled with zeros. Note that an MVI instruction could have been used originally to place the byte of zeros in location 358.

Notes:

1. Although the field occupying locations 358-360 contains nine bytes, the length coded in the assembler format is equal to the number of moves (one less than the field length).
2. The order of operands is important even though only one field is involved.

MVI Example

The MOVE (MVI) instruction places one byte of information from the instruction stream into storage. For example, the instruction:

Machine Format

Op Code	I_2	B_1	D_1
92	5B	1	000

Assembler Format

Op Code	$D_1(B_1),I_2$
MVI	0(1),C'$'

may be used, in conjunction with the instruction EDIT AND MARK, to insert the EBCDIC code for a dollar symbol at the storage address contained in general register 1 (see also the example for EDIT AND MARK).

MOVE INVERSE (MVCIN)

The MOVE INVERSE (MVCIN) instruction can be used to move data from one storage location to another while reversing the order of the bytes within the field. For example, assume that the following two fields are in storage:

	2048										2052
Field 1	C1	C2	C3	C4	C5	C6	C7	C8	C9	CA	CB

	3840								3848
Field 2	F1	F2	F3	F4	F5	F6	F7	F8	F9

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
E8	07	1	000	2	007

Assembler Format

Op Code $D_1(L,B_1),D_2(B_2)$

```
  MVCIN  0(8,1),7(2)
```

After the instruction is executed, field 1 becomes:

	2048										2052
Field 1	F8	F7	F6	F5	F4	F3	F2	F1	C9	CA	CB

2048   2052

Field 2 is unchanged.

Note: This example uses the same general registers, storage locations, and original values as the first example for MVC. For MVCIN, the second-operand address must designate the rightmost byte of the field to be moved, in this case location 3847. This is accomplished by means of the 7 in the D_2 field of the instruction.

MOVE LONG (MVCL)

The MOVE LONG (MVCL) instruction can be used for moving data in storage as in the first example of the MVC instruction, provided that the two operands do not overlap. MVCL differs from MVC in that the address and length of each operand are specified in an even-odd pair of general registers. Consequently, MVCL can be used to move more than 256 bytes of data with one instruction. As an example, assume:

Register 2 contains 00 0A 00 00.

Register 3 contains 00 00 08 00.

Register 8 contains 00 06 00 00.

Register 9 contains 00 00 08 00.

Execution of the instruction:

Machine Format

Op Code	R_1	R_2
0E	8	2

Assembler Format

Op Code R_1,R_2

```
  MVCL   8,2
```

moves $2{,}048_{10}$ bytes from locations A0000-A07FF to locations 60000-607FF. Assuming that the CPU is in the 24-bit addressing mode, bits 8-31 of registers 2 and 8 are incremented by 800_{16}, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of registers 3 and 9 are decremented to zero. Condition code 0 is set to indicate that the operand lengths are equal.

If register 3 had contained F0 00 04 00, only the $1{,}024_{10}$ bytes from locations A0000-A03FF would have been moved to locations 60000-603FF. The remaining locations 60400-607FF of the first operand would have been filled with 1,024 copies of the padding byte X‘F0’, as specified by the leftmost byte of register 3. Bits 8-31 of register 2 would have been incremented by 400_{16}, bits 8-31 of register 8 would have been incremented by 800_{16}, and bits 0-7 of registers 2 and 8 would have been set to zeros. Bits 8-31 of registers 3 and 9 would still have been decremented to zero. Condition code 2 would have been set to indicate that the first operand was longer than the second.

The technique for setting a field to zeros that is illustrated in the second example of MVC cannot be used with MVCL. If the registers were set up to attempt such an operation with MVCL, no data movement would take place and condition code 3 would indicate destructive overlap.

Instead, MVCL may be used to clear a storage area to zeros as follows. Assume register 8 and 9 are set up as before. Register 3 contains only zeros, specifying zero length for the second operand and a zero padding byte. Register 2 is not used to access storage, and its contents are not significant. Executing the instruction MVCL 8,2 causes locations 60000-607FF to be filled with zeros. Bits 8-31 of register 8 are incremented by 800_{16}, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of register 9 are decremented to zero, and condition code 2 is set to indicate that the first operand is longer than the second.

MOVE NUMERICS (MVN)

Two related instructions, MOVE NUMERICS and MOVE ZONES, may be used with decimal data in the zoned format to operate separately on the rightmost four bits (the numeric bits) and the leftmost four bits (the zone bits) of each byte. Both are similar to MOVE (MVC), except that MOVE NUMERICS moves only the numeric bits and MOVE ZONES moves only the zone bits.

To illustrate the operation of the MOVE NUMERICS instruction, assume that the following two fields are in storage:

Field A

7090			7093
C6	C7	C8	C9

Field B

7041					7046
F0	F1	F2	F3	F4	F5

Also assume:

Register 14 contains 00 00 70 90.

Register 15 contains 00 00 70 40.

After the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D1	03	F	001	E	000

Assembler Format

Op Code $D_1(L,B_1),D_2(B_2)$

```
 MVN    1(4,15),0(14)
```

is executed, field B becomes:

7041					7046
F6	F7	F8	F9	F4	F5

The numeric bits of the bytes at locations 7090-7093 have been stored in the numeric bits of the bytes at locations 7041-7044. The contents of locations 7090-7093 and 7045-7046 are unchanged.

MOVE STRING (MVST)

The MOVE STRING instruction is used to move a second operand designated by general register R_2 to a first-operand location designated by general register R_1. The movement is made left to right until an ending character specified in general register 0 has been moved or a CPU-determined number of bytes have been moved. The condition code is set to 1 if the ending character was moved or to 3 if a CPU-determined number of bytes were moved.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively.

Following is an example program that sets string A equal to the concatenation of string B followed by string C, where the length of each of strings B and C is unknown, and the end of each of strings B and C is indicated by an ending character of 00 hex (as in the C programming language). The program is not written for execution in the access-register mode.

```
           L       4,STRAADR
           L       5,STRBADR
           SR      0,0
LOOP1      MVST    4,5
           BC      1,LOOP1
           L       5,STRCADR
LOOP2      MVST    4,5
           BC      1,LOOP2
           [Any instruction]
```

MOVE WITH OFFSET (MVO)

MOVE WITH OFFSET may be used to shift a signed-packed-decimal number an odd number of digit positions or to concatenate a sign to an unsigned-packed-decimal number.

Assume that the three-byte unsigned-packed-decimal number in storage locations 4500-4502 is to be moved to locations 5600-5603 and given the sign of the signed-packed-decimal number ending at location 5603. Also assume:

Register 12 contains 00 00 56 00.

Register 15 contains 00 00 45 00.

Storage locations 5600-5603 contain 77 88 99 0C.

Storage locations 4500-4502 contain 12 34 56.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F1	3	2	C	000	F	000

Assembler Format
Op Code $D_1(L_1,B_1),D_2(L_2,B_2)$

```
  MVO    0(4,12),0(3,15)
```

is executed, the storage locations 5600-5603 contain 01 23 45 6C. Note that the second operand is extended on the left with one zero to fill out the first-operand field.

MOVE ZONES (MVZ)

The MOVE ZONES instruction can operate on overlapping or nonoverlapping fields, as can the instructions MOVE (MVC) and MOVE NUMERICS. When operating on nonoverlapping fields, MOVE ZONES works like the MOVE NUMERICS instruction (see its example), except that MOVE ZONES moves only the zone bits of each byte. To illustrate the use of MOVE ZONES with overlapping fields, assume that the following data field is in storage:

800					805
F1	C2	F3	C4	F5	C6

Also assume that register 15 contains 00 00 08 00. The instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D3	04	F	001	F	000

Assembler Format
Op Code $D_1(L,B_1),D_2(B_2)$

```
  MVZ    1(5,15),0(15)
```

propagates the zone bits from the byte at address 800 through the entire field, so that the field becomes:

800					805
F1	F2	F3	F4	F5	F6

MULTIPLY (M, MR)

Assume that a number in register 5 is to be multiplied by the contents of a four-byte field at address 3750. Initially:

The contents of register 4 are not significant.

Register 5 contains 00 00 00 9A = 154_{10} = the multiplicand.

Register 11 contains 00 00 06 00.

Register 12 contains 00 00 30 00.

Storage locations 3750-3753 contain 00 00 00 83 = 131_{10} = the multiplier.

The instruction required for performing the multiplication is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
5C	4	B	C	150

Assembler Format
Op Code $R_1,D_2(X_2,B_2)$

```
  M      4,X'150'(11,12)
```

After the instruction is executed, the product is in the register pair 4 and 5:

Register 4 contains 00 00 00 00.

Register 5 contains 00 00 4E CE = $20{,}174_{10}$.

Storage locations 3750-3753 are unchanged.

The RR format of the instruction can be used to square the number in a register. Assume that register 7 contains 00 01 00 05. The contents of register 6 are not significant. The instruction:

Machine Format

Op Code	R_1	R_2
1C	6	7

Assembler Format
Op Code R_1,R_2

```
  MR     6,7
```

multiplies the number in register 7 by itself and places the result in the pair of registers 6 and 7:

Register 6 contains 00 00 00 01.

Register 7 contains 00 0A 00 19.

MULTIPLY HALFWORD (MH)

The MULTIPLY HALFWORD instruction is used to multiply the contents of a register by a two-byte field in storage. For example, assume that:

Register 11 contains 00 00 00 15 =21_{10} = the multiplicand.

Register 14 contains 00 00 01 00.

Register 15 contains 00 00 20 00.

Storage locations 2102-2103 contain FF D9 = -39_{10} = the multiplier.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4C	B	E	F	002

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
MH	11,2(14,15)

multiplies the two numbers. The product, FF FF FC CD = -819_{10}, replaces the original contents of register 11.

Only the rightmost 32 bits of a product are stored in a register; any significant bits on the left are lost. No program interruption occurs on overflow.

OR (O, OC, OI, OR)

When the Boolean operator OR is applied to two bits, the result is one when either bit is one; otherwise, the result is zero. When two bytes are ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ORing two bytes:

First-operand byte: $0011\ 0101_2$
Second-operand byte: $0101\ 1100_2$

Result byte: $0111\ 1101_2$

OI Example

A frequent use of the OR instruction is to set a particular bit to one. For example, assume that storage location 4891 contains $0100\ 0010_2$. To set the rightmost bit of this byte to one without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

Op Code	I_2	B_1	D_1
96	01	8	001

Assembler Format

Op Code	D_1(B_1),I_2
OI	1(8),X'01'

When this instruction is executed, the byte in storage is ORed with the immediate byte (the I_2 field of the instruction):

Location 4891: $0100\ 0010_2$
Immediate byte: $0000\ 0001_2$

Result: $0100\ 0011_2$

The resulting byte with bit 7 set to one is stored back in location 4891. Condition code 1 is set.

PACK (PACK)

Assume that storage locations 1000-1003 contain the following zoned-decimal number that is to be converted to a signed-packed-decimal number and left in the same location:

	1000			1003
Zoned number	F1	F2	F3	C4

Also assume that register 12 contains 00 00 10 00. After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F2	3	3	C	000	C	000

Assembler Format

Op Code $D_1(L_1,B_1),D_2(L_2,B_2)$

```
 PACK    0(4,12),0(4,12)
```

is executed, the result in locations 1000-1003 is in the signed-packed-decimal format:

	1000			1003
Signed-packed number	00	01	23	4C

Notes:

1. This example illustrates the operation of PACK when the first- and second-operand fields overlap completely.

2. During the operation, the second operand was extended on the left with zeros.

ROTATE THEN EXCLUSIVE OR SELECTED BITS

The following example illustrates the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS to determine if the access-control bits of a page's storage-protection key match the key in the PSW. In this example, only the condition code is set; the result is not placed in the first-operand register.

```
LAY   9,BLOCK   Point to storage block.
IVSK  14,9      Insert key into bits 56-63.
EPSW  4,0       Extract PSW key (bits 40-43).
RXSBG 4,14,128+40,43,16 Compare keys.
```

On completion, the condition code will be set to zero if the PSW key matches the access-control bits in the storage key of page addressed by general register 9. Condition code 1 will be set if the keys do not match.

ROTATE THEN INSERT SELECTED BITS

1. The following example illustrates the use of ROTATE THEN INSERT SELECTED BITS to extract the various DAT-table indices of a virtual address contained in general register 8. This example shows the use of the zero-remaining-bits control to set the remaining bits of the result registers to zero.

   The virtual address in general register 8 is assumed to be 123456789ABCDEF0 hex.

   ```
   RISBG 1,8,53,128+63,11 Get reg. 1st index.
   RISBG 2,8,53,128+63,22 Get reg. 2nd index.
   RISBG 3,8,53,128+63,33 Get reg. 3rd index.
   RISBG 4,8,53,128+63,44 Get segment index.
   RISBG 5,8,56,128+63,52 Get page index.
   RISBG 6,8,52,128+63,0  Get byte index.
   ```

   The condition code following each RISBG is 2. On completion, general registers 1-6 contain the region-first index, region-second index, region-third index, segment index, page index, and byte index, respectively, as follows:

   ```
   GR1: 0000000000000091 (RFX)
   GR2: 0000000000000515 (RSX)
   GR3: 00000000000004F1 (RTX)
   GR4: 00000000000001AB (SX)
   GR5: 00000000000000CD (PX)
   GR6: 0000000000000EF0 (BX)
   ```

2. The following example illustrates shifting a 64-bit value to the left by *L* bits:

   RISBG R_1,R_2,0,X'80'+63-*L*,*L*

3. The following example illustrates shifting a 32-bit value to the right by *R* bits and setting the leftmost 32 bits to zero:

   RISBG R_1,R_2,32+*R*,X'80'+63,-*R*

4. The following example illustrates zeroing bits *S* through *E* of general register 3.

   RISBG 3,3,mod64(*E*+1),128+mod64(*S*-1),0

   Mod64 represents a modulo function which effectively ANDs the value in parentheses with 3F hex.

ROTATE THEN OR SELECTED BITS

The following example illustrates the use of ROTATE THEN OR SELECTED BITS to rotate and combine selected bits of general registers 6 and 8.

```
LG    6,=X'004C487040CF4600'
LG    8,=X'C07FAF37FC968280'
ROSBG 6,8,8,54,32
```

On completion, condition code 1 is set, and general register 6 is as follows:

```
GR6: 00DECAF0C0FFEE00
```

Note that only bits 8-54 of the registers are ORed; bits 0-7 and 55-63 of general register 6 are not modified.

SEARCH STRING (SRST)

The SEARCH STRING instruction is used to search a second operand designated by general register R_2 for a character specified in general register 0. The length of the second operand is known — the address of the first byte after the second operand is in general register R_1.

When the specified character is found, condition code 1 is set, the address of the character is placed in general register R_1, and the contents of general register R_2 remain unchanged. When the address of the next second-operand byte to be examined equals the address in general register R_1, condition code 2 is set, and the contents of general register R_1 and R_2 remain unchanged. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged.

SRST Example 1

Following is an example program that determines the end of string A, as indicated by an ending character equal to 00 hex (as in the C programming language), and then determines the address of the first character equal to C1 hex in the string. The program is based on the assumption that the second operand does not begin at location 0 or wrap around in storage, and, therefore, condition code 2 will not be set by the first SEARCH STRING instruction because of the address in general register 0. The program is not written for execution in the access-register mode.

```
      L     5,STRAADR
      SR    0,0
LOOP1 SRST  0,5
      BC    1,LOOP1
      L     5,STRAADR
      LR    4,0
      LA    0,X'C1'
LOOP2 SRST  4,5
      BC    1,LOOP2
      BC    2,NOTFND
FOUND [Any instruction]
      ...
NOTFND [Any instruction]
```

SRST Example 2

Following is an example program that determines the address of the first character equal to C1 hex in the string A whose length is known. The program is not written for execution in the access-register mode.

```
      L     5,STRAADR
      L     4,STRALEN
      AR    4,5
      LA    0,X'C1'
LOOP1 SRST  4,5
      BC    1,LOOP1
      BC    2,NOTFND
FOUND [Any instruction]
      ...
NOTFND [Any instruction]
```

In this example, the value in STRALEN may be a length that either does or does not include an ending character at the end of the string, provided that the ending character is not the character for which the search is made.

SHIFT LEFT DOUBLE (SLDA)

The SHIFT LEFT DOUBLE instruction shifts the 63 numeric bits of an even-odd register pair to the left, leaving the sign bit unchanged. Thus, the instruction performs an algebraic left shift of a 64-bit signed binary integer.

For example, if the contents of registers 2 and 3 are:

```
00 7F 0A 72   FE DC BA 98 =
00000000 01111111 00001010 01110010
11111110 11011100 10111010 10011000₂
```

The instruction:

Machine Format

Op Code	R_1		B_2	D_2
8F	2	////	0	01F

Assembler Format
Op Code R_1,D_2(B_2)

```
 SLDA    2,31(0)
```

results in registers 2 and 3 both being left-shifted 31 bit positions, so that their new contents are:

7F 6E 5D 4C   00 00 00 00 =
01111111 01101110 01011101 01001100
00000000 00000000 00000000 00000000$_2$

Because significant bits are shifted out of bit position 1 of register 2, overflow is indicated by setting condition code 3, and, if the fixed-point-overflow mask bit in the PSW is one, a fixed-point-overflow program interruption occurs.

SHIFT LEFT SINGLE (SLA)

The SHIFT LEFT SINGLE instruction is similar to SHIFT LEFT DOUBLE, except that it shifts only the 31 numeric bits of a single register. Therefore, this instruction performs an algebraic left shift of a 32-bit signed binary integer.

For example, if the contents of register 2 are:

00 7F 0A 72 = 00000000 01111111 00001010 01110010$_2$

The instruction:

Machine Format

Op Code	R_1		B_2	D_2
8B	2	////	0	008

Assembler Format
Op Code R_1,D_2(B_2)

```
  SLA    2,8(0)
```

results in register 2 being shifted left eight bit positions so that its new contents are:

7F 0A 72 00 = 01111111 00001010 01110010 00000000$_2$

Condition code 2 is set to indicate that the result is greater than zero.

If a left shift of nine places had been specified, a significant bit would have been shifted out of bit position 1. Condition code 3 would have been set to indicate this overflow and, if the fixed-point-overflow mask bit in the PSW were one, a fixed-point overflow interruption would have occurred.

STORE CHARACTERS UNDER MASK (STCM)

STORE CHARACTERS UNDER MASK (STCM) may be used to place selected bytes from a register into storage. For example, if it is desired to store a three-byte address from general register 8 into location FIELD3, assume:

Machine Format

Op Code	R_1	M_3	S_2
BE	8	7	* * * *

Register Format
Op Code R_1,M_3,S_2

```
 STCM    8,B'0111',FIELD3

Register 8:        12 34 56 78
FIELD3 (before):   not significant
FIELD3 (after):    34 56 78
```

As another example:

Machine Format

Op Code	R_1	M_3	S_2
BE	9	5	* * * *

Register Format
Op Code R_1,M_3,S_2

```
 STCM    9,B'0101',FIELD2

Register 9:       01 23 45 67
FIELD2 (before): not significant
FIELD2 (after):  23 67
```

STORE MULTIPLE (STM)

Assume that the contents of general registers 14, 15, 0, and 1 are to be stored in consecutive four-byte fields starting with location 4050 and that:

Register 14 contains 00 00 25 63.

Register 15 contains 00 01 27 36.

Register 0 contains 12 43 00 62.

Register 1 contains 73 26 12 57.

Register 6 contains 00 00 40 00.

The initial contents of locations 4050-405F are not significant.

The STORE MULTIPLE instruction allows the use of just one instruction to store the contents of the four registers:

Machine Format

Op Code	R_1	R_3	B_2	D_2
90	E	1	6	050

Assembler Format
Op Code R_1,R_3,D_2(B_2)

```
  STM    14,1,X'50'(6)
```

After the instruction is executed:

Locations 4050-4053 contain 00 00 25 63.

Locations 4054-4057 contain 00 01 27 36.

Locations 4058-405B contain 12 43 00 62.

Locations 405C-405F contain 73 26 12 57.

TEST UNDER MASK (TM)

The TEST UNDER MASK instruction examines selected bits of a byte and sets the condition code accordingly. For example, assume that:

Storage location 9999 contains FB.

Register 7 contains 00 00 99 90.

Assume the instruction to be:

Machine Format

Op Code	I_2	B_1	D_1
91	C3	7	009

Assembler Format
Op Code D_1(B_1),I_2

```
   TM    9(7),B'11000011'
```

The instruction tests only those bits of the byte in storage for which the mask bits are ones:

FB = $1111\ 1011_2$
Mask = $1100\ 0011_2$

Test = $11xx\ xx11_2$

Condition code 3 is set: all selected bits in the test result are ones. (The bits marked “x” are ignored.)

If location 9999 had contained B9, the test would have been:

B9 = $1011\ 1001_2$
Mask = $1100\ 0011_2$

Test = $10xx\ xx01_2$

Condition code 1 is set: the selected bits are both zeros and ones.

If location 9999 had contained 3C, the test would have been:

3C = $0011\ 1100_2$
Mask = $1100\ 0011_2$

Test = $00xx\ xx00_2$

Condition code 0 is set: all selected bits are zeros.

Note: Storage location 9999 remains unchanged.

TRANSLATE (TR)

The TRANSLATE instruction can be used to translate data from any character code to any other desired code, provided that each character code consists of eight bits or fewer. An appropriate translation table is required in storage.

In the following example, EBCDIC code is translated to ASCII code. The first step is to create a 256-byte table in storage locations 1000-10FF. This table contains the characters of the ASCII code in the sequence of the binary representation of the EBCDIC code; that is, the ASCII representation of a character is placed in storage at the starting address of the table plus the binary value of the EBCDIC representation of the same character.

For simplicity, the example shows only the part of the table containing the decimal digits:

10F0									10F9
30	31	32	33	34	35	36	37	38	39

Assume that the four-byte field at storage location 2100 contains the EBCDIC code for the digits 1984:

Locations 2100-2103 contain F1 F9 F8 F4.

Register 12 contains 00 00 21 00.

Register 15 contains 00 00 10 00.

As the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DC	03	C	000	F	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
─────────────────────────
   TR    0(4,12),0(15)
```

is executed, the binary value of each EBCDIC byte is added to the starting address of the table, and the resulting address is used to fetch an ASCII byte:

```
Table starting address:    1000
First EBCDIC byte:           F1
─────────────────────────────────
Address of ASCII byte:     10F1
```

After execution of the instruction:

Locations 2100-2103 contain 31 39 38 34.

Thus, the ASCII code for the digits 1984 has replaced the EBCDIC code in the four-byte field at storage location 2100.

TRANSLATE AND TEST (TRT)

The TRANSLATE AND TEST instruction can be used to scan a data field for characters with a special meaning. To indicate which characters have a special meaning, a table similar to the one used for the TRANSLATE instruction is set up, except that zeros in the table indicate characters without any special meaning and nonzero values indicate characters with a special meaning.

Figure A-4 on page A-34 has been set up to distinguish alphameric characters (A to Z and 0 to 9) from blanks, certain special symbols, and all other characters which are considered invalid. EBCDIC coding is assumed. The 256-byte table is assumed stored at locations 2000-20FF.

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
200_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
201_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
202_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
203_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
204_	04	40	40	40	40	40	40	40	40	40	40	08	40	0C	10	40
205_	14	40	40	40	40	40	40	40	40	40	40	18	1C	20	40	40
206_	24	28	40	40	40	40	40	40	40	40	40	2C	40	40	40	40
207_	40	40	40	40	40	40	40	40	40	40	40	30	34	38	3C	40
208_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
209_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20A_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20B_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20C_	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20D_	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20E_	40	40	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20F_	00	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40

Note: If the character codes in the statement being translated occupy a range smaller than 00 through FF_{16}, a table of fewer than 256 bytes can be used.

Figure A-4. Translate and Test Table

The table entries for the alphameric characters in EBCDIC are 00; thus, the letter A (code C1) corresponds to byte location 20C1, which contains 00.

The 15 special symbols have nonzero entries from 04_{16} to $3C_{16}$ in increments of 4. Thus, the blank (code 40) has the entry 04_{16}, the period (code 4B) has the entry 08_{16}, and so on.

All other table positions have the entry 40_{16} to indicate an invalid character.

The table entries are chosen so that they may be used to select one of a list of 16 words containing addresses of different routines to be entered for each special symbol or invalid character encountered during the scan.

Assume that this list of 16 branch addresses is stored at locations 3004-3043.

Starting at storage location CA80, there is the following sequence of 21_{10} EBCDIC characters, where “b” stands for a blank.

Locations CA80-CA94:
UNPKbPROUT(9),WORD(5)

Also assume:

Register 1 contains 00 00 CA 7F.

Register 2 contains 00 00 30 00.

Register 15 contains 00 00 20 00.

As the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DD	14	1	001	F	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
________________________

  TRT    1(21,1),0(15)
```

is executed, the value of the first source byte, the EBCDIC code for the letter U, is added to the starting address of the table to produce the address of the table entry to be examined:

```
Table starting address      2000
First source byte (U)         E4
________________________________

Address of table entry      20E4
```

Because zeros were placed in storage location 20E4, no special action occurs. The operation continues with the second and subsequent source bytes until it reaches the blank in location CA84. When this symbol is reached, its value is added to the starting address of the table, as usual:

```
Table starting address      2000
Source byte (blank)           40
________________________________

Address of table entry      2040
```

Because location 2040 contains a nonzero value, the following actions occur:

The address of the source byte, 00CA84, is placed in the rightmost 24 bits of register 1.

The table entry, 04, is placed in the rightmost eight bits of register 2, which now contains 00 00 30 04.

Condition code 1 is set (scan not completed).

The TRANSLATE AND TEST instruction may be followed by instructions to branch to the routine at the address found at location 3004, which corresponds to the blank character encountered in the scan. When this routine is completed, program control may return to the TRANSLATE AND TEST instruction to continue the scan, except that the length must first be adjusted for the characters already scanned.

For this purpose, the TRANSLATE AND TEST may be executed by the use of an EXECUTE instruction, which supplies the length specification from a general register. In this way, a complete statement scan can be performed with a single TRANSLATE AND TEST instruction used repeatedly by means of EXECUTE, and without modifying any instructions in storage. In the example, after the first execution of TRANSLATE AND TEST, register 1 contains the address of the last source byte translated. It is then a simple matter to subtract this address from the address of the last source byte (CA94) to produce a length specification. This length minus one is placed in the register that is referenced as the R_1 field of the EXECUTE instruction. (Note that the length code in the machine format is one less than the total number of bytes in the field.) The second-operand address of the EXECUTE instruction points to the TRANSLATE AND TEST instruction, which is the same as illustrated above, except for the length (L) which is set to zero.

UNPACK (UNPK)

Assume that storage locations 2501-2502 contain a signed-packed-decimal number that is to be unpacked and placed in storage locations 1000-1004. Also assume:

Register 12 contains 00 00 10 00.

Register 13 contains 00 00 25 00.

Storage locations 2501-2502 contain 12 3D.

The initial contents of storage locations 1000-1004 are not significant.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F3	4	1	C	000	D	001

Assembler Format

Op Code	$D_1(L_1,B_1),D_2(L_2,B_2)$
UNPK	0(5,12),1(2,13)

is executed, the storage locations 1000-1004 contain F0 F0 F1 F2 D3.

UPDATE TREE (UPT)

See “Sorting Instructions” on page A-53.

Decimal Instructions

(See Chapter 8, “Decimal Instructions” for a complete description of the decimal instructions.)

ADD DECIMAL (AP)

Assume that the signed-packed-decimal number at storage locations 500-503 is to be added to the signed-packed-decimal number at locations 2000-2002. Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 05 00.

Storage locations 2000-2002 contain 38 46 0D (a negative number).

Storage locations 500-503 contain 01 12 34 5C (a positive number).

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FA	2	3	C	000	D	000

Assembler Format

Op Code	$D_1(L_1,B_1),D_2(L_2,B_2)$
AP	0(3,12),0(4,13)

is executed, the storage locations 2000-2002 contain 73 88 5C; condition code 2 is set to indicate that the result is greater than zero. Note that:

1. Because the two numbers had different signs, they were in effect subtracted.
2. Although the second operand is longer than the first operand, no overflow interruption occurs because the result can be entirely contained within the first operand.

COMPARE DECIMAL (CP)

Assume that the signed-packed-decimal contents of storage locations 700-703 are to be algebraically compared with the signed-packed-decimal contents of locations 500-502. Also assume:

Register 12 contains 00 00 06 00.

Register 13 contains 00 00 03 00.

Storage locations 700-703 contain 17 25 35 6D.

Storage locations 500-502 contain 72 14 2D.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F9	3	2	C	100	D	200

Assembler Format

Op Code	$D_1(L_1,B_1),D_2(L_2,B_2)$
CP	X'100'(4,12),X'200'(3,13)

is executed, condition code 1 is set, indicating that the first operand (the contents of locations 700-703) is less than the second.

DIVIDE DECIMAL (DP)

Assume that the signed-packed-decimal number at storage locations 2000-2004 (the dividend) is to be divided by the signed-packed-decimal number at locations 3000-3001 (the divisor). Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 30 00.

Storage locations 2000-2004 contain 01 23 45 67 8C.

Storage locations 3000-3001 contain 32 1D.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FD	4	1	C	000	D	000

Assembler Format

```
Op Code  D₁(L₁,B₁),D₂(L₂,B₂)
___________________________

   DP    0(5,12),0(2,13)
```

is executed, the dividend is entirely replaced by the signed quotient and remainder, as follows:

	2000				2004
Locations 2000-2004	38	46	0D	01	8C
	quotient			remainder	

Notes:

1. Because the dividend and divisor have different signs, the quotient receives a negative sign.
2. The remainder receives the sign of the dividend and the length of the divisor.
3. If an attempt were made to divide the dividend by the one-byte field at location 3001, the quotient would be too long to fit within the four bytes allotted to it. A decimal-divide exception would exist, causing a program interruption.

EDIT (ED)

Before data in the signed-packed-decimal or unsigned-packed-decimal format can be used in a printed report, digits and signs must be converted to printable characters. Moreover, punctuation marks, such as commas and decimal points, may have to be inserted in appropriate places. The highly flexible EDIT instruction performs these functions in a single instruction execution.

This example shows step-by-step one way that the EDIT instruction can be used. The field to be edited (the source) is four bytes long; it is edited against a pattern 13 bytes long. The following symbols are used:

Symbol	Meaning
b (Hexadecimal 40)	Blank character
((Hexadecimal 21)	Significance starter
d (Hexadecimal 20)	Digit selector

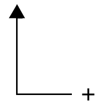
Assume that register 12 contains:

```
00 00 10 00
```

and that the source and pattern fields are:

Source

1200			1203
02	57	42	6C



Pattern

1000												100C
40	20	20	6B	20	21	20	4B	20	20	40	C3	D9
b	d	d	,	d	(	d	.	d	d	b	C	R

Execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DE	0C	C	000	C	200

Assembler Format

```
Op Code  D₁(L,B₁),D₂(B₂)
________________________

   ED    0(13,12),X'200'(12)
```

alters the pattern field as follows:

Pattern	Digit	Significance Indicator (Before/ After)	Rule	Location 1000-100C
b		off/off	leave(1)	bdd,d(d.ddbCR
d	0	off/off	fill	bbd,d(d.ddbCR
d	2	off/on(2)	digit	bb2,d(d.ddbCR
,		on/on	leave	same
d	5	on/on	digit	bb2,5(d.ddbCR
(	7	on/on	digit	bb2,57d.ddbCR
d	4	on/on	digit	bb2,574.ddbCR
.		on/on	leave	same
d	2	on/on	digit	bb2,574.2dbCR
d	6+	on/off(3)	digit	bb2,574.26bCR
b		off/off	fill	same
C		off/off	fill	bb2,574.26bbR
R		off/off	fill	bb2,574.26bbb

Notes:
1. This character is the fill byte.
2. First nonzero decimal source digit turns on significance indicator.
3. Plus sign in the four rightmost bits of the byte turns off significance indicator.

Thus, after the instruction is executed, the pattern field contains the result as follows:

Pattern

1000												100C
40	40	F2	6B	F5	F7	F4	4B	F2	F6	40	40	40
b	b	2	,	5	7	4	.	2	6	b	b	b

This pattern field prints as:

```
2,574.26
```

The source field remains unchanged. Condition code 2 is set because the number was greater than zero.

If the number in the source field is changed to the negative number 00 00 02 6D and the original pattern is used, the edited result this time is:

Pattern

1000												100C
40	40	40	40	40	40	F0	4B	F2	F6	40	C3	D9
b	b	b	b	b	b	0	.	2	6	b	C	R

This pattern field prints as:

```
0.26 CR
```

The significance starter forces the significance indicator to the on state and hence causes a leading zero and the decimal point to be preserved. Because the minus-sign code has no effect on the significance indicator, the characters CR are printed to show a negative (credit) amount.

Condition code 1 is set (number less than zero).

EDIT AND MARK (EDMK)

The EDIT AND MARK instruction may be used, in addition to the functions of EDIT, to insert a currency symbol, such as a dollar sign, at the appropriate position in the edited result. Assume the same source in storage locations 1200-1203, the same pattern in locations 1000-100C, and the same contents of general register 12 as for the EDIT instruction above. The previous contents of general register 1 (GR1) are not significant; a LOAD ADDRESS instruction is used to set up the first digit position that is forced to print if no significant digits occur to the left.

The instructions:

LA	1,6(0,12)	Load address of forced significant digit into GR1
EDMK	0(13,12),X‘200’(12)	Leave address of first significant digit in GR1
BCTR	1,0	Subtract 1 from address in GR1
MVI	0(1),C ‘$’	Store dollar sign at address in GR1

produce the following results for the two examples under EDIT:

Pattern

1000												100C
40	5B	F2	6B	F5	F7	F4	4B	F2	F6	40	40	40
b	$	2	,	5	7	4	.	2	6	b	b	b

This pattern field prints as:

```
$2,574.26
```

Condition code 2 is set to indicate that the number edited was greater than zero.

Pattern

1000												100C
40	40	40	40	40	5B	F0	4B	F2	F6	40	C3	D9
b	b	b	b	b	$	0	.	2	6	b	C	R

This pattern field prints as:

```
    $0.26 CR
```

Condition code 1 is set because the number is less than zero.

MULTIPLY DECIMAL (MP)

Assume that the signed-packed-decimal number in storage locations 1202-1204 (the multiplicand) is to be multiplied by the signed-packed-decimal number in locations 500-501 (the multiplier).

	1202		1204
Multiplicand	38	46	0D

	500	501
Multiplier	32	1D

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field. Assume:

Register 4 contains 00 00 12 00.

Register 6 contains 00 00 05 00.

Then execution of the instruction:

```
ZAP X'100'(5,4),2(3,4)
```

sets up a new multiplicand in storage locations 1300-1304:

	1300				1304
Multiplicand (new)	00	00	38	46	0D

Now, after the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FC	4	1	4	100	6	000

Assembler Format
Op Code $D_1(L_1,B_1),D_2(L_2,B_2)$

```
   MP  X'100'(5,4),0(2,6)
```

is executed, storage locations 1300-1304 contain the product: 01 23 45 66 0C.

SHIFT AND ROUND DECIMAL (SRP)

The SHIFT AND ROUND DECIMAL (SRP) instruction can be used for shifting decimal numbers in storage to the left or right. When a number is shifted right, rounding can also be done.

Decimal Left Shift

In this example, the contents of storage location FIELD1 are shifted three places to the left, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

Machine Format

Op Code	L_1	I_3	S_1	B_2	D_2
F0	5	0	* * * *	0	003

Assembler Format
Op Code $S_1(L_1),S_2,I_3$

```
  SRP   FIELD1(6),3,0

FIELD1 (before):  00 01 23 45 67 8C

FIELD1 (after):   12 34 56 78 00 0C
```

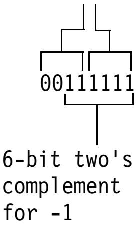
The second-operand address in this instruction specifies the shift amount (three places). The rounding digit, I_3, is not used in a left shift, but it must be a valid decimal digit. After execution, condition code 2 is set to show that the result is greater than zero.

Decimal Right Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively dividing the contents of FIELD2 by 10 and discarding the remainder. FIELD2 is five bytes in length. The following instruction performs this operation:

Machine Format

Op Code	L_1	I_3	S_1	B_2	D_2
F0	4	0	* * * *	0	03F



Assembler Format
Op Code $S_1(L_1),S_2,I_3$

```
  SRP   FIELD2(5),64-1,0

FIELD 2 (before):  01 23 45 67 8C

FIELD 2 (after):   00 12 34 56 7C
```

In the SRP instruction, shifts to the right are specified in the second-operand address by negative shift values, which are represented as a six-bit value in two's complement form.

The six-bit two's complement of a number, n, can be specified as 64 - n. In this example, a right shift of one is represented as 64 - 1.

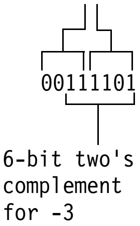
Condition code 2 is set.

Decimal Right Shift and Round

In this example, the contents of storage location FIELD3 are shifted three places to the right and rounded, in effect dividing by 1000 and rounding up. FIELD3 is four bytes in length.

Machine Format

Op Code	L_1	I_3	S_1	B_2	D_2
F0	3	5	* * * *	0	03D



Assembler Format
Op Code $S_1(L_1),S_2,I_3$

```
  SRP   FIELD3(4),64-3,5

FIELD 3 (before):  12 39 60 0D

FIELD 3 (after):   00 01 24 0D
```

The shift amount (three places) is specified in the D_2 field. The I_3 field specifies a rounding digit of 5. The rounding digit is added to the last digit shifted out (which is a 6), and the carry is propagated to the left. The sign is ignored during the addition.

Condition code 1 is set because the result is less than zero.

Multiplying by a Variable Power of 10

Since the shift value specified by the SRP instruction specifies both the direction and amount of the shift, the operation is equivalent to multiplying the decimal first operand by 10 raised to the power specified by the shift value.

If the shift value is to be variable, it may be specified by the B_2 field instead of the displacement D_2 of the SRP instruction. The general register designated by B_2 should contain the shift value (power of 10) as a signed binary integer.

A fixed scale factor modifying the variable power of 10 may be specified by using both the B_2 field (variable part in a general register) and the D_2 field (fixed part in the displacement).

The SRP instruction uses only the rightmost six bits of the effective address $D_2(B_2)$ and interprets them as a six-bit signed binary integer to control the left or right shift as in the preceding shift examples.

ZERO AND ADD (ZAP)

Assume that the signed-packed-decimal number at storage locations 4500-4502 is to be moved to locations 4000-4004 with four leading zeros in the result field. Also assume:

> Register 9 contains 00 00 40 00.
>
> Storage locations 4000-4004 contain 12 34 56 78 90.
>
> Storage locations 4500-4502 contain 38 46 0D.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F8	4	2	9	000	9	500

Assembler Format

Op Code $D_1(L_1,B_1),D_2(L_2,B_2)$

```
  ZAP   0(5,9),X'500'(3,9)
```

is executed, the storage locations 4000-4004 contain 00 00 38 46 0D; condition code 1 is set to indicate a negative result without overflow.

Note that, because the first operand is not checked for valid sign and digit codes, it may contain any combination of hexadecimal digits before the operation.

Hexadecimal-Floating-Point Instructions

(See Chapter 9, “Floating-Point Overview and Support Instructions” for a complete description of the hexadecimal-floating-point instructions.)

In this section, the abbreviations FPR0, FPR2, FPR4, and FPR6 stand for floating-point registers 0, 2, 4, and 6 respectively.

ADD NORMALIZED (AD, ADR, AE, AER, AXR)

The ADD NORMALIZED instruction performs the addition of two HFP numbers and places the normalized result in a floating-point register. Neither of the two numbers to be added must necessarily be in normalized form before addition occurs. For example, assume that:

> FPR6 contains the unnormalized number C3 08 21 00 00 00 00 00 = -82.1_{16} = -130.06_{10} approximately.
>
> Storage locations 2000-2007 contain the normalized number 41 12 34 56 00 00 00 00 = $+1.23456_{16}$ = $+1.14_{10}$ approximately.
>
> Register 13 contains 00 00 20 00.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
7A	6	0	D	000

Assembler Format

Op Code $R_1,D_2(X_2,B_2)$

```
   AE    6,0(0,13)
```

performs the short-precision addition of the two operands, as follows.

The characteristics of the two numbers (43 and 41) are compared. Since the number in storage has a characteristic that is smaller by 2, it is right-shifted two hexadecimal digit positions. One guard digit is retained on the right. The fractions of the two numbers are then added algebraically:

	Fraction	GD[1]
FPR6	-43 08 21 00	
Shifted number from storage	+43 00 12 34	5
Intermediate sum	-43 08 0E CB	B
Left-shifted sum	-42 80 EC BB	

[1] Guard digit

Because the intermediate sum is unnormalized, it is left-shifted to form the normalized HFP number $-80.ECBB_{16}$ = -128.92_{10} approximately. Combining the sign with the characteristic, the result is C2 80 EC BB, which replaces the left half of FPR6. The right half of FPR6 and the contents of storage locations 2000-2007 are unchanged. Condition code 1 is set to indicate a result less than zero.

If the long-precision instruction AD were used, the result in FPR6 would be C2 80 EC BA A0 00 00 00. Note that use of the long-precision instruction would avoid a loss of precision in this example.

ADD UNNORMALIZED (AU, AUR, AW, AWR)

The ADD UNNORMALIZED instruction operates the same as the ADD NORMALIZED instruction, except that the final result is not normalized. For example, using the same operands as in the example for ADD NORMALIZED, when the short-precision instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
7E	6	0	D	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
─────────────────────
  AU     6,0(0,13)
```

is executed, the two numbers are added as follows:

```
                              Fraction GD1
FPR6                          -43 08 21 00
Shifted number from storage   +43 00 12 34  5
─────────────────────────────────────────────
Intermediate sum              -43 08 0E CB  B
```

[1] Guard digit

The guard digit participates in the addition but is discarded. The unnormalized sum replaces the left half of FPR6. Condition code 1 is set because the result is less than zero.

The truncated result in FPR6 (C3 08 0E CB 00 00 00 00) shows a loss of a significant digit when compared to the result of short-precision normalized addition.

COMPARE (CD, CDR, CE, CER)

Assume that FPR4 contains 43 00 00 00 00 00 00 00 (zero), and FPR6 contains 35 12 34 56 78 9A BC DE (a positive number). The contents of the two registers are to be compared using a long-precision COMPARE instruction.

Machine Format

Op Code	R_1	R_2
29	4	6

Assembler Format

```
Op Code  R1,R2
──────────────
  CDR    4,6
```

The number with the smaller characteristic, which is in register FPR6, is right-shifted 43 - 35 hex (67 - 53 decimal) or 14 digit positions, so that the two characteristics agree. The shifted number is 43 00 00 00 00 00 00 00, with a guard digit of one. Therefore, when the two numbers are compared, condition code 1 is set, indicating that operand 1 in FPR4 is less than operand 2 in FPR6.

If the example is changed to a second operand with a characteristic of 34 instead of 35, so that FPR6 contains 34 12 34 56 78 9A BC DE, the operand is right-shifted 15 positions, leaving all fraction digits and the guard digit as zeros. Condition code 0 is set, indicating equality. This example shows that two HFP numbers with different characteristics or fractions may compare equal if the numbers are unnormalized or zero.

As another example of comparing unnormalized HFP numbers, 41 00 12 34 56 78 9A BC compares equal to all numbers of the form 3F 12 34 56 78 9A BC 0X (X represents any hexadecimal digit). When the COMPARE instruction is executed, the two rightmost digits are shifted right two places, the 0 becomes the guard digit, and the X does not participate in the comparison.

However, when two normalized HFP numbers are compared, the relationship between numbers that compare equal is unique: each digit in one number must be the same as the corresponding digit in the other number.

DIVIDE (DD, DDR, DE, DER)

Assume that the first operand (the dividend) is in FPR2 and the second operand (the divisor) in FPR0. If the operands are in the short-precision format, the resulting quotient is returned to FPR2 by the instruction:

Machine Format

Op Code	R_1	R_2
3D	2	0

Assembler Format

```
Op Code  R1,R2
──────────────
  DER    2,0
```

Several examples of short-precision HFP division, with the dividend in FPR2 and the divisor in FPR0, are shown below. For case A, the result, which replaces the dividend, is obtained in the following steps.

```
              7.2522F
       ______________
.123400|.821000
         7F6C00
         --------
          2A400 0
          24680 0
           --------
           5D80 00
           5B04 00
            --------
            27C 000
            246 800
             --------
             35 8000
             24 6800
             --------
             11 18000
             11 10C00
             --------
                 7400
```

Case	FPR2 Before (Dividend)	FPR0 (Divisor)	FPR2 After (Quotient)
A	-43 082100	+43 001234	-42 72522F
B	+42 101010	+45 111111	+3D F0F0F0
C	+48 30000F	+41 400000	+47 C0003C
D	+48 30000F	+41 200000	+48 180007
E	+48 180007	+41 200000	+47 C00038

Case C shows a number being divided by 4.0. Case D divides the same number by 2.0, and case E divides the result of case D again by 2.0. The results of cases C and E differ in the rightmost hexadecimal digit position, which illustrates an effect of result truncation.

HALVE (HDR, HER)

HALVE produces the same result as HFP DIVIDE with a divisor of 2.0. Assume FPR2 contains the long-precision number +48 30 00 00 00 00 00 0F. The following HALVE instruction produces the result +48 18 00 00 00 00 00 07 in FPR2:

Machine Format

Op Code	R_1	R_2
24	2	2

Assembler Format

```
Op Code  R1,R2
──────────────
  HDR    2,2
```

MULTIPLY (MD, MDR, MDE, MDER, MXD, MXDR, MXR)

For this example, the following long-precision operands are in FPR0 and FPR2:

```
FPR0:  -33 606060 60606060
FPR2:  -5A 200000 20000020
```

A long-precision product is generated by the instruction:

Machine Format

Op Code	R_1	R_2
2C	0	2

Assembler Format

```
Op Code  R1,R2
──────────────
  MDR    0,2
```

If the operands were not already normalized, the instruction would first normalize them. It then generates an intermediate result consisting of the full 28-digit hexadecimal product fraction obtained by multiplying the 14-digit hexadecimal operand fractions, together with the appropriate sign and a characteristic that is the sum of the operand characteristics less 64 (40 hex):

The fraction multiplication is performed as follows:

```
              .60606060606060
              .20000020000020
              ---------------
              C0C0C0C0C0C0C00
        C0C0C0C0C0C0C0
  C0C0C0C0C0C0C0
-----------------------------
.0C0C0C181818241818180C0C0C00
```

Attaching the sign and characteristic to the fraction gives:

```
+4D 0C0C0C 18181824 1818180C 0C0C00
```

Because this intermediate product has a leading zero, it is then normalized. The truncated final result placed in FPR0 is:

```
+4C C0C0C1 81818241
```

Hexadecimal-Floating-Point-Number Conversion

The following examples illustrate one method of converting between binary fixed-point numbers (32-bit signed binary integers) and normalized HFP numbers. Conversion must provide for the different representations used with negative numbers: the two's-complement form for signed binary integers, and the signed-absolute-value form for the fractions of HFP numbers.

Fixed Point to Hexadecimal Floating Point

The method used here inverts the leftmost bit of the 32-bit signed binary integer, which is equivalent to adding 2^{31} to the number and considering the result to be positive. This changes the number from a signed integer in the range 2^{31} - 1 through -2^{31} to an unsigned integer in the range 2^{32} - 1 through 0. After conversion to the long HFP format, the value 2^{31} is subtracted again.

Assume that general register 9 (GR9) contains the integer -59 in two's-complement form:

```
GR9:     FF FF FF C5
```

Further, assume two eight-byte fields in storage: TEMP, for use as temporary storage, and TWO31, which contains the floating-point constant 2^{31} in the following format:

```
TWO31:   4E 00 00 00 80 00 00 00
```

This is an unnormalized long HFP number with the characteristic 4E, which corresponds to a radix point (hexadecimal point) to the right of the number.

The following instruction sequence performs the conversion:

		Result
X	9,TWO31+4	GR9: 7FFF FFC5
ST	9,TEMP+4	TEMP: xxxx xxxx 7FFF FFC5
MVC	TEMP(4),TWO31	TEMP: 4E00 0000 7FFF FFC5
LD	2,TEMP	FPR2: 4E00 0000 7FFF FFC5
SD	2,TWO31	FPR2: C23B 0000 0000 0000

The EXCLUSIVE OR (X) instruction inverts the leftmost bit in general register 9, using the right half of the constant as the source for a leftmost one bit. The next two instructions assemble the modified number in an unnormalized long HFP format, using the left half of the constant as the plus sign, the characteristic, and the leading zeros of the fraction. LOAD (LD) places the number unchanged in floating-point register 2. The SUBTRACT NORMALIZED (SD) instruction performs the final two steps by subtracting 2^{31} in HFP form and normalizing the result.

Hexadecimal Floating Point to Fixed Point

The procedure described here consists basically in reversing the steps of the previous procedure. Two additional considerations must be taken into account. First: the HFP number may not be an exact integer. Truncating the excess hexadecimal digits on the right requires shifting the number one digit position farther to the right than desired for the final result, so that the units digit occupies the position of the guard digit. Second: the HFP number may have to be tested as to whether it is outside the range of numbers representable as a 32-bit signed binary integer.

Assume that floating-point register 6 contains the number $59.25_{10} = 3B.4_{16}$ in normalized form:

```
FPR6:     42 3B 40 00 00 00 00 00
```

Further, assume three eight-byte fields in storage: TEMP, for use as temporary storage, and the constants 2^{32} (TWO32) and 2^{31} (TWO31R) in the following formats:

```
TWO32:    4E 00 00 01 00 00 00 00
TWO31R:   4F 00 00 00 08 00 00 00
```

The constant TWO31R is shifted right one more position than the constant TWO31 of the previous example, so as to force the units digit into the guard-digit position.

The following instruction sequence performs the integer truncation, range tests, and conversion to a signed binary integer in general register 8 (GR8):

		Result
SD	6,TWO31R	FPR6: C87F FFFF C500 0000
BC	11,OVERFLOW	Branch to overflow routine if result is greater than or equal to zero
AW	6,TWO32	FPR6: 4E00 0000 8000 003B
BC	4,OVERFLOW	Branch to overflow routine if result is less than zero
STD	6,TEMP	TEMP: 4E00 0000 8000 003B
XI	TEMP+4,X‘80’	TEMP: 4E00 0000 0000 003B
L	8,TEMP+4	GR8: 0000 003B

The SUBTRACT NORMALIZED (SD) instruction shifts the fraction of the number to the right until it lines up with TWO31R, which causes the fraction digit 4 to fall to the right of the guard digit and be lost; the result of subtracting 2^{31} from the remaining digits is renormalized. The result should be less than zero; if not, the original number was too large in the positive direction. The first BRANCH ON CONDITION (BC) performs this test.

The ADD UNNORMALIZED (AW) instruction adds 2^{32}: 2^{31} to correct for the previous subtraction and another 2^{31} to change to an all-positive range. The second BC tests for a result less than zero, showing that the original number was too large in the negative direction. The unnormalized result is placed in temporary storage by the STORE (STD) instruction. There the leftmost bit of the binary integer is inverted by the EXCLUSIVE OR (XI) instruction to subtract 2^{31} and thus convert the unsigned number to the signed format. The final result is loaded into GR8.

Multiprogramming and Multiprocessing Examples

When two or more programs sharing common storage locations are being executed concurrently in a multiprogramming or multiprocessing environment, one program may, for example, set a flag bit in the common-storage area for testing by another program. It should be noted that the instructions AND (NI, NIY, or NC), EXCLUSIVE OR (XI, XIY, or XC), and OR (OI, OIY, or OC) could be used to set flag bits in a multiprogramming environment; but when the interlocked-access facility 2 is not installed, the same instructions may cause program logic errors in a multiprocessing configuration where two or more CPUs can fetch, modify, and store data in the same storage locations simultaneously.

Example of a Program Failure Using OR Immediate

The following example assumes that the interlocked-access facility 2 is not installed.

Assume that two independent programs try to set different bits to one in a common byte in storage. The following example shows how the use of the instruction OR immediate (OI) can fail to accomplish this, if the programs are executed simultaneously on two different CPUs. One of the possible error situations is depicted.

Execution of instruction OI FLAGS,X’01’ on CPU A	FLAGS	Execution of instruction OI FLAGS,X’80’ on CPU B
	X’00’	Fetch FLAGS X’00’
Fetch FLAGS X’00’	X’00’	
	X’00’	OR X’80’ into X’00’
OR X’01’ into X’00’	X’00’	
	X’80’	Store X’80’ into FLAGS
Store X’01’ into FLAGS	X’01’	
FLAGS should have value of X’81’ following both updates.		

The problem shown here is that the value stored by the OI instruction executed on CPU A overlays the value that was stored by CPU B. The X‘80’ flag bit was erroneously turned off, and the data is now invalid.

The COMPARE AND SWAP instruction has been provided to overcome this and similar problems.

When the interlocked-access facility 2 is installed, the update performed by OR (OI) instruction is an interlocked-update reference, and the problem illustrated here does not occur.

Conditional Swapping Instructions (CS, CDS)

The COMPARE AND SWAP (CS) and COMPARE DOUBLE AND SWAP (CDS) instructions can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas.

The following examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions illustrate the applications for which the instructions are intended. It is important to note that these are examples of functions that can be performed by programs while the CPU is enabled for interruption (multiprogramming) or by programs that are being executed in a multiprocessing configuration. That is, the routine allows a program to modify the contents of a storage location while the CPU is enabled, even though the routine may be interrupted by another program on the same CPU that will update the location, and even though the possibility exists that another CPU may simultaneously update the same location.

The COMPARE AND SWAP instruction first checks the value of a storage location and then modifies it only if the value is what the program expects; normally this would be a previously fetched value. If the value in storage is not what the program expects, then the location is not modified; instead, the current value of the location is loaded into a general register, in preparation for the program to loop back and try again. During the execution of COMPARE AND SWAP, no other CPU can perform a store access or interlocked-update access at the specified location.

To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference. See the programming notes of COMPARE AND SWAP for an example of how COMPARE AND SWAP can be unsuccessful due to an OR IMMEDIATE instruction executed by another CPU.

Setting a Single Bit

The following instruction sequence shows how the COMPARE AND SWAP instruction can be used to set a single bit in storage to one. Assume that the first byte of a word in storage called “WORD” contains eight flag bits.

```
      LA  6,X'80'  Put bit to be ORed into GR6
      SLL 6,24     Shift left 24 places to
                     align the byte to be ORed
                     with the location of the
                     flag bits within WORD
      L   7,WORD   Fetch current flag values
RETRY LR  8,7      Load flags into GR8
      OR  8,6      Set bit to one
      CS  7,8,WORD Store new flags if current
                     flags unchanged, or re-
                     fetch current flag values
                     if changed
      BC  4,RETRY  If new flags are not stored,
                     try again
```

The format of the COMPARE AND SWAP instruction is:

Machine Format

Op Code	R_1	R_3	S_2
BA	7	8	* * * *

Assembler Format

Op Code R_1,R_3,S_2

```
   CS    7,8,WORD
```

The COMPARE AND SWAP instruction compares the first operand (general register 7 containing the current flag values) to the second operand in storage (WORD) while no CPU other than the one executing the COMPARE AND SWAP instruction is permitted to perform a store access or interlocked-update access at the specified storage location.

If the comparison is successful, indicating that the flag bits have not been changed since they were fetched, the modified copy in general register 8 is stored into WORD. If the flags have been changed, the compare will not be successful, and their new values are loaded into general register 7.

The conditional branch (BC) instruction tests the condition code and reexecutes the flag-modifying instructions if the COMPARE AND SWAP instruction indicated an unsuccessful comparison (condition code 1). When the COMPARE AND SWAP instruction is successful (condition code 0), the flags contain valid data, and the program exits from the loop.

The branch to RETRY will be taken only if some other program modifies the contents of WORD. This type of a loop differs from the typical “bit-spin” loop. In a bit-spin loop, the program continues to loop until the bit changes. In this example, the program continues to loop only if the value does change during each iteration. If a number of CPUs simultaneously attempt to modify a single location by using the sample instruction sequence, one CPU will fall through on the first try, another will loop once, and so on until all CPUs have succeeded.

Updating Counters

In this example, a 32-bit counter is updated by a program using the COMPARE AND SWAP instruction to ensure that the counter will be correctly updated. The original value of the counter is obtained by loading the word containing the counter into general register 7. This value is moved into general register 8 to provide a modifiable copy, and general register 6 (containing an increment to the counter) is added to the modifiable copy to provide the updated counter value. The COMPARE AND SWAP instruction is used to ensure valid storing of the counter.

The program updating the counter checks the result by examining the condition code. The condition code 0 indicates a successful update, and the program can proceed. If the counter had been changed between the time that the program loaded its original value and the time that it executed the COMPARE AND SWAP instruction, the execution would have loaded the new counter value into general register 7 and set the condition code to 1, indicating an unsuccessful update. The program must then repeat the update sequence until the execution of the COMPARE AND SWAP instruction results in a successful update.

The following instruction sequence performs the above procedure:

```
     LA  6,1      Put increment (1) into GR6
     L   7,CNTR   Put original counter value
                    into GR7
LOOP LR  8,7      Set up copy in GR8 to modify
     AR  8,6      Increment copy
     CS  7,8,CNTR Update counter in storage
     BC  4,LOOP   If original value had
                    changed, update new value
```

The following shows two CPUs, A and B, executing this instruction sequence simultaneously: both CPUs attempt to add one to CNTR.

CPU A			CPU B		
GR7	GR8	CNTR	GR7	GR8	Comments
		16			
16	16				CPU A loads GR7 and GR8 from CNTR
			16	16	CPU B loads GR7 and GR8 from CNTR
				17	CPU B adds one to GR8
	17				CPU A adds one to GR8
		17			CPU A executes CS; successful match, store
			17		CPU B executes CS; no match, GR7 changed to CNTR value
				18	CPU B loads GR8 from GR7, adds one to GR8
		18			CPU B executes CS; successful match, store

Bypassing Post and Wait

See the *MVS Programming: Authorized Assembler Services Guide* (SA22-7608) for details on bypassing the z/OS WAIT and POST routines.

Lock/Unlock

When a common storage area larger than a doubleword is to be updated, it is usually necessary to provide special interlocks to ensure that a single program at a time updates the common area. Such an area is called a serially reusable resource (SRR).

In general, updating a list, or even scanning a list, cannot be safely accomplished without first “freezing” the list. However, the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions can be used in certain restricted situations to perform queuing and list manipulation. Of prime importance is the capability to perform the lock/unlock functions and to provide sufficient queuing to resolve contentions, either in a LIFO or FIFO manner. The lock/unlock functions can then be used as the interlock mechanism for updating an SRR of any complexity.

The lock/unlock functions are based on the use of a “header” associated with the SRR. The header is the common starting point for determining the states of the SRR, either free or in use, and also is used for queuing requests when contentions occur. Contentions are resolved using WAIT and POST. The general programming technique requires that the program that encounters a “locked” SRR must “leave a mark on the wall” indicating the address of an ECB on which it will WAIT. The “unlocking” program sees the mark and posts the ECB, thus permitting the waiting program to continue. In the two examples given, all programs using a particular SRR must use either the LIFO queuing scheme or the FIFO scheme; the two cannot be mixed. When more complex queuing is required, it is suggested that the queue for the SRR be locked using one of the two methods shown.

Lock/Unlock with LIFO Queuing for Contentions

The header consists of a word, that is, a four-byte field aligned on a word boundary. The word can contain zero, a positive value, or a negative value.

- A zero value indicates that the serially reusable resource (SRR) is free.
- A negative value indicates that the SRR is in use but no additional programs are waiting for the SRR.
- A positive value indicates that the SRR is in use and that one or more additional programs are waiting for the SRR. Each waiting program is identified by an element in a chained list. The positive value in the header is the address of the element most recently added to the list.

Each element consists of two words. The first word is used as an ECB; the second word is used as a pointer to the next element in the list. A negative value in a pointer indicates that the element is the last element in the list. The element is required only if the program finds the SRR locked and desires to be placed in the list.

The following chart describes the action taken for LIFO LOCK and LIFO UNLOCK routines. The routines following the chart allow enabled code to perform the actions described in the chart.

	Action		
Function	Header Contains Zero	Header Contains Positive Value	Header Contains Negative Value
LIFO LOCK (the incoming element is at location A)	SRR is free. Set the header to a negative value. Use the SRR.	SRR is in use. Store the contents of the header into location A+4. Store address A into the header. WAIT; the ECB is at location A.	
LIFO UNLOCK	Error	Some program is waiting for the SRR. Move the pointer from the “last in” element into the header. POST; the ECB is in the “last in” element.	The list is empty. Store zeros into the header. The SRR is free.

LIFO LOCK Routine:

Initial Conditions:

- GR1 contains the address of the incoming element.
- GR2 contains the address of the header.

```
LLOCK  SR    3,3      GR3 = 0
       ST    3,0(1)   Initialize the ECB
       LNR   0,1      GR0 = a negative value
TRYAGN CS    3,0,0(2) Set the header to a
                        negative value if the
                        header contains zeros
       BC    8,USE    Did the header contain
                        zeros?
       ST    3,4(1)   No, store the value of
                        the header into the
                        pointer in the in-
                        coming element
       CS    3,1,0(2) Store the address of
                        the incoming element
                        into the header
       LA    3,0(0)   GR3 = 0
       BC    7,TRYAGN Did the header get up-
                        dated?
       WAIT  ECB=(1)  Yes, wait for the re-
                        source; the ECB is in
                        the incoming element
USE    [Any instruction]
```

LIFO UNLOCK Routine:

Initial Conditions:

- GR2 contains the address of the header.

```
LUNLK L    1,0(2)    GR1 = the contents of
                       the header
A     LTR  1,1       Does the header contain
      BC   4,B         a negative value?
      L    0,4(1)    No, load the pointer
      CS   1,0,0(2)    from the 'last in'
                       element and store it in
                       the header
      BC   7,A       Did the header get
                       updated?
      POST (1)       Yes, post the 'last in'
                       element
      BC   15,EXIT   Continue
B     SR   0,0       The header contains a
      CS   1,0,0(2)    negative value; free
      BC   7,A         the header and continue
EXIT  [Any instruction]
```

Note that the LOAD instruction L 1,0(2) at location LUNLK would have to be CS 1,1,0(2) if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD instruction to fetch a four-byte operand aligned on a word boundary such that, if another CPU changes the word being fetched by an operation which is also at least word-consistent, either the entire new or the entire old value of the word is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-125.)

Lock/Unlock with FIFO Queuing for Contentions

The header always contains the address of the most recently entered element. The header is originally initialized to contain the address of a posted ECB. Each program using the serially reusable resource (SRR) must provide an element regardless of whether contention occurs. Each program then enters the address of the element which it has provided into the header, while simultaneously it removes the address previously contained in the header. Thus, associated with any particular program attempting to use the SRR are two elements, called the “entered element” and the “removed element” The “entered element” of one program becomes the “removed element” for the immediately following program. Each program then waits on the removed element, uses the SRR, and then posts the entered element.

When no contention occurs, that is, when the second program does not attempt to use the SRR until after the first program is finished, then the POST of the first program occurs before the WAIT of the second program. In this case, the bypass-post and bypass-wait routines described in the preceding section are applicable. For simplicity, these two routines are shown only by name rather than as individual instructions.

In the example, the element need be only a single word, that is, an ECB. However, in actual practice, the element could be made larger to include a pointer to the previous element, along with a program identification. Such information would be useful in an error situation to permit starting with the header and chaining through the list of elements to find the program currently holding the SRR.

It should be noted that the element provided by the program remains pointed to by the header until the next program attempts to lock. Thus, in general, the entered element cannot be reused by the program. However, the removed element is available, so each program gives up one element and gains a new one. It is expected that the element removed by a particular program during one use of the SRR would then be used by that program as the entry element for the next request to the SRR.

It should be noted that, since the elements are exchanged from one program to the next, the elements cannot be allocated from storage that would be freed and reused when the program ends. It is expected that a program would obtain its first element and release its last element by means of the routines described in “Free-Pool Manipulation”.

The following chart describes the action taken for FIFO LOCK and FIFO UNLOCK.

Function	Action
FIFO LOCK (the incoming element is at location A)	Store address A into the header. WAIT; the ECB is at the location addressed by the old contents of the header.
FIFO UNLOCK	POST; the ECB is at location A.

The following routines allow enabled code to perform the actions described in the previous chart.

FIFO Lock Routine:

Initial conditions:

- GR3 contains the address of the header.
- GR4 contains the address, A, of the element currently owned by this program. This element becomes the entered element.

```
FLOCK  LR   2,4       GR2 now contains
                        address of element to
                        be entered
       SR   1,1       GR1 = 0
       ST   1,0(2)    Initialize the ECB
       L    1,0(3)    GR1 = contents of the
                        header
TRYAGN CS   1,2,0(3)  Enter address A into
                        header while remember-
       BC   7,TRYAGN    ing old contents of
                        header into GR1; GR1
                        now contains address
                        of removed element
       LR   4,1       Removed element becomes
                        new currently owned
                        element
       HSWAIT         Perform bypass-wait
                        routine; if ECB
                        already posted, con-
                        tinue; if not, wait;
                        GR1 contains the
                        address of the ECB
USE    [Any instruction]
```

FIFO Unlock Routine:

Initial conditions:

- GR2 contains the address of the removed element, obtained during the FLOCK routine.
- GR5 contains 40 00 00 00$_{16}$

```
FUNLK  LR  1,2  Place address of entered

```

Free-Pool Manipulation

It is anticipated that a program will need to add and delete items from a free list without using the lock/unlock routines. This is especially likely since the lock/unlock routines require storage elements for queuing and may require working storage. The lock/unlock routines discussed previously allow simultaneous lock routines but permit only one unlock routine at a time. In such a situation, multiple additions and a single deletion to the list may all occur simultaneously, but multiple deletions cannot occur at the same time. In the case of a chain of pointers containing free storage buffers, multiple deletions along with additions can occur simultaneously. In this case, the removal cannot be done using the COMPARE AND SWAP instruction without a certain degree of exposure.

Consider a chained list of the type used in the example in section “Lock/Unlock with LIFO Queuing for Contentions” on page A-48. Assume that the first two elements are at locations A and B, respectively. If one program attempted to remove the first element and was interrupted between the fourth and fifth instructions of the LUNLK routine, the list could be changed so that elements A and C are the first two elements when the interrupted program resumes execution. The COMPARE AND SWAP instruction would then succeed in storing the value B into the header, thereby destroying the list.

The probability of the occurrence of such list destruction can be reduced to *near* zero by appending to the header a counter that indicates the number of times elements have been added to the list. The use of a 32-bit counter guarantees that the list will not be destroyed unless the following events occur, in the exact sequence:

1. An unlock routine is interrupted between the fetch of the pointer from the first element and the update of the header.
2. The list is manipulated, including the deletion of the element referenced in 1, and exactly 2^{32} (or an integer multiple of 2^{32}) additions to the list are performed. Note that this takes on the order of days to perform in any practical situation.
3. The element referenced in 1 is added to the list.
4. The unlock routine interrupted in 1 resumes execution.

The following routines use such a counter in order to allow multiple, simultaneous additions and removals at the head of a chain of pointers.

The list consists of a doubleword header and a chain of elements. The first word of the header contains a pointer to the first element in the list. The second word of the header contains a 32-bit counter indicating the number of additions that have been made to the list. Each element contains a pointer to the next element in the list. A zero value indicates the end of the list.

The following chart describes the free-pool-list manipulation.

Function	Action	
	Header = 0,Count	Header = A,Count
ADD TO LIST (the incoming element is at location A)	Store the first word of the header into location A. Store the address A into the first word of the header. Decrement the second word of the header by one.	
DELETE FROM LIST	The list is empty.	Set the first word of the header to the value of the contents of location A. Use element A.

The following routines allow enabled code to perform the free-pool-list manipulation described in the above chart.

ADD TO FREE LIST Routine:

Initial Conditions:

- GR2 contains the address of the element to be added.
- GR4 contains the address of the header.

```
ADDQ   LM   0,1,0(4) GR0,GR1 = contents of
                       the header
TRYAGN ST   0,4(2)   Point the new element to
                       the top of the list
       LR   3,1      Move the count to GR3
       AHI  3,1      Increment the count
       CDS  0,2,0(4) Update the header
       BC   7,TRYAGN
```

DELETE FROM FREE LIST Routine:

Initial conditions:

- GR4 contains the address of the header.

```
DELETQ LM   2,3,0(4)     GR2,GR3 = contents
                           of the header
TRYAGN LTR  2,2          Is the list empty?
       BC   8,EMPTY      Yes, get help
       L    0,4(2)       No, GR0 = the pointer
                           from the first
                           element
       LR   1,3          Move the count to GR1
       CDS  2,0,0(4)     Update the header
       BC   7,TRYAGN
USE    [Any instruction] The address of the re-
                           moved element is in
                           GR2
```

Notes:

1. The LM (LOAD MULTIPLE) instructions at locations ADDQ and DELETQ would have to be CDS (COMPARE DOUBLE AND SWAP) instructions if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD MULTIPLE instructions to fetch an eight-byte operand aligned on a doubleword boundary such that, if another CPU changes the doubleword being fetched by an operation which is also at least doubleword-consistent, either the entire new or the entire old value of the doubleword is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-125.)

2. The add-to-free-list and delete-from-free-list examples shown above assume that the pointer to the next element in the list is in the second word of the element, as described “Lock/Unlock with LIFO Queuing for Contentions” on page A-48.

PERFORM LOCKED OPERATION (PLO)

The PERFORM LOCKED OPERATION instruction can be used in a multiprogramming or multiprocessing environment to perform compare, load, compare-and-swap, and store operations on two or more discontiguous locations that can be words or doublewords. The operations are performed as an atomic set of operations under the control of a lock that is held only for the duration of the execution of a single PERFORM LOCKED OPERATION instruction, as opposed to across the execution of multiple instructions. Since lock contention is resolved by the CPU and is very brief, the program need not include a method for dealing with the case when the lock to be used is held by a program being executed by another CPU. Also, there need be no concern that the program may be interrupted while it holds a lock, since PERFORM LOCKED OPERATION will complete its operation and release its lock before an interruption can occur.

PERFORM LOCKED OPERATION can be thought of as performing concurrent interlocked updates of multiple operands. However, the instruction does not actually perform any interlocked update, and a serially reusable resource cannot be updated predictably through the use of both PERFORM LOCKED OPERATION and conditional-swapping instructions (CS and CDS).

Following is an example of how PERFORM LOCKED OPERATION can be used to add an element at the beginning of a queue.

Assume the following variables associated with the queue: S, which is a sequence number that is incremented anytime the queue is changed; H (for head), which is the address of the first element on the queue; and C, which is a count of the number of elements on the queue. Assume a queue element contains a variable, F (for forward), which is the address of the next element on the queue. If a new element, N, is to be enqueued at the head of the queue, that can be done by setting F in N to H and then performing the following atomic set of operations:

S+1 → S
A(N) → H
C+1 → C

where A(N) is the address of N.

The enqueueing of N can be done by means of the following steps:

1. Obtain consistent values of S, H, and C, meaning obtain S and obtain the H and C that are consistent with that value of S.

2. Store H in N.F.

3. By means of PLO.csdst (PERFORM LOCKED OPERATION performing compare and swap and double store), with S as the swap variable and H and C as the store variables, add one to S, set H to A(N), and add one to C, provided that S still has the value obtained in step 1. If S has already been changed, go back to step 1.

Consistent values of S, H, and C cannot necessarily be obtained simply by using three LOAD instructions because a PERFORM LOCKED OPERATION instruction being executed by another CPU may have completed an update of S but not yet of H or C. In this case, the three LOAD instructions will obtain the new S but the old H or C. However, as will be described, it may be possible to use three LOAD instructions.

If S is obtained while holding the lock, meaning by means of PERFORM LOCKED OPERATION, then H and C can be obtained by LOAD instructions since no other CPU can subsequently change H or C without changing S, as observed when the lock is held.

The parameter list used by the PLO.csdst is as follows, assuming the access-register mode is not used:

0		
8 ⋮ 48		
56		A(N)
64		
72		A(H)
80		
88		C+1
96		
104		A(C)

The program is as follows:

```
      LA    RT,H        Initialize addresses in
                         PL (T = temp)
      ST    RT,PL+76    Op4 address (address of
                         H)
      LA    RT,C
      ST    RT,PL+108   Op6 address (address of
                         C)
      LA    RN,N       Address of N
      ST    RN,PL+60   Initialize op3 in PL
                         (address of N)
      LA    R1,S       PLT address = address
                         of S
-------------------------------------------------
      SR    RS,RS      Dummy S.  CC1 will
                         probably be set
      SR    R0,R0      Function code 0
                         (compare and load)
      PLO   RS,S,RS,S Obtain S while holding
                        lock
---------------------------------------------
      LA    R0,16     Function code 16 (csdst)
LOOP  L     RT,H      Consistent H
      ST    RT,OFSTF(,RN)  OFSTF = offset of
                           F in N
      L     RT,C      Consistent C
      LA    RT,1(,RT) C+1
      ST    RT,PL+92  Initialize op5 in PL
                        (C+1)
      LA    RSP,1(,RS) RS/RSP = even-odd pair.
                        S+1 in RSP
      PLO   RS,S,0,PL
      BNZ   LOOP      Br if S changed (if CC
                        not 0)
```

Note the following about the first PERFORM LOCKED OPERATION instruction (PLO.cl). If S is not zero (which is probably true), S (the second operand, op2) is loaded into RS (the first-operand comparison value, op1c). If S is zero, S (the fourth operand, op4) is loaded into RS (the third operand, op3). Either of these loads occurs while the lock is held. It is unnecessary to test the condition code to determine which load occurred.

The above program may be a simplification. If the queue has associated with it a variable, T (for tail), that is the address of the last element on the queue, and the queue is currently empty, T also must be set when N is added to the queue. This would require a different program using a compare-and-swap-and-triple-store operation.

If the queue is added to, deleted from, and rearranged by means of PERFORM LOCKED OPERATION instructions in which the sequence number, S, is always the second operand, then, since the definition of PERFORM LOCKED OPERATION specifies that the second operand is always stored last, the first PERFORM LOCKED OPERATION instruction in the above program can be replaced by a LOAD instruction. The three instructions within the dashed lines would be replaced by L   RS,S.

Sorting Instructions

Tree Format

Two instructions, COMPARE AND FORM CODEWORD and UPDATE TREE, refer to a tree — a data structure with a specific format. A tree consists of some number (always odd) of consecutively numbered nodes. Node 1 is the root of the tree. Every node except the root has one parent node in the same tree. Every parent node has two son nodes. Every even-numbered node is the *leftson* of its parent node, and every odd-numbered node (except node 1) is the *rightson* of its parent node. Division by two (ignoring remainder) of the node number gives the parent node number. Nodes with sons are also called internal nodes, and nodes without sons are called terminal nodes. Figure A-5 on page A-54 illustrates schematically a 21-node tree with arrows drawn from each parent node to each son node.

A tree is used for merging several sorted sequences of records into a single merged sequence of records. At each step in the merging process, there exists the initial part of the merged sequence and the remaining parts of each of the sorted sequences that are being merged. Each step consists in selecting the lowest record (the record with the lowest key when sorting in ascending sequence) from all of the as yet unmerged parts of the sorted sequences and adding it to the merged sequence. Each terminal node in the tree represents one of the sorted sequences. The number of internal nodes in the tree is one less than the number of sorted sequences. Each internal node conceptually contains one record from each of the sorted sequences but one; these are the lowest records, from all but one of the sorted sequences, that have not yet been added to the merged sequence. In addition, there is the lowest record from the one remaining sorted sequence. This additional record is compared and interchanged with nodes of the tree to select the record to be added next to the merged sequence. This processing begins with the parent of the terminal node that represents the one remaining sorted sequence, and it continues from that node along the path to the root of the tree. The selected record emerges from the root of the tree.

The tree may perhaps be most easily explained by considering each node to represent a comparison operation in an “elimination tournament” to find the lowest record. After the tournament has been completed, each node has an associated "loser" record which had a higher key in the comparison represented by that node. Besides a loser record at each node, there is one record (the "winner") which is not associated with any node since it never compared high. The next step would be to introduce a new record from the same sorted sequence from which the winner record originated and replay the tournament with the new record in place of the former winner. It can be seen that it is unnecessary to do all the comparisons represented by all the nodes in the tree — most of them are unaffected by the new record replacing the former winner. In fact, it is sufficient to redo only those node comparisons in which the former winner record participated. Each new record is inserted into the tree at the terminal node that represents the sorted sequence containing the record. The use of the tree assumes that programming provides a method of remembering at which terminal node each winning record originated. The instruction UPDATE TREE allows for a new record to be inserted at a terminal node and the tree to be updated so that a new winner record is left in the general registers.

Rather than comparing the actual keys of records, much of the merge logic can be performed using "codewords" to represent a record key rather than referring to actual keys. The value of a codeword at a node in the tree depends not only on the record's key but also on the key of the winning record in the last comparison at that node. The codeword consists of two parts:

1. Bits 16-31 contain the one's complement of the first halfword in which the record key differs from that of the node's winning record.
2. Bits 0-15 specify the byte offset of the halfword in this record's key just beyond the halfword value (complemented) in bit positions 16-31.

When comparing records in the path of the last winner record, if the new record is also represented by a codeword resulting from a comparison with the last winner, all codewords in the update path are with respect to the same winner. When comparing such codewords, a high codeword represents a low key and vice versa. Thus, when codewords are unequal, a node entry with a high codeword (representing a low actual key) should move up the tree.

In the case of a tie value of codewords, it is necessary to refer to the actual keys. This is done by the instruction COMPARE AND FORM CODEWORD, which resolves the ambiguity and computes a new codeword for the high-key (loser) record.

The eight bytes at each node of a tree consist of (1) a codeword for this record, computed with respect to the last record which compared low against this record and (2) a parameter usable to locate this record, for example, a direct or indirect address.

The instruction UPDATE TREE is so defined that tree updating stops after equal codewords are detected and the tie-breaking instruction COMPARE AND FORM CODEWORD can be used, after which UPDATE TREE can resume tree updating at the point where equal codewords were previously found.

COMPARE AND FORM CODEWORD may alternatively be used for merging in descending sequence. In that case, bits 16-31 of the codeword at a node contain the true value of the first halfword in which the record key differs from that of the node's winning record. When the descending option of COMPARE AND FORM CODEWORD is used, the higher of two codewords represents the higher key.

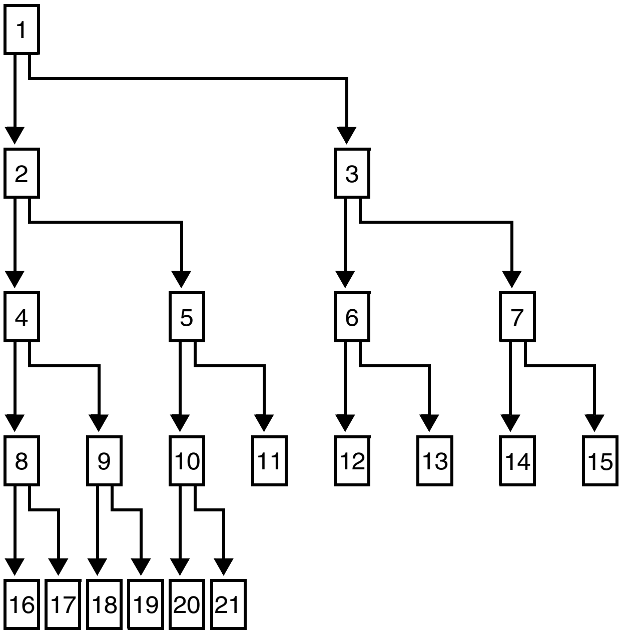

Figure A-5. Schematic Diagram of Merge Control Tree with 21 Nodes

Example of Use of Sort Instructions

An example illustrates how the instructions UPDATE TREE and COMPARE AND FORM CODEWORD may be used in the merge operation within a sort program. A five-way merge requires a tree data structure with four internal nodes and five terminal-node positions. The schematic diagram shown later in this section illustrates such a tree, containing four internal nodes (not counting the dummy node) and five input sequences for a merge, one sequence at each terminal-node position. Each record in an input sequence in the diagram is indicated by its address. The actual record contents are shown in Figure A-7 on page A-58. Each record contains 16 bytes, consisting of the following fields:

Byte Offset (hexadecimal)	Field
0-5	Six-byte record key.
6-7	Halfword node index specifying the input sequence of the next record of this input sequence.
8-B	Address of the next record in the same input sequence.
C-F	This chaining field is initially zero. At the completion of the merge, this field is to contain the address of the next record in the merged sequence.

The merge process forms a single sorted sequence from five input sequences, each of which is in sorted order. This process can be subdivided into three steps:

1. A priming step takes the first record from each of the five input sequences and places them in the tree data structure. For each record to be introduced into the tree, first its codeword value is computed with respect to the lowest possible key value of all zeros. This codeword, with a second word which contains the address of the actual record, forms a doubleword node value that can be placed at the appropriate node. After priming, the node values, one each from each of the five input sequences, will have been placed in the tree so that each of the four internal nodes contains one node value and the node value for a winner record has emerged from the root of the tree.

2. After each winner emerges from the tree, the main merge process is performed repeatedly. Each iteration introduces the node value for one new record into the tree and produces a node value for a new winner record. The tree plus the winner must at all times contain precisely one node value from each input sequence being merged. Therefore, the new node value that is introduced into the tree on each iteration must come from the same input sequence from which the winner node value in the preceding iteration originated.

3. When the node value for the last record of an input sequence emerges as a winner, there is no successor record from that input sequence to be introduced into the tree on the next iteration. Hence, the order of the merge must be reduced by one for each such occurrence. This runout process will consist of one or more iterations for each of a four-way, three-way, two-way, and one-way merge. The onset of runout occurs in the example when it is found that the next input record from a sequence is lower than its predecessor (a sequence break).

The priming process is discussed next, and the state of the tree is shown after priming is complete. Then, a short program that uses the instructions UPDATE TREE and COMPARE AND FORM CODEWORD to perform the main merge is described. An abbreviated trace is then presented to show the status of the tree and certain general registers for 16 iterations of the main merge. The runout process is not discussed in this example.

Priming begins by forming the node value for the first record of each input sequence. The first word of the node value is the codeword formed by executing COMPARE AND FORM CODEWORD on a record key containing all binary zeros. The second word of the node value is the address of the record represented by that node value. The node values for the first record of each input sequence are:

```
Sequence Index          Node Values

      28              0006 FFFC 0000 1030
      30              0006 FFFB 0000 1040
      38              0006 FFFA 0000 1050
      40              0004 FFFE 0000 1080
      48              0006 FFF0 0000 1060
```

In the example, the tree data structure is assumed to have base address X‘1000’, which is kept in general register 4 (to match the expected use in UPDATE TREE). Similarly, internal-node index values and input-sequence index values are always used from general register 5.

Although the tree-priming program is not part of this example, the UPDATE TREE instruction is used in creating it as follows. First, the codeword position for each internal node of the tree is initialized to all ones (X‘FFFF FFFF’). This artifice fills the tree with dummy low records. Then, for each record in the table, (1) the sequence index is loaded into general register 5, (2) the node value is loaded into general registers 0 and 1, and (3) UPDATE TREE is executed. At the completion of this priming process, the tree-node contents in the example are as shown on line 0 of Figure A-9 on page A-60. The contents of the general registers are as shown on the first line of Figure A-8 on page A-59.

The figure illustrating the program for the main merge is divided into three groups of columns, containing the absolute program, the general-register trace, and the symbolic program. The first part of the program extends from symbolic locations L1 through L2; it introduces a new record into the tree and executes an UPDATE TREE instruction. If no tied codewords are encountered in UPDATE TREE, then the BRANCH ON CONDITION instruction following UPDATE TREE loops back to L1 to introduce the next record into the tree. This BRANCH ON CONDITION instruction is suitable for use when UPDATE TREE operates in accordance with either its method 1 (setting condition code 1) or its method 2 (setting condition code 3). (The preceding sentence applies to 370-XA. In ESA/370 and ESA/390, UPDATE TREE operates in accordance with only method 2, which is not to say that it cannot set condition code 1. Method 2, but not method 1, tests for the condition that sets condition code 3.)

If UPDATE TREE encounters tied codewords, then the UPDATE TREE instruction is completed, the subsequent BRANCH ON CONDITION instruction does not branch, and control falls through to the second part of the program, which handles entries with tied codewords. This part then branches back to UPDATE TREE at L2, which resumes the tree updating. It is possible for tied codewords to be encountered at any level in the tree (or indeed at all levels), so that the tied-codeword part of the program may be entered up to three times for each record introduced.

The general-register trace for the first part of the main merge shows the contents of the first seven general registers after each instruction is executed during the first iteration. Note that the merged-chain field (at 1140) serves as the anchor for the merged-chain address chain through the records. The trace shows only the lower half of certain general registers, whose upper half is always zero.

Figure A-9 on page A-60 gives an abbreviated trace of the entire main merge of 16 records. For each record introduced into the tree, there are one or more lines (always an odd number) given in the figure to show the tree updating, which results finally in a winner in GR0 and GR1. The first line for each record shows the values of GR5, GR2, and GR3 before the first or only execution of UPDATE TREE. For the even-numbered lines, the storage updating by UPDATE TREE of tree nodes is shown (read left to right to follow the order of swapping). For example, consider line 10 and the corresponding UPDATE TREE: since GR5 contains 28, the first storage node examined is 1010 (refer to the schematic diagram). Since the codeword in GR0 is 0004 FFFE (same as for GR2), which is less than that of the word at 1010 (0006 FFF0), the doubleword at 1010 is swapped with that in GR0 and GR1. A second comparison at 1008 in the same execution of UPDATE TREE causes another register-storage doubleword swap, which leaves the winner (record 1040) in GR1 at the completion of UPDATE TREE (see the column at the far right of Figure A-9 on page A-60).

When a codeword comparison is made which does not result in a tie or a swap (that is, when the storage-codeword value is low), an asterisk appears in the trace for that storage entry.

When equal codewords are found, the execution of UPDATE TREE is completed. The following line in each such case shows the result of the tied-codeword routine, which always stores a new codeword and may also store a new record address before branching back to L2 to execute UPDATE TREE again. In this line, the notation “loses” or “wins” means that the node loses or wins, respectively.

The tie-break trace part of Figure A-8 on page A-59 shows the treatment of the third record (that is, the first record for which UPDATE TREE encounters a tied codeword). This corresponds to line 31 in Figure A-9 on page A-60.

The following is a summary of the steps that are needed to use this example for verification purposes:

1. Initialize storage as follows:

a. 1008 through 102F from line 0 of Figure A-9 on page A-60

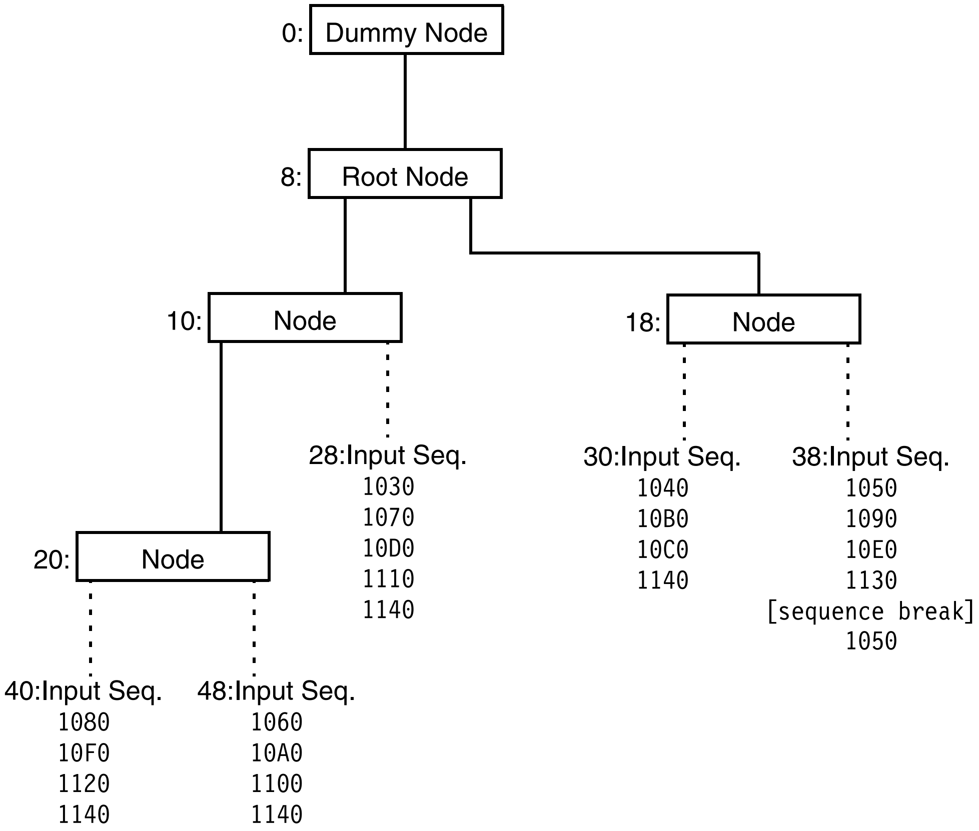
b. 1030 through 114F from Figure A-7 on page A-58

c. 1150 through 1189 from Figure A-8 on page A-59

2. Initialize GRs per first line in Figure A-8 and trace first record per Figure A-8.

3. Trace to completion of each UPT or BC 15,L2 (once for each line of Figure A-9). A detailed trace of the GRs for the tied-codeword part of line 31 of Figure A-9 is given in the lower part of Figure A-8.

4. Verify that addresses in the chain beginning at 103C and continuing through 114C are as shown in the right-hand column of Figure A-7.



Note: Each node and input sequence is identified by a number which is the hexadecimal node index. Each input sequence is given as a list of record addresses (also in hexadecimal).

Figure A-6. Schematic Diagram for Example of Merge to Be Performed

							Successor Record						Merged-Chain Address			
	Record Key at Hex Byte Offset						Index		Location							
Location	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
1030	0 0	0 0	0 0	0 0	0 0	0 3	0 0	2 8	0 0	0 0	1 0	7 0	0 0	0 0	1 0	4 0
1040	0 0	0 0	0 0	0 0	0 0	0 4	0 0	3 0	0 0	0 0	1 0	B 0	0 0	0 0	1 0	5 0
1050	0 0	0 0	0 0	0 0	0 0	0 5	0 0	3 8	0 0	0 0	1 0	9 0	0 0	0 0	1 0	6 0
1060	0 0	0 0	0 0	0 0	0 0	0 F	0 0	4 8	0 0	0 0	1 0	A 0	0 0	0 0	1 0	8 0
1070	0 0	0 0	0 0	0 1	F F	F F	0 0	2 8	0 0	0 0	1 0	D 0	0 0	0 0	1 0	9 0

Explanation:

[1] Line 0 shows the values in the tree after it is primed.

* Means no swap.

** Means no swap if UPDATE TREE method 1 is used or no examination if UPDATE TREE method 2 is used. Only method 2 is included in ESA/370 and ESA/390.

CC = 0 UPDATE TREE finds a tie and sets condition code 0.

Loses The tied-codeword routine finds that the node loses.

Wins The tied-codeword routine finds that the node wins.

Equal The tied-codeword routine finds that the keys are equal.

Branch Branches to terminate at 118A on sequence break.

No compNo compare.

Figure A-9. Abbreviated Trace of Main Merge Processing

Appendix B. Lists of Instructions

The following figures list instructions by name, mnemonic, and operation code. Some models may offer instructions that do not appear in the figures, such as those provided for assists or as part of special or custom features.

The operation code for the interpretive execution facility is not included in this appendix. See the publication *IBM System/370 Extended Architecture Interpretive Execution*, SA22-7095, for the operation code associated with that facility.

The operation code 00 hex with a two-byte instruction format is allocated for use by the program when an indication of an invalid operation is required. Operation code 00 hex will never be assigned to an instruction implemented in the CPU.

Explanation of Symbols in "Characteristics" Columns:

$ Causes serialization.

¢ Causes serialization and checkpoint synchronization.

£ Causes specific-operand serialization.

¢^{1} Causes serialization and checkpoint synchronization when the M_1 and R_2 fields contain 1111 binary and 0000 binary, respectively. Causes only serialization when the fast-BCR-serialization facility is installed, and the M_1 and R_2 fields contain 1110 binary and 0000 binary, respectively.

£^{1} Causes specific-operand serialization when the interlocked-access facility 1 is installed and the storage operand is aligned on an integral boundary corresponding to its size.

¤^{1} Restricted from transactional execution.

¢^{2} Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.

£^{2} Causes specific-operand serialization when the interlocked-access facility 2 is installed.

¤^{2} Restricted from transactional execution when R_2 nonzero and branch tracing is enabled.

¢^{3} Causes serialization and checkpoint synchronization when the set-key control is one.

¤^{3} Restricted from transactional execution when mode tracing is enabled.

¢^{4} Causes serialization and checkpoint synchronization when the KFC value is 4 or 5.

¤^{4} Restricted from transactional execution when a monitor-event condition occurs.

¤^{5} Model dependent whether the instruction is restricted from transactional execution.

¤^{6} Restricted from transactional execution when the effective allow-AR-modification control is zero.

¤^{7} Restricted from transactional execution when the effective allow-floating-point-operation control is zero.

¤^{8} May be restricted from transactional execution depending on machine conditions.

¤^{9} Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized. For STCMH, the instruction is restricted only when the M_3 field is zero.

¤^{10} Restricted to forward branches in the constrained transactional-execution mode.

¤^{11} For PFD and PFDRL, it is model dependent whether the instruction is restricted from transactional execution when the code in the M_1 field is 6 or 7; for STCMH, it is model dependent whether the instruction is restricted when the M_3 field is zero and the code in the R_1 field is 6 or 7.

¤^{12} Restricted from transactional execution when a guarded-storage event is recognized. When in the transactional-execution mode, the transaction is aborted, and the guarded-storage event is processed.

A* Access exceptions for logical addresses. The optional asterisk indicates that a PER ZAD event is not recognized.

A^{1}* Access exceptions; not all access exceptions may occur; see instruction description for details. The optional asterisk indicates that a PER ZAD event is not recognized.

AI Access exceptions for instruction address.

B PER branch event. (For LGG and LLGFSG, the PER branch event is only recognized coincident with a guarded-storage event.)

B†	B_1 field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.
B‡	B_2 field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.
B_1	B_1 field designates an access register in the access-register mode.
B_2	B_2 field designates an access register in the access-register mode.
B_4	B_4 field designates an access register in the access-register mode.
BP	B_2 field designates an access register when PSW bits 16 and 17 have the value 01.
C	Condition code is set.
C*	Condition code is optionally set.
C^1	Condition code is set when the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one.
CS	Compare-and-swap-and-store facility.
CT	Configuration-topology facility.
CX	Constrained transactional-execution facility.
D2	DAT-enhancement facility 2.
Da	AFP-register data exception.
Db	BFP-instruction data exception.
Dc	Compare-and-trap data exception.
DE	DAT-enhancement facility.
DF	Decimal-overflow exception.
DF*	Decimal-overflow exception conditionally recognized.
Dg	General-operand data exception.
DK	Decimal-divide exception.
DM	Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.
DO	Distinct-operands facility.
Dt	DFP-instruction data exception.
Dv	Vector-instruction data exception.
E	E instruction format.
E2	Extended-translation facility 2.
E3	Extended-translation facility 3.
ED1	Enhanced-DAT facility 1.
ED2	Enhanced-DAT facility 2.
EH	Execution-hint facility.
EI	Extended-immediate facility.
EO	HFP-exponent-overflow exception.
ES	Expanded-storage facility.
ET	Extract-CPU-time facility.
EU	HFP-exponent-underflow exception.
EX	Execute exception.
F	Floating-point-extension facility.
FC	Designation of access registers depends on the function code of the instruction.
FG	FPR-GR-transfer facility.
FK	HFP-divide exception.
FL	Store-facility-list-extended facility.
FS	Floating-point-support-sign-handling facility.
G0	Instruction execution includes the implied use of general register 0.
G1	Instruction execution includes the implied use of general register 1.
G2	Instruction execution includes the implied use of general register 2.
G4	Instruction execution includes the implied use of general register 4.
GE	General-instructions-extension facility.
GF	Guarded-storage facility.
GM	Instruction execution includes the implied use of multiple general registers.
GS	Instruction execution includes the implied use of general register 1 as the subsystem-identification word.
GZ	DEFLATE-conversion facility.
HM	HFP-multiply-add/subtract facility.
HW	High-word facility.
I	I instruction format.
I1	Access register 1 is implicitly designated in the access-register mode.
I4	Access register 4 is implicitly designated in the access-register mode.
IA	Interlocked-access facility.
IC	Condition code alternative to interruptible instruction.
IE	IE instruction format.
IF	Fixed-point-overflow exception.
IF*	Fixed-point-overflow exception conditionally recognized.
II	Interruptible instruction.
IK	Fixed-point-divide exception.
IM	Insert-reference-bits-multiple facility
K	PER storage-key-alteration event.
L	New condition code is loaded.

L1	Load/store-on-condition facility 1.
L2	Load/store-on-condition facility 2.
LD	Long-displacement facility.
LS	HFP-significance exception.
LT	Load-and-trap facility.
LZ	Load-and-zero-rightmost-byte facility.
M3	Message-security assist extension 3.
M4	Message-security assist extension 4.
M5	Message-security assist extension 5.
M8	Message-security assist extension 8.
M9	Message-security assist extension 9.
MD	Designation of access registers in the access-register mode is model-dependent.
ME	Monitor event.
MI1	Miscellaneous-instruction-extensions facility 1.
MI2	Miscellaneous-instruction-extensions facility 2.
MI3	Miscellaneous-instruction-extensions facility 3.
MII	MII instruction format.
MO	Move-with-optional-specifications facility.
MS	Message-security assist.
N	Instruction is new in z/Architecture as compared to ESA/390.
N3	Instruction is new in z/Architecture and has been added to ESA/390.
OP	Operand exception.
P	Privileged-operation exception; also, restricted from transactional execution.
PA	Processor-assist facility.
PC	DFP packed-conversion facility.
PE	Parsing-enhancement facility.
PF	PFPO facility.
PK	Population-count facility.
Q	Privileged-operation exception for semiprivileged instructions; also, restricted from transactional execution.
R_1	R_1 field designates an access register in the access-register mode.
R_2	R_2 field designates an access register in the access-register mode.
R_3	R_3 field designates an access register in the access-register mode.
RA	Reusable-ASN-and-LX facility.
RB	Reset-reference-bits-multiple facility.
RI	RI instruction format.
RIE	RIE instruction format.
RIL	RIL instruction format.
RIS	RIS instruction format.
RM	R_1 field designates an access register in the access-register mode, and access-register 1 also is used in the access-register mode.
RR	RR instruction format.
RRD	RRD instruction format.
RRE	RRE instruction format.
RRF	RRF instruction format.
RRS	RRS instruction format.
RS	RS instruction format.
RSI	RSI instruction format.
RSL	RSL instruction format.
RSY	RSY instruction format.
RX	RX instruction format.
RXE	RXE instruction format.
RXF	RXF instruction format.
RXY	RXY instruction format.
S	S instruction format.
SC	Store-clock-fast facility.
SE	Special operation, stack-empty, stack-specification, and stack-type exceptions.
SF	Special-operation, stack-full, and stack-specification exceptions.
SI	SI instruction format.
SIL	SIL instruction format.
SIY	SIY instruction format.
SMI	SMI instruction format.
SO	Special-operation exception.
SP	Specification exception.
SQ	HFP-square-root exception.
SS	SS instruction format.
SSE	SSE instruction format.
SSF	SSF instruction format.
ST	PER storage-alteration event. (For LGG and LLGFSG, the PER storage-alteration event is only recognized coincident with a guarded-storage event.)
SU	PER store-using-real-address event.
SW	Special-operation exception and space-switch event.
T	Trace exceptions (which include trace table, addressing, and low-address protection).
TE	Test-pending-external-interruption facility.
TF	Decimal-floating-point facility.
TR	Decimal-floating-point-rounding facility.
TS	TOD-clock-steering facility.

TX	Transactional-execution facility.
U	Condition code is unpredictable.
U_1	R_1 field designates an access register unconditionally.
U_2	R_2 field designates an access register unconditionally.
UB	R_1 and R_3 fields designate access registers unconditionally, and B_2 field designates an access register in the access-register mode.
UE	HFP unnormalized-extensions facility.
V1	Vector-enhancements facility 1.
V2	Vector-enhancements facility 2.
VD	Vector packed-decimal facility.
VF	Vector facility for z/Architecture.
VRI	VRI instruction format.
VRR	VRR instruction format.
VRS	VRS instruction format.
VRV	VRV instruction format.
VRX	VRX instruction format.
VSI	VSI instruction format.
WE	Space-switch event.
XF	IEEE-exception-simulation facility.
Xg	Simulated IEEE exception.
Xi	IEEE invalid-operation data or vector-processing exception.
Xo	IEEE overflow data or vector-processing exception.
Xq	Quantum data exception (if the floating-point extension facility is installed).
Xu	IEEE underflow data or vector-processing exception.
XX	Execute-extension facility.
Xx	IEEE inexact data or vector-processing exception.
Xz	IEEE division-by-zero data or vector-processing exception.
Z^1	Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, and stack-specification exceptions and space-switch event).
Z^2	Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, and special-operation exceptions and space-switch event).
Z^3	Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, and special operation).
Z^4	Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, and stack-type exceptions and space-switch event).
Z^5	Additional exceptions for BRANCH AND STACK (which include special operation, stack full, and stack specification).
Z^6	Additional exceptions and events for PROGRAM TRANSFER WITH INSTANCE (which include AFX-translation, ASTE-instance, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).
Z^7	Additional exceptions for SET SECONDARY ASN WITH INSTANCE (which include AFX translation, ASTE instance, ASX translation, secondary authority, special operation, and subspace replacement).
ZF	Decimal-floating-point-zoned-conversion facility.

Appendix C. Condition-Code Settings

This appendix lists the condition-code setting for instructions in z/Architecture which set the condition code. In addition to those instructions listed which set the condition code, the condition code may be changed by DIAGNOSE and the target of EXECUTE. The condition code is loaded by LOAD PSW, LOAD PSW EXTENDED, PROGRAM RETURN, RESUME PROGRAM, and SET PROGRAM MASK and by an interruption. The condition code is set to zero by initial CPU reset and is loaded by the successful conclusion of the initial-program-loading sequence.

Some models may offer instructions which set the condition code and do not appear in this document, such as those provided for assists or as part of special or custom features.

Instruction	Condition Code			
	0	1	2	3
ADD (BFP, DFP)	Zero	< zero	> zero	NaN
ADD (general)	Zero	< zero	> zero	Overflow
ADD DECIMAL	Zero	< zero	> zero	Overflow
ADD HALFWORD	Zero	< zero	> zero	Overflow
ADD HALFWORD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD HIGH	Zero	< zero	> zero	Overflow
ADD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD IMMEDIATE HIGH	Zero	< zero	> zero	Overflow
ADD LOGICAL	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL HIGH	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL IMMEDIATE	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH CARRY	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH SIGNED IMMEDIATE	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH SIGNED IMMEDIATE HIGH	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD NORMALIZED	Zero	< zero	> zero	—
ADD UNNORMALIZED	Zero	< zero	> zero	—
AND	Zero	Not zero	—	—
AND IMMEDIATE	Zero	Not zero	—	—
AND WITH COMPLEMENT	Zero	Not zero	—	—
CANCEL SUBCHANNEL	Function initiated	—	—	Not operational
CHECKSUM	Checksum complete	—	—	CPU-determined completion
CIPHER MESSAGE	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH AUTHENTICATION	Normal completion	Verification mismatch	Partial completion (LAAD or LPC zero)	Partial completion (time out)
CIPHER MESSAGE WITH CHAINING	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH CIPHER FEEDBACK	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH COUNTER	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH OUTPUT FEEDBACK	Normal completion	Verification mismatch	—	Partial completion
CLEAR SUBCHANNEL	Function initiated	—	—	Not operational
COMPARE (BFP, DFP)	Equal	Low	High	Unordered
COMPARE (general, HFP)	Equal	Low	High	—

COMPARE AND FORM CODEWORD	Equal	OCB=0: low
		OCB=1: high
			OCB=0: high
			OCB=1: low
				—

COMPARE AND REPLACE DAT TABLE ENTRY	Equal	Not equal	—	—

Figure C-1. Summary of Condition-Code Settings (Part 1 of 7)

Instruction	Condition Code			
	0	1	2	3
COMPARE AND SIGNAL	Equal	Low	High	Unordered
COMPARE AND SWAP	Equal	Not equal	—	—
COMPARE AND SWAP AND PURGE	Equal	Not equal	—	—
COMPARE AND SWAP AND STORE	Equal	Not equal	—	—
COMPARE BIASED EXPONENT	Equal	Low	High	Unordered
COMPARE DECIMAL	Equal	Low	High	—
COMPARE DOUBLE AND SWAP	Equal	Not equal	—	—
COMPARE HALFWORD	Equal	Low	High	—
COMPARE HALFWORD IMMEDIATE	Equal	Low	High	—
COMPARE HALFWORD RELATIVE LONG	Equal	Low	High	—
COMPARE HIGH	Equal	Low	High	—
COMPARE IMMEDIATE	Equal	Low	High	—
COMPARE IMMEDIATE HIGH	Equal	Low	High	—
COMPARE LOGICAL	Equal	Low	High	—
COMPARE LOGICAL CHARACTERS UNDER MASK	Equal	Low	High	—
COMPARE LOGICAL HIGH	Equal	Low	High	—
COMPARE LOGICAL IMMEDIATE	Equal	Low	High	—
COMPARE LOGICAL IMMEDIATE HIGH	Equal	Low	High	—
COMPARE LOGICAL LONG	Equal	Low	High	—
COMPARE LOGICAL LONG EXTENDED	Equal	Low	High	CPU-determined completion
COMPARE LOGICAL LONG UNICODE	Equal	Low	High	CPU-determined completion
COMPARE LOGICAL RELATIVE LONG	Equal	Low	High	—
COMPARE LOGICAL STRING	Equal	Low	High	CPU-determined completion
COMPARE RELATIVE LONG	Equal	Low	High	—
COMPARE UNTIL SUBSTRING EQUAL	Equal substrings	Last bytes equal	Last bytes unequal	CPU-determined completion
COMPRESSION CALL	Op2 processed	Op1 full and op2 not processed	—	CPU-determined completion
COMPUTE DIGITAL SIGNATURE AUTHENTICATION	Verify: Signature verified; Sign: Normal Completion	Verify: public key not on curve; Sign: key verification-pattern mismatch; Sign & Verify: reserved area	Verify: signature is incorrect or invalid; Sign: random number is not invertible if deterministic	Partial completion
COMPUTE INTERMEDIATE MESSAGE DIGEST	Normal completion	—	—	Partial completion
COMPUTE LAST MESSAGE DIGEST	Normal completion	—	—	Partial completion
COMPUTE MESSAGE AUTHENTICATION CODE	Normal completion	Verification mismatch	—	Partial completion
CONVERT BFP TO HFP	Zero	< zero	> zero	Special case
CONVERT HFP TO BFP	Zero	< zero	> zero	Special case
CONVERT TO FIXED	Zero	< zero	> zero	Special case
CONVERT TO LOGICAL	Zero	< zero	> zero	Special case
CONVERT TO PACKED	Source is zero	Source is less than zero	Source is greater than zero	Infinity, QNaN, SNaN, Partial result
CONVERT TO ZONED	Source is zero	Source is less than zero	Source is greater than zero	Infinity, QNaN, SNaN, Partial result

Figure C-1. Summary of Condition-Code Settings (Part 2 of 7)

Instruction	Condition Code			
	0	1	2	3
CONVERT UTF-16 TO UTF-32	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-16 TO UTF-8	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-32 TO UTF-16	Data processed	Op1 full	Invalid UTF-32 character	CPU-determined completion
CONVERT UTF-32 TO UTF-8	Data processed	Op1 full	Invalid UTF-32 character	CPU-determined completion
CONVERT UTF-8 TO UTF-16	Data processed	Op1 full	Invalid UTF-8 character	CPU-determined completion
CONVERT UTF-8 TO UTF-32	Data processed	Op1 full	Invalid UTF-8 character	CPU-determined completion
DEFLATE CONVERSION CALL	Normal Completion	op1 length insufficient	op2 length insufficient (DFLTCC-XPND) or invalid input	CPU-determined completion
DIAGNOSE[1]	See note	See note	See note	See note
DIVIDE TO INTEGER	Remainder complete; normal quotient	Remainder complete; quotient overflow or NaN	Remainder incomplete; normal quotient	Remainder incomplete; quotient overflow or NaN
EDIT	Zero	< zero	> zero	—
EDIT AND MARK	Zero	< zero	> zero	—
EXCLUSIVE OR	Zero	Not zero	—	—
EXCLUSIVE OR IMMEDIATE	Zero	Not zero	—	—
EXTRACT STACKED STATE	Branch state entry	Program-call state entry	—	—
FIND LEFTMOST ONE	No one bit found	—	One bit found	—
HALT SUBCHANNEL	Function initiated	Status-pending with other than intermediate status	Busy	Not operational
INSERT ADDRESS SPACE CONTROL	Primary-space mode	Secondary-space mode	Access-register mode	Home-space mode
INSERT CHARACTERS UNDER MASK	All zeros	First bit one	First bit zero	—
LOAD ADDRESS SPACE PARAMETERS	Parameters loaded	Primary ASN not available	Secondary ASN not available or not authorized	Space-switch event
LOAD AND TEST (BFP, DFP)	Zero	< zero	> zero	NaN
LOAD AND TEST (general, HFP)	Zero	< zero	> zero	—
LOAD COMPLEMENT (BFP)	Zero	< zero	> zero	NaN
LOAD COMPLEMENT (gen)	Zero	< zero	> zero	Overflow
LOAD COMPLEMENT (HFP)	Zero	< zero	> zero	—
LOAD COUNT TO BLOCK BOUNDARY	Operand 1 = 16	—	—	Operand 1 < 16
LOAD NEGATIVE (BFP)	Zero	< zero	—	NaN
LOAD NEGATIVE (gen, HFP)	Zero	< zero	—	—
LOAD PAGE TABLE ENTRY ADDRESS	Translation, STE.P = 0	Translation, STE.P = 1	I bit on in RTE or STE, or enhanced-DAT applies and STE.FC=1	Exception condition exists
LOAD POSITIVE (BFP)	Zero	—	> zero	NaN
LOAD POSITIVE (gen)	Zero	—	> zero	Overflow

Figure C-1. Summary of Condition-Code Settings (Part 3 of 7)

Instruction	Condition Code			
	0	1	2	3
LOAD POSITIVE (HFP)	Zero	—	> zero	—
LOAD PSW[3] / LOAD PSW EXTENDED[3]	See note	See note	See note	See note
LOAD REAL ADDRESS [2]	Translation available	ST entry invalid	PT entry invalid	ASCE or entry not available or length violation
MODIFY SUBCHANNEL	SCHIB information placed in subchannel	Status-pending	Busy	Not operational
MOVE LONG	Length equal	Length low	Length high	Destructive overlap
MOVE LONG EXTENDED	Length equal	Length low	Length high	CPU-determined completion
MOVE LONG UNICODE	Length equal	Length low	Length high	CPU-determined completion
MOVE PAGE	Data moved	Operand 1 invalid, both valid in ES, locked, or ES error	Operand 2 invalid	—
MOVE STRING	—	Data moved	—	CPU-determined completion
MOVE TO PRIMARY	Length ≤ 256	—	—	Length > 256
MOVE TO SECONDARY	Length ≤ 256	—	—	Length > 256
MOVE WITH KEY	Length ≤ 256	—	—	Length > 256
MOVE WITH OPTIONAL SPECIFICATIONS	Length ≤ 4,096	—	—	Length > 4,096
NAND	Zero	Not zero	—	—
NOR	Zero	Not zero	—	—
NOT EXCLUSIVE OR	Zero	Not zero	—	—
OR	Zero	Not zero	—	—
OR IMMEDIATE	Zero	Not zero	—	—
OR WITH COMPLEMENT	Zero	Not zero	—	—
PAGE IN	Page-in operation completed	Expanded-storage data error	—	Expanded-storage block not available
PAGE OUT	Page-out operation completed	Expanded-storage data error	—	Expanded-storage block not available
PERFORM CRYPTOGRAPHIC COMPUTATION	Normal completion	Verification mismatch; Scalar-Multiply: source not on curve or out of range, d out of range	Invalid index or length; Scalar-Multiply: d is zero which yields result of infinity	Partial completion
PERFORM FLOATING-POINT OPERATION (test bit one)	Function code valid	—	—	Function code invalid
PERFORM FLOATING-POINT OPERATION (test bit zero)	Normal result	Nontrap exception	Trap exception with alternate action	—
PERFORM LOCKED OPERATION (test bit one)	Function code valid	—	—	Function code invalid
PERFORM LOCKED OPERATION (test bit zero)	Equal	Op1 not equal	Op1 equal, op3 not equal (dcs only)	—
PERFORM RANDOM NUMBER OPERATION	Normal completion	—	—	Partial completion
PERFORM TIMING FACILITY FUNCTION	Function performed	—	—	Function not available
PERFORM TOPOLOGY FUNCTION (FC 0 or 1)	Change initiated	—	Request rejected	—
PERFORM TOPOLOGY FUNCTION (FC 2)	Report not pending	Report pending	—	—
POPULATION COUNT	Zero	Not zero	—	—
PROGRAM RETURN	See note	See note	See note	See note
RESET CHANNEL PATH	Function initiated	—	Busy	Not operational

Figure C-1. Summary of Condition-Code Settings (Part 4 of 7)

Instruction	Condition Code			
	0	1	2	3
RESET REFERENCE BIT EXTENDED	R bit zero, C bit zero	R bit zero, C bit one	R bit one, C bit zero	R bit one, C bit one
RESUME PROGRAM[3]	See note	See note	See note	See note
RESUME SUBCHANNEL	Function initiated	Status pending	Function not applicable	Not operational
ROTATE THEN AND SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN EXCLUSIVE OR SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN INSERT SELECTED BITS	Zero	< zero	> zero	—
ROTATE THEN OR SELECTED BITS	Zero	Not zero	—	—
SEARCH STRING	—	Found	Not found	CPU-determined completion
SEARCH STRING UNICODE	—	Found	Not found	CPU-determined completion
SET CLOCK	Set	Secure	—	Not operational
SET PROGRAM MASK[4]	See note	See note	See note	See note
SET STORAGE KEY EXTENDED	Storage key not set	Entire storage key set	Partial storage key set	Entire storage key set; bits 48-55 of GR R_1 unpredictable
SHIFT AND ROUND DECIMAL	Zero	< zero	> zero	Overflow
SHIFT LEFT (DOUBLE/SINGLE)	Zero	< zero	> zero	Overflow
SHIFT RIGHT (DOUBLE/SINGLE)	Zero	< zero	> zero	—
SIGNAL PROCESSOR	Order accepted	Status stored	Busy	Not operational
START SUBCHANNEL	Function initiated	Status-pending	Busy	Not operational
STORE CHANNEL REPORT WORD	CRW stored	Zeros stored	—	—
STORE CLOCK	Set	Not set	Error	Stopped or not operational
STORE CLOCK EXTENDED	Set	Not set	Error	Stopped or not operational
STORE CLOCK FAST	Set	Not set	Error	Stopped or not operational
STORE FACILITY LIST EXTENDED	Complete facility list stored	—	—	Incomplete facility list stored
STORE SUBCHANNEL	SCHIB stored	—	—	Not operational
STORE SYSTEM INFORMATION	Information provided	—	—	Information not available
SUBTRACT (BFP, DFP)	Zero	< zero	> zero	NaN
SUBTRACT (general)	Zero	< zero	> zero	Overflow
SUBTRACT DECIMAL	Zero	< zero	> zero	Overflow
SUBTRACT HALFWORD	Zero	< zero	> zero	Overflow
SUBTRACT HIGH	Zero	< zero	> zero	Overflow
SUBTRACT LOGICAL	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL HIGH	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL IMMEDIATE	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL WITH BORROW	Zero, borrow	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT NORMALIZED (HFP)	Zero	< zero	> zero	—
SUBTRACT UNNORMALIZED (HFP)	Zero	< zero	> zero	—

Figure C-1. Summary of Condition-Code Settings (Part 5 of 7)

Instruction	Condition Code			
	0	1	2	3
TEST ACCESS	ALET 0	DU access list, no exceptions	PS access list, no exceptions	ALET 1 or exceptions
TEST ADDRESSING MODE	Twenty-four bit mode	Thirty-one bit mode	—	Sixty-four bit mode
TEST AND SET	Left bit zero	Left bit one	—	—
TEST BLOCK	Usable	Not usable	—	—
TEST DATA CLASS	Zero (no match)	One (match)	—	—
TEST DATA GROUP	Zero (no match)	One (match)	—	—
TEST DECIMAL	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid
TEST PENDING EXTERNAL INTERRUPTION	None pending	One or more pending	—	—
TEST PENDING INTERRUPTION	Interruption code not stored	Interruption code stored	—	—
TEST PROTECTION	Can fetch, can store	Can fetch, cannot store	Cannot fetch, cannot store	Translation not available
TEST SUBCHANNEL	IRB stored; subchannel status-pending	IRB stored; subchannel not status-pending	—	Not operational
TEST UNDER MASK	All zeros	Mixed	—	All ones
TEST UNDER MASK (HIGH/LOW)	All zeros	Mixed, left bit zero	Mixed, left bit one	All ones
TRANSACTION BEGIN	Initiated successfully	—	—	—
TRANSACTION END	CPU in transactional-execution mode at start of instruction	—	CPU not in trans.-execution mode at start of instruction	—
TRANSLATE AND TEST	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE AND TEST REVERSE	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST REVERSE EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE EXTENDED	Data processed	Op1 byte equal test byte	—	CPU-determined completion
TRANSLATE ONE TO ONE, ONE TO TWO, TWO TO ONE, TWO TO TWO	Character equal test character not found	Character equal test character found	—	CPU-determined completion
UNPACK ASCII	Sign plus	Sign minus	—	Sign invalid
UNPACK UNICODE	Sign plus	Sign minus	—	Sign invalid
UPDATE TREE	Equal	Not equal or no comparison	—	GR5 nonzero, GR0 negative
VECTOR ADD DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR COMPARE DECIMAL	Equal	Low	High	—
VECTOR COMPARE EQUAL[5]	All elements equal	Some elements equal	—	No element equal
VECTOR COMPARE HIGH LOGICAL[5]	All elements high	Some elements high	—	No element high
VECTOR COMPARE HIGH[5]	All elements high	Some elements high	—	No element high
VECTOR CONVERT TO BINARY[5]	No overflow	—	—	Overflow
VECTOR CONVERT TO DECIMAL[5]	No overflow	—	—	Overflow
VECTOR DIVIDE DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR ELEMENT COMPARE	Equal	Low	High	—
VECTOR ELEMENT COMPARE LOGICAL	Equal	Low	High	—
VECTOR FIND ANY ELEMENT EQUAL[5]	None equal, zero found	Equal element found, no zeros if ZS=1	Equal element found and zero found	No equal elements, no zeros

Figure C-1. Summary of Condition-Code Settings (Part 6 of 7)

Instruction	Condition Code			
	0	1	2	3
VECTOR FIND ELEMENT EQUAL[5]	Zero found	Equal element found, no zeros	Equal element found, and zero	Not equal, no zeros
VECTOR FIND ELEMENT NOT EQUAL[5]	Zero found	Not equal element found, less than	Not equal found, greater than	Equal, no zero
VECTOR FP COMPARE AND SIGNAL SCALAR	Elements equal	First element low	First element high	Elements unordered
VECTOR FP COMPARE EQUAL[5]	All elements equal	Mix of equal and unequal (or unordered) elements	—	All elements not equal (or unordered)
VECTOR FP COMPARE HIGH OR EQUAL[5]	All elements ≥	Mix of ≥ and <	—	All elements < (or unordered)
VECTOR FP COMPARE HIGH[5]	All elements >	Mix of > and ≤	—	All elements ≤ (or unordered)
VECTOR FP COMPARE SCALAR	Elements equal	First element low	First element high	Elements unordered
VECTOR FP TEST DATA CLASS IMMEDIATE	Match	Selected bit 1 for some (but not all) elements	—	No match
VECTOR ISOLATE STRING[5]	Zero element found	—	—	All elements nonzero
VECTOR MULTIPLY AND SHIFT DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR MULTIPLY DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR PACK LOGICAL SATURATE[5]	No saturation	Some saturated		All saturated
VECTOR PACK SATURATE[5]	No saturation	Some saturated		All saturated
VECTOR PERFORM SIGN OPERATION DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR REMAINDER DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR SHIFT AND DIVIDE DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR SHIFT AND ROUND DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR STRING RANGE COMPARE[5]	Zero found	At least one in ranges, no zero	At least one in ranges, zero found	No ranges match, no zeros
VECTOR STRING SEARCH	no match found[6]	no match found[6]	full match found	partial match found
VECTOR SUBTRACT DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR TEST DECIMAL	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid
VECTOR TEST UNDER MASK	All zeros or mask zero	Mixed	—	All ones
ZERO AND ADD	Zero	< zero	> zero	Overflow

Explanation and Notes:

— Code is not set by the instruction.

[1] For DIAGNOSE, the resulting condition code is model-dependent.

[2] For LOAD REAL ADDRESS, the following applies:

Condition code 1 is set if segment-table entry is invalid for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros.

Condition code 2 is set if page-table entry is invalid for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros.

Condition code 3 is set if address-space-control element not available, region-table entry outside table or invalid, segment-table entry outside table, or, for LRA in 24- or 31-bit mode when bits 0-32 of entry address not all zeros, segment- or page-table entry invalid.

[3] For LOAD PSW, LOAD PSW EXTENDED, and RESUME PROGRAM, the condition code is loaded from the condition-code field of the second operand.

[4] For SET PROGRAM MASK, the condition code is loaded from bit positions 2 and 3 of the first operand.

[5] For various vector-facility instructions, the condition code is optionally set based on the CS control (in a mask field of the instruction)

[6] For VECTOR STRING SEARCH, refer to the instruction description for the distinction between condition codes 0 and 1.

Introduction to Compression Call Facility

The compression call facility consists of the COMPRESSION CALL (CMPSC) instruction, which compresses or expands data as specified by a bit in general register 0. COMPRESSION CALL is primarily intended to operate on randomly accessed DB2* data, typically 80-byte records, so that the data can be kept on DASD in compressed form, thus saving DASD space. However, COMPRESSION CALL can also be used to compress any randomly or sequentially accessed data, provided that there is some degree of repetition of character strings (which may be actual characters or bytes of numeric or graphic data) in the data. COMPRESSION CALL also has an option, named the symbol-translation option and the order-preservation option, that allows the instruction to be used to compress VTAM* network data and DB2 keys, respectively.

In the following material, COMPRESSION CALL is first described for the case in which the symbol translation and order preservation options are not used, and then the differences due to the options are described.

Compression and Expansion Dictionaries

COMPRESSION CALL uses two static dictionaries that must be prepared by the program, before the compression operation, by scanning data that is typical of that to be compressed. One of these dictionaries is named the compression dictionary and is used only during compression. The other dictionary is named the expansion dictionary, is used during expansion, and may, depending on an option, be used slightly during compression. During expansion, the beginning of the expansion dictionary is designated by an address in general register 1. During compression, this same address designates the beginning of the compression dictionary, and the expansion dictionary, if used, immediately follows the compression dictionary.

Each of the compression and expansion dictionaries contains 512, 1K, 2K, 4K, or 8K doubleword entries, as determined by bits in general register 0. An entry in either of the dictionaries is identified or designated by means of the *index* to its position in that dictionary. That is, the first entry in a dictionary is identified or designated by index 0, the next by index 1, and so forth. The two entries at the same index position in each of the two dictionaries correspond to each other in that they both represent the same character string, which string is called a *symbol*.

Compression-Dictionary Entries

The entries in the compression dictionary correspond approximately to a Ziv-Lempel tree. There are 256 *alphabet* entries corresponding to the 256 possible values of a single-byte character, and these are the topmost entries in the tree (which is upside down). The alphabet entries may be *parent* entries that point to *child* entries. The child entries may in turn be parent entries that point to their child entries. Each of the alphabet entries and the child entries is called a *character entry*. A character entry represents one or more *extension characters*. An alphabet entry represents one extension character. (The character represented by an alphabet entry is the *first* character of a character symbol, which term is defined in the next paragraph. The character is an extension to a null character represented by a physically non-existing null root entry that conceptually is the parent of the 256 alphabet entries.) A lower-level character entry represents from one to five extension characters. (In a pure Ziv-Lempel tree, each node represents only one extension character.)

In addition to representing one or more extension characters, a compression-dictionary entry represents a *character symbol* that is the extension characters of the entry preceded by the extension characters of all of the entry's ancestor entries, up to an alphabet entry.

The alphabet entries are the first entries in a dictionary and have the indexes 0-255. If an entry is a parent, it contains the index, called a *child pointer*, of its first child. Its other children, if any, follow the first child contiguously in the dictionary (and thus in storage).

Compression Process

Compression occurs as follows. The first character of the string to be compressed is used as an index to locate the alphabet entry that represents the first character. If the alphabet entry has children, the children are processed in the left-to-right order of the children, and the extension characters represented by each child are compared to the next characters of the string until a match is found or all children have been examined. If a match is found, the process is repeated using the children of that child and the next characters of the string. When the last match has been found, which might be just the match on the alphabet entry, the index of the last matching entry is output as the compressed data. This index is called an *index symbol*. The length in bits of an index symbol is the power of 2 that defines the number of entries in the dictionary. Thus, the length is nine, 10, 11, 12, or 13 bits depending on whether the number of entries is 512, 1K, 2K, 4K, or 8K, respectively.

There is an exception to the above that is described below in the section "Restriction on Identical Child and Sibling Characters."

The unqualified term "symbol" can mean either a character symbol or an index symbol. The first meaning applies when discussing the uncompressed data or the dictionary entries. The second meaning applies when discussing the compressed data.

Child and Sibling Characters

It is a fundamental goal of the compression call facility to minimize the number of storage references required when processing dictionary entries to find matches. To this end, a character entry never contains its own first extension character and always contains the first extension characters of some number of its children, if any. These first extension characters of the children are named *child characters*. The positional number of a child character in a parent along with the pointer to the first child locates the child. If an entry represents more than one extension character, the characters after the first are in the entry and are called *additional extension characters.*

If a parent has more children than the number of bytes available in the parent to contain child characters, the first extension characters of the additional children are in a *sibling-descriptor* dictionary entry that follows the last child entry able to be represented by means of its child character in the parent. These first extension characters in a sibling descriptor are named *sibling characters*. COMPRESSION CALL provides the option of having either format-0 or format-1 sibling descriptors. A format-0 sibling descriptor is one doubleword, contains up to seven sibling characters, and resides entirely within the compression dictionary. It resides at an index position that would otherwise be used by a character entry. A format-1 sibling descriptor is two doublewords, contains up to 14 sibling characters, and has its first doubleword at an index position in the compression dictionary and its second doubleword at the same index position in the expansion dictionary. This position in the expansion dictionary would otherwise be wasted. This partial residence of sibling descriptors in the expansion dictionary is the only way the expansion dictionary is used during compression.

A sibling descriptor contains from one to seven or 14 sibling characters that correspond to the additional children of the parent. The additional child entries follow the sibling descriptor in the dictionary. If there are more than seven or 14 additional children, another sibling descriptor follows the seventh or fourteenth additional child. This following of seven or 14 children by another sibling descriptor can be repeated again and again. However, a parent must have no more than 260 children; otherwise, a data exception may be recognized when an attempt is made to find a match on a child after the 260th child.

Child and Extension-Character Combinations

The compression dictionary contains only two types of entries: character entries and sibling descriptors. However, the character entries have different formats depending on how many additional extension characters an entry represents and on whether an entry has zero, one, or more than one children. Only the following combinations are allowed:

- If an entry has zero children, it can have from zero to four additional extension characters.
- If an entry has one chid, it can have from zero to four additional extension characters.
- If an entry has more than one child it can have only zero or one additional extension character.

Character entries and sibling descriptors contain count fields whose contents specify the numbers of additional extension characters, child characters, or sibling characters in the entries and also whether a sibling descriptor follows a child. Character entries and sibling descriptors also contain *examine-child* bits that specify whether child entries, whether designated from a parent or a sibling descriptor, need to be examined. A child entry need not be examined if the entry represents only one extension character and has no children. Conversely, if the entry represents (contains) one or more additional extension characters or has children, the entry must be examined in order to continue the matching process.

Restriction on Identical Child and Sibling Characters

The compression process is described above with some lack of detail, which detail is provided here. However, this section, including its programming notes, does not apply if the order-preservation option is used.

After a match has been found on a parent entry, and if the parent has children, the next character of the string is compared against the child characters in the parent and the sibling characters in the sibling descriptors that are among the children of the parent until a match is found or all child and sibling characters have been processed. If a match is found, the next characters of the string are compared against the additional extension characters, if any, in the child designated by means of the matched child or sibling character. If the additional extension characters match, or if there are no additional extension characters, the matching process is repeated using the matched child as the next parent. If there are additional extension characters that do not match the next characters of the string, then, except in one case, it is model-dependent whether the matching process is ended, with the match on the current parent being the last match, or whether the matching process is continued by attempting to match on a remaining child of the current parent. The one exceptional case is when the designated child and also the next child are in a set of children designated by means of consecutive identical child characters (not sibling characters) beginning with the first child character in the parent. In this case, an attempt is made to match on the following children in the set until either a match is found or all such children have been processed.

The effect of the detailed operation just described is that it is assured that it is useful for two or more identical characters to appear as child characters in a parent or sibling characters in a sibling descriptor under a parent only when the characters are all consecutive child characters beginning with the first child character in the parent. In any case where the identical characters are not consecutive child characters beginning with the first child character in the parent, the second character and any subsequent identical child or sibling character may be wasted since, depending on the model, they may never be compared against a string character equal to them.

Programming Notes:

1. When an examine-child bit indicates that the corresponding child need not be examined, it does not necessarily cause the child not to be examined. Therefore, the count fields in the child must contain all zeros as they correctly should; otherwise, there may be a match on one or more false additional extension characters or a false child character in the child. Since the expansion dictionary will not have been built to recreate the falsely matched character or characters, the

expanded data will not be equal to the original uncompressed data.

2. The restriction against identical child or sibling characters may improve performance because it generally allows the matching process to be ended immediately after a match on a child or sibling character followed by a failure to match on additional extension characters in the designated child. On the other hand, the provision that attempted matching continues in the case of identical consecutive leading child characters improves performance in the case of compressing strings, of many different lengths, of the same repeated character. For example, consider the following two different sets of compression-dictionary entries that might be used for compressing strings, of lengths 1-15, of the character A. (Strings of binary zeros or of blanks are a more important case, but those two characters are unprintable and, therefore, cannot be shown in this example.)

   In the first set of entries (Set 1), each parent has only one child, and there are no additional extension characters -- each child represents only one more character than its parent. Set 1 is shown abstractly as follows:

Set 1

Entry Number	Character Symbol Represented by Entry
1	A
2	AA
3	AAA
4	AAAA
5	AAAAA
6	AAAAAA
7	AAAAAAA
8	AAAAAAAA
9	AAAAAAAAA
10	AAAAAAAAAA
11	AAAAAAAAAAA
12	AAAAAAAAAAAA
13	AAAAAAAAAAAAA
14	AAAAAAAAAAAAAA
15	AAAAAAAAAAAAAAA

   The entries in Set 1 are shown with the first and only child of a parent immediately beneath the parent except indented one character position to the right. Part of the abstraction is that the entries are numbered 1-15 even though, in an actual dictionary, entries 0-255 must be alphabet entries. Note that the number of A's represented by an entry is equal to the number of the entry.

   The number of storage references made to the dictionary during compression may be an important determinant of performance, depending on the model. Using Set 1, the number of dictionary storage references needed to compress a string of 1-15 A's is equal to the number of A's in the string.

   In the second set of entries (Set 2), each parent has two children, the first child has one additional extension character, and the second child has no additional extension character -- the first child represents two more characters than its parent, and the second child represents one more character than its parent. Set 2 is shown abstractly as follows. The following also explicitly shows the number of A's represented by each entry and the number of storage references needed to match on each entry.:

Set 2

Entry Number	Character Symbol Represented by Entry	A's	Stg. Refs
1	A	1	1
2	AAA	3	2
4	AAAAA	5	3
6	AAAAAAA	7	4
8	AAAAAAAAA	9	5
10	AAAAAAAAAAA	11	6
12	AAAAAAAAAAAAA	13	7
14	AAAAAAAAAAAAAAA	15	8
15	AAAAAAAAAAAAAA	14	9
13	AAAAAAAAAAAA	12	8
11	AAAAAAAAAA	10	7
9	AAAAAAAA	8	6
7	AAAAAA	6	5
5	AAAA	4	4
3	AA	2	3

   The entries in Set 2 are shown with the first child of a parent immediately beneath the parent, except indented one character position to the right, and with the other child of the same parent aligned vertically with the first child. For example, entry 1 (A) has the children 2 (AAA) and 3 (AA), and entry 2 (AAA) has the children 4 (AAAAA) and 5 (AAAA). Entries 3 (AA) and 5 (AAAA) do not have a child. The entries are numbered as they are because the children of a parent must be numbered consecutively.

It can be seen that except for entries 5 and 3 of Set 2, the number of storage references needed to match on a Set-2 entry is always less than the number of storage references needed to match on the Set-1 entry representing the same number of A's.

A dictionary might contain entries in the style of either Set 1 or Set 2 that would allow compression of a string of up to 260 repeated characters as a single index symbol. Using entries in the style of Set 2, instead of the style of Set 1, reduces the number of required storage references by approximately 50%. (Matching a string of 101 A's would require 101 references using the Set-1 style but only 51 references using the Set-2 style.)

3. Long strings of a repeated character can be compressed with even fewer storage references if entries in the style of Set 3, shown below, are used. Using entries in the style of Set 3, instead of the style of Set 1, reduces the number of required storage references by approximately 67%.

Set 3

Entry Number	Character Symbol Represented by Entry	A's	Stg. Refs
1	A	1	1
2	AAAAAA	6	2
7	AAAAAAA	7	3
8	AAAAAAAAAAAA	12	4
13	AAAAAAAAAAAAA	13	5
14	AAAAAAAAAAAAAAAAAA	18	6
15	AAAAAAAAAAAAAAAAA	17	7
16	AAAAAAAAAAAAAAAA	16	8
17	AAAAAAAAAAAAAAA	15	9
18	AAAAAAAAAAAAAA	14	10
9	AAAAAAAAAAA	11	5
10	AAAAAAAAAA	10	6
11	AAAAAAAAA	9	7
12	AAAAAAAA	8	8
3	AAAAA	5	3
4	AAAA	4	4
5	AAA	3	5
6	AA	2	6

In Set 3, an odd-level parent has no additional extension character and five children, and the children, in order, have four, three, two, one, and zero additional extension characters -- the children represent from five to one more characters than their parent. An even-level parent, which is the first child of an odd-level parent, has four additional extension characters and one child, which is the next odd-level parent. The second through fifth children of an oddlevel parent do not have a child. Specifically in Set 3, entry 1 (A) has the children 2 (AAAAAA), 3 (AAAAA), 4 (AAAA), 5 (AAA), and 6 (AA); entry 2 (AAAAAA) has the child 7 (AAAAAAA); entry 7 has the children 8-12; entry 8 has the child 13, and entry 13 has the children 14-18. Entries 3-6, 9-12, and 15-18 do not have a child. Entry 14 might have a child to continue the pattern.

Matching a string of 18 A's requires six storage references, which is 33% of the number required when using the Set-1 style.

Entries should not be arranged as in the following examples.

Set 4 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AA
3	AAA

Entry 3 in Set 4 is useless because if the string to be matched is AAA, a match of the AA at the beginning of the string will be found on entry 2, and entry 3 will not be examined. (This would be true also if the string to be matched were AAB and entry 3 represented AAB.)

Set 5 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AAA
3	AB
4	AA

Entry 4 in Set 5 may be useless because if the string to be matched is AAX, the matching process may end, depending on the model, after the failure to match the AAX to entry 2. (Entries 2 and 4 are designated by identical child characters in entry 1, and the first of these child characters is the first child character in entry A, but the two child characters are not consecutive.)

Set 5 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AB
3	AAA
4	AA

Entry 4 in Set 6 may be useless because if the string to be matched is AAX, the matching process may end, depending on the model, after the failure to match the AAX to entry 3. (Entries 3 and 4 are designated by identical consecutive child characters in entry 1, but the first of these child characters is not the first child character in entry A.)

Expansion-Dictionary Entries

The expansion dictionary contains three types of entries: *unpreceded character entries*, *preceded character entries*, and the second halves of the format-1 sibling descriptors that begin in the compression dictionary. An unpreceded character entry represents a character symbol by containing all of the characters of the symbol -- these are the extension characters represented by the corresponding entry in the compression dictionary and the extension characters represented by all the ancestors of that compression-dictionary entry. An unpreceded character entry can contain from one to seven characters. A preceded character entry represents a character symbol by containing from one to five of the rightmost characters of the symbol and also a pointer, called a *predecessor pointer*, to another expansion-dictionary character entry that contains some or all of the next lefthand characters of the character symbol. That is, the predecessor pointer in a preceded character entry can point to either an unpreceded or a preceded character entry.

A predecessor pointer is not necessarily a parent pointer, which term has no role in this definition. That is, a predecessor pointer may designate a higher-level entry that is more remote than simply a parent.

An unpreceded character entry contains a complete-symbol-length field whose contents specify the number of characters in the entry. A preceded character entry contains a partial-symbol-length field whose contents specify the number of characters in the entry, and it also contains an offset that may be used to position the leftmost character of the entry in the expanded-data operand.

Expansion Process

Expansion of an index symbol occurs in a way that depends on whether the value of the symbol is in the range 0-255 or is 256 or larger. If the value of the index symbol is in the range 0-255, a byte containing the value of the symbol is simply stored as the next byte of expanded data, and no reference is made to the expansion dictionary. That is, the index symbol is assumed to designate an expansion-dictionary entry that represents the same character symbol as does the alphabet entry that is designated by the index symbol in the compression dictionary -- the index symbol can be said to designate an alphabet entry in the expansion dictionary. If the value of the index symbol is 256 or larger, expansion occurs by using the value as an index to locate the corresponding expansion-dictionary character entry and then (1) outputting the characters in the entry, and (2) if the entry is a preceded entry, proceeding up the chain of preceded entries and outputting the characters in each of them on the left of the characters already output, until finally an unpreceded entry has been encountered. Following is a more detailed description of the case when the value of the index symbol is 256 or larger.

1. The rightmost byte of the first preceded character entry obtained during the expansion of an index symbol contains the byte offset from the current location in the expanded-data operand to where the first extension character represented by the character entry is to be placed. (All preceded character entries contain an offset since any entry can be the first one obtained during an expansion.) The address of the current location is named the current origin address. At the end of the operation, the current origin address is updated in accordance with one of two methods, and which method is used is unpredictable. When the first method is used, the current origin address is updated by adding to it the sum of the partial symbol length and the offset in the first-obtained preceded entry. When the second method is used, the current origin address is updated by adding to it the number of characters

placed in the first operand location due to the expansion of the index symbol. If the expansion-dictionary entries processed specify a logically correct operation, the results are the same regardless of which method is used. The entries are considered to specify a logically correct operation if they together contain n characters and cause placement of those n characters, without overlaps or spaces, in the n character positions beginning at the original current origin address and ending at the address that is one less than the updated current origin address. The machine does not check in any way that the operation is logically correct.

2. If the first character entry obtained during expansion of an index symbol is an unpreceded entry, the characters in the entry are placed at the current origin address, and then the current origin address is updated by adding to it the complete symbol length in the unpreceded entry.

3. When the first character entry obtained during expansion of an index symbol is a preceded entry, the processing of the preceding entries, which may include additional preceded entries, is in accordance with one of two methods, and which method is used is unpredictable. When the first method is used, the processing is the same as in items 1 and 2; that is, the characters in a preceded entry are placed as determined by the offset in the entry, and the characters in an unpreceded entry are placed at the current origin address. When the second method is used, the characters in each preceding entry are placed immediately to the left of the characters resulting from the previously processed preceded entry. Either the same or different methods may be used for each of preceded and unpreceded entries and for each of multiple preceded entries. If the entries processed specify a logically correct operation, the results are the same regardless of which method is used. The updated current origin address is determined as specified in item 1. If the operation is logically incorrect and leaves spaces in the n character positions beginning at the original current origin address, the contents of those spaces are unpredictable.

   When method 1 is used, storing may be specified to occur at or to the right of the updated current origin address because either the offset in a subsequent preceded entry is larger than the offset in the first one or because the offset in the first one is too small, considering the complete symbol length in the unpreceded entry. (The preceding is incomplete because it does not deal with partial symbol lengths, but the point should be clear.) When method 2 is used, storing may be specified to occur to the left of the original current origin address because the offset in the first preceded entry is too small. In the method-1 or method-2 case, such storing may be within or outside the first-operand location. It may cause a data exception to be recognized, or it may be attempted. If it is attempted, it may cause an access exception to be recognized and the operation to be nullified or suppressed, depending on the exception. If an access exception is recognized, the results may not be true nullification or suppression because storing may have occurred in a location for which no access exception was recognized. Recognition of an access exception may cause condition code 3 to be set instead of being treated as a program-interruption condition.

4. When entropy-encoding is not enabled and the value of a predecessor pointer is in the range 0-255, either the pointer may be used to reference a dictionary entry as already described, or the value may simply be stored as the next byte of expanded data. When entropy-encoding is enabled and the value of a predecessor pointer is in the range 0-255 the pointer is always used to reference a dictionary entry as already described.

Programming Note: If no predecessor pointer designates one of the entries 0-255 in the expansion dictionary, those entries need not actually be provided, and the storage that would be occupied by the entries can be used for other purposes. However, the storage must exist and have the correct storage key since the CPU may pretest the entire expansion dictionary, including entries 0-255, for access exceptions.

Compressed-Data Symbol Size

The bits in general register 0 that specify the number of bits in an index symbol and the size in entries and bytes of a dictionary are named the compressed-data symbol size (CDSS).

Symbol Translation

During compression, symbol translation can be specified by means of a bit in general register 0; this bit is ignored during expansion. When symbol translation is specified, the index symbols generated by the compression process are used to locate two-byte entries in a symbol-translation table (STT), and *interchange symbols* are taken from the STT entries and placed in the compressed-data operand. The beginning of the STT is designated by the address and an offset in general register 1.

When symbol-translation is specified, the CDSS does not specify either the number of bits in an index symbol or the size of the compression dictionary; the CDSS specifies the number of bits in an interchange symbol, the compression dictionary is considered to extend to the beginning of the STT, and the size of the STT in bytes is considered to be one fourth that of the compression dictionary.

Symbol translation is not performed during (before) expansion because the expansion dictionary can be formed to directly expand interchange symbols, that is, during expansion, interchange symbols and index symbols are considered to be identical, and only the term index symbol is used.

Symbol translation and format-1 sibling descriptors must not both be specified; otherwise, the results are unpredictable.

Programming Note: Symbol translation is for use by VTAM. During compression, VTAM will form an adaptive dictionary until compression becomes good, and VTAM will then freeze its dictionary and transform it to the architected form used by COMPRESSION CALL. VTAM will also signal the other end of the session to freeze its dictionary also, but the other end will then continue to use its frozen adaptive dictionary. Since the architected dictionary must contain some entries that are sibling-descriptor entries while the adaptive dictionary has no similar requirement (all of its entries are character entries), most of the entries in the architected dictionary cannot have the same indexes as the logically corresponding entries in the adaptive dictionary, and symbol translation must be used to generate the correct interchange symbols.

Order Preservation

During compression, order preservation can be specified by means of a bit in general register 0. When order preservation is specified, the symbol-translation bit in the register is ignored, but a modified form of symbol translation occurs.

When an appropriate compression dictionary and symbol-translation table are used, order preservation causes, for successive units of uncompressed data that are in collating-sequence order, production of corresponding successive units of compressed data that also are in collating-sequence order.

The compression process used in the basic compression operation uses what is referred to here as the *unordered* comparison algorithm: the children of a parent are not considered to be in any particular order, and the next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until either a match is found or all of the children have been processed. The result of the compression process is the index symbol that designates the last matched entry, which is the parent entry if no match was found on any child or there are no children.

The order-preservation option causes the compression process to use an *ordered* comparison algorithm: the children of a parent are considered to be ordered such that the string of one or more extension characters represented by any child is always earlier in the collating sequence than the string of one or more extension characters represented by the next child of the same parent, that is, the children are considered to be in collating-sequence order. The next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until any of the following is true: (1) a match is found on an entry without children, or a match is found on an entry with children but there is not another character in the string; (2) the next characters from the string have a collating-sequence value less than that of the extension characters represented by a child of the last matched parent; or (3) the next characters from the string have a collating-sequence value greater than that of the extension characters represented by the last child of the last matched parent. The result of the compression process in each of the three cases is as follows:

1. If the process ends because of a match on an entry without children or because of a match on an entry when there is not another character in the string, the result is the index symbol that designates the entry.
2. If the process ends because the next characters of the string have a value less than that of the characters represented by a child, the result is the index symbol that designates the child.
3. If the process ends because the next characters of the string have a value greater than that of the characters represented by the last child, the result is the index symbol that designates the last child.

Note that Case 2 includes the case when the next character of the string match the leftmost extension characters represented by a child but there are not as many next characters remaining in the string as there are additional extension characters represented in the child.

The index symbol produced by the compression process is used to locate a symbol-translation-table entry containing an interchange symbol just as when the symbol-translation option is specified. The resulting interchange symbol that is placed in the compressed-data operand is then as follows:

1. In Case 1, the interchange symbol in the entry.
2. In Case 2, the interchange symbol in the entry, minus one; that is, one is subtracted from the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.
3. In Case 3, the interchange symbol in the entry, plus one; that is, one is added to the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.

Although the order-preservation option does not affect the expansion process, the expansion dictionary must be formed so that the interchange symbols produced by compression are properly expanded when they are treated as index symbols during expansion. During expansion, an index symbol equal to an interchange symbol produced during compression must designate a dictionary entry that represents the same character symbol as did the last entry that was matched during the compression. In Case 2 or 3, the last matched entry is the parent of the entry that caused the Case 2 or Case 3 condition to be satisfied.

Programming Note: The assumption that an index symbol in the range 0-255 designates an alphabet entry in the expansion dictionary requires that interchange symbols be assigned as follows when the order-preservation option is used. If n is the number of the lowest-numbered alphabet entry in the compression dictionary having a child, then the interchange symbols 0-n must be assigned to alphabet entries 0-n, the interchange symbol 256 must be assigned to the first epsilon entry or child under entry n, and the interchange symbols (n+1)-255 must not be assigned.

Entropy Encoding

Entropy encoding can be specified by means of a bit in general register 0. When entropy encoding is specified, a higher degree of compression may be obtained due to using shorter codewords for more frequent symbols.

The compressed operand does not contain index symbols, instead it contains codewords. The codewords may vary from 1-16 bits in length. Each codeword represents an index symbol. The most frequent index symbols will have codewords with fewer bits, and less frequent index symbols will have codewords with more bits.

The mapping of index symbols to codewords is handled differently for compression and expansion. However, the entropy descriptor is common. The entropy descriptor describes the valid codewords from most frequent to least frequent. The entropy descriptor consists of sixteen halfword entries each of which contain a count of the number of entries of the corresponding bit length from one to sixteen.

The mapping of index symbols to codewords is done by generating a prefix tree for all index symbols. The prefix tree is formed using the frequency that each index symbol is seen when compressing data. The codewords are grouped by their information content and enumerated in descending order. This is sometimes called a cannonical Huffman code or an Shannon-Fano code. Since all of the codewords are ordered, it is possible to describe the tree by enumerating the number of entries of each codeword length. The maximum codeword size supported is 16-bits. The entropy descriptor must fully represent a valid tree. The sum of all of the entries in the entropy descriptor must add up to the number of dictionary entries plus one; otherwise, a general-operand data exception is recognized. Also there cannot be any underflow or overflow when computing the lower and upper bound codewords for each bit length otherwise a general-operand data exception is recognized.

The entropy descriptor is located immediately after the compression or expansion dictionary and is pointed to by the offset field in general register 1. During compression a symbol translation table is located immediately after the entropy descriptor. The symbol translation table is one fourth the size of the compression dictionary.

During compression index symbols which are formed during compression are used to index into the symbol translation table. Each halfword in the symbol translation table contains the codeword which maps to the index symbol left aligned in the halfword. Any unused bits in the symbol translation table entry must contain zeros; otherwise, a general-operand data exception is recognized. The number of bits from the symbol translation table entry to be copied to the first operand location is computed for each symbol translation table entry.

During expansion the bits of the second operand are broken into codewords using the information in the entropy description. The codewords are converted to sequence numbers and used to index directly into the expansion dictionary. Indices 0-255 have no special meaning in the expansion dictionary when the entropy encoding option is specified. Since the entries in the expansion dictionary are indexed by sequence numbers they must be ordered by likelihood. The sequence number is the number of codewords with a higher probability than the current input codeword.

Results of Dictionary Errors

The following may be truncated on the left to eliminate bits not needed because of the dictionary size, or they may always be treated as 13 bits regardless of the dictionary size: child pointers, predecessor pointers, and index symbols that are used to locate entries in a symbol-translation table. If the pointers or symbols are not truncated and a child pointer specifies an entry beyond the end of the compression dictionary, a predecessor pointer specifies an entry beyond the end of the expansion dictionary, or an index symbol specifies an entry beyond the end of the symbol-translation table, any of the following may occur: in the case of a child pointer and a zero examine-child bit, an index symbol containing too many bits may be generated and stored in the first-operand location (possibly overlaying a rightmost bit or bits of the previous index symbol); the contents at the improper location may be used in the normal way as a dictionary or table entry; or a data exception may be recognized. If the contents are to be used in the normal way, an access exception can be recognized for the improper location even after a store has occurred in the first-operand location. Such an access exception does not result in true nullification or suppression, except that the instruction address in the PSW is correct for the type of exception recognized. When order-preservation is specified, the results when dictionary entries are not in collating-sequence order are unpredictable and may include recognition of a data exception.

Dictionary Formats

Notation

(m-n) Value allowed in the field

[EC] Extension character may be present

Three periods (...) means the preceding field may be repeated.

Compression Dictionary

Character Entry

When CCT = 0

CCT		ACT		[EC]	[EC]	[EC]	[EC]	
0	3	8	11	24	32	40	48	56 63

ACT Additional-extension-character count (0-4); number of ECs in entry. if ACT is 5, 6, or 7, it may be treated as 4, may cause data exception, or may cause comparison to mod(ACT,4) additional entries that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry; see Note 1

EC Additional extension character

When CCT = 1

CCT	X		ACT	CPTR	[EC]	…	CC		
0	3	4	8	11	24		n		63

X examine-child bit; child has one or more additional extension characters or has children; see Note 2

ACT Additional-extension-character count (0-4). if ACT is 5, 6, or 7, it may be treated as 4, may cause data exception, or may cause comparison to mod(ACT,4) additional entries that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry.

CPTR Index of first child

EC Additional extension character(s)

CC Child character

When CCT >1

CCT	XXXXX	YY	D	CPTR	[EC]	CC	CC	…	…
0	3	8		11	24	n	n+8		63

CCT Child count (2-6 if D=0, 2-5 if D=1). If D=0 and CCT=6, sibling descriptor follows 5th child (CCT = 7 may be treated as 6 or it may cause a data exception). If D=1 and CCT=5, sibling descriptor follows 4th child ACT (CCT = 6 or 7 may be treated as 5 or it may cause a data exception)

XXXXX Examine-child bits for children 1-5 (D=0) or 1-4 (D=1). Bit(s) ignored if respective child does not exist.

YY Examine child bits for 6th & 7th siblings designated by first format-0 sibling descriptor for children of this entry; or examine-child-bits for 13th and 14th siblings designated by first format-1 sibling descriptor for children of this entry. Bit(s) ignored if sibling does not exist.

EC Additional extension character(s)

CC Child character

Format-0 Sibling Descriptor

SCT	YYYYY	SC	[SC]	…	…	…	…	…
0	3	8	16	24	n	n+8		63

SCT Sibling Count (0-7); zero is treated as 7 and indicates another SD follows 7th sibling

YYY… Examine-child bits for siblings 1-5; bit is ignored if sibling does not exist; if this is the first sibling descriptor under parent, bits for siblings 6 and 7 are in parent — otherwise, 6th and 7th siblings must be examined since bits for them are not provided.

SC Sibling character

Format-1 Sibling Descriptor

SCT	YYYYYYYYYYYYY	SC	[SC]	…	…	…	…	
0	3	16	24	n	n+8			63

SCT Sibling Count (1-15); 15 is treated as 14 and indicates another SD follows 14th sibling. 0 may be treated as 15 or cause a data exception)

YYY… Examine-child bits for siblings 1-12; bit is ignored if sibling does not exist; if this is the first sibling descriptor under parent, bits for siblings 13 and 14 are in parent — otherwise, 1‘3th and 14th siblings must be examined since bits for them are not provided.

SC Sibling character

Notes:

1. If ACT or D is nonzero in alphabet entry, any of the following may result:
   - ACT or D is treated as zero.
   - ACT or D does not cause comparison to additional extension characters but does determine the position of the first child character.
   - ACT or D is treated the same as in a nonalphabet entry except that, if this causes a mismatch on the next characters to be compressed, a data exception is recognized.
2. A child may be examined even if its examine-child bit (X or Y) is zero. If an examine-child bit (X or Y) is one and the corresponding child or sibling exists, but it is not true that the child or sibling either has one or more additional extension characters or has children, a data exception may be recognized.

Expansion Dictionary

Character Entry

Generic Form

PSL		
0	3	63

PSL Partial-symbol length (0-5); number of ECs in entry; 0 indicates an unpreceded entry; 6 and 7 may be treated as 5, may cause a data exception, or may cause movement to the first operand location of one or two, respectively, additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

If PSL=0 (Unpreceded Entry)

PSL		CSL	EC	[EC]	[EC]	[EC]	[EC]	[EC]	[EC]	
0	3	5	8	16	24	32	40	48	56	63

CSL Complete-symbol length (1-7); number of ECs in the entry; 0 may cause a data exception or may cause movement to the first operand location of up to 256 ECs that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry

EC Extension character

Bits 3 and 4 of the entry should be zeros; otherwise, any of the following may occur: the bits may be ignored, they may cause a data exception, or they may cause movement to the first operand location of up to 24 additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

If PSL>0 (Preceded Entry)

PSL	PPTR	EC	[EC]	[EC]	[EC]	[EC]	OFST
0	3	16	24	32	40	48	56 63

PSL Partial-symbol length (1-5); number of ECs in the entry; 0 indicates an unpreceded entry; 6 and 7 may be treated as 5, may cause a data exception, or may cause movement to the first operand location of one or two, respectively, additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

PPTR Predecessor pointer; index of preceding entry that should contain the next left-hand characters of the character symbol represented by this entry

OFST Offset (0-255) from the current position in the output area to where first EC in this entry is placed; however, for preceded entries after the first one, either method 1 or method 2 may be used -- see the text

When expansion is completed, the output pointer is advanced either by the sum of the PSL and OFST in the first-encountered preceded entry or by the number of characters placed in the first-operand location due to expansion of the index symbol. If the first method is used and PSL is 6 or 7, either 5 or the actual value of PSL may be used.

There is no checking for logical correctness of the operation.

Format-1 Sibling Descriptor

The expansion dictionary contains bits 64-127 of the format-1 sibling descriptors that begin in the compression dictionary.

Appendix H. Hexadecimal Tables

The following tables aid in converting hexadecimal values to decimal values, or the reverse.

Direct Conversion Table

This table provides direct conversion of decimal and hexadecimal numbers in these ranges:

Hexadecimal	Decimal
000 to FFF	0000 to 4095

To convert numbers outside these ranges, and to convert fractions, use the hexadecimal and decimal conversion tables that follow the direct conversion table in this appendix.

TO CONVERT HEXADECIMAL TO DECIMAL

1. Locate the column of the decimal numbers corresponding to the leftmost digit or letter of the hexadecimal; select from this column and record the number that corresponds to the position of the hexadecimal digit or letter.
2. Repeat step 1 for the next (second from the left) position.
3. Repeat step 1 for the units (third from the left) position.
4. Add the numbers selected from the table to form the decimal number.

EXAMPLE

Conversion of Hexadecimal Value		D34
1.	D	3328
2.	3	48
3.	4	+ 4
4.	Decimal	3380

To convert integer numbers greater than the capacity of the table, use the techniques below:

HEXADECIMAL TO DECIMAL

Successive cumulative multiplication from left to right, adding units position.

```
Example: D34₁₆ = 3380₁₀    D =    13
                                x 16
                                 208
                          3 =  +   3
                                 211
                                x 16
                                3376
                          4 =  +   4
                                3380
```

TO CONVERT DECIMAL TO HEXADECIMAL

1. (a) Select from the table the highest decimal number that is equal to or less than the number to be converted.
(b) Record the hexadecimal of the column containing the selected number.
(c) Subtract the selected decimal from the number to be converted.
2. Using the remainder from step 1(c), repeat all of step 1 to develop the second position of the hexadecimal (and a remainder)
3. Using the remainder from step 2, repeat all of step 1 to develop the units position of the hexadecimal.
4. Combine the terms to form the hexadecimal number.

EXAMPLE

```
Conversion of
Decimal Value        3380

1.  D               -3328
                       52

2.  3               -  48
                        4

3.  4               -   4

4.  Hexadecimal       D34
```

DECIMAL TO HEXADECIMAL

Divide and collect the remainder in reverse order

```
Example:   3380₁₀ = X₁₆
                            Remainder
           16 | 3380 →    4    ↑
           16 |  211 →    3    |
           16 |   13 →    D    |

                     3380₁₀ = D34₁₆
```

POWERS OF 16 TABLE

Example: $268{,}435{,}456_{10} = (2.68435456 \times 10^{8})_{10} = 1000\ 0000_{16} = (10^{7})_{16}$

16^n	n
1	0
16	1
256	2
4 096	3
65 536	4
1 048 576	5
16 777 216	6
268 435 456	7

16^n	n
4 294 967 296	8
68 719 476 736	9
1 099 511 627 776	10 = A
17 592 186 044 416	11 = B
281 474 976 710 656	12 = C
4 503 599 627 370 496	13 = D
72 057 594 037 927 936	14 = E
1 152 921 504 606 846 976	15 = F

TO CONVERT .ABC HEXADECIMAL TO DECIMAL

```
Find .A      in position 1        .6250
Find .0B     in position 2        .0429 6825
Find .00C    in position 3     +  .0029 2968 7500
             .ABC is equal to     .6708 9843 7500
```

TO CONVERT .13 DECIMAL TO HEXADECIMAL

```
1.  Find .1250 next lowest to       .1300
                 subtract         – .1250                = .2 Hex

2.  Find .0039 0625 next lowest to  .0050 0000
                                  – .0039 0625           = .01

3.  Find .0009 7656 2500            .0010 9375 0000
                                  – .0009 7656 2500      = .004

4.  Find .0001 0681 1523 4375       .0001  1718 7500 0000
                                  – .0001  0681 1523 4375  = .0007
                                    .0000 1037 5976 5625   = .2147 Hex

5.  .13 Decimal is approximately equal to ________________↑
```

To convert fractions beyond the capacity of the table, use techniques below:

HEXADECIMAL TO FRACTION DECIMAL

Convert the hexadecimal fraction to its decimal equivalent using the same technique as for integer numbers. Divide the results by 16n (n is the number of fraction positions).

Example: .8A7 $= .540771_{10}$

$8A7_{16} = 2215_{10}$

$16^3 = 4096$

$$4096 \overline{)\,2215.000000} \quad .540771$$

DECIMAL FRACTION TO HEXADECIMAL

Collect integer parts of product in the order of calculation.

Example: $.5408_{10} = .8A7_{16}$

```
             .5408
           ×  16
 │ 8 ◄── [ 8.] 6528
 │         ×  16
 │ A ◄── [10.] 4448
 │         ×  16
 ▼ 7 ◄── [ 7.] 1168
```

Hexadecimal Addition and Subtraction Table

Example: 6 + 2 = 8, 8 - 2 = 6, and 8 - 6 = 2

	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F

BASR (BRANCH AND SAVE) instruction 7-36
example A-8
BASSM (BRANCH AND SAVE AND SET MODE) instruction 7-36
example A-8
BASTEO (base-AST-entry origin) 5-67
BC (BRANCH ON CONDITION) instruction 7-39
example A-12
BCR (BRANCH ON CONDITION) instruction 7-39
BCT (BRANCH ON COUNT) instruction 7-40
example A-12
BCTG (BRANCH ON COUNT) instruction 7-40
BCTGR (BRANCH ON COUNT) instruction 7-40
BCTR (BRANCH ON COUNT) instruction 7-40
example A-12
BFP
data class
testing of 19-41
BFP (binary floating point) 9-4
BFP data 19-2
conversion of 9-27
BFP facility 19-1
BFP-instruction data exception 6-25
bias for exponent 9-2, 19-2, 20-3
function of view 9-2
summary for BFP 19-2, 19-3
summary for DFP 20-3, 20-6
biased exponent 9-2, 19-2, 20-3
BIC (BRANCH INDIRECT ON CONDITION) instruction 7-38
big endian 7-287, 7-394
bimodal addressing
See addressing mode

real-space 3-42
in AST entry 3-32
used for access-register translation 5-58
used for subspace groups 5-69
region-table 3-42
in AST entry 3-32
used for access-register translation 5-58
used for subspace groups 5-69
secondary real-space 3-44
secondary region-table 3-44
secondary segment-table 3-44

segment-table 3-42
in AST entry 3-32
used for access-register translation 5-58
used for subspace groups 5-69
designation (origin and length)
access-list 5-55
designation-type-control bits
home 3-45
primary 3-44
secondary 3-44
destructive overlap 5-128, 7-290, 7-295, 7-298
in the access-register mode 5-116
device 2-8, 13-5
console 12-1
effect of I/O-system reset on 17-14
device-active bit 16-16, 16-36
device-active-only measurement (I/O) 17-9
device-active-only-time interval (in measurement block) 17-6
device address 13-6
device-busy time (in extended measurement word) 16-58
device-busy time (in measurement block) 17-6
device-command word
See DCW
device-connect-time interval
See DCTI
device-connect-time measurement 17-10
effect of suspension on 15-75
enable 15-4
device-disconnect-time interval (in measurement block) 17-5
device identifier 13-6
device number 13-6
assignment of 13-6
in PMCW 15-5
device-number valid (bit in PMCW) 15-4
device status 16-24
field-validity flag for (in subchannel logout) 16-29, 16-49
with inappropriate bit combination 16-50
device status check 16-50
DFLTCC (DEFLATE CONVERSION CALL) 26-16
DFP
canonical data 20-6
canonical declets 20-6
classes of DFP data 20-6
data signaling and quiet NaNs 20-7
infinities 20-7
normal numbers 20-7
subnormal numbers 20-6
zero 20-6
cohort 20-2
data class
testing of 20-56
data formats 20-3

VPKS (VECTOR PACK SATURATE) vector instruction 21-17
VPKZ (VECTOR PACK ZONED) instruction 25-13
VPOPCT (VECTOR POPULATION COUNT) vector instruction 22-21
VPSOP (VECTOR PERFORM SIGN OPERATION DECIMAL) instruction 25-14
VREP (VECTOR REPLICATE) vector instruction 21-19
VREPI (VECTOR REPLICATE IMMEDIATE) vector instruction 21-20
VRP (VECTOR REMAINDER DECIMAL) instruction 25-16
VS (VECTOR SUBTRACT) vector instruction 22-27

VSBCBI (VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION) vector instruction 22-29
VSBI (VECTOR SUBTRACT WITH BORROW INDICATION) vector instruction 22-28
VSCBI (VECTOR SUBTRACT COMPUTE BORROW INDICATION) vector instruction 22-28
VSCEF (VECTOR SCATTER ELEMENT) vector instruction 21-20
VSCEG (VECTOR SCATTER ELEMENT) vector instruction 21-20
VSDP (VECTOR SHIFT AND DIVIDE DECIMAL) instruction 25-18
VSEG (VECTOR SIGN EXTEND TO DOUBLEWORD) vector instruction 21-21
VSEL (VECTOR SELECT) vector instruction 21-21
VSL (VECTOR SHIFT LEFT) vector instruction 22-25
VSLB (VECTOR SHIFT LEFT BY BYTE) vector instruction 22-25
VSLD (VECTOR SHIFT LEFT DOUBLE BY BIT) vector instruction 22-25
VSLDB (VECTOR SHIFT LEFT DOUBLE BY BYTE) vector instruction 22-26
VSP (VECTOR SUBTRACT DECIMAL) instruction 25-21
VSRA (VECTOR SHIFT RIGHT ARITHMETIC) vector instruction 22-26
VSRAB (VECTOR SHIFT RIGHT ARITHMETIC BY BYTE) vector instruction 22-26
VSRD (VECTOR SHIFT RIGHT DOUBLE BY BIT) vector instruction 22-26
VSRL (VECTOR SHIFT RIGHT LOGICAL) vector instruction 22-27
VSRLB (VECTOR SHIFT RIGHT LOGICAL) vector instruction 22-27
VSRP (VECTOR SHIFT AND ROUND DECIMAL) instruction 25-19
VST (VECTOR STORE) vector instruction 21-21
VSTBR (VECTOR STORE BYTE REVERSED ELEMENTS) vector instruction 21-22
VSTEB (VECTOR STORE ELEMENT) vector instruction 21-22, 21-23
VSTEBRF (VECTOR STORE BYTE REVERSED ELEMENT) vector instruction 21-22
VSTEBRG (VECTOR STORE BYTE REVERSED ELEMENT) vector instruction 21-22
VSTEBRH (VECTOR STORE BYTE REVERSED ELEMENT) vector instruction 21-22
VSTEF (VECTOR STORE ELEMENT) vector instruction 21-23
VSTEG (VECTOR STORE ELEMENT) vector instruction 21-23
VSTEH (VECTOR STORE ELEMENT) vector instruction 21-22, 21-23, 21-24
VSTER (VECTOR STORE ELEMENTS REVERSED) vector instruction 21-24
VSTL (VECTOR STORE WITH LENGTH) vector instruction 21-26
VSTM (VECTOR STORE MULTIPLE) vector instruction 21-24
VSTRC (VECTOR STRING RANGE COMPARE) vector instruction 23-6
VSTRLR (VECTOR LOAD RIGHTMOST WITH LENGTH) vector instruction 21-25
VSTRLR (VECTOR STORE RIGHTMOST WITH LENGTH) vector instruction 21-25
VSTRS (VECTOR STRING SEARCH) vector instruction 23-8
VSUM (VECTOR SUM ACROSS WORD) vector instruction 22-30
VSUMG (VECTOR SUM ACROSS DOUBLEWORD) vector instruction 22-29
VSUMQ (VECTOR SUM ACROSS QUADWORD) vector instruction 22-30
VTAM use of symbol translation 7-179
VTM (VECTOR TEST UNDER MASK) vector instruction 22-31
VTP (VECTOR TEST DECIMAL) instruction 25-22
VUPH (VECTOR UNPACK HIGH) vector instruction 21-26
VUPKZ (VECTOR UNPACK ZONED) instruction 25-22
VUPL (VECTOR UNPACK LOW) vector instruction 21-27
VUPLH (VECTOR UNPACK LOGICAL) vector instruction 21-26
VUPLL (VECTOR UNPACK LOGICAL LOW) vector instruction 21-27
VX (VECTOR EXCLUSIVE OR) vector instruction 22-11
VXC (vector-exception code) 6-20

W

wait indicator 12-6
wait-state bit
  in the PSW 4-6
warning (machine-check condition) 11-17
  subclass-mask bit for 11-27
warning-track-interruption facility 1-29
WFC (VECTOR FP COMPARE SCALAR) vector instruction 24-7
WFK (VECTOR FP COMPARE AND SIGNAL SCALAR) vector instruction 24-8
word 3-3
word-concurrent storage references 5-127

working allegiance (I/O) 15-12
wraparound
    of instruction addresses 5-10
    of PER addresses 4-35
    of register numbers
        for LOAD MULTIPLE instruction 7-281
        for STORE MULTIPLE instruction 7-392
    of storage addresses 3-7
        controlled by addressing mode 3-7
        for MOVE INVERSE instruction 7-289
        for MOVE LONG EXTENDED instruction 7-295
        for MOVE LONG instruction 7-291
        for MOVE LONG UNICODE instruction 7-298
        for MOVE WITH OPTIONAL SPECIFICATIONS instruction 10-70
    of TOD clock 4-48

X

X (EXCLUSIVE OR) instruction 7-253
X field of instruction 5-11
XA (extended architecture)
    See 370-XA architecture
XC (EXCLUSIVE OR) instruction 7-254
    examples A-20
XG (EXCLUSIVE OR) instruction 7-253
XGR (EXCLUSIVE OR) instruction 7-253
XI (EXCLUSIVE OR) instruction 7-254
    example A-21
XIHF (EXCLUSIVE OR IMMEDIATE) instruction 7-255
XILF (EXCLUSIVE OR IMMEDIATE) instruction 7-255
XIY (EXCLUSIVE OR) instruction 7-254
XR (EXCLUSIVE OR) instruction 7-253
XRK (EXCLUSIVE OR) binary instruction 7-253
XSCH (CANCEL SUBCHANNEL) instruction 14-3
XY (EXCLUSIVE OR) instruction 7-253

Z

Z bit (zero condition-code bit) 16-12
    as cause of intermediate interruption condition 16-18
z/Architecture architecture
    additions to 1-2, 1-7
    original highlights of 1-2
ZAP (ZERO AND ADD) instruction 8-14
    example A-41
zero
    instruction-length code 6-7
    negative
        See negative zero
    normal meaning for byte value 0-xxix
    setting floating-point register to 9-35
    true (HFP number) 18-1
zero-address-detection PER event
    mask for 4-27
ZERO AND ADD instruction 8-14
    example A-41
zero condition code (Z bit in SCSW) 16-12
zero-padding control 7-172
zone bits 8-1
    moving of 7-303
zoned decimal numbers 8-1
zoned-decimal numbers
    examples A-4

Communicating Your Comments to IBM

Title: z/Architecture Principles of Operation

Publication No: SA22-7832-12

If you especially like or dislike anything about this book, please direct your comments to:

Internet e-mail: mhvrcfs@us.ibm.com

Be sure to send your name, address, and telephone number if you would like a reply.

Feel free to comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. However, the comments you send should pertain to only the information in this manual and the way in which the information is presented. To request additional publications, or to ask questions or make comments about the functions of IBM products or systems, you should talk to your IBM representative or to your IBM authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

Make sure to include the following in your note:

- Title and publication number of this book
- Page number or topic to which your comment applies

Optionally, if you include your telephone number, we will be able to respond to your comments by phone.
