# Supplementary Material

Supplementary Material is available in online versions of the report.

## Introduction and Scope

are discussed in Sections 11.3.1 and 12.2.2 to 12.2.3. The reflaction of past trends is assessed in Box 11.2, which concludes that the

This Annex presents a series of gures showing global and regional and maps cannot be interpreted literally as probability patterns of climate change computed from global climate rhoutelons. They should not be interpreted as 'forecasts'. output gathered as part of the Coupled Model Intercomparison Project

Phase 5 (CMIP5; Taylor et al., 2012). Maps of surface air temperajections of future climate change are conditional on assumptions of change and relative precipitation change (i.e., change expressetimentenesset forcing, affected by shortcomings of climate models and inevipercentage of mean precipitation) in different seasons are pretactivealso subject to internal variability when considering specific perifor the globe and for a number of different sub-continental-sdale projected patterns of climate change may differ from one climate regions. Twenty-year average changes for the near term (2016-12003) generation to the next due to improvements in models. Some for the mid term (2046–2065) and for the long term (2081–2106) cartel-inadequacies are common to all models, but so are many pat given, relative to a reference period of 1986–2005. Time series furthernof change across successive generations of models, which give

perature and relative precipitation changes are shown for globaldamed con dence in projections. The information presented is intended and sea averages, the 26 sub-continental SREX (IPCC Special Repended) a starting point for anyone interested in more detailed infor Managing the Risks of Extreme Events and Disasters to Advantation on projections of future climate change and complements the mate Change Adaptation) regions (IPCC, 2012) augmented with starting point for anyone interested in more detailed information projections of future climate change and complements the mate Change Adaptation) regions (IPCC, 2012) augmented with starting point for anyone interested in more detailed information projections.

regions and the Caribbean, two Indian Ocean and three Paci c Ocean

regions. In total this Annex gives projections for 35 regions, 2 validation Notes

and 2 seasons. The projections are made under the Representative

Concentration Pathway (RCP) scenarios, which are introduced ibabajand ProcessingThe gures have been constructed using the ter 1 with more technical detail given in Section 12.3 (also no@Mhe5 model output available at the time of the AR5 cut-off for discussion of near-term biases in Sections 11.3.5.1 and 11.3.6.1achtapped papers (15 March 2013). This data set comprises 32/42/25/38 are shown only for the RCP4.5 scenario; however, the time-seriese paerio experiments for RCP2.6/4.5/6.0/8.5 from 42 climate models sented show how the area-average response varies among the RCP4.6, l.1). Only concentration-driven experiments are used (i.e., those RCP4.5, RCP6.0 and RCP8.5 scenarios. Spatial maps for the outherhible boncentrations rather than emissions of greenhouse gases are scenarios and additional seasons are presented in the Annex I presplitived) and only one ensemble member from each model is select mentary Material. Figures Al.1 and Al.2 give a graphical explanation if multiple realizations exist with different initial conditions of aspects of both the time series plots and the spatial maps.al/thibitiferent realizations of natural variability. Hence each model is some of the background to the information presented is givergivene equal weight. Maps from only one scenario (RCP4.5) are shown discussion of the maps and time series, as well as important additionale series are included from all four RCPs. Maps from other RCPs background, is provided in Chapters 9, 11, 12 and 14. Figure captions entered in the Annex I Supplementary Material. on each page of the Atlas reference the speci c sub-sections in the

report relevant to the regions considered on that page.

Reference Period:Projections are expressed as anomalies with respect to the reference period of 1986–2005 for both time series and

The projection of future climate change involves the careful evaluation maps (i.e., differences between the future period and the ref of models, taking into account uncertainties in observations and reone period). Thus the changes are relative to the climate change sideration of the physical basis of the indings, in order to characterizes already occurred since the pre-industrial period and which is the credibility of the projections and assess their sensitivity to discensed in Chapters 2 and 10. For quantities where the trend is large tainties. As discussed in Chapter 9, different climate models-have example natural variability such as large-area temperature changes, a ing degrees of success in simulating past climate variability and models recent reference period would give better estimates (see Section state when compared to observations. Veri cation of regional triendles.1); for quantities where the natural variability is much larger is discussed in Box 11.2 and provides further information on the theoretic trend a longer reference period would be preferable. ibility of model projections. The information presented in this Annex is

based entirely on all available CMIP5 model output with equal weight Model Weighting Model evaluation uses a multitude of tech given to each model or version with different parameterizations niques (see Chapter 9) and there is no consensus in the community about how to use this information to assign likelihood to different

Complementary methods for making quantitative projections, in whotel projections. Consequently, the different CMIP5 models used for model output is combined with information about model perform the considered in the Atlas are all considered to give equally-likely profusing statistical techniques, exist and should be considered in ijeptions in the sense of 'one model, one vote'. Models with variations studies (see Sections 9.8.3, 11.3.1 and 12.2.2 to 12.2.3). Althoughsical parameterization schemes are treated as distinct models. results from the application of such methods can be assessed along

side the projections from CMIP5 presented here, it is beyond the size bles: Two variables have been plotted: surface air temperature of this Annex. Nor do the simple maps provided represent a **chlaust** and relative precipitation change. The relative precipitation estimate of the uncertainty associated with the projections. Here the time is defined as the percentage change from the 1986–2005 reforming and the provided as a simple, albeit imperfecte guide period in each ensemble member. For the time series, the variation to the range of possible futures (including the effect of natural laters are rest averaged over the domain and then the changes from ability). Alternative approaches used to estimate projection uncertainty ference period are computed. This implies that in regions with

large climatological precipitation gradients, the change is gerouf raths emble members is shown, on the right the 75th percentile. The dominated by the areas with the most precipitation. median is shown in the middle (different from similar plots in Chapters

11 and 12 and the time series which show the multi-model mean).

SeasonsFor temperature, the standard meteorological seasonsTbendestribution combines the effects of natural variability and model to August and December to February are shown, as these oftespread. The colour scale is kept constant over all maps. spond roughly with the warmest and coldest seasons. The annual mean

and remaining seasons, March to May and September to Octoblatedaing: Hatching indicates regions where the magnitude of the be found in the Annex I Supplementary Material. For precipitation at the 20-year mean is less than 1 standard deviation of mod half-years April to September and October to March are shown sbetstätnated present-day natural variability of 20-year mean differ in most monsoon areas the local rain seasons are entirely constanced. The natural variability is estimated using all pre-industrial conare included in the Supplementary Material.

within the seasonal range plotted. Because the seasonal aveinableuiss which are at least 500 years long. The rst 100 years of the computed rst, followed by the percentile change, these numberseared ustrial are ignored. The natural variability is then calculated for dominated by the rainy months within the half-year. The annual excernisgrid point as the standard deviation of non-overlapping 20-year means after a quadratic t is subtracted at every grid point to eliminate model drift. This is multiplied by the square root of 2, a factor that

Regions:In addition to the global maps, the areas de ned in the SREE's as the comparison is between two distributions of numbers. The (IPCC, 2012) are plotted with the addition of six regions containing them across all models of that quantity is used. This characterizes Caribbean, Indian Ocean and Paci c Island States and land athet sepaical difference between two 20-year averages that would be areas of the two polar regions. For regions containing large landes peemsed due to unforced internal variability. The hatching is applied averages are computed only over land grid points only. For tocal amaps so, for example, if the 25th percentile of the distribution regions, averages are computed over both land and ocean gridopoinots projections is less than 1 standard deviation of natural vari (see gure captions). A grid box is considered land if the land fraction, it is hatched.

long coastlines (west coast of South America, North Europe, Brouthatching can be interpreted as some indication of the strength of those over the surrounding sea.

is larger than 50% and sea if it is smaller than this. SREX regions with

east Asia) therefore include some in uence of the ocean. Notte effature anomalies from present-day climate, when compared to the temperature and precipitation over islands may be very differentifering to present day internal 20-year variability. It either means that the change is relatively small or that there is little agreement between models on the sign of the change. It is presented only as a guide

Time SeriesFor each of the resulting areas the areal mean is cotopassessing the strength of change as the difference between two ed on the original model grid using land, sea or all points, depen@@gyear intervals. Using other measures of natural variability would the de nition of the region (see above). As an indication of the region destination of the region (see above). As an indication of the region destination of the region (see above). uncertainty and natural variability, the time series of each mode atomid would not be very different. Other methods of hatching and scenario over the common period 1900-2100 are shown on the stipp bing are possible (see Box 12.1) and, in cases where such informa the page as anomalies relative to 1986-2005 (the seasons Determberritical, it is recommended that thorough attention is paid to to February and October to March are counted towards the seasons sing signi cance using a statistical test appropriate to-the prob year in the interval). The multi-model ensemble means are also lenoweing considered.

Finally, for the period 2081-2100, the 20-year means are computed

and the box-and-whisker plots show the 5th, 25th, 50th (me@siaen)ariosSpatial patterns of changes for scenarios other than RCP4.5 75th and 95th percentiles sampled over the distribution of the 20ayreae found in the Annex I Supplementary Material.

means of the model time series indicated in Table Al.1, including both natural variability and model spread. In the 20-year means-the natu

ral variability is suppressed relative to the annual values in the therences

series whereas the model uncertainty is the same. Note that owing to

a smaller number of models, the box-and-whisker plots for the RCP2201Managing the Risks of Extreme Events and Disasters to Advance Climate scenario and especially the RCP6.0 scenario are less certain than those Adaptation Special Report of Working Groups I and II of the Intergov for RCP4.5 and RCP8.5.

ernmental Panel on Climate Change [C. B. Field, V. Baros, T. F. Stocker, D. Qin, D. J. Dokken, K. L. Ebi, M. D. Mastrandrea, K. J. Mach, G.-K. Plattner, S. K. Allen, M. Tignor and P. M. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 2 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of precipitation changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 10.3.2.2, Box 11.2, 12.4.5.2, 14.8.15 contain relevant information regarding the evaluation of models in this region, the model spread other methods of projecting changes and the role of modes of variability and other climate phenomena.
