16 management and interoperability. Members and non-members may reproduce DMTF specifications and  
17 documents, provided that correct attribution is given. As DMTF specifications may be revised from time to  
18 time, the particular version and release date should always be noted.

19 Implementation of certain elements of this standard or proposed standard may be subject to third party  
20 patent rights, including provisional patent rights (herein "patent rights"). DMTF makes no representations  
21 to users of the standard as to the existence of such rights, and is not responsible to recognize, disclose,  
22 or identify any or all such third party patent right, owners or claimants, nor for any incomplete or  
23 inaccurate identification or disclosure of such rights, owners or claimants. DMTF shall have no liability to  
24 any party, in any manner or circumstance, under any legal theory whatsoever, for failure to recognize,  
25 disclose, or identify any such third party patent rights, or for such party's reliance on the standard or  
26 incorporation thereof in its product, protocols or testing procedures. DMTF shall have no liability to any  
27 party implementing such standard, whether such implementation is foreseeable or not, nor to any patent  
28 owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is  
29 withdrawn or modified after publication, and shall be indemnified and held harmless by any party  
30 implementing the standard from any and all claims of infringement by a patent owner for such  
31 implementations.

32 For information about patents held by third-parties which have notified the DMTF that, in their opinion,  
33 such patent may relate to or impact implementations of DMTF standards, visit  
34 <http://www.dmtf.org/about/policies/disclosures.php>.

87

## Foreword

88 The *Managed Object Format (MOF)* specification (this document) was prepared by the DMTF  
89 Architecture Working Group.

90 Versions marked as "DMTF Standard" are approved standards of the Distributed Management Task  
91 Force (DMTF).

92 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems  
93 management and interoperability. For information about the DMTF see <http://www.dmtf.org>.

## 94 Acknowledgments

95 The DMTF acknowledges the following individuals for their contributions to this document:

96 Editors:

- 97 • George Ericson – EMC
- 98 • Wojtek Kozaczynski – Microsoft

99 Contributors:

- 100 • Jim Davis – WBEM Solutions
- 101 • Lawrence Lamers – VMware
- 102 • Andreas Maier – IBM
- 103 • Karl Schopmeyer – Inova Development

104

## Introduction

105 This document specifies the DMTF *Managed Object Format (MOF)*, which is a schema description  
106 language used for specifying the interface of managed resources (storage, networking, compute,  
107 software) conformant with the CIM Metamodel defined in [DSP0004](#).

### 108 **Typographical conventions**

109 The following typographical conventions are used in this document:

- 110 • Document titles are marked in *italics*.
- 111 • Important terms that are used for the first time are marked in *italics*.
- 112 • Examples are shown in the `code` blocks.

### 113 **Deprecated material**

114 Deprecated material is not recommended for use in new development efforts. Existing and new  
115 implementations may use this material, but they should move to the favored approach as soon as  
116 possible. CIM services shall implement any deprecated elements as required by this document in order to  
117 achieve backwards compatibility. Although CIM clients can use deprecated elements, they are directed to  
118 use the favored elements instead.

119 Deprecated material should contain references to the last published version that included it as normative,  
120 and to a description of the favored approach.

121 The following typographical convention indicates deprecated material:

---

---

#### 122 **DEPRECATED**

123 Deprecated material appears here.

---

#### 124 **DEPRECATED**

125 In places where this typographical convention cannot be used (for example, tables or figures), the  
126 "DEPRECATED" label is used alone.

### 127 **Experimental material**

128 Experimental material has yet to receive sufficient review to satisfy the adoption requirements set forth by  
129 the DMTF. Experimental material included in this document is an aid to implementers who are interested  
130 in likely future developments. Experimental material might change as implementation experience is  
131 gained. Until included in future documents as normative, all experimental material is purely informational.

132 The following typographical convention indicates experimental material:

---

---

#### 133 **EXPERIMENTAL**

134 Experimental material appears here.

---

#### 135 **EXPERIMENTAL**

136 In places where this typographical convention cannot be used (for example, tables or figures), the  
137 "EXPERIMENTAL" label is used alone.

138

139

# Managed Object Format (MOF)

## 1 Scope

141 This document describes the syntax, semantics and the use of the Managed Object Format (MOF)  
142 language for specifying management models conformant with the DMTF Common Information Model  
143 (CIM) Metamodel as defined in [DSP0004](#) version 3.0.

144 The MOF provides the means to write interface definitions of managed resource types including their  
145 properties, behavior and relationships with other objects. Instances of managed resource types represent  
146 logical concepts like policies, as well as real-world resource such as disk drives, network routers or  
147 software components.

148 MOF is used to define industry-standard managed resource types, published by the DMTF as the CIM  
149 Schema and other schemas, as well as user/vendor-defined resource types that may or may not be  
150 derived from object types defined in schemas published by the DMTF.

151 This document does not describe specific CIM implementations, application programming interfaces  
152 (APIs), or communication protocols.

## 2 Normative references

154 The following documents are indispensable for the application of this document. For dated or versioned  
155 references, only the cited edition (including any corrigenda or DMTF update versions) applies. For  
156 references without a date or version, the latest published edition of the referenced document (including  
157 any corrigenda or DMTF update versions) applies.

## 174 **3 Terms and definitions**

175 Some terms used in this document have a specific meaning beyond the common English interpretation.  
176 Those terms are defined in this clause.

177 The terms "shall" ("required"), "shall not", "should" ("recommended"), "should not" ("not recommended"),  
178 "may", "need not" ("not required"), "can" and "cannot" in this document are to be interpreted as described  
179 in [ISO/IEC Directives, Part 2](#), Annex H. The terms in parenthesis are alternatives for the preceding terms,  
180 for use in exceptional cases when the preceding term cannot be used for linguistic reasons. Note that  
181 [ISO/IEC Directives, Part 2](#) Annex H specifies additional alternatives. Occurrences of such additional  
182 alternatives shall be interpreted in their normal English meaning.

183 The terms "clause", "subclause", "paragraph", and "annex" in this document are to be interpreted as  
184 described in [ISO/IEC Directives, Part 2](#), Clause 5.

185 The terms "normative" and "informative" in this document are to be interpreted as described in [ISO/IEC](#)  
186 [Directives, Part 2](#), Clause 3. In this document, clauses, subclauses, or annexes labeled "(informative)" do  
187 not contain normative content. Notes and examples are always informative elements.

188 The terms defined in [DSP0004](#) apply to this document. The following additional terms are used in this  
189 document.

### 190 **3.1**

#### 191 **Managed Object Format**

192 Refers to the language described in this specification.

### 193 **3.2**

#### 194 **MOF grammar**

195 Refers to the MOF language syntax description included in this document. The MOF grammar is specified  
196 using the ABNF (see [RFC5234](#)).

### 197 **3.3**

#### 198 **MOF file**

199 Refers to a document with the content that conforms to the MOF syntax described by this specification.

### 200 **3.4**

#### 201 **MOF compilation unit**

202 Refers to a set of MOF files, which includes the files explicitly listed as the input to the MOF compiler and  
203 the files directly or transitively included from those input files using the include pragma compiler directive.

### 204 **3.5**

#### 205 **MOF compiler**

206 A MOF compiler takes as input a compilation unit, and in addition can also accept as input a  
207 representation of previously compiled types and qualifiers.

208 A MOF compiler transforms types defined in the compilation unit into another representation, like schema  
209 repository entries or provider skeletons.

210 A MOF compiler shall verify the consistency of its input; the compiler input shall include definitions of all  
211 types that are used by other types, and all super-types of the defined and used types.

## 212 **4 Symbols and abbreviated terms**

213 The abbreviations defined in [DSP0004](#) apply to this document. The following additional abbreviations are  
214 used in this document.

### 215 **4.1**

#### 216 **AST**

217 Abstract Syntax Tree

### 218 **4.2**

#### 219 **MOF**

220 Managed Object Format

### 221 **4.3**

#### 222 **ABNF**

223 Augmented BNF (see [RFC5234](#))

### 224 **4.4**

#### 225 **IDL**

226 Interface Definition Language (see [ISO/IEC 14750](#))

### 227 **4.5**

#### 228 **OCL**

229 Object Constraint Language (see [OMG Object Constraint Language](#))

## 230 **5 MOF file content**

231 A MOF file contains MOF language statements, compiler directives and comments.

### 232 **5.1 Encoding**

233 The content of a MOF file shall be represented in Normalization Form C ([Unicode, Annex 15](#)) and in the  
234 coded representation form UTF-8 ([ISO 10646](#)).

235 The content represented in UTF-8 shall not have a signature sequence (EF BB BF, as defined in Annex H  
236 of [ISO 10646](#)).

### 237 **5.2 Whitespace**

238 Whitespace in a MOF file is any combination of the following characters:

- 239 • Space (U+0020),
- 240 • Horizontal Tab (U+0009),
- 241 • Carriage Return (U+000D) and
- 242 • Line Feed (U+000A).

243 The `ws` ABNF rule represents any one of these whitespace characters:

244 `ws = U+0020 / U+0009 / U+000D / U+000A`

### 245 5.3 Line termination

246 The end of a line in a MOF file is indicated by one of the following:

- 247 • A Carriage Return (U+000D) followed by Line Feed (U+000A)
- 248 • A Carriage Return (U+000D) not followed by Line Feed (U+000A)
- 249 • A Line Feed (U+000A) not preceded by a Carriage Return (U+000D)
- 250 • Implicitly by the end of the MOF specification file, if the line is not ended by line end characters.

251 The different line-end characters may be arbitrarily mixed within a single MOF file.

### 252 5.4 Comments

253 Comments in a MOF file do not create, modify, or annotate language elements. They shall be treated as if  
254 they were whitespace.

255 Comments may appear anywhere in MOF syntax where whitespace is allowed and are indicated by either  
256 a leading double slash ( // ) or a pair of matching /\* and \*/ character sequences. Occurrences of these  
257 character sequences in string literals shall not be treated as comments.

258 A // comment is terminated by the end of line (see 5.3), as shown in the example below.

```
259 Integer MyProperty; // This is an example of a single-line comment
```

260 A comment that begins with /\* is terminated by the next \*/ sequence, or by the end of the MOF file,  
261 whichever comes first.

```
262 /* example of a comment between property definition tokens and a multi-line comment */
263 Integer /* 16-bit integer property */ MyProperty; /* and a multi-line
264 comment */
```

## 265 6 MOF and OCL

266 This MOF language specification refers to [OCL](#) in two contexts:

- 267 • It refers to specific OCL constraints of the CIM Metamodel, which are defined in [DSP0004](#).
- 268 • A schema specified in MOF may include zero or more OCL qualifiers, where each of those  
269 qualifiers contains at least one OCL statement. The statements on a qualifier should be  
270 interpreted as a collection. For example a variable defined in one statement can be used in  
271 another statement.

272 The OCL rules defined in CIM Metamodel specify the schema integrity rules that a MOF compiler shall  
273 check. For example one of those rules states that a structure cannot inherit from another structure that  
274 has been qualified as terminal, and therefore MOF compilers shall implement a corresponding model  
275 integrity validation rule. The CIM Metamodel constraints are specified in clause 6 of [DSP0004](#) and then  
276 listed in ANNEX G of that document.

277 Within a user-defined schema, an OCL qualifier is used to define rules that all instances of the qualified  
278 element shall conform to. As an example, consider a class-level OCL qualifier that defines an invariant,  
279 which states that one of the class properties must be always greater than another of its properties. The  
280 implementations of the schema should assure that all instances of that class satisfy that condition. This  
281 has the following implications for the MOF compiler developers and the provider developers:

- 282 • The MOF compilers should parse the content of the OCL qualifiers and verify
- 283 – conformance of the OCL expressions with the OCL syntax defined in the [OMG Object](#)
- 284 [Constraint Language](#)
- 285 – consistency of the statements with the schema elements
- 286 • The provider developers should implement the logic, which assures that resource instances
- 287 conform to the requirements specified by the schema, including those specified as the OCL
- 288 constraints.

## 289 7 MOF language elements

290 MOF is an interface definition language (IDL) that is implementation language independent, and has

291 syntax that should be familiar to programmers that have worked with other IDLs.

292 A MOF specification includes the following kinds of elements:

- 293 • Compiler directives that direct the processing of the compilation unit
- 294 • Qualifier declarations
- 295 • Type declarations such as classes, structures or enumerations
- 296 • Instance and value specifications

297 Elements of MOF language are introduced and exemplified one at a time, in a sequence that

298 progressively builds a meaningful MOF specification. To make the examples consistent, the document

299 uses a small, fictitious, and simplified golf club membership schema. The files of the schema are listed in

300 ANNEX E.

### 301 7.1 MOF grammar description

302 The grammar is defined by using the ABNF notation described in [RFC5234](#).

303 The definition uses the following conventions:

- 304 • Punctuation terminals like `" ; "` are shown verbatim.
- 305 • Terminal symbols are spelled in CAPITAL letters when used and then defined in the keywords
- 306 and symbols section (they correspond to the lexical tokens).

307 The grammar is written to be lexically permissive. This means that some of the CIM Metamodel

308 constraints are expected to be checked over an in-memory MOF representation (the [AST](#)s) after all MOF

309 files in a compilation unit have been parsed. For example, the constraint that a property in a derived class

310 must not have the same name as an inherited property unless it overrides that property (has the Override

311 qualifier) is not encoded in the grammar. Similarly the default values of qualifier definitions are lexically

312 permissive to keep parsing simple.

313 The MOF compiler developers should assume that unless explicitly stated otherwise, the terminal

314 symbols are separated by whitespace (see 5.2).

315 The MOF v3 grammar is written with the objective to minimize the differences between this version the

316 MOF v2 version. The three differences that the MOF compiler developer will have to take into account

317 are:

- 318 • The qualifier declaration has a different grammar
- 319 • Arbitrary UCS characters are no longer supported as identifiers
- 320 • Octetstring values do not have the length bytes at the beginning

- 321 • Fixed size arrays are no longer supported
- 322 • The char16 datatype has been removed

## 323 7.2 MOF specification

324 A MOF specification defines one or more schema elements and is derived by a MOF compiler from a  
 325 MOF compilation unit. A MOF specification shall conform to ABNF rule `mofSpecification` (whitespace  
 326 as defined in 5.2 is allowed between the elements of the rules in this ABNF section):

```

327 mofSpecification      = *mofProduction
328 mofProduction        = compilerDirective /
329                       structureDeclaration /
330                       classDeclaration /
331                       associationDeclaration /
332                       enumerationDeclaration /
333                       instanceValueDeclaration /
334                       structureValueDeclaration /
335                       qualifierTypeDeclaration
336 WS                    = U+0020 / U+0009 / U+000D / U+000A
337   ; Space (U+0020),
338   ; Horizontal Tab (U+0009),
339   ; Carriage Return (U+000D) and
340   ; Line Feed (U+000A).

```

## 341 7.3 Compiler directives

342 Compiler directives direct the processing of MOF files. Compiler directives do not create, modify, or  
 343 annotate the language elements.

344 Compiler directives shall conform to the format defined by ABNF rule `compilerDirective` (whitespace  
 345 as defined in 5.2 is allowed between the elements of the rules in this ABNF section):

```

346 compilerDirective    = PRAGMA ( pragmaName / standardPragmaName )
347                       ("pragmaParameter ")
348 pragmaName           = directiveName
349 standardPragmaName   = INCLUDE
350 pragmaParameter      = stringValue           ; if the pragma is INCLUDE,
351                                                           ; the parameter value
352                                                           ; shall represent a relative
353                                                           ; or full file path
354 PRAGMA               = "#pragma"           ; keyword: case insensitive
355 INCLUDE              = "include"           ; keyword: case insensitive

```

356 The current standard compiler directives are listed in Table 1.

357

**Table 1 – Standard compiler directives**

Compiler Directive	Description
#pragma include (<filePath>)	The included directive specifies that the referenced MOF specification file should be included in the compilation unit. The content of the referenced file shall be textually inserted in place of the directive. The included file name can be either an absolute file system path, or a relative path. If the path is relative, it is relative to the directory of the file with the pragma. The format of <filePath> is defined in 7.6.1.7.

358 A MOF compiler may support additional compiler directives. Such new compiler directives are referred to  
 359 as *vendor-specific compiler directives*. Vendor-specific compiler directives should have names that are  
 360 unlikely to collide with the names of standard compiler directives defined in future versions of this  
 361 specification. Future versions of this specification will not define compiler directives with names that  
 362 include the underscore (`_`, U+005F). Therefore, it is recommended that the names of vendor-specific  
 363 compiler directives conform to the following format (no whitespace is allowed between the elements of  
 364 this ABNF rule):

```
365 directiveName = org-id "_" IDENTIFIER
```

366 where `org-id` includes a copyrighted, trademarked, or otherwise unique name owned by the business  
 367 entity that defines the compiler directive or that is a registered ID assigned to the business entity by a  
 368 recognized global authority.

369 Vendor-specific compiler directives that are not understood by a MOF compiler shall be reported and  
 370 should be ignored. Thus, the use of vendor-specific compiler directives may affect the interoperability of  
 371 MOF.

### 372 7.4 Qualifiers

373 A qualifier is a named and typed metadata element associated with a schema element, such as a class or  
 374 method, and it provides information about or specifies the behavior of the qualified element. A detailed  
 375 discussion of the qualifier concept is in subclause 5.6.12 of [DSP0004](#), and the list of standard qualifiers is  
 376 in clause 7 of [DSP0004](#).

377 NOTE A MOF v2 qualifier declaration has to be converted to MOF v3 `qualifierTypeDeclaration` because the  
 378 MOF v2 qualifier flavor has been replaced by the MOF v3 `qualifierPolicy`.

379 Each qualifier is defined by its qualifier type declaration. The `qualifierTypeDeclaration` MOF  
 380 grammar rule corresponds to the `QualifierType` CIM Metamodel element defined in [DSP0004](#), and is  
 381 defined by the following ABNF rules (whitespace as defined in 5.2 is allowed between the elements of the  
 382 rules in this ABNF section):

```
383 qualifierTypeDeclaration = [ qualifierList ] QUALIFIER qualifierName ":"
384                             qualifierType qualifierScope
385                             [ qualifierPolicy ] ";"
386 qualifierName = elementName
387 qualifierType = primitiveQualifierType / enumQualifierType
388 primitiveQualifierType = primitiveType [ array ]
389                             [ "=" primitiveTypeValue ] ";"
390 enumQualifierType = enumName [ array ] "=" enumTypeValue ";"
391 qualifierScope = SCOPE "(" ANY / scopeKindList ")"
```

```

392 qualifierPolicy      = POLICY "(" policyKind ")"
393 policyKind          = DISABLEOVERRIDE /
394                     ENABLEOVERRIDE /
395                     RESTRICTED
396 scopeKindList       = scopeKind *( "," scopeKind )
397 scopeKind           = STRUCTURE / CLASS / ASSOCIATION /
398                     ENUMERATION / ENUMERATIONVALUE /
399                     PROPERTY / REFPROPERTY /
400                     METHOD / PARAMETER /
401                     QUALIFIERTYPE
402 SCOPE                = "scope"           ; keyword: case insensitive
403 ANY                  = "any"             ; keyword: case insensitive
404 POLICY               = "policy"         ; keyword: case insensitive
405 ENABLEOVERRIDE      = "enableoverride"  ; keyword: case insensitive
406 DISABLEOVERRIDE     = "disableoverride" ; keyword: case insensitive
407 RESTRICTED          = "restricted"      ; keyword: case insensitive
408 ENUMERATIONVALUE    = "enumerationvalue"; keyword: case insensitive
409 PROPERTY             = "property"       ; keyword: case insensitive
410 REFPROPERTY         = "reference"       ; keyword: case insensitive
411 METHOD                = "method"         ; keyword: case insensitive
412 PARAMETER           = "parameter"      ; keyword: case insensitive
413 QUALIFIERTYPE       = "qualifiertype"   ; keyword: case insensitive

```

414 Only numeric and Boolean primitive qualifier types (see `primitiveQualifierType` above) can be  
 415 specified without specifying a value. If not specified, the implied value is as follows:

- 416 • For data type Boolean, the implied value is True.
- 417 • For numeric data types, the implied value is Null.
- 418 • For arrays of numeric or Boolean data type, the implied value is that the array is empty.

419 For all other types, including enumeration qualifier types (see `enumQualifierType` above), the value  
 420 must be defined.

421 The following MOF fragment is an example of the qualifier type `AggregationKind`. The `AggregationKind`  
 422 qualifier type defines the enumeration values that are used on properties of associations that are  
 423 references, to indicate the kind of aggregation they represent. The type of the qualifier is an enumeration  
 424 with three values; None, Shared, and Exclusive.

```

425 [Description ("The value of this qualifier indicates the kind of aggregation "
426             "relationship defined between instances of the class containing the qualified "
427             "reference property and instances referenced by that property. The value may "
428             "indicate that the kind of aggregation is unspecified.")]
429 Qualifier AggregationKind : CIM_AggregationKindEnum = None
430             Scope(reference) Flavor (disableoverride);

```

```

431
432 enumeration CIM_AggregationKindEnum : string {
433     None,
434     Shared,
435     Composite
436 };

```

### 437 7.4.1 QualifierList

438 The `qualifierValue` rule in MOF corresponds to the Qualifier CIM Metamodel element defined in  
 439 [DSP0004](#), and defines the representation of an instance of a qualifier. A list of qualifier values describing  
 440 a schema element shall conform to the following `qualifierList` ABNF rule (whitespace as defined in  
 441 5.2 is allowed between the elements of the rules in this ABNF section):

```

442 qualifierList      = "[" qualifierValue *( "," qualifierValue ) "]"
443 qualifierValue     = qualifierName [ qualifierValueInitializer /
444                               qualifierValueArrayInitializer ]
445 qualifierValueInitializer = "(" literalValue ")"
446 qualiferValueArrayInitializer = "{" literalValue *( "," literalValue ) "}"

```

447 The list of qualifier scopes (see the `scopeKind` rule above) includes "qualifiertype", which implies that  
 448 qualifier declarations can be themselves qualified. Examples of standard qualifiers that can be used to  
 449 describe a qualifier declaration are Description and Deprecated.

## 450 7.5 Types

451 CIM Metamodel defines the following hierarchy of types:

- 452 • Structure
  - 453 • Class
    - 454 • Association
  - 455 • Enumeration
  - 456 • Primitive type, and
  - 457 • Reference type.

458 CIM Metamodel has a predefined list of primitive types, and their MOF representations are described in  
 459 7.5.8.

460 Elements of type reference represent references to instances of class. The declarations of properties and  
 461 method parameters of type reference are described in subclauses 7.5.5 and 7.5.7, respectively. The  
 462 representation of the reference type value is described in 7.5.10.

463 Structures, classes, associations, and enumerations are types defined in a schema. The following sub-  
 464 clauses describe how those types are declared using MOF.

### 465 7.5.1 Structure declaration

466 A CIM structure defines a complex type that has no independent identity, but can be used as a type of a  
 467 property, a method result, or a method parameter. A structure can be also used as a base for a class, in  
 468 which case the class derived from the structure inherits all of its features.

469 The syntactic difference between schema level and nested structure declarations is that the schema level  
 470 declarations must use schema-qualified names. This constraint can be verified after the MOF files have  
 471 been parsed into the corresponding abstract syntax trees.

472 The `structureDeclaration` MOF grammar rule corresponds to the Structure CIM metaelement  
 473 defined in [DSP0004](#) and shall conform to the following set of ABNF rules (whitespace as defined in 5.2 is  
 474 allowed between the elements of the rules in this ABNF section):

```

475 structureDeclaration = [ qualifierList ] STRUCTURE structureName
476                       [ superStructure ]
477                       "{" *structureFeature "}" ";"
478 structureName       = elementName
479 superStructure      = ":" structureName
480 structureFeature    = structureDeclaration / ; local structure
481                    enumerationDeclaration / ; local enumeration
482                    propertyDeclaration
483 STRUCTURE           = "structure"           ; keyword: case insensitive
  
```

484 Structure is a, possibly empty, collection of properties, local structure declarations, and local enumeration  
 485 declarations. A structure can derive from another structure (see the *superType* reflective association of  
 486 the Type CIM metaelement in [DSP0004](#)). A structure can be declared at the schema level, and therefore  
 487 be globally visible to all other structures, classes and associations, or its declaration can be local to a  
 488 structure, a class or an association declaration and be visible only in that structure, class, or association  
 489 and its derived types.

## 490 7.5.2 Class declaration

491 A class defines properties and methods (the behavior) of its instances, which have unique identity in the  
 492 scope of a server, a namespace, and the class. A class may also define methods that do not belong to  
 493 instances of the class, but to the class itself.

494 In the CIM Metamodel the Class metaelement derives from the Structure metaelement, so like a structure  
 495 a class can define local structures and enumerations that can be used in that class or its subclasses.

496 The `classDeclaration` MOF grammar rule corresponds to the Class CIM metaelement defined in  
 497 [DSP0004](#), and shall conform to the following ABNF rules (whitespace as defined in 5.2 is allowed  
 498 between the elements of the rules in this ABNF section):

```

499 classDeclaration     = [ qualifierList ] CLASS className [ superClass ]
500                       "{" *classFeature "}" ";"
501 className           = elementName
502 superClass          = ":" className
503 classFeature        = structureFeature /
504                    methodDeclaration
505 CLASS               = "class"               ; keyword: case insensitive
  
```

506 The `propertyDeclaration` rule is also described in 7.5.5.

### 507 7.5.3 Association declaration

508 An association represents a relationship between two or more classes. The associated classes are  
 509 specified by the reference properties of the association. Within an association instance each reference  
 510 property refers to one instance of the referenced class or its subclass. An association instance is the  
 511 relationship between all referenced class instances.

512 The `associationDeclaration` MOF grammar rule corresponds to the Association CIM metamodel  
 513 defined in [DSP0004](#), and shall conform to the following ABNF rules (whitespace as defined in 5.2 is  
 514 allowed between the elements of the rules in this ABNF section):

```
515 associationDeclaration = [ qualifierList ] ASSOCIATION associationName
516                       [ superAssociation ]
517                       "{" * classFeature "}" ";"
518 associationName       = elementName
519 superAssociation      = ":" elementName
520 ASSOCIATION          = "association"      ; keyword: case insensitive
```

521 In the CIM Metamodel the Association metamodel derives from Class metamodel, and is structurally  
 522 identical to Class. However an association declaration

- 523 • must have at least two scalar reference properties, and
- 524 • each reference property represents a role in the association.

525 The [GOLF\\_MemberLocker](#) is an example of an association with two roles and it represents an  
 526 assignment of lockers to golf club members.

527 The multiplicity of the association ends can be defined using the Max and Min qualifiers (see the  
 528 discussion of associations in subclause 6.2.2 of [DSP0004](#)).

529 In addition to the grammar rules stated above a MOF compiler shall verify the integrity of association  
 530 declarations using the applicable CIM Metamodel constraints, which are stated as OCL constraints in  
 531 clause 6 of [DSP0004](#) and listed in ANNEX G of that document.

### 532 7.5.4 Enumeration declaration

533 There are two kinds of enumerations in CIM:

- 534 • Integer enumerations
- 535 • String enumerations

536 Integer enumerations, which are comparable to enumerations in programming languages, represent  
 537 enumeration values as distinct integer values.

538 String enumerations, which can be found in [UML](#) and are similar to XML enumerations (see [XML  
 539 Schema, Part2: Datatypes](#)), represent enumeration values as distinct string values that in most cases are  
 540 identical to the values themselves.

541 The `enumerationDeclaration` MOF grammar rule corresponds to the Enumeration CIM Metamodel  
 542 element defined in [DSP0004](#), and conforms to the following ABNF rules (whitespace as defined in 5.2 is  
 543 allowed between the elements of the rules in this ABNF section):

```

544 enumerationDeclaration = enumTypeHeader enumName ":" enumTypeDeclaration ";"
545 enumTypeHeader         = [ qualifierList ] ENUMERATION
546 enumName               = elementName
547 enumTypeDeclaration    = (DT_INTEGER / integerEnumName ) integerEnumDeclaration /
548                       (DT_STRING / stringEnumName) stringEnumDeclaration
549 integerEnumName        = enumName
550 stringEnumName         = enumName
551 integerEnumDeclaration = "{" [ integerEnumElement
552                       *( "," integerEnumElement) ] "}"
553 stringEnumDeclaration  = "{" [ stringEnumElement
554                       *( "," stringEnumElement) ] "}"
555 integerEnumElement     = [ qualifierList ] enumLiteral "=" integerValue
556 stringEnumElement      = [ qualifierList ] enumLiteral [ "=" stringValue ]
557 enumLiteral            = IDENTIFIER
558 ENUMERATION           = "enumeration" ; keyword: case insensitive

```

559 The `integerEnumElement` rule states that integer enumeration elements must have explicit and unique  
560 integer values as defined in [DSP0004](#). There are two reasons for the requirement to explicitly assign  
561 values to integer enumeration values:

- 562 • The enumeration values can be declared in any order and, unlike in string enumerations, their  
563 value cannot be defaulted
- 564 • The derived enumerations can define enumeration values, which fill gaps left in their super-  
565 enumeration(s)

566 The `stringEnumElement` rule states that the values of string enumeration elements are optional. If not  
567 declared the value of a string enumeration value is assigned the name of the value itself.

568 The `integerEnumElement` and the `stringEnumElement` rules also state that enumeration values can  
569 be qualified. This is most commonly used to add the Description qualifier to individual iteration elements,  
570 but the Experimental and Deprecated qualifiers can be also used (see [DSP0004](#) clause 7).

571 As defined in [DSP0004](#), enumerations can be defined at the schema level or inside declarations of  
572 structures, classes, or associations. Enumerations defined inside those other types are referred to as the  
573 "local" enumeration declarations. All other enumerations are defined at the schema level. The names of  
574 schema level enumerations shall conform to the `schemaQualifiedName` format rule, which requires  
575 that their names begin with the name of the scheme followed by the underscore (U+005F).

576 The GOLF schema contains a number of enumeration declarations. An example of local string  
577 enumeration is `MonthsEnum`, which is defined in the structure `GOLF_Date`.

578 It is a string enumeration, and string enumerations do not require that values are assigned. If a value is  
579 not assigned, it is assumed to be identical to the name, so in the example above the value of January is  
580 "January".

581 The `GOLF_StatesEnum` is an example of a schema level string enumeration that assigns explicit values,  
582 which are different than the enumeration names.

583 The following are two schema level integer enumerations `GOLF_ProfessionalStatusEnum` and  
584 `GOLF_MemberStatusEnum`) that derive from each other.

```
585 // =====  
586 // GOLF_ProfessionalStatusEnum  
587 // =====  
588 enumeration GOLF_ProfessionalStatusEnum : Integer  
589 {  
590     Professional = 6,  
591     SponsoredProfessional = 7  
592 };  
593  
594 // =====  
595 // GOLF_MemberStatusEnum  
596 // =====  
597 enumeration GOLF_MemberStatusEnum : GOLF_ProfessionalStatusEnum  
598 {  
599     Basic = 0,  
600     Extended = 1,  
601     VP = 2,  
602 };
```

603 The example may look a bit contrived, but it illustrates two important points:

- 604 • The values of the integer enumeration values can be defined in any order. In the example the  
605 base enumeration `GOLF_ProfessionalStatusEnum` defines values 6 and 7, while the derived  
606 enumeration `GOLF_MemberStatusEnum` adds values 0, 1, and 2.
- 607 • When the type of an enumeration property is overridden in a subclass, the new type can only be  
608 the supertype of the overridden type. This is illustrated by the definitions of the  
609 `GOLF_ClubMember` and `GOLF_Professional` classes and described in the subclause 5.6.3.3 of  
610 [DSP0004](#). The reason for this restriction is that an overriding property in a subclass must  
611 constrain its values to the same set or a subset of the values of the overridden property.

612 In addition to the grammar rules stated above a MOF compiler shall verify the integrity of enumeration  
613 declarations using the applicable CIM Metamodel constraints, which are stated as OCL constraints in  
614 subclause 5.6.1 of [DSP0004](#) and listed in ANNEX G of that document.

### 615 7.5.5 Property declaration

616 The `propertyDeclaration` in MOF corresponds to the Property CIM metaelement defined in  
617 [DSP0004](#) and shall conform to the following ABNF rules (whitespace as defined in 5.2 is allowed between  
618 the elements of the rules in this ABNF section):

```

619 propertyDeclaration      = [ qualifierList ] ( primitivePropertyDeclaration /
620                               complexPropertyDeclaration /
621                               enumPropertyDeclaration /
622                               referencePropertyDeclaration ) ";"
623 primitivePropertyDeclaration = primitiveType propertyName [ array ]
624                               [ "=" primitiveTypeValue ]
625 complexPropertyDeclaration = structureOrClassName propertyName [ array ]
626                               [ "=" complexTypeValue ]
627 enumPropertyDeclaration = enumName propertyName [ array ]
628                               [ "=" enumTypeValue ]
629 referencePropertyDeclaration = classReference propertyName [ array ]
630                               [ "=" referenceTypeValue ]
631 array                      = "[" "]"
632 propertyName              = IDENTIFIER
633 structureOrClassName      = structureName / className

```

634 The `GOLF_Date` is an example of a schema-level structure with locally defined enumeration and three  
635 properties. All three properties have default values that set the default value of the entire structure to  
636 January 1, 2000.

637 The general form of a reference to an enumeration value is qualified with the name of the enumeration,  
638 as it is shown in the example of the default value of the `Month` property of the `GOLF_Date` structure.

```
639 GOLF_MonthsEnum Month = MonthsEnum.January
```

640 However when the enumeration type is implied, as in the example above, a reference to enumeration  
641 value can be simplified by omitting the enumeration name.

```
642 GOLF_MonthsEnum Month = January
```

643 The use of the `GOLF_Date` structure as the type of a property is shown in the declaration of the  
644 `GOLF_ClubMember` class; the property is called `MembershipEstablishedDate`.

645 An example of a local structure is `Sponsor`, which is defined in the `GOLF_Professional` class. It can be  
646 used only in the `GOLF_Professional` class or a class that derives from it.

647 In addition to the grammar rules stated above, a MOF compiler shall verify the integrity of structure  
648 declarations by using the applicable CIM Metamodel constraints, which are stated as OCL constraints in  
649 clause 6 of [DSP0004](#) and listed in ANNEX G of that document.

## 650 7.5.6 Method declaration

651 The `methodDeclaration` rule corresponds to the Method CIM metaelement defined in [DSP0004](#), and  
652 shall conform to the following ABNF rules (whitespace as defined in 5.2 is allowed between the elements  
653 of the rules in this ABNF section):

```

654 methodDeclaration      = [ qualifierList ]
655                        ( ( returnType [ array ] ) / VOID ) methodName
656                        "(" [ parameterList ] ")" ";"
657 returnType             = primitiveType /
658                        structureOrClassName /
659                        enumName /
660                        classReference
661 methodName             = IDENTIFIER
662 classReference          = DT_REFERENCE
663 VOID                   = "void"           ; keyword: case insensitive
664 parameterList          = parameterDeclaration *( "," parameterDeclaration )

```

### 665 7.5.7 Parameter declaration

666 A method can have zero or more parameters. The `parameterDeclaration` MOF grammar rule  
 667 corresponds to the Parameter CIM metaelement in [DSP0004](#), and it shall conform to the following ABNF  
 668 rules (whitespace as defined in 5.2 is allowed between the elements of the rules in this ABNF section):

```

669 parameterDeclaration    = [ qualifierList ] ( primitiveParamDeclaration /
670                        complexParamDeclaration /
671                        enumParamDeclaration /
672                        referenceParamDeclaration )
673 primitiveParamDeclaration = primitiveType parameterName [ array ]
674                        [ "=" primitiveTypeValue ]
675 complexParamDeclaration = structureOrClassName parameterName [ array ]
676                        [ "=" complexTypeValue ]
677 enumParamDeclaration    = enumName parameterName [ array ]
678                        [ "=" enumTypeValue ]
679 referenceParamDeclaration = classReference parameterName [ array ]
680                        [ "=" referenceTypeValue ]
681 parameterName           = IDENTIFIER

```

682 A class may define two kinds of methods:

- 683 • Instance methods, which are invoked on an instance and receive that instance as an  
 684 additional/implied argument (a concept similar to the "this" method argument in dynamic  
 685 programming languages)
- 686 • Static methods, designated with the `Static` qualifier, which can be invoked on an instance of the  
 687 class or the class, but when invoked on the instance do not get that instance as an additional  
 688 argument

689 A class can derive from another class, in which case it inherits the enumerations, structures, properties  
 690 and methods of its superclass. A class can also derive from a structure, in which case it inherits the  
 691 properties, enumerations, structures of that super-structure.

692 A class may be designated as abstract by specifying the Abstract qualifier. An abstract class cannot be  
693 separately instantiated, but can be the superclass of non-abstract classes that can have instances (see  
694 the Class CIM metaelement and the Abstract qualifier in [DSP0004](#) for more details). The `GOLF_Base`  
695 class is an example of an abstract class.

696 Non-abstract classes can have one or more key properties. A key property is specified with the Key  
697 qualifier (see the Property CIM metaelement and the Key qualifier in [DSP0004](#) for more details). The key  
698 properties of a class instance collectively provide a unique identifier for the class instance within a  
699 namespace.

700 The `InstanceID` property of the `GOLF_Base` class is an example of a key property. A key property should  
701 be of type string, although other primitive types can be used, and must have the Key qualifier. The key  
702 property is used by class implementations to uniquely identify instances.

703 The parameter `Status` in the method `GetNumberOfProfessionals` of the `GOLF_Professional` class  
704 illustrates parameter default values. CIM v3 introduces the ability to define default values for method  
705 parameters (see the `primitiveParamDeclaration`, `structureParamDeclaration`,  
706 `enumParamDeclaration`, `classParamDeclaration` and `referenceParamDeclaration` MOF  
707 grammar rules).

708 The second parameter of the `GetNumberOfProfessionals` method has the default value  
709 `MemberStatusEnum.Professional`. The parameter default values have been introduced to support method  
710 extensions. The idea of the method extensions is as follows:

- 711 • A derived class may override a method and add a new parameter.
- 712 • The added parameter is declared with a default value.
- 713 • A client written against the base class calls the method without that parameter, because it does  
714 not know about it.
- 715 • The class implementation does not error out, but takes the default value of the missing  
716 parameter and executes the "extended" method implementation.

717 The example does not illustrate method overriding to keep the example simple. However the  
718 `GetNumberOfProfessionals` method can be called with all three arguments, or only with the `NoOfPros`  
719 and `Club` arguments.

720 The same mechanism can be used when upgrading a schema, where clients written against a previous  
721 schema version can call extended methods in the new version.

722 Method parameters are identified by name and not by position and clients invoking a method can pass  
723 the corresponding arguments in any order. Therefore parameters with default values can be added to the  
724 method signature at any position.

725 In addition to the grammar rules stated above, a MOF compiler shall verify the integrity of class  
726 declarations using the applicable CIM Metamodel constraints, which are stated as OCL constraints in  
727 clause 5.6.7 of [DSP0004](#) and listed in ANNEX G of that document.

## 728 7.5.8 Primitive type declarations

729 CIM defines the following set of primitive data types:

- 730 • numeric
  - 731 • integer
  - 732 • real
  - 733 • real32, real64

- 734 • string
- 735 • datetime
- 736 • boolean, and
- 737 • octetstring

738 Each MOF primitive data type corresponds to a CIM Metamodel element derived from the PrimitiveType  
 739 metaelement as defined in [DSP0004](#). A MOF primitive data type shall conform to the following  
 740 primitiveType ABNF rule (whitespace as defined in 5.2 is allowed between the elements of the rules  
 741 in this ABNF section):

```

742 primitiveType      = DT_INTEGER /
743                    DT_REAL /
744                    DT_STRING /
745                    DT_DATETIME /
746                    DT_BOOLEAN /
747                    DT_OCTETSTRING
748 DT_INTEGER         = "integer"           ; keyword: case insensitive
749 DT_REAL            = DT_REAL32 /
750                    DT_REAL64 /
751 DT_REAL32          = "real32"           ; keyword: case insensitive
752 DT_REAL64          = "real64"           ; keyword: case insensitive
753 DT_STRING          = "string"           ; keyword: case insensitive
754 DT_DATETIME        = "datetime"         ; keyword: case insensitive
755 DT_BOOLEAN         = "boolean"          ; keyword: case insensitive
756 DT_OCTETSTRING    = "octetstring"       ; keyword: case insensitive
  
```

757 The primitive types are used in the declarations of

- 758 • Qualifiers types
- 759 • Properties
- 760 • Enumerations
- 761 • Method parameters
- 762 • Method results

763 **7.5.9 Complex type value**

764 The `complexTypeValue` MOF grammar rule corresponds to the `ComplexValue` CIM metaelement, and  
 765 shall conform to the following ABNF rules (whitespace as defined in 5.2 is allowed between the elements  
 766 of the rules in this ABNF section):

767 NOTE The grammar is not attempting to verify that the type of the property value is consistent with the type of the  
 768 property to which the value is assigned. For example, if a property type is a structure containing a string and an  
 769 integer, its value shall be an instance of that structure with a value for its two properties.

```

770 complexTypeValue      = complexValue / complexValueArray
771 complexValueArray    = "{" [ complexValue *( "," complexValue) ] "}"
772 complexValue         = aliasIdentifier /
773                       ( VALUE OF
774                         ( structureName / className / associationName )
775                         propertyValueList )
776 propertyValueList    = "{" *propertySlot "}"
777 propertySlot         = propertyName "=" propertyValue ";"
778 propertyValue        = primitiveTypeValue / complexTypeValue /
779                       referenceTypeValue / enumTypeValue
780 alias                = AS aliasIdentifier
781 INSTANCE             = "instance"           ; keyword: case insensitive
782 VALUE               = "value"             ; keyword: case insensitive
783 AS                  = "as"                ; keyword: case insensitive
784 OF                  = "of"                ; keyword: case insensitive
  
```

785 A complex value specification can start with one of two keywords; `"instance"` or `"value"`.

786 The keyword `"value"` corresponds to the `StructureValue` CIM metaelement. It shall be used to define a  
 787 value of a structure, class, or association that only will be used as the

- 788 • value of complex property in instances of a class or association, or in structure value
- 789 • default value of a property
- 790 • default value of a method parameter

791 The keyword `"instance"` corresponds to the `InstanceSpecification` CIM metaelement and shall be used to  
 792 define an instance of a class or association.

793 The `JohnDoe_mof` is an example of an instance value that represents a person with the first name "John"  
 794 and the last name "Doe".

795 Values of structures can be defined in two ways:

- 796 • By inlining them inside the owner class or structure instance. An example is the value of  
 797 `LastPaymentDate` property, or
- 798 • By defining them separately and giving them aliases. Examples are `$JohnDoesPhoneNo` and  
 799 `$JohnDoesStartDate`, which are first predefined and then used in the definition of the John Doe  
 800 instance.

801 The rules for the representation of the values of schema elements of type enumeration or reference are  
802 described in 7.6.2 and 7.6.4 respectively.

803 In addition to the grammar rules stated above a MOF compiler shall verify the integrity of value  
804 description statements by using the applicable CIM Metamodel constraints, which are stated as OCL  
805 constraints in clause 6 of [DSP0004](#) and listed in ANNEX G of that document.

### 806 7.5.10 Reference type declaration

807 The reference type corresponds to the ReferenceType CIM metaelement. A declaration of a reference  
808 type shall conform to ABNF rule `DT_REFERENCE` (whitespace as defined in 5.2 is allowed between the  
809 elements of the rules in this ABNF section):

```
810 DT_REFERENCE           = className REF
811 REF                    = "ref"                ; keyword: case insensitive
```

## 812 7.6 Value definitions

813 In MOF a value, or an array of values, can be specified as:

- 814 • default value of a property or a method parameter
- 815 • default value of a qualifier type declaration
- 816 • qualifier value
- 817 • value of a property in a specification of a structure value or class or association instance

818 MOF divides values into four categories:

- 819 • Primitive type values
- 820 • Complex type values
- 821 • Enumeration type values
- 822 • Reference type values

### 823 7.6.1 Primitive type value

824 The `primitiveTypeValue` MOF grammar rule corresponds to the LiteralSpecification CIM  
825 metaelement and represents a single value, or an array of values of the predefined primitive types  
826 (whitespace as defined in 5.2 is allowed between the elements of the rules in this ABNF section).

```
827 primitiveTypeValue     = literalValue / literalValueArray
828 literalValueArray      = "{" [ literalValue *( "," literalValue ) ] "}"
829 literalValue           = integerValue /
830                         realValue /
831                         booleanValue /
832                         nullValue /
833                         stringValue
834                         ; NOTE stringValue covers octetStringValue and
835                         ; dateTimeValue
```

836 The MOF grammar rules for the different types of literals are defined as follows.

837 **7.6.1.1 Integer value**

838 No whitespace is allowed between the elements of the rules in this ABNF section.

```

839 integerValue           = binaryValue / octalValue / hexValue / decimalValue
840 binaryValue           = [ "+" / "-" ] 1*binaryDigit ( "b" / "B" )
841 binaryDigit           = "0" / "1"
842 octalValue            = [ "+" / "-" ] unsignedOctalValue
843 unsignedOctalValue    = "0" 1*octalDigit
844 octalDigit            = "0" / "1" / "2" / "3" / "4" / "5" / "6" / "7"
845 hexValue              = [ "+" / "-" ] ( "0x" / "0X" ) 1*hexDigit
846 hexDigit              = decimalDigit / "a" / "A" / "b" / "B" / "c" / "C" /
847                       "d" / "D" / "e" / "E" / "f" / "F"
848 decimalValue          = [ "+" / "-" ] unsignedDecimalValue
849 unsignedDecimalValue  = "0" / positiveDecimalDigit *decimalDigit

```

850 **7.6.1.2 Real value**

851 No whitespace is allowed between the elements of the rules in this ABNF section.

```

852 realValue              = [ "+" / "-" ] *decimalDigit "." 1*decimalDigit
853                       [ ( "e" / "E" ) [ "+" / "-" ] 1*decimalDigit ]
854 decimalDigit          = "0" / positiveDecimalDigit
855 positiveDecimalDigit  = 1"...9"

```

856 **7.6.1.3 String values**857 Unless explicitly specified via ABNF rule [WS](#), no whitespace is allowed between the elements of the rules  
858 in this ABNF section.

```

859 singleStringValue     = DOUBLEQUOTE *stringChar DOUBLEQUOTE
860 stringValue          = singleStringValue *( *WS singleStringValue )
861
862 stringChar           = stringUCSchar / stringEscapeSequence
863 stringUCSchar        = U+0020...U+0021 / U+0023...U+D7FF /
864                       U+E000...U+FFFF / U+10000...U+10FFFF
865                       ; Note that these UCS characters can be
866                       ; represented in XML without any escaping
867                       ; (see W3C XML).
868 stringEscapeSequence = BACKSLASH ( BACKSLASH / DOUBLEQUOTE / SINGLEQUOTE /
869                                   BACKSPACE_ESC / TAB_ESC / LINEFEED_ESC /
870                                   FORMFEED_ESC / CARRIAGERETURN_ESC /
871                                   escapedUCSchar )

```

```

872 BACKSPACE_ESC      = "b"          ; escape for back space (U+0008)
873 TAB_ESC           = "t"          ; escape for horizontal tab (U+0009)
874 LINEFEED_ESC     = "n"          ; escape for line feed (U+000A)
875 FORMFEED_ESC     = "f"          ; escape for form feed (U+000C)
876 CARRIAGERETURN_ESC = "r"          ; escape for carriage return (U+000D)
877 escapedUCSchar     = ( "x" / "X" ) 1*6( hexDigit ) ; escaped UCS
878                   ; character with a UCS code position that is
879                   ; the numeric value of the hex number

```

880 The following special characters are also used in other ABNF rules in this specification:

```

881 BACKSLASH          = U+005C          ; \
882 DOUBLEQUOTE        = U+0022          ; "
883 SINGLEQUOTE        = U+0027          ; '
884 UPPERALPHA         = U+0041...U+005A ; A ... Z
885 LOWERALPHA         = U+0061...U+007A ; a ... z
886 UNDERSCORE        = U+005F          ; _

```

#### 887 7.6.1.4 OctetString value

888 No whitespace is allowed between the elements of the rules in this ABNF section.

```

889 octetStringValue    = DOUBLEQUOTE "0x" *( octetStringElementValue )
890                   DOUBLEQUOTE
891                   *( *WS DOUBLEQUOTE *( octetStringElementValue )
892                   DOUBLEQUOTE )
893 octetStringElementValue = 2(hexDigit)

```

#### 894 7.6.1.5 Boolean value

895 No whitespace is allowed between the elements of the rules in this ABNF section.

```

896 booleanValue       = TRUE / FALSE
897 FALSE              = "false"          ; keyword: case insensitive
898 TRUE               = "true"           ; keyword: case insensitive

```

#### 899 7.6.1.6 Null value

900 No whitespace is allowed between the elements of the rules in this ABNF section.

```

901 nullValue          = NULL
902 NULL               = "null"           ; keyword: case insensitive
903                   ; second

```

904 **7.6.1.7 File path**

905 The `filePath` ABNF rule defines the format of the file path used as the string value in the `INCLUDE`  
906 compiler directive (see Table 1).

907 The escape mechanisms defined for the `stringValue` ABNF rule apply. For example, backslash characters  
908 in file paths must be escaped.

909 A file path can be either a relative path or a full path. The relative path is in relationship to the directory of  
910 the file in which the `INCLUDE` compiler directive is found. File paths are subject to platform-specific  
911 restrictions on the character set used in directory names and on the length of single directory names and  
912 the entire file path.

913 MOF compilers shall support both forward and backward slashes in path delimiters, including a mix of  
914 both.

915 If the platform has restrictions with respect to these path delimiters, the MOF compiler shall transform the  
916 path delimiters to what the platform supports.

917 No whitespace is allowed between the elements of the rules in this ABNF section.

```

918 filePath           = [absoluteFilePrefix] relativeFilePath
919 relativeFilePath   = IDENTIFIER *( pathDelimiter IDENTIFIER)
920 pathDelimiter      = "/" / "\"          absoluteFilePrefix = rootDirectory /
921 driveLetter
922 rootDirectory      = pathDelimiter
923 driveLetter        = UPPERALPHA ":" [pathDelimiter]

```

## 924 7.6.2 Complex type value

925 Whitespace as defined in 5.2 is allowed between the elements of the rules in this ABNF section.

926 An `instanceValueDeclaration` is treated as an instruction to create a new instance where the key  
 927 values of the object do not already exist or an instruction to modify an existing instance where an object  
 928 with identical key values already exists. The value of the instance may optionally be accessed within the  
 929 MOF compilation unit.

930 A `structureValueDeclaration` creates a value that may only be used within a MOF compilation unit.

```

931 instanceValueDeclaration = INSTANCE OF ( className / associationName )
932                             [alias]
933                             propertyValueList ";"
934
935 structureValueDeclaration = VALUE OF
936                             ( className / associationName / structureName )
937                             alias
938                             propertyValueList ";"

```

## 939 7.6.3 Enum type value

940 Whitespace as defined in 5.2 is allowed between the elements of the rules in this ABNF section.

```

941 enumTypeValue         = enumValue / enumValueArray
942 enumValueArray        = "{" [ enumName *( "," enumName ) ] "}"
943 enumValue             = [ enumName "." ] enumLiteral
944 enumLiteral           = IDENTIFIER

```

## 945 7.6.4 Reference type value

946 ReferenceTypeValues enable a protocol agnostic serialization of a reference.

947 Whitespace as defined in 5.2 is allowed between the elements of the rules in this ABNF section.

```
948 referenceTypeValue      = objectPathValue / objectPathValueArray
949 objectPathValueArray    = "{" [ objectPathValue *( "," objectPathValue ) ]
950                          "}"
```

951 No whitespace is allowed between the elements of the rules in this ABNF section.

```
952 ; Note: objectPathValues are URLs and shall conform to RFC 3986 (Uniform
953 ; Resource Identifiers (URI): Generic Syntax) and to the following ABNF.
954 objectPathValue         = [namespacePath ":" ] instanceId
955 namespacePath           = [serverPath] namespaceName
956 ; Note: The production rules for host and port are defined in IETF
957 ; RFC 3986 (Uniform Resource Identifiers (URI): Generic Syntax).
958 serverPath              = (host / LOCALHOST) [ ":" port] "/"
959 LOCALHOST               = "localhost"           ; Case insensitive
960 instanceId              = className "." instanceKeyValue
961 instanceKeyValue        = keyValue *( "," keyValue )
962 keyValue                = propertyName "=" literalValue
```

## 963 7.7 Names and identifiers

### 964 7.7.1 Names

965 MOF names are identifiers with the format defined by the IDENTIFIER rule.

966 No whitespace is allowed between the elements of the rules in this ABNF section.

```
967 IDENTIFIER              = firstIdentifierChar *( nextIdentifierChar )
968 firstIdentifierChar     = UPPERALPHA / LOWERALPHA / UNDERSCORE
969 nextIdentifierChar      = firstIdentifierChar / decimalDigit
970 elementName            = localName / schemaQualifiedName
971 localName               = IDENTIFIER
```

### 972 7.7.2 Schema-qualified name

973 To assure schema level uniqueness of the names of structures, classes, associations, enumerations, and  
 974 qualifiers, CIM follows a naming convention referred to as the schema-qualified names. A schema-  
 975 qualified name starts with a globally unique, preferably registered, string associated with a company,  
 976 business, or organization followed by the underscore "\_". That unique string is referred to as the schema  
 977 name. The schemaQualifiedName MOF rule defines the format of the schema-qualified names.

978 No whitespace is allowed between the elements of the rules in this ABNF section.

```
979 schemaQualifiedName    = schemaName UNDERSCORE IDENTIFIER
980 schemaName             = firstSchemaChar *( nextSchemaChar )
981 firstSchemaChar        = UPPERALPHA / LOWERALPHA
982 nextSchemaChar         = firstSchemaChar / decimalDigit
```

### 983 7.7.3 Alias identifier

984 An aliasIdentifier identifies an Instance or Value within the context of a MOF compilation unit.

985 No whitespace is allowed between the elements of this rule.

```
986 aliasIdentifier         = "$" IDENTIFIER
```

### 987 7.7.4 Namespace name

988 The format of the names of namespaces is defined by the namespaceName MOF rule.

989 No whitespace is allowed between the elements of this rule.

```
990 namespaceName          = IDENTIFIER *( "/" IDENTIFIER )
```

991  
992  
993  
994**ANNEX A  
(normative)****MOF keywords**

995 Below are the MOF keywords, listed in alphabetical order.

996

#pragma	false	qualifier
	flavor	
any		real32
as	include	real64
association	instance	ref
	integer	restricted
boolean		
	method	scope
class		string
	null	structure
datetime		
disableoverride	octetstring	true
	of	
enableoverride		
enumeration	parameter	value
enumerationvalue	property	void

997

## ANNEX B (informative)

### Datetime values

998  
999  
1000  
1001

1002 The representation of time-related values is defined in [DSP0004](#), clause 5.5.1. The values of the datetime  
1003 primitive type have one of two formats:

- 1004 • `timestampValue`, which represents a specific moment in time
- 1005 • `durationValue`, which represents the length of a time period

1006 No whitespace is allowed between the elements of the rules in this ABNF section.

```

1007 datetimeValue      = timestampValue / durationValue
1008 timestampValue     = DOUBLEQUOTE yearMonthDayHourMinSec "." microseconds
1009                    ( "+" / "-" ) datetimeTimezone DOUBLEQUOTE
1010 yearMonthDayHourMinSec = 4Y 2M 2D 2h 2m 2s /
1011                    4Y 2M 2D 2h 2m 2"*" /
1012                    4Y 2M 2D 2h 4"*" /
1013                    4Y 2M 2D 6"*" /
1014                    4Y 2M 8"*" /
1015                    4Y 10"*" /
1016                    14"*"
1017 datetimeTimezone  = 3m
1018 durationValue     = DOUBLEQUOTE dayHourMinSec "." microseconds
1019                    ":000" DOUBLEQUOTE
1020 dayHourMinSec     = 8D 2h 2m 2s /
1021                    8D 2h 2m 2"*" /
1022                    8D 2h 4"*" /
1023                    8D 6"*" /
1024                    14"*"
1025 microseconds     = 6decimalDigit /
1026                    5decimalDigit "*" /
1027                    4decimalDigit 2"*" /
1028                    3decimalDigit 3"*" /

## ANNEX C (informative)

### Programmatic units

1042 The following rules define the string representation of a unit of measurement for programmatic access.  
1043 Programmatic unit is described in detail and exemplified in ANNEX D of [DSP0004](#).

1044 The following special characters are used only in programmatic units.

1045	HYPHEN	= U+002D	; -
1046	CARET	= U+005E	; ^
1047	COLON	= U+003A	; :
1048	PARENS	= U+0028 / U+0029	; ( and )
1049	SPACE	= U+0020	; " "

1050 A programmatic unit can be used as a

- 1051 • value of the PUnit qualifier
- 1052 • value of a string typed model element qualified with the boolean IsPUnit qualifier

1053 Unless specified via the ABNF rule `SPACE`, no whitespace is allowed between the elements of the rules in  
1054 this ABNF section.

1055	<code>programmaticUnitValue</code>	= <code>DOUBLEQUOTE programmaticUnit DOUBLEQUOTE</code>
1056	<code>programmaticUnit</code>	= <code>[HYPHEN] *SPACE unitElement</code>
1057		<code>*( *SPACE unitOperator *SPACE unitElement )</code>
1058	<code>unitElement</code>	= <code>( floatingPointNumber / exponentialNumber ) /</code>
1059		<code>[ unitPrefix ] baseUnit [ CARET exponent ]</code>
1060	<code>floatingPointNumber</code>	= <code>1*( decimalDigit) [ "." ] *( decimalDigit )</code>
1061	<code>exponentialNumber</code>	= <code>unsignedDecimalValue CARET exponent</code>
1062		<code>; shall be interpreted as a floating point number</code>
1063		<code>; with the specified decimal base and decimal</code>
1064		<code>; exponent and a mantissa of 1</code>
1065	<code>exponent</code>	= <code>[ HYPHEN ] unsignedDecimalValue</code>
1066	<code>unsignedDecimalValue</code>	= <code>positiveDecimalDigit *( decimalDigit)</code>
1067	<code>unitOperator</code>	= <code>"*" / "/"</code>
1068	<code>unitPrefix</code>	= <code>decimalPrefix / binaryPrefix</code>
1069		<code>; The numeric equivalents of these prefixes shall</code>
1070		<code>; be interpreted as multiplication factors for the</code>
1071		<code>; directly succeeding base unit. In other words,</code>
1072		<code>; if a prefixed base unit is in the denominator</code>
1073		<code>; of the overall programmatic unit, the numeric</code>

```
1074         ; equivalent of that prefix is also in the
1075         ; denominator.
1076
1077 ; SI decimal prefixes as defined in ISO 1000:1992:
1078 decimalPrefix      = "deca" /           ; 10^1
1079                   "hecto" /           ; 10^2
1080                   "kilo" /            ; 10^3
1081                   "mega" /           ; 10^6
1082                   "giga" /           ; 10^9
1083                   "tera" /           ; 10^12
1084                   "peta" /           ; 10^15
1085                   "exa" /            ; 10^18
1086                   "zetta" /          ; 10^21
1087                   "yotta" /          ; 10^24
1088                   "deci" /           ; 10^-1
1089                   "centi" /          ; 10^-2
1090                   "milli" /          ; 10^-3
1091                   "micro" /          ; 10^-6
1092                   "nano" /           ; 10^-9
1093                   "pico" /           ; 10^-12
1094                   "femto" /          ; 10^-15
1095                   "atto" /           ; 10^-18
1096                   "zepto" /          ; 10^-21
1097                   "yocto" /          ; 10^-24
1098
1099 ; IEC binary prefixes as defined in ISO/IEC 80000-13:
1100 binaryPrefix       = "kibi" /           ; 2^10
1101                   "mebi" /           ; 2^20
1102                   "gibi" /           ; 2^30
1103                   "tebi" /           ; 2^40
1104                   "pebi" /           ; 2^50
1105                   "exbi" /           ; 2^60
1106                   "zebi" /           ; 2^70
1107                   "yobi" /           ; 2^80
1108 baseUnit            = unitIdentifier / extensionUnit
1109                   ; If unitIdentifier begins with a prefix
1110                   ; (see prefix ABNF rule), the meaning of
```

```
1111 ; that prefix shall not be changed by the extension

## ANNEX E (informative)

### Change log

1630  
1631  
1632  
1633

1634 In earlier versions of CIM the MOF specification was part of the [DSP0004](#). See ANNEX I in [DSP0004](#) for  
1635 the change log of the CIM specification.

1636

Version	Date	Description
3.0.0	2012-12-13	
3.0.1	2015-04-16	Errata: <ul style="list-style-type: none"> <li>• Remove integer subclasses</li> <li>• Interval did not recognize 0</li> <li>• octetValue and datetimeValue indistinguishable from stringValue. They are removed from literalValue rule.</li> <li>• enumDeclaration changed to enumerationDeclaration for consistency</li> <li>• Fixed syntax of instanceValueDeclaration and structureValueDeclaration</li> <li>• Clarify that objectPath is a URL and therefore cannot contain whitespace.</li> <li>• Rearranged to remove mostly redundant Annex A. This also assures no inconsistencies between main text and Annex.</li> <li>• Fixes for several syntax errors</li> </ul>
