14 IMPORTANT: This specification is not a standard. It is an exploratory, informational document developed  
15 in order to obtain industry feedback. It does not reflect the views of the DMTF or all of its members. It is  
16 possible that future standards may or may not consider this work product to be an input in whole or in  
17 part.

18 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems  
19 management and interoperability. Members and non-members may reproduce DMTF specifications and  
20 documents, provided that correct attribution is given. As DMTF specifications may be revised from time to  
21 time, the particular version and release date should always be noted.

22 Implementation of certain elements of this standard or proposed standard may be subject to third party  
23 patent rights, including provisional patent rights (herein "patent rights"). DMTF makes no representations  
24 to users of the standard as to the existence of such rights, and is not responsible to recognize, disclose,  
25 or identify any or all such third party patent right, owners or claimants, nor for any incomplete or  
26 inaccurate identification or disclosure of such rights, owners or claimants. DMTF shall have no liability to  
27 any party, in any manner or circumstance, under any legal theory whatsoever, for failure to recognize,  
28 disclose, or identify any such third party patent rights, or for such party's reliance on the standard or  
29 incorporation thereof in its product, protocols or testing procedures. DMTF shall have no liability to any  
30 party implementing such standard, whether such implementation is foreseeable or not, nor to any patent  
31 owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is  
32 withdrawn or modified after publication, and shall be indemnified and held harmless by any party  
33 implementing the standard from any and all claims of infringement by a patent owner for such  
34 implementations.

35 For information about patents held by third-parties which have notified the DMTF that, in their opinion,  
36 such patent may relate to or impact implementations of DMTF standards, visit  
37 <http://www.dmtf.org/about/policies/disclosures.php>.

## Foreword

104 The *Software Defined Data Center (SDDC) Definition* (DSP-IS0501) was prepared by the Open Software  
105 Defined Data Center (OSDDC) Incubator.

106 The goal of the OSDDC Incubator is to develop [SDDC](#) use cases, reference architectures, and  
107 requirements based on real world customer requirements. Based on these inputs, the Incubator will  
108 develop a set of white papers and set of recommendations for industry standardization for the SDDC.

109 The work coming out of this incubator will result in:

- 110 1. Clear definition and scope of the SDDC concept.
- 111 2. New work items to existing chartered working groups.
- 112 3. Expanded scope to existing chartered groups
- 113 4. Creation of new working groups, if needed.

114 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems  
115 management and interoperability. For information about the DMTF, see <http://www.dmtf.org>.

## 116 Acknowledgments

117 The DMTF acknowledges the following individuals for their contributions to this document:

- 118 • Ali, Ghazanfar - ZTE Corporation
- 119 • Black, David - EMC
- 120 • Bumpus, Winston - VMware, Inc.
- 121 • Carlson, Mark - Toshiba America Electronic Components. Inc.
- 122 • Dolin, Rob - Microsoft Corporation
- 123 • Fayed, Wassim – Microsoft Corporation
- 124 • Khasnabish, Bhumip - ZTE
- 125 • Leung, John - Intel
- 126 • McDonald, Alex - NetApp
- 127 • Ronco, Enrico - Telecom Italia
- 128 • Snelling, David - Fujitsu
- 129 • Shah, Hemal - Broadcom
- 130 • Wells, Eric - Hitachi, Ltd.

- 132 • Zhdankin, Alex - Cisco

133

# Software Defined Data Center (SDDC) Definition

## 1 Executive summary

### 1.1 Introduction

The Software Defined Data Center (SDDC) is an evolutionary result of virtualization and [cloud](#) computing technologies. To date, the SDDC has been defined in many ways. The following examples are a few of the more prevalent (and realistic) definitions gleaned from a large number of resources used for this paper:

*“A Software Defined Data Center (SDDC) is a data storage facility in which all elements of the infrastructure – networking, storage, CPU and security – are virtualized and delivered as a service. Deployment, provisioning, configuration and the operation, monitoring and automation of the entire infrastructure is abstracted from hardware and implemented in software.” (Forrester)*

Another:

*“SDDC is the phrase used to refer to a data center where the entire infrastructure is virtualized and delivered as a service.” (VMware)*

It is clear that the move to the SDDC is a major technology shift. While other definitions have been proposed by various vendors, they all have similar intent.

The goal of this paper is to outline use cases, and definitions, and identify existing standards gaps, and possible architectures for the various implementations of SDDC.

### 1.2 SDDC definition

Software Defined Data Center (SDDC): a programmatic abstraction of logical compute, network, storage, and other resources, represented as software. These resources are dynamically discovered, provisioned, and configured based on workload requirements. Thus, the SDDC enables policy-driven orchestration of workloads, as well as measurement and management of resources consumed.

The SDDC comprises a set of features that include:

- Logical compute, network, storage, and other resources
- Discovery of resource capabilities
- Automated provisioning of logical resources based on workload requirements
- Measurement and management of resources consumed
- Policy-driven orchestration of resources to meet service requirements of the workloads

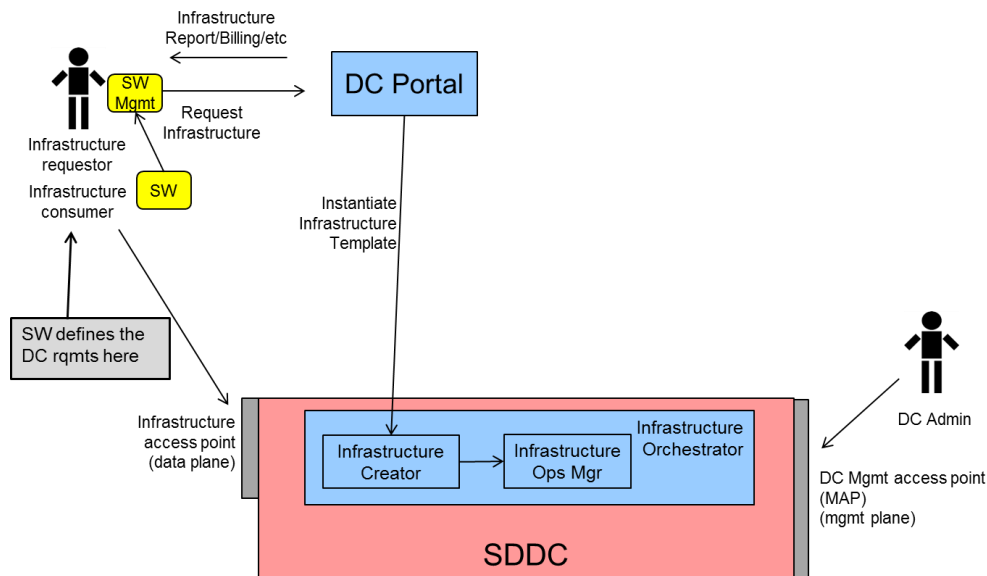

## 2 Use cases

This clause describes use cases for various services that can be provided by an SDDC, including Infrastructure as a Service ([IaaS](#)) and Software as a Service ([SaaS](#)).

165 **2.1 Infrastructure as a Service (IaaS)**

166 In IaaS, the customer wants to execute a workload and uses the data center to host the infrastructure.  
 167 After the infrastructure is available, the customer installs the necessary software and content/data, then  
 168 executes the workload.

169 Figure 1 shows the interactions in an IaaS environment based on a software-defined data center.

170 **Figure 1 - IaaS use case for SDDC**

172 **2.1.1 Actors**

173 There are two actors: the customer and the IaaS data center (DC) administrator. The customer has two  
 174 aspects: the infrastructure requestor and the infrastructure consumer.

175 The infrastructure requestor performs the following tasks:

- 176 • Designs an application composed of a workload that executes on a specific compute/storage
- 177 topology
- 178 • Requests an infrastructure with specific workload requirements
- 179 • Verifies infrastructure (including firmware/BIOS)
- 180 • Requests that infrastructure be increased or decreased
- 181 • Receives usage reports and billing

182 The infrastructure consumer performs the following tasks:

- 183 • Installs the OS, and applications and delivers content
- 184 • Starts the workload

185 The IaaS DC administrator performs the following tasks:

- 186 • Monitors power and cooling in the data center
- 187 • Adds (or replaces) platforms/resources to the data center
- 188 • Receives notification of resource depletion (or surplus?)
- 189 • Takes inventory (accounting, SW licenses, etc.)
- 190 • Performs security audit (or sec. contractor)
- 191 • Receives notification of potential brown-outs
- 192 • Updates platform firmware (security, etc.)

### 2.1.2 Use case

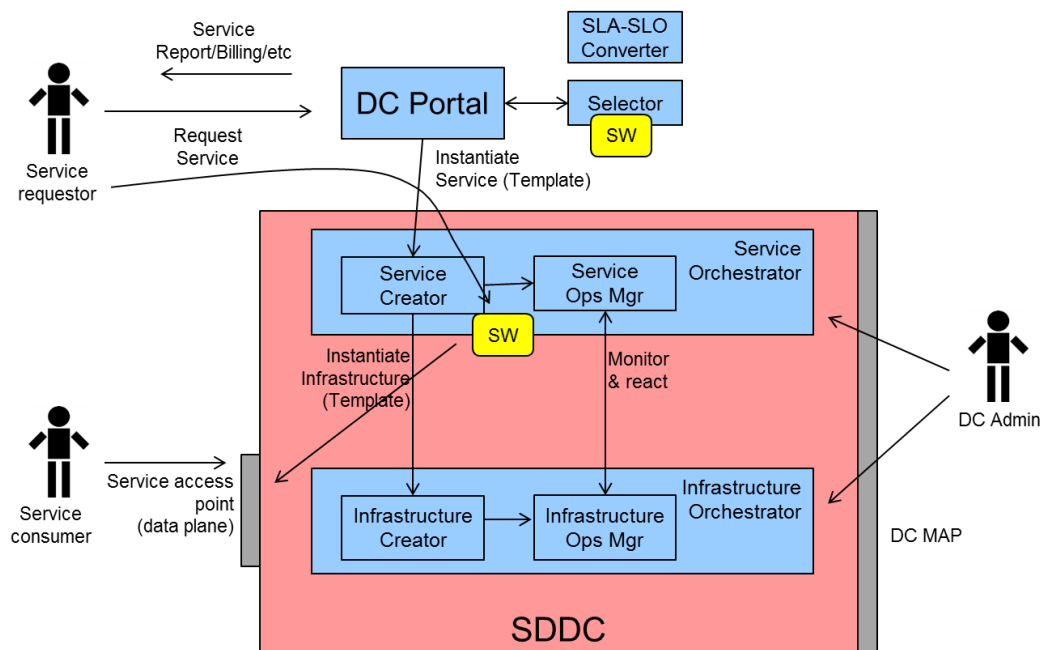

The workload is known to the infrastructure requestor.

In the diagram, the flow proceeds as follows:

1. The infrastructure requestor inspects the workload (WL) and determines the infrastructure to request.
2. The infrastructure requestor requests an infrastructure with specific service requirements from the service portal.
3. The service portal makes a request to the infrastructure orchestrator to instantiate the infrastructure.
4. The infrastructure orchestrator instantiates the infrastructure.
5. The infrastructure starts the infrastructure. At this point, both the infrastructure move to the operational phase and are managed by the infrastructure operation manager.
6. Once running, the infrastructure is available to the infrastructure consumer.

## 2.2 Software as a Service (SaaS)

In SaaS, the customer wants to instantiate a service and uses the data center to host the service. The service may be consumed by a service consumer, which is distinct from the SaaS customer. Once the service is instantiated the service requestor may need to provide additional content before the service is enabled and ready to be consumed.

**Figure 2 - SaaS use case for SDDC**

Figure 2 shows the interactions in a SaaS environment based on a software-defined data center.

### 2.2.1 Actors

There are three actors: the service requestor, the service consumer, and the SaaS DC administrator.

216 The service requestor wants to instantiate a service and performs the follow tasks:

- 217 • Requests a service with specific service requirements
- 218 • Monitors the service
- 219 • Changes the service requirements of an operational service
- 220 • Requests that the service scales up or scales down
- 221 • Requests migration of the service to another service provider
- 222 • Requests the service be terminated

223 The service consumer performs the following task:

- 224 • Uses the service

225 The SaaS DC administrator performs the following tasks:

- 226 • Monitors the service
- 227 • Monitors power and cooling in the data center
- 228 • Adds (or replaces) platforms/resources in the data center
- 229 • Receives notification of resource depletion (or surplus?)
- 230 • Takes inventory (accounting, SW licenses, etc.)
- 231 • Performs security audits (or sec. contractor)
- 232 • Receives notification of potential brown-outs
- 233 • Stages/tests new services
- 234 • Updates platform firmware (security, etc.)

### 235 2.2.2 Use case

236 The workload that defines the service infrastructure is known to the DC service portal. In the diagram, the  
237 flow proceeds as follows:

- 238 1. The service requestor requests a service with specific service requirements from the service  
239 portal.
- 240 2. If multiple service templates are possible, the service portal or the service requestor may select  
241 the specific service template.
- 242 3. The service portal makes a request to the service orchestrator to instantiate the service.
- 243 4. The service creator makes a request to the infrastructure orchestrator to instantiate the  
244 infrastructure.
- 245 5. After the infrastructure is instantiated, the service creator installs the OS, applications, and the  
246 content and configures accordingly.
- 247 6. Finally, the service creator starts the service and the service is available to the server consumer
- 248 7. At this point, both the infrastructure and service move to the operational phase and are managed  
249 by their respective operation managers.

## 250 3 SDDC technology and functionality

251 An SDDC incorporates and is heavily dependent upon the use of topologies that abstract, optionally pool,  
252 and automate the use of the virtualized resources. Virtualization technologies can be thought of as

253 common resources when integrated and used by the SDDC. The focus on industry standardized  
254 management models and application programming interfaces ([APIs](#)) provide this level of abstraction.  
255 Various vendors and [SDOs](#) are championing their respective offerings into the new SDDC community.

256 The SDDC comprises a set of features that include:

- 257 1. Logical compute, network, storage and other resources
- 258 2. Discovery of resource capabilities
- 259 3. Automated provisioning of logical resources based on workload requirements
- 260 4. Measurement and management of resources consumed
- 261 5. Policy-driven orchestration of resources to meet service requirements of the workloads

262 Additional SDDC features and functionalities include:

- 263 • Topology automation
- 264 • Security (authentication, authorization, auditing), intrusion detection system ([IDS](#)), intrusion  
265 prevention system (IPS), [firewall](#)

266 The SDDC should be:

- 267 • Standardized – API and functional model
- 268 • Holistic – system wide abstractions
- 269 • Adaptive - elasticity driven by the workload
- 270 • Automated - provisioning, configuration, and run-time management

### 271 **3.1 SDDC, virtualization and cloud relationships**

272 Virtualization is central to the SDDC but in itself is not sufficient. The three major building blocks that  
273 virtualization delivers are: compute, storage, and network:

- 274 1. Compute Virtualization – Abstraction of compute resources that can be realized with underlying  
275 collection of physical server resources. This concept includes abstraction of the number, type,  
276 and identity of physical servers, processors, and memory. Other technologies, such as  
277 containers, may also be used.
- 278 2. Storage Virtualization – Abstraction of storage resources that can be realized with underlying  
279 physical and logical storage resources. This concept includes abstraction of the number, type,  
280 and identity of physical disks.
- 281 3. Network Virtualization - Abstraction of network resources that can be realized using underlying  
282 physical and logical resources. This concept includes abstraction of the number, type, and  
283 identity of physical media, connectivity, and protocol.

## 284 **4 SDDC architectures**

285 Building on virtualization technology through standard APIs allows the SDDC automation to provision  
286 exactly those resources required for the software that will be deployed on those resources. This is shown  
287 in the lowest two layers of Figure 3 as the Data center Abstraction Layer (DAL) and Virtualization and  
288 Resource Characterization layer. This automation is envisioned to interpret the requirements for the  
289 deployed software and configure the resources appropriately to meet those requirements. The  
290 requirements may be conveyed to the administrator out of band, as is typical today, and in this case the  
291 administrator must interpret these requirements. However the requirements may also be conveyed  
292 through an API, the implementation of which interprets the requirements and automates what the  
293 administrator would otherwise need to do manually. This is shown in Figure 3 with the thin black arrows

294 being the manual requirements conveyed to the administrator and the results of the administrators  
295 interpretation conveyed manually, out of band, back as service levels. The administrator responds by  
296 providing resources that will meet the service levels required by the software. The blue arrow represents  
297 a self-service management interface that incorporates elements with the ability to convey the Compute,  
298 Storage and Networking requirements in-band such that the manual, out-of-band, requirements path is no  
299 longer needed. This has been identified as a gap for such interfaces as DMTF CIMI. The requirements  
300 need to be abstracted and added to the interface as [metadata](#) for the various loads that need resources.

301 Short term, the Infrastructure Service Characteristics shown in the top box as Provisioning, Protection,  
302 Availability, Performance, Security, and Energy Consumption are typically implemented for  
303 coarse-grained virtual and in some cases physical resources. Thus while the resources themselves may  
304 be virtualized and provisioned with fine-grained control (provisioned at the granularity of individual  
305 workloads), the services that provide these characteristics may not. To accommodate this, the top box  
306 contains pools of resources configured and provisioned at this coarse granularity with the coarse-grained  
307 services. Resource pooling is a technique used for various reasons and includes similarly configured  
308 resources both unused and already provisioned. We use some example pool names for clarity, but there  
309 may be many differently configured pools from which to draw. This way the administrator, if he is  
310 manually interpreting the requirements, can simply pick the pool with the best match of resource  
311 configurations for those requirements. If there is similar automation software receiving the requirements  
312 via the self-service interface, that software can do the interpretation and select the correct pool with an  
313 algorithm. We see this resource pooling technique as a temporary approach that should be obviated after  
314 the infrastructure services are able to act at a finer grained level.

315 SDDC builds upon virtualization technology by expanding the scope from individually virtualized  
316 components to the entire data center, and envisions a unified control and management solution.

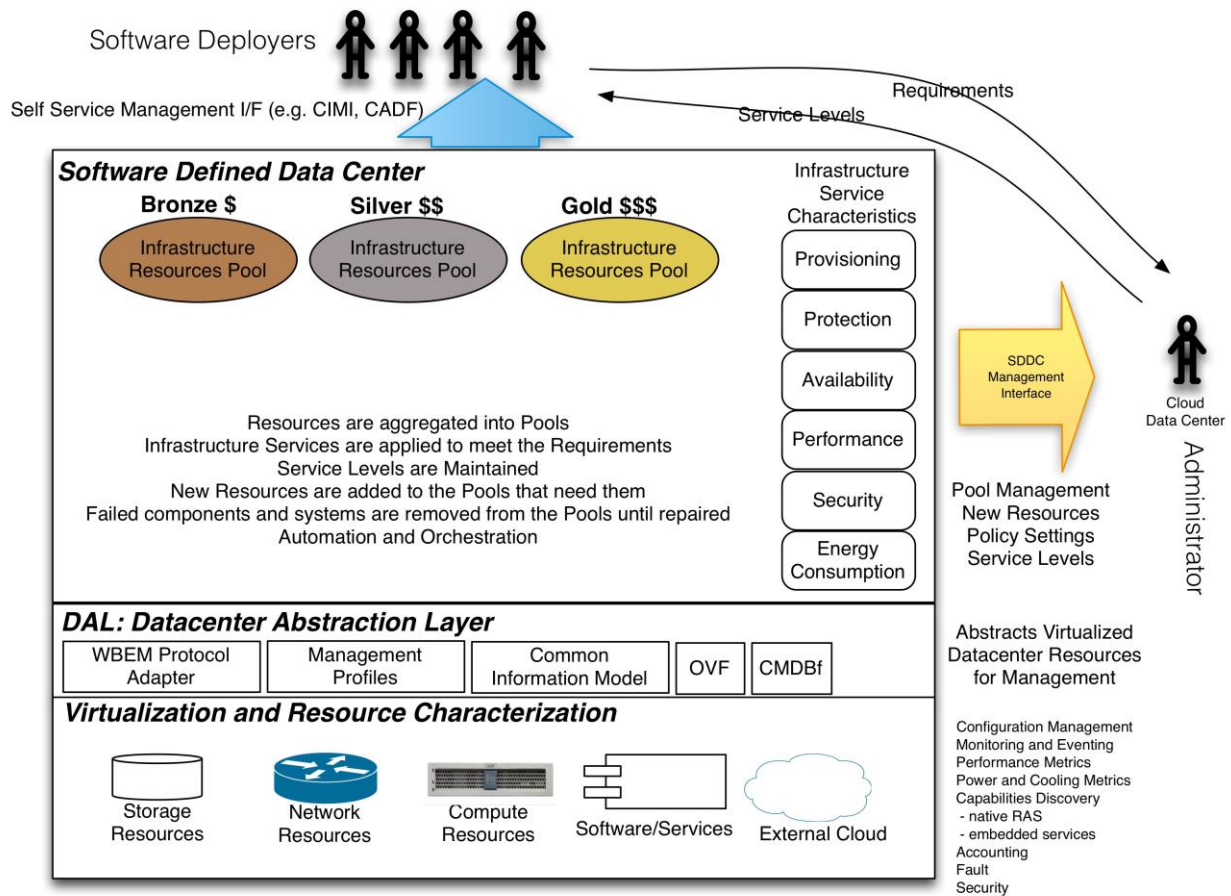

Figure 3 - SDDC architecture

317

318 Figure 3 shows all the elements of an SDDC. The SDDC architecture defines data center resources that  
 319 include software-based services. The DAL layer provides abstraction of compute, network, and storage  
 320 resources, which are then virtualized and configured according to the requirements of the workload.

321 The DAL is a unifying and consistent abstraction for the underlying resources and provides a  
 322 standardized interface and common model that may be used by the SDDC management automation  
 323 software.

#### 324 4.1 Server virtualization

325 Server virtualization releases CPU and memory from the limitations of the underlying physical hardware.  
 326 As a standard infrastructure technology, server virtualization is the basis of the SDDC, which extends the  
 327 same principles to all infrastructure services.

#### 328 4.2 Software Defined Network

329 In a Software Defined Network ([SDN](#)), the network control plane is moved from the switch to the software  
 330 running on a server. This improves programmability, efficiency, and extensibility. SDN is to date the most  
 331 developed and understood software-defined technology. Therefore this paper does not delve into the  
 332 details of this software-defined component.

### 333 4.3 Software Defined Storage

334 Software Defined Storage ([SDS](#)) is an emerging ecosystem of products and requires further discussion  
335 here. This software should make visible all physical and virtual resources and enables programmability  
336 and automated provisioning based on consumption or need. SDS separates the control plane from the  
337 data plane and dynamically leverages heterogeneity of storage to respond to changing workload  
338 demands. The SDS enables the publishing of storage service catalogs and enables resources to be  
339 provisioned on-demand and consumed according to policy.

340 In many respects, SDS is more about packaging and how IT users think about and design data centers.  
341 Storage has been largely software defined for more than a decade: the vast majority of storage features  
342 have been designed and delivered as software components within a specific, storage-optimized  
343 environment.

344 The Storage Networking Industry Association (SNIA) definition of SDS allows for both proprietary and  
345 heterogeneous platforms. To satisfy the SNIA definition, the platform must offer a self-service interface for  
346 provisioning and managing virtual instances of itself.

#### 347 4.3.1 Necessary SDS functionality

348 Because many storage offerings today have already been abstracted and virtualized, what capabilities  
349 should be offered to claim the title of Software Defined Storage?

350 Software Defined Storage should include:

- 351 • **Automation** – Simplified management that reduces the cost of maintaining the storage  
352 infrastructure.
- 353 • **Standard Interfaces** – APIs for the management, provisioning, and maintenance of storage  
354 devices and services.
- 355 • **Virtualized Data Path** – Block, File, and Object interfaces that support applications written to  
356 these interfaces.
- 357 • **Scalability** – Seamless ability to scale the storage infrastructure without disruption to availability  
358 or performance.

359 Ideally, SDS offerings allow applications and data producers to manage the treatment of their data by the  
360 storage infrastructure without the need for intervention from storage administrators, without explicit  
361 provisioning operations, and with automatic service level management. In addition, data services should  
362 be able to be deployed dynamically and policies should be used to maintain service levels and match the  
363 requirements with capabilities. Metadata should be used to:

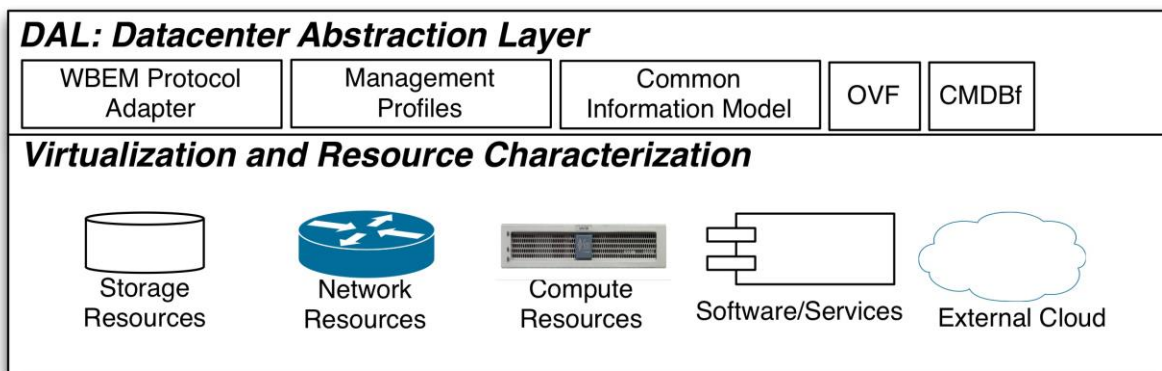

- 364 • Express requirements
- 365 • Control the data services
- 366 • Express service level capabilities

### 367 4.4 Data center Abstraction Layer

368 The Data center Abstraction Layer (DAL) is a unifying and consistent abstraction for the virtual and  
369 physical resources within the data center. It extends the concept of a Hardware Abstraction Layer (HAL)  
370 to the entire data center.

371 Prior to the development of the HAL, operating systems and applications were dependent on specific  
372 features provided by the hardware of the PC architecture. By adopting standard protocols, the HAL  
373 provided an abstract interface that allowed these variations to be isolated from the operating systems and  
374 applications.

375 In a similar manner the DAL abstracts variations in data center compute, network, storage, and software  
376 resources, presenting them as standardized resources within the SDDC.

377

378

**Figure 4 - Data center Abstraction Layer**

379 The DAL enables:

- 380 • Management layers in the SDDC to manage resources in a consistent manner
- 381 • Introduction of new resources without requiring changes to the management or application
- 382 layers

383 Improved efficiency and utilization of resources by the SDDC

#### 384 **4.5 Trust Boundary and Multi-Tenant Isolation Requirements**

385 As shown in Figure 3 (SDDC Architecture), it is expected that in a typical SDDC implementation,  
 386 virtualized computing, networking, storage and other resources will be shared by multiple tenants who are  
 387 hosted in the same set of physical devices.

388

389 It is therefore imperative that explicit trust boundaries are set among these tenants in order to maintain  
 390 appropriate isolation among the often competing tenants. Without proper isolation, policy, security, and  
 391 automation related information may be compromised and these in turn may result in loss of revenue for  
 392 the well-behaved tenants.

393

394 From the applications, services and administration viewpoints, it may be required to support tenancy-  
 395 specific resources and their configurations including service-quality (resiliency), even when the needs  
 396 span multiple physical devices in multiple physical locations. This may need to be achieved by using  
 397 tenancy-specific embedded authorization and authentication.

398

399 Trust boundary can be established using perimeters for physical, logical, address space, domain and  
 400 topology segmentation, peering and routing profiles, and so on.

401

402 It may be required to routinely monitor and log tenant's identification, credentials, service and resources-  
 403 usage contracts, etc. so that these can be frequently verified and updated in order to prevent spoofing or  
 404 other types of attacks.

### 405 **5 Applicable standards activity**

406 While the DMTF is currently the only SDO specifically focusing on developing models for the SDDC,  
 407 many other organizations have work that is relevant. Work in other SDOs is mainly focused on SDN and  
 408 SDS, but it is important to look at emerging standards and how they may be relevant to SDDC.

## 409 5.1 DMTF

410 DMTF standards enable effective management of IT environments through well-defined interfaces that  
411 collectively deliver complete management capabilities. DMTF standard interfaces are critical to enabling  
412 interoperability among multivendor IT infrastructures, and systems and network management including  
413 cloud computing, virtualization, desktop, network, servers, and storage.

414 Some of the key DMTF standards and initiatives under development that will enable the new SDDC  
415 paradigm are described below.

### 416 Open SDDC Incubator

417 The DMTF is the only SDO currently that is focusing on developing initial management models for the  
418 SDDC marketplace. The DMTF recently launched its 'SDDC Incubator' with the charter of directing all  
419 future work in the DMTF for SDDC.

### 420 Cloud Management Initiative

421 The DMTF's Cloud Management Initiative is focused to promote interoperable cloud infrastructure  
422 management between cloud service providers and their consumers and developers. Working groups  
423 within the initiative develop open standards with the aim of achieving this interoperability.

### 424 Network Management Initiative

425 DMTF's Network Management Initiative (NETMAN) is an integrated set of standards for management of  
426 physical, virtual, application-centric, and software-defined networks. The NETMAN initiative aims at  
427 unifying network management across traditional data centers, cloud infrastructures, [NFV](#) environments,  
428 and SDDC ecosystems.

### 429 Virtualization Management Initiative

430 DMTF's Virtualization Management (VMAN) initiative includes a set of specifications and profiles that  
431 address the management life cycle of a heterogeneous virtualized environment.

#### 432 5.1.1 Cloud Infrastructure Management Interface (CIMI)

433 CIMI is a high-level, self-service, interface for infrastructure clouds that greatly simplifies cloud systems  
434 management, allowing users to dynamically provision, configure, and administer their cloud usage. The  
435 specification standardizes interactions between cloud environments, using JSON and XML, to achieve  
436 interoperable cloud infrastructure management.

437 CIMI was adopted as an International Standard by the Joint Technical Committee 1 (JTC 1) of the  
438 [International Organization for Standardization](#) (ISO) and the [International Electrotechnical Commission](#)  
439 (IEC) in March 2015.

440 Version 2 of the CIMI specification, which is currently under development, extends the previous work with  
441 an enhanced network model and modelling of multicloud and intercloud scenarios.

#### 442 5.1.2 Open Virtualization Format (OVF)

443 The [OVF](#) specification provides a standard format for packaging and describing virtual machines and  
444 applications for deployment across heterogeneous virtualization platforms. OVF was adopted by the  
445 [American National Standards Institute](#) (ANSI) in August 2010 and as an International Standard in August  
446 2011 by the Joint Technical Committee 1 (JTC 1) of the [International Organization for Standardization](#)  
447 (ISO), and the [International Electrotechnical Commission](#) (IEC). In January 2013, DMTF released the  
448 second version of the standard, OVF 2.0, which applies to emerging cloud use cases and provides  
449 important developments from OVF 1.0 including improved network configuration support and package  
450 encryption capabilities for safe delivery.

### 451 **5.1.3 Web-Based Enterprise Management (WBEM)**

452 Web-Based Enterprise Management (WBEM) is a set of specifications that define how resources can be  
453 discovered, accessed, and manipulated, facilitating the exchange of data across otherwise disparate  
454 technologies and platforms.

455 [WBEM](#) defines protocols for the interaction between systems management infrastructure components  
456 implementing the Common Information Model (CIM), and is a major component of the DAL.

### 457 **5.1.4 Common Information Model (CIM)**

458 The CIM Schema is a [conceptual schema](#) that defines how managed elements in an IT environment are  
459 represented as a common set of objects and relationships. CIM is extensible in order to allow product  
460 specific extensions to the common definition of these managed elements. CIM uses a model based upon  
461 [UML](#) to define the CIM Schema and is the basis for most other DMTF standards.

### 462 **5.1.5 Configuration Management Database Federation (CMDBf)**

463 [CMDBf](#) facilitates the sharing of information between configuration management databases (CMDBs) and  
464 other management data repositories (MDRs). The CMDBf standard enables organizations to federate and  
465 access information from complex, multivendor infrastructures, simplifying the process of managing related  
466 configuration data stored in multiple CMDBs and MDRs.

### 467 **5.1.6 Systems Management Architecture for Server Hardware (SMASH)**

468 DMTF's SMASH standards are a suite of specifications that deliver architectural semantics, industry  
469 standard protocols and profiles to unify the management of the data center. The SMASH Server  
470 Management (SM) Command Line Protocol (CLP) specification enables simple and intuitive management  
471 of heterogeneous servers in the data center. SMASH takes full advantage of the DMTF's Web Services  
472 for Management (WS-Management) specification - delivering standards-based Web services  
473 management for server environments. Both provide server management independent of machine state,  
474 operating system state, server system topology, or access method, facilitating local and remote  
475 management of server hardware. SMASH also includes the SM Managed Element Addressing  
476 Specification, SM CLP-to-CIM Mapping Specification, SM CLP Discovery Specification, SM Profiles, as  
477 well as a SM CLP Architecture White Paper.

### 478 **5.1.7 Redfish API**

479 Scalability in today's data center is increasingly achieved with horizontal, scale-out solutions, which often  
480 include large numbers of simple servers. The usage model of scale-out hardware is drastically different  
481 from that of traditional enterprise platforms, and requires a new approach to management.

482 The DMTF's Redfish API is an open industry standard specification and schema designed to meet the  
483 expectations of end users for simple, modern, and secure management of scalable platform hardware.  
484 The Redfish API specifies a RESTful interface and utilizes JSON and OData to help customers integrate  
485 solutions within their existing tool chains.

## 486 **5.2 OASIS**

487 OASIS (Organization for the Advancement of Structured Information Standards) is a nonprofit,  
488 international consortium whose goal is to promote the adoption of product-independent standards for  
489 information formats.

### 490 **5.2.1 Cloud Application Management for Platforms (CAMP)**

491 OASIS CAMP advances an interoperable protocol that cloud implementers can use to package and  
492 deploy their applications. CAMP defines interfaces for self-service provisioning, monitoring, and control.

493 Based on [REST](#), CAMP is expected to foster an ecosystem of common tools, plug-ins, libraries, and  
494 frameworks, which will allow vendors to offer greater value-add.

495 Common CAMP use cases include:

- 496 • Moving on-premises applications to the cloud (private or public)
- 497 • Redeploying applications across cloud platforms from multiple vendors

## 498 **5.2.2 Topology and Orchestration Specification for Cloud Applications (TOSCA)**

499 The TOSCA TC substantially enhances the portability of cloud applications and the IT services that  
500 comprise them running on complex software and hardware infrastructure. The IT application and service  
501 level of abstraction in TOSCA will also provide essential support to the continued evolution of cloud  
502 computing. For example, TOSCA would enable essential application and service life cycle management  
503 support, e.g., deployment, scaling, patching, etc., in Software Defined Environments (SDE), such as  
504 Software Defined Data Centers (SDDC) and Software Defined Networks (SDN).

505 TOSCA facilitates this goal by enabling the interoperable description of application and infrastructure  
506 cloud services, the relationships between parts of the service, and the operational behavior of these  
507 services (e.g., deploy, patch, shutdown) independent of the supplier creating the service, and any  
508 particular cloud provider or hosting technology. TOSCA enables the association of that higher-level  
509 operational behavior with cloud infrastructure management.

510 TOSCA models integrate the collective knowledge of application and infrastructure experts, and enable  
511 the expression of application requirements independently from IaaS- and [PaaS](#)-style platform capabilities.  
512 Thus, TOSCA enables an ecosystem where cloud service providers can compete and differentiate to add  
513 value to applications in a software defined environment.

514 These capabilities greatly facilitate much higher levels of cloud service/solution portability, the continuous  
515 delivery of applications (DevOps) across their life cycle without lock-in, including:

- 516 • Portable deployment to any compliant cloud
- 517 • Easier migration of existing applications to the cloud
- 518 • Flexible selection and movement of applications between different cloud providers and cloud  
519 platform technologies
- 520 • Dynamic, multicloud provider applications

## 521 **5.3 SNIA**

522 The Storage Networking Industry Association (SNIA) mission is to “Lead the storage industry worldwide in  
523 developing and promoting standards, technologies, and educational services to empower organizations in  
524 the management of information”.

525 Working towards this goal, SNIA has produced a number of specifications, of which the following have  
526 particular relevance to the SDDC.

### 527 **5.3.1 Cloud Data Management Interface (CDMI)**

528 The SNIA Cloud Data Management Interface (CDMI) is an ISO/IEC standard that enables cloud solution  
529 vendors to meet the growing need of interoperability for data stored in the cloud. The CDMI standard is  
530 applicable to all types of clouds – private, public, and hybrid. There are currently more than 20 products  
531 that meet the CDMI specification.

532 CDMI provides end users with the ability to control the destiny of their data and ensure hassle-free data  
533 access, data protection, and data migration from one cloud service to another.

## 534 **Metadata in CDMI**

535 The Cloud Data Management Interface (CDMI) uses many different types of metadata, including HTTP  
536 metadata, data system metadata, user metadata, and storage system metadata. To address the  
537 requirements of enterprise applications and the data managed by them, this use of metadata allows  
538 CDMI to deliver simplicity through a standard interface. CDMI leverages previous SNIA standards, such  
539 as the eXtensible Access Method (XAM), for metadata on each data element. In particular, XAM has  
540 metadata that drives retention data services useful in compliance and eDiscovery.

541 CDMI's use of metadata extends from individual data elements and can apply to containers of data, as  
542 well. Thus, any data placed into a container essentially inherits the data system metadata of the container  
543 into which it was placed. When creating a new container within an existing container, the new container  
544 would similarly inherit the metadata settings of its parent container. Of course, the data system metadata  
545 can be overridden at the container or individual data element level, as desired.

546 The extension of metadata to managing containers, not just data, enables a reduction in the number of  
547 paradigms for managing the components of storage – a significant cost savings. By supporting metadata  
548 in a cloud storage interface standard and proscribing how the storage and data system metadata is  
549 interpreted to meet the requirements of the data, the simplicity required by the cloud storage paradigm is  
550 maintained, while still addressing the requirements of enterprise applications and their data.

## 551 **5.3.2 Storage Management Initiative**

552 The SNIA's Storage Management Initiative (SMI) gathers and prioritizes industry requirements that guide  
553 the Technical Work Groups to cooperatively develop the Storage Management Initiative Specification  
554 (SMI-S), an international standard implemented in over 500 products.

### 555 **SMI-S Technical Specification**

556 SMI-S standardizes and streamlines storage management functions and features into a common set of  
557 tools that address the day-to-day tasks of the IT environment. Initially providing a foundation for  
558 identifying the attributes and properties of storage devices, SMI-S now also delivers services such as  
559 discovery, security, virtualization, performance, and fault reporting.

560 SMI-S defines a method for the interoperable management of a heterogeneous Storage Area Network  
561 ([SAN](#)), and describes the information available to a WBEM Client from an SMI-S compliant CIM Server  
562 and an object-oriented, XML-based, messaging-based interface designed to support the specific  
563 requirements of managing devices in and through SANs. The latest publicly released version of SMI-S is  
564 the SMI-S V1.6.1 SNIA Technical Position.

565 SMI-S uses the [WBEM](#) and [CIM](#) specifications from the DMTF.

## 566 **5.4 Other SDOs**

### 567 **5.4.1 ETSI/ISG – Network Function Virtualization (NFV)**

568 The first use case of ETSI/ISG NFV discusses NFV Infrastructure as a Service (NFVlaaS), which may  
569 have a lot of similarity with SDDC. The NFVI includes compute, networking, and storage infrastructure in  
570 virtualized forms. NFVlaaS calls for combining and interconnecting network as a service (NaaS), and  
571 other compute/storage Infrastructure as a Service (IaaS) in order to provide virtual network function (VNF)  
572 to the network administrators. The VNFs from different administrative domains can be interconnected and  
573 clustered for developing an end-to-end service. The NFV use case document is available at the following  
574 URL:

575 [http://www.etsi.org/deliver/etsi\\_gs/NFV/001\\_099/001/01.01.01\\_60/gs\\_NFV001v010101p.pdf](http://www.etsi.org/deliver/etsi_gs/NFV/001_099/001/01.01.01_60/gs_NFV001v010101p.pdf).

## 576 **5.4.2 IETF/IRTF**

577 There are a few [IETF](#) and [IRTF](#) working/research groups (WGs/RGs) and drafts that discuss Virtual Data  
578 Center (VDC). The concept of VDC and the service that can be offered by using VDC are very similar to  
579 the SDDC concept that we discuss here in this paper.

580 The NVO3 (Network Virtualization Overlays/Over-Layer-3) Working Group (WG) focuses on developing  
581 interoperable solutions for traffic isolation, address independence, and virtual machine (VM) migration in  
582 a Data Center Virtual Private Network (DCVPN).

583 DCVPN is defined as a VPN that is viable across a scaling range of a few thousand VMs to several  
584 million VMs running on more than 100,000 physical servers. DCVPN supports several million endpoints  
585 and hundreds of thousands of VPNs within a single administrative domain. Further details about IETF  
586 NVO3 activities can be found at <http://datatracker.ietf.org/wg/nvo3/charter/>.

587 The SCIM (System for Cross-domain Identity Management) WG is developing the core schema and  
588 interfaces based on HTTP and REST for creating, reading, searching, modifying, and deleting user  
589 identities and identity-related objects across administrative domains.

590 Initial focus areas of the SCIM WG are developing a core schema definition, a set of operations for  
591 creation, modification, and deletion of users, schema discovery, read and search, bulk operations, and  
592 mapping between the inetOrgPerson LDAP object class (RFC 2798) and the SCIM schema. Further  
593 details about IETF SCIM activities can be found at <http://datatracker.ietf.org/wg/scim/charter/>.

594 The SDN (Software-Defined Networking) Research Group (RG) is currently focusing on developing  
595 definition and taxonomy for SDN. Future work may include a study of model scalability and applicability,  
596 multilayer programmability and feedback control system, network description languages, abstractions,  
597 interfaces and compilers, and security-related aspects of SDN. Further details about IRTF SDN activities  
598 can be found at <https://irtf.org/sdnrg>.

## 599 **5.4.3 Open Networking Foundation (ONF)**

600 [ONF](#) has developed a southbound interface (SBI; south of the controller) called OpenFlow™ to enable  
601 remote programming of the flow forwarding.

602 Currently ONF is focusing on Software Defined Networking (SDN) related issues especially the concepts,  
603 frameworks, and architecture.

604 The network segmentation, multipath and multitenancy support, and security-related activities of the  
605 Forwarding Abstraction WG, Northbound Interface (NBI) WG, Configuration and Management WG, Layer  
606 4-7 Services DG, and Security DG may be very helpful for open SDDCs and their interconnections.

## 607 **5.4.4 Open DayLight (ODL)**

608 [ODL](#) focuses on control and programmability of the abstracted network functions and entities. The  
609 objective is to develop northbound interfaces (NBIs) for gathering network intelligence including  
610 performing analytics, and then use the controller to orchestrate adaptive new rules throughout the  
611 network for efficient automated operations. A detailed technical overview of ODL initiatives is available at  
612 <http://www.opendaylight.org/project/technical-overview>.

613 ODL supports OpenFlow and other protocols as SBIs, and released Base (Enterprise), Virtualization, and  
614 Service Provider editions of the software packages (<http://www.opendaylight.org/software>).

## 615 **5.4.5 Open Data Center Alliance (ODCA)**

616 [ODCA](#) initiatives and activities are focused on developing open, interoperable solutions for secure cloud  
617 federation, automation of cloud infrastructure, common management, and transparency of cloud service  
618 delivery.

## 6 Standards gaps - What is missing?

620 After we have analyzed this concept of the software defined data center and the various use cases and  
621 architectures as well as enumerating the current standards activity we realize there are several  
622 technologies that do not have well defined standards to date. This section will attempt to identify some of  
623 the key standards that will need to be explored and developed to have a truly standards based SDDC  
624 solution.

### 6.1 Standards for metrics

626 Currently there appears to be no standard metrics to be able to report and adjust resource utilization of  
627 the infrastructure and the associated application and services that are hosted upon those resources. If  
628 workloads are to be able to self-manage their required infrastructure then clearly a standard set of metrics  
629 will need to be developed. We do not have any real standard units of measure to identify both resource  
630 requirements and resource utilization.

### 6.2 Application and workload management

632 Additional work needs to be done in the instrumentation of requirements for applications and workloads.  
633 Some work has been done on deployment requirements for workloads such as specified in DMTF Open  
634 Virtualization Format (OVF) but much work still needs to be done for instrumentation of workloads and  
635 applications once they have been deployed to enable auto configuration and scaling. We also see a need  
636 for additional work for the emerging containerized applications to have their requirements be exposed in a  
637 standard way so that software defined resources may be created and removed dynamically.

### 6.3 Policy and service levels

639 To drive this level of automation there is still much work to be done in standardized policy management  
640 as well as standards to specify Service Level Objectives (SLO) that have been set based on contractual  
641 Service Level Agreements (SLA). To date work has been done on policy languages and standardized  
642 Service Level Management by organizations such as IEC/JTC1 SC38, however there is additional work to  
643 be done to create a pervasive set of standards for policy-based service level management including the  
644 standardized metrics discussed above.

## 7 Conclusion

646 To realize an SDDC, data center resources, such as compute, network, and storage, are expressed as  
647 software. They also need to have certain characteristics, such as multitenancy, rapid resource  
648 provisioning, elastic scaling, policy-driven resource management, shared infrastructure, instrumentation,  
649 and self-service, accounting, and auditing. This ultimately entails a programmable infrastructure that  
650 enables resources to be automatically cataloged, commissioned, decommissioned, repurposed, and  
651 repositioned.

669 **9 Glossary**

670 **Table 1 – Glossary of terms**

Acronym or Phrase	Definition	Explanation
AAA	Authentication, Authorization, and Auditing	The three major areas of concern in system security.
API	Application Programming Interface	An interface used by an application to request services. The term API is usually used to denote interfaces between applications and the software components that compose the operating environment (e.g., operating system, file system, volume manager, device drivers, etc.) Source: <a href="http://www.snia.org/education/dictionary/a">http://www.snia.org/education/dictionary/a</a>
Block storage		Storage organized and allocated in blocks of fixed size.
BYOD	Bring Your Own Device	The policy of permitting employees to bring personally owned mobile devices (laptops, tablets, and smart phones) to their workplace, and to use those devices to access privileged company information and applications Source: <a href="http://en.wikipedia.org/wiki/Bring_your_own_device">http://en.wikipedia.org/wiki/Bring_your_own_device</a>
Cloud	Cloud Computing	Computing facilities based on remote servers accessed via internet protocols, in contrast with facilities local to their usage.

Acronym or Phrase	Definition	Explanation
Fiber Channel		A high-speed LAN technology, most commonly used for SANs.
Firewall		A device, often implemented in software, to control data flows between two or more networks. Firewalls typically reject network traffic that does not originate from trusted address and/or ports and thus provides a degree of isolation between networks.
IaaS	Infrastructure as a Service	A delivery model for IT infrastructure whereby resources are provided as a service via network protocols. IaaS usually also provides interfaces to provision and manage resources.
IDS	Intrusion Detection System	A system used to detect unauthorized access to resources.
HIDS	Host Intrusion Detection Systems	An IDS specifically designed to protect host systems.
LAN	Local Area Network	A network with a small, restricted, scope. LAN's may be connected to larger networks, such as the internet.
Load Balancing		A mechanism used to distribute demands for resources amongst those available. Usually used in reference to processing resources but may be applied to any resource.
Metadata		Metadata is "data about data" and there are two types: structural metadata and descriptive metadata. Structural metadata is data about the containers of data. Descriptive metadata concerns the application data content.
NAS	Network Attached Storage	A term used to refer to storage devices that connect to a network and provide file access services to computer systems. These devices generally consist of an engine that implements the file services, and one or more devices, on which data is stored. Source: <a href="http://www.snia.org/education/dictionary/n#network_attached_storage">http://www.snia.org/education/dictionary/n#network_attached_storage</a>

Acronym or Phrase	Definition	Explanation
NFV	Network Function Virtualization	The concept of replacing dedicated network appliances, such as routers and firewalls, with software applications running on general purpose servers.
Object storage		Storage organized and allocated as self-contained data.
PaaS	Platform as a Service	A delivery model that encapsulates underlying infrastructure to simplify developing, running, and managing applications via network protocols.
pDC	Physical Data Center	
REST	Representational State Transfer	A software architecture style consisting of guidelines and best practices for creating scalable web services. REST is a coordinated set of constraints applied to the design of components in a distributed hypermedia system that can lead to a more performant and maintainable architecture. Source: <a href="https://en.wikipedia.org/wiki/Representational_state_transfer">https://en.wikipedia.org/wiki/Representational_state_transfer</a>
SaaS	Software as a Service	A delivery model whereby software applications are provided as a service via network protocols.
SAN	Storage Area Network	A network whose primary purpose is the transfer of data between computer systems and storage devices and among storage devices. Source: <a href="http://www.snia.org/education/dictionary/s#storage_area_network">http://www.snia.org/education/dictionary/s#storage_area_network</a>
SDDC	Software Defined Data Center	Refer to this document.
SDN	Software Defined Network	The physical separation of the network control plane from the forwarding plane, and where a control plane controls several devices. Source: <a href="https://www.opennetworking.org/sdn-resources/sdn-definition">https://www.opennetworking.org/sdn-resources/sdn-definition</a>
SDO	Standards Development Organization	

Acronym or Phrase	Definition	Explanation
SDS	Software Defined Storage	<p>Virtualized storage with a service management interface.</p> <p>SDS includes pools of storage with data service characteristics that may be applied to meet the requirements specified through the service management interface.</p> <p>Source:  <a href="http://www.snia.org/education/dictionary/s#software_defined_storage">http://www.snia.org/education/dictionary/s#software_defined_storage</a></p>
Virtual Appliance		<p>A software application preconfigured with (usually minimal) OS facilities required to run on a specific type of virtual machine.</p> <p>Virtual Appliances are typically used to provide services in IaaS and SaaS system architectures.</p>
VLAN	Virtual LAN	A virtualized local area network
WAN	Wide area network
