173

174

Introduction

175 This document presents the *CIM Simplified Policy Language (CIM-SPL)*, a proposed standard submitted
176 by the DMTF Policy Working Group. The objective of CIM-SPL is to provide a means for specifying *if-*
177 *condition-then-action* style policy rules to manage computing resources using constructs defined by CIM.

178 The design of CIM-SPL is inspired by existing policy languages and models including policy definition
179 language (PDL) from Bell Laboratories, the Ponder policy language from Imperial College, and autonomic
180 computing policy language (ACPL) from IBM Research. One of the main design points of CIM-SPL is to
181 provide a policy language compatible with the CIM Policy Model and the CIM Schema.

182

CIM Simplified Policy Language (CIM-SPL)

183 1 Scope

184 The objective of CIM-SPL is to provide a means for specifying *if-condition-then-action* style policy rules to
185 manage computing resources using constructs defined by the underlying model of CIM Information
186 Model. Using CIM-SPL, one can write policy rules whose condition may consist of CIM data that contains
187 the properties of managed resources. The CIM data may be available through various types of CIM data
188 repositories. The action part of a CIM-SPL policy can invoke any operations or function calls in general. In
189 particular, the action part can contain operations on the CIM data repository to change the properties of a
190 CIM instance. This document provides several examples drawn from storage provisioning and network
191 management to illustrate the usage of CIM-SPL.

192 The basic unit of a CIM-SPL policy is a policy rule. A CIM-SPL policy rule consists of a condition, an
193 action, and other supporting fields (for example, Import). Multiple policy rules can be grouped into a policy
194 group. Policy groups can be nested (that is, a policy group can contain other policy groups). In general,
195 the structure of a policy group reflects a hierarchy of managed resources. For the specification of the
196 policy condition, CIM-SPL provides the following rich set of operators described in sections 9 and 11, all
197 based on the intrinsic CIM types:

- 198 • signed and unsigned short, regular, and long integers
- 199 • float and long float
- 200 • string
- 201 • Boolean
- 202 • calendar

203 This document presents a detailed description of the basic CIM-SPL operators with examples. These
204 operations can also be used to compute the arguments passed as parameters to the policy actions.

205 2 Normative References

206 The following referenced documents are indispensable for the application of this document. For dated
207 references, only the edition cited applies. For undated references, the latest edition of the referenced
208 document (including any amendments) applies.

215 **3 Terms and Definitions**

216 For the purposes of this document, the following terms and definitions apply.

217 **3.1**

218 **can**

219 used for statements of possibility and capability, whether material, physical, or causal

220 **3.2**

221 **cannot**

222 used for statements of possibility and capability, whether material, physical, or causal

223 **3.3**

224 **conditional**

225 indicates requirements to be followed strictly in order to conform to the document when the specified
226 conditions are met

227 **3.4**

228 **mandatory**

229 indicates requirements to be followed strictly in order to conform to the document and from which no
230 deviation is permitted

231 **3.5**

232 **may**

233 indicates a course of action permissible within the limits of the document

234 **3.6**

235 **need not**

236 indicates a course of action permissible within the limits of the document

237 **3.7**

238 **optional**

239 indicates a course of action permissible within the limits of the document

240 **3.8**

241 **shall**

242 indicates requirements to be followed strictly in order to conform to the document and from which no
243 deviation is permitted

244 **3.9**

245 **shall not**

246 indicates requirements to be followed in order to conform to the document and from which no deviation is
247 permitted

248 **3.10**

249 **should**

250 indicates that among several possibilities, one is recommended as particularly suitable, without
251 mentioning or excluding others, or that a certain course of action is preferred but not necessarily required

252 **3.11**

253 **should not**

254 indicates that a certain possibility or course of action is deprecated but not prohibited

255 **4 Symbols and Abbreviated Terms**

256 **4.1**

257 **CIMOM**

279 Unicode Transformation Format

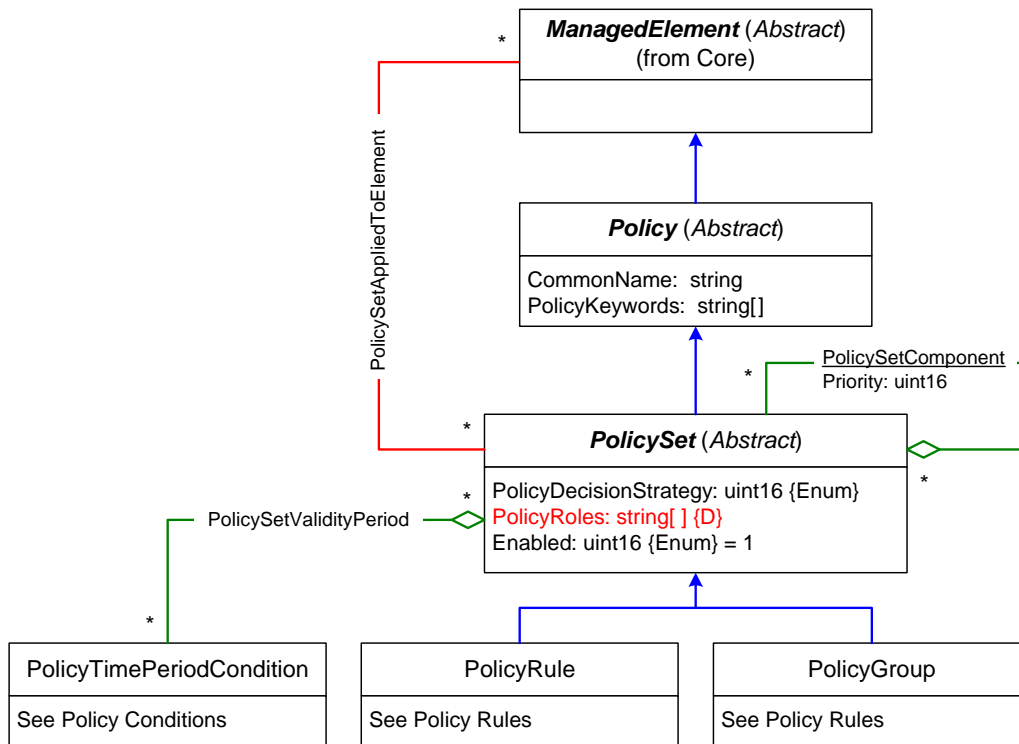

280 **5 CIM Policy Model**

281 This section briefly summarizes the CIM Policy Model, on which CIM-SPL is based. The CIM Policy
282 Model is an information model defined by the DMTF to describe policy management systems. At its core,
283 it provides a model for policy systems where the administrator can specify if-condition-then-action style
284 policies for various distributed capabilities (for example, network filters and access control).

285 The highest-level constructs of the CIM Policy Model are the CIM_Policy class, the CIM_PolicySet class,
286 the CIM_PolicyRule class, the CIM_PolicyGroup class, the CIM_PolicyTimePeriodCondition class, and
287 the associations among them. In addition, the CIM_PolicyRule class is associated with the
288 CIM_PolicyCondition and CIM_PolicyAction classes, which specify policy conditions and actions. See
289 Figure 1, which shows the top portion of the hierarchy.

290 The information model of CIM-SPL is derived from the CIM Policy Model, that is, a policy rule in CIM-SPL
291 is a subclass of CIM_PolicyRule called CIM_SPL_PolicyRule and contains a string property called
292 PolicyString. The PolicyString property stores a policy written in CIM-SPL. No separately defined and
293 associated conditions or actions may need to exist for this PolicyRule. Conditions and actions are
294 embedded in the text of the CIM-SPL policy in the PolicyString. CIM policies are either a policy rule or an
295 aggregation of policy rules in a PolicyGroup. This aggregation can contain policy rules or other policy
296 groups, and either a policy rule or a policy group can be applied to managed elements to govern their

297 operations. In practice, grouping policy rules that are commonly applied to the same kind of managed
 298 resources makes sense. Thus, it is important to have a way to define policy groups to simplify authoring
 299 and managing of policies. Mechanisms to define CIM-SPL Policies based on the combination of
 300 separately defined conditions, actions and policy groups may be created but are not described in this
 301 document.

302

303

Figure 1 – CIM Policy Information Model

304 6 Usage Models

305 This section outlines some of the ways in which CIM-SPL can be used. The usage models described in
 306 this section are not intended to be exhaustive; rather they are presented here for illustrative purposes.

307 6.1 Best Practice Checker

308 Policy-based best practice checking is a promising area in validating network configurations. In this
 309 section, the examples are drawn from storage area network (SAN) management. One of the main
 310 challenges in SAN management is the complexity encountered during system setup and reconfiguration.
 311 Typically a SAN consists of a large number of components from multiple manufacturers, and many of the
 312 components may have interoperability constraints. For example, a storage device from a certain vendor
 313 may work with only certain types of SAN switches (with certain firmware levels). Such interoperability
 314 constraints are usually documented and published by device vendors. In addition, over time, SAN
 315 administrators have developed best practices for avoiding typical problems associated with misconfigured
 316 devices. Following is a short list of sample best practices from field practitioners:

- 317 • All zones should be configured so that the same host bus adapter (HBA) cannot talk to both
 318 tape and disk devices.
- 319 • Both Windows server and Linux server should not be members of the same zone.

- 320 • Every active and connected port should be a member of at least one active zone.

321 To enforce these best practices, the storage management software queries the configuration and status
 322 of all the devices in a SAN and stores the configuration information in a CIM database. The policy
 323 management system can check for violations of the best practices that have been encoded in CIM-SPL.
 324 To ensure correct operation, the system administrator may run a configuration checker to validate all best
 325 practices for a particular device after making changes. The configuration checker can also run on a
 326 schedule (for example, every day at midnight), when it pulls the current configuration information from the
 327 database and checks it against best practices.

328 Alternatively, the policy evaluation may be triggered manually by the system administrator after making a
 329 configuration change. For example, after replacing an old HBA, the system administrator may want to
 330 validate the best practices against the new HBA. In this case, the administrator can evaluate only the
 331 policies relevant to an HBA and only for the configuration of the new HBA, as opposed to evaluating all
 332 the policies for the entire SAN.

333 6.2 Routing in Networks

334 Typical security policies for networks are implemented during the configuration of network devices such
 335 as switches, routers, or firewalls. The following list provides a few examples of these policies:

- 336 • Allow telnet connections within the local network.
 337 • Block any connection from locations outside the local network.
 338 • Block any telnet connection to locations outside the local network.
 339 • Allow ssh connections to locations outside the local network.

340 To capture these policies, most systems provide support for accepting configuration entries in the form of
 341 “if-then” rules. For example, given the prefix of the local network, the first rule can be written as follows: “If
 342 the input connection comes from an IP address with the local prefix and the destination port is the telnet
 343 port, then accept the connection.” Similarly, the second rule can be written as follows: “If the input
 344 connection comes from an IP address with no local prefix, then drop the connection.” The specification of
 345 these rules in CIM-SPL is straightforward. The implementation most likely depends on the device
 346 enforcing the policy. For example, routers that may directly support an interpreter for CIM-SPL will accept
 347 the CIM_Policies and reprogram themselves accordingly. Other systems, such as a computer running
 348 Linux, can translate the rules into *iptables* filter rules and perhaps dynamically load the rules into the
 349 operating system kernel. This file with rules is read by the system kernel, and the rules are applied at the
 350 appropriate time.

351 7 SPL Policy Rules

352 A policy in CIM-SPL is always a policy group but the most basic element in a CIM-SPL policy is a policy
 353 rule. A CIM-SPL policy rule is essentially a stream of characters that specifies a Condition/Action policy
 354 rule. To store, transmit, and represent policy strings in a byte-oriented medium or protocol, the characters
 355 need to be encoded in a byte format. CIM-SPL parsers shall support at least UTF-8 encoding of
 356 characters. A parser may support additional encodings, such as GB18030, the official character set of the
 357 People's Republic of China, to specify identifiers and strings.

358 The following example illustrates the CIM-SPL format. A detailed description of the syntax is provided in
 359 Section 13.

```
360 4.1 # This is an example of a CIM-SPL policy.
361 # 2005/07/15
362 Import SAMPLE CIM_V_2_8_CIM_Core28-Final::PhysicalElement;
363 Strategy Execute_All_Applicable;
```

```

364 Declaration{
365     InstallDate="ManagedSystemElement.InstallDate";
366     Macro { Name = Age;
367         Type = Long;
368         Arguments Born:DATETIME;
369         Procedure = getYear(CurrentDate) - getYear(Born)
370     }
371 }
372 Policy {
373     Condition { 4 > Age(InstallDate) AND
374                 VendorEquipmentType == "switch"}
375     Decision { Upgrade (SKU) }
376 }:1
377 # End of Policy

```

378 As shown in the preceding example, a policy string comprising a single rule has four components:

- 379 1) **Import statement:** The Import statement in the example refers to a CIM class that is relevant to
380 the policy string. In the remainder of the policy string, a policy rule is written as if an instance,
381 called instance under evaluation, of this class is available for manipulation. The rule may be
382 able to access other objects by traversing the references in associations where the instance
383 under evaluation participates. An Import statement is required in each policy string. Section
384 8.1.1 elaborates on the manner in which the object instance may be obtained.
- 385 2) **Strategy statement:** The Strategy statement indicates how many policy rules can be executed.
386 In the example, this statement can be ignored because the example contains a single rule.
- 387 3) **Declaration section:** A Declaration section defines named constants and macros that can be
388 used in the policy section of the policy string. In this way, the actual policy specification can be
389 clearer and easier to understand. The Declaration section is optional.
- 390 4) **Policy section:** The Policy section contains the main body of the policy string, with a condition
391 statement, a decision statement, and priority. Both the condition and the decision can refer to
392 the named constants and use the macros defined in the declaration section. The priority helps
393 to determine what policy rule to execute in case multiple rules are triggered.

394 In addition, a policy string can have comment statements. Each comment statement starts on a new line
395 with the # character as the first non-space character. Comment statements can occur anywhere in the
396 policy string. Comment statements are for human users and for maintenance; they are ignored by the
397 policy compiler.

398 Following are conventions and rules that are observed unless specified otherwise:

- 399 • Each policy string consists of multiple lines¹.
- 400 • Consecutive white space characters² in a line are treated as a single space character.
- 401 • Blank lines or lines with only white space characters are ignored.
- 402 • Reserved keywords in CIM-SPL are not case-sensitive.
- 403 • As the preceding example shows, each policy string may contain multiple sections.
- 404 • Each section is separated from the others by a label and opening and closing curly brackets.

¹ Lines in a policy string are delimited by line separators that include LF(u000A), CR(u000D), NEL(u0085), FF(u000C), LS(u2028), and PS(u2029).

² White space characters include characters in the space separator category (Zs) in the Unicode specification.

- 405 • The order of the data inside the sections is not important.
- 406 • A policy string may refer to identifiers that are either the named constants or macros defined in
- 407 the declaration section, or are properties or methods of the instance under consideration or any
- 408 property or method of an object that can be reached traversing associations. Identifiers are
- 409 described in Section 9.70.
- 410 • Semicolons are used at the end of the Import statement and at the end of primitive statements
- 411 within the Declaration section and the Policy declaration section (see section 7.1.3) where no
- 412 grouping characters (parentheses and curly brackets) occur.

413 7.1 Policy String Components

414 In the following three subsections the different parts of a simple policy, that is, a policy group with a single
 415 rule, are described in detail. Groups are described in Section 8. Normative grammar is given in
 416 Section 13.

417 7.1.1 Import Statement

418 When a policy rule is evaluated, the evaluation shall be done for a *target set* of managed elements. A
 419 policy rule, being part of a policy set, is meant to be applied to a managed element. The target set shall
 420 define instances of PolicySetAppliesToElement.

421 Every policy group shall have an Import statement and it shall refer to a CIM MOF file and a class
 422 included in that file. For brevity, the class referred to by the Import statement of a policy will be called the
 423 *import class* of the policy. The object instances in the target shall all be instances of the import class of
 424 the policy and they may further filter to only the objects that satisfy the optional simple Boolean condition
 425 in the Import statement. The syntax for the simple Boolean condition is defined later in Section 10. Note
 426 that the method used for an evaluator of a policy o get access to the managed elements in the target set
 427 of the policy is outside the scope of the language definition and is an implementation issue.

428 Format:

```
429 Import <name> CIM_V<major>_<minor>_<release><final or preliminary><mof file  
430 name w/o extension>::<class name>:<simple Boolean condition> ;
```

431 The Import statement specifies that an instance of the class specified in the statement is available during
 432 the evaluation of the policy rules. Policy rules may reference properties of this instance, including the
 433 properties in its super classes. Any other object that a policy rule may refer to in any part of the rule shall
 434 be accessible through reference associations related to this managed element. Operators are available to
 435 traverse associations in which this element participates to get access to other elements and their
 436 properties. The name is an identifier for the policy. It can be any sequence of letters or numbers always
 437 starting with a letter.

438 7.1.2 Declaration Section

439 The Declaration section contains declarations for named constants and macro procedures. For example,
 440 InstallDate can be defined as "PhysicalElement.ManagedSystemElement.InstallDate", and the InstallDate
 441 constant can be used when specifying the installDate in the Age macro. InstallDate refers to a property of
 442 the super class ManagedSystemElement of PhysicalElement. Details of how identifiers are interpreted
 443 are in Section 9.70. Macro procedures are used for common operations that may appear repeatedly in
 444 the policy sections. The Declaration section is optional.

445 Format:

```
446 Declaration {  
447     <List of constant definitions> (Optional)  
448     <List of macro definitions> (Optional)
```

449 }
 450 The names of constants and macros shall be different from the policy name.

451 Constant Definition

452 Format:

453 <constant name> = <constant value>;

454 Macro Definition

455 Format:

456 **Macro** {

457 **Name**=<string that is the macro's name>; (Required)

458 **Type**=type; (Required)

459 **Argument**= name1:type1[,name2:type2]*; (Optional)

460 **Procedure**=<expression> (Required)

461 }

462 Name is the identifier of a macro and Type is the return type of the macro call. Each argument is a
 463 Name:Type pair. Procedure defines the expression that is used as a result of a call to this macro. Here
 464 <expression> can be any valid CIM-SPL expression. See section 7.1.3.3 for CIM-SPL expressions and
 465 operators. The expression can include a macro call as long as the macro name has already been defined.
 466 See Section 9.70 for the definition of a macro call.

467 7.1.3 Policy Section

468 The Policy section contains the main body of a policy rule. It consists of the Policy Declaration, Condition,
 469 and Decision sections.

470 **Format:**

471 **Policy** {

472 **Declaration** {

473 <List of constant definition> (Optional)

474 <List of macro definitions> (Optional)

475 }

476 **Condition** { (Optional)

477 <If Condition>

478 }

479 **Decision** { (Required)

480 <Then Decision>

481 }

482 }: Priority

483 7.1.3.1 Declaration

484 The meaning of this section is the same as the global Declaration section except that the scope of the
 485 policy rule declarations is within the policy rule only. The policy declarations override global declarations if
 486 the names happen to clash.

487 7.1.3.2 Condition

488 The Condition section is an optional subsection of the Policy section. This is the "if" condition part of the
 489 policy rule. If the Condition section is omitted, the policy is considered always active (that is, an
 490 "unconditional" policy or a policy with a "true" condition).

491 **Format:**
 492 **Condition** {
 493 <Boolean Expression> (An expression that results in a Boolean constant
 494 after evaluation)
 495 }

496 Following is a summary of the operators and the functions that can be used to create Boolean
 497 expressions used in a Condition section. A more detailed description is provided in section 9.1

498 **7.1.3.3 Predefined Operators and Functions**

499 With few exceptions (for example, the minus operator, which can be either a unary or binary operator),
 500 each operator has a fixed number of typed arguments. CIM-SPL is a strongly-typed language (that is, the
 501 types of the arguments shall match the types supported by the operators). For example, numeric
 502 operators can take only numeric arguments; string operators can take only string arguments, and so on.
 503 Any named constants and macros, and other expressions, can be arguments to CIM-SPL operators.

504 *Alpha*, *beta*, and *gamma* in the examples shown in Table 1, Table 2 and

505 Table 5 represent numeric constants, and *time*, *date*, *date1*, *date2* shown in Table 6 represent a date
 506 time constant.

507 **Table 1 – Numeric Operators**

Operator	Example
+	(alpha + 2)
-	(alpha - 2), - alpha
*	(alpha * beta)
/	(alpha / beta)

508 **Table 2 – Boolean Operators**

Operator	Example
&&	(alpha < 10) && (beta > 3)
	(alpha < 10) (beta > 3)
^	(alpha < 10) ^ (beta > 3)
!	!(alpha)

509 *Alpha*, *beta*, and *gamma* in the examples shown in Table 3 are either all numeric values or all strings.

510 **Table 3 – Relational Operators**

Operator	Example
==	(alpha == beta)
!=	(alpha != beta)
>=	(alpha >= beta)
<=	(alpha <= beta)
>	(alpha > beta)
<	(alpha < beta)

511

Table 4 – String Functions

Function	Example
stringLength	stringLength("John Doe") ; returns 8
toUpper	toUpper("John Doe") ; returns "JOHN DOE"
toLower	toLower("John Doe") ; returns "john doe"
concatenate	concatenate("John ", "Doe") ; returns "John Doe"
substring	substring("John Doe", 1, 5) ; returns "ohn "
matchesRegExp	matchesRegExp(IP, "\d{1,3}+\.\d{1,3}+\.\d{1,3}+")
leftSubstring	leftSubstring("Mississippi", 4, "LeftToRight") ; returns "Miss" leftSubstring("Mississippi", 4, "RightToLeft") ; returns "Mississ"
rightSubstring	rightSubstring("Mississippi", 4, "LeftToRight") ; returns "issippi" rightSubstring("Mississippi", 4, "RightToLeft") ; returns "ippi"
middleSubstring	middleSubstring("Mississippi", 4, 5, "LeftToRight") ; returns "issip" middleSubstring("Mississippi", 4, 5, "RightToLeft") ; returns "ippi"
replaceSubstring	replaceSubstring("Illinois", "nois", "i") ; returns "Illini"
toUINT8	toUINT8("2")
toSINT8	toSINT8("2")
toSINT16	toSINT16("12")
toUINT16	toUINT16("12")
toSINT32	toSINT32("-12341234")
toUINT32	toUINT32("12341234")
toSINT64	toSINT64("-1234")
toUINT64	toUINT64("1234")
toREAL64	toREAL64("123.45")
toREAL32	toREAL32("12345.678")
toBoolean	toBoolean("true")
word	word(alpha, " ", 3)
startsWith	startsWith("Just a test", "Just") ; returns true
endsWith	endsWith("Just a test", "test") ; returns true
contains	contains("Just a test", "t a t") ; returns true
containsOnlyDigits	containsOnlyDigits("1234")
containsOnlyLetters	containsOnlyLetters("aBcD")
containsOnlyLettersOrDigits	containsOnlyLettersOrDigits("a1b2C3")

512

513

Table 5 – Numeric Functions

Function	Example
min	min(alpha, beta, gamma)
max	max(alpha, beta, gamma)
remainder	remainder(alpha, beta)
power	power(alpha, beta)
abs	abs(alpha)
toBoolean	toBoolean(0)
round	round(alpha)
exp	exp(alpha)
log	log(alpha)
sqrt	sqrt(alpha)
floor	floor(alpha)
ceiling	ceiling(alpha)

514

Table 6 – Time Functions

Function	Example
getMillisecond	getMillisecond(time)
getSecond	getSecond(time)
getMinute	getMinute(time)
getHour12	getHour12(time)
getHour24	getHour24(time)
getDayOfWeek	getDayOfWeek(date)
getDayOfWeekInMonth	getDayOfWeekInMonth(date)
getDayOfMonth	getDayOfMonth(date)
getDayOfYear	getDayOfYear(date)
getWeekOfMonth	getWeekOfMonth(date)
getWeekOfYear	getWeekOfYear(date)
getMonth	getMonth(date)
getYear	getYear(date)
isWithin	isWithin(date, date1, date2)
toMilliseconds	toMilliseconds(time)

515 7.1.3.4 Decision

516 The Decision section is a required subsection of the Policy section. It contains the then-action clause of
 517 the "if-condition-then-action" policy statement. The statement describes which CIM PolicyActions are
 518 called when the "if" condition is true. If some part of the action block encounters an error and thus the
 519 execution could not complete successfully, a CIM_ERROR_POLICY_EXECUTION should be thrown. In
 520 the implementation, a failure may be defined by a time out, that is, if an action does not complete within a
 521 predefined time, then it is considered a failure.

522 **Format:**

```
523 Decision {
524     <action block>
525 }
```

526 An <action block> may take one of the following forms:

527 **<policy action name> () <cop> <constant>**

528 A single PolicyAction evaluation without arguments.

529 **<policy action name> (<expression>[, <expression>]*) <cop> <constant>**

530 A single PolicyAction evaluation with at least one argument. The argument expression types shall
531 match the argument types of the concrete PolicyAction being evaluated. If this is not the case, a
532 CIM_ERROR_POLICY_EXECUTION may be thrown. **<cop>** is one of the comparison operators ==,
533 !=, <, <=, >, >=, and **<constant>** is a numeric constant. The **<cop> <constant>** pair is optional.

534 **<cascaded policy name> (Collection)**

535 The cascaded policy name is an identifier that shall refer to a PolicySet element that will be
536 evaluated as a result of the current policy execution. The collection shall be an expression that
537 results in a collection of managed elements that are used during the evaluation of the cascaded
538 policy (that is, it represents the target set). See section 7.1.1.

539 **<action block1> -> <action block2>**

540 This represents a sequence of action evaluations, where action block 1 is executed first, and then
541 action block 2 is executed if action block 1 executes successfully. If action block 1 does not complete
542 successfully, action block 2 should not be executed and the whole block returns failure. If the first
543 block succeeds, the second block is evaluated and the whole block returns whatever the second
544 block returns.

545 **<action block1> || <action block2>**

546 This represents the concurrency "some" semantics, where at least one of the action blocks (action
547 block 1 or action block 2) should be executed. In this case, both the blocks should be executed
548 concurrently (without any particular order), and the whole block succeeds as soon as one of the two
549 action blocks succeeds.

550 **<action block1> && <action block2>**

551 This represents the concurrency "all" semantics. Both action blocks should be executed, but there is
552 no explicit sequence defined for the execution. In this case, both the blocks should be evaluated
553 concurrently (without any particular order), and the whole block succeeds if both internal blocks
554 return success.

555 **<action block1> | <action block2>**

556 This represents the conditional semantics. If action block 1 completes successfully, then the whole
557 block succeeds, and action block 2 is not executed. If action block 1 could not complete successfully,
558 action block 2 will be executed, and the whole block returns whatever the second block returns.

559 **(<action block>)**

560 The parentheses are used to change the association precedence of combination operators. In the
561 action block, all decisions have equal precedence and are evaluated left to right by default. When
562 enclosed in parentheses, an action block is evaluated as a single block (see the following example).

563 A PolicyAction name can take one of the following forms:

- 564 1) Set.Identifier, with the identifier referring to a managed element. The argument names shall be
 565 properties of the element, and the effect is to set all the properties passed as arguments to the
 566 values returned by the expressions.
- 567 2) Identifier.MethodName, with the identifier referring to a managed element. The method name
 568 shall be a method of the managed element to which the identifier refers. The arguments shall
 569 match the signature of the method. The `<cop> <constant>` pair can only appear in this case.

570 Any evaluation of a concrete PolicyAction (in the form `<policy action name> (<expression> ...)`) or the
 571 setting of properties in a PolicySet instance return either success or failure. For an `<action block>`, if the
 572 block is just an action or a cascaded policy instance, the block returns whatever the action or the policy
 573 set returns if no `<cop> <constant>` pair appears after the action. If the pair appears, the execution will be
 574 considered a failure if the value returned by the action does not match the condition.

575 To see the effect of parentheses, consider the following decision example: $a \rightarrow b / c$. The association left
 576 to right makes this expression equivalent to $((a \rightarrow b) / c)$. In this case, if the evaluation of a succeeds, b is
 577 evaluated; otherwise c is evaluated. If b is evaluated and succeeds, nothing else is evaluated. On the
 578 other hand if b fails, c is evaluated. So c is evaluated whenever a or b fails. In the expression $a \rightarrow (b / c)$,
 579 c is evaluated only if a succeeds and b fails.

580 The same syntax for expressions pertains to specifying arguments for policy action invocations as applies
 581 in condition clauses (see section 7.1.3.3).

582 7.1.4 Strategy and Priorities

583 The Strategy statement and policy priorities are explained in Section 8, in which policy groups are
 584 introduced.

585 8 SPL Policy Groups

586 Policies in CIM are not only individual policy rules — they can be policy groups. A policy group in the CIM
 587 Policy Model aggregates policy rules and other policy groups using PolicySetComponent aggregations
 588 (see Figure 1).

589 This section provides the syntax for writing policy groups and describes how the *target set* for the
 590 evaluation of the rules inside a policy group is determined. Similar to CIM-SPL policy rules, a CIM-SPL
 591 policy group is represented by a policy string. The policy string for a policy group has the format
 592 presented in the following section.

593 8.1 Policy Group Components

594 A policy group has the following format:

```
595 Import CIM_V<major>_<minor>_<release><final or preliminary><mof file name w/o  
596 extension>::<class name>:<simple Boolean condition> ;
```

```
597 Strategy [Execute_All_Applicable | Execute_First_Applicable] ; (Required)
```

```
598 Declaration {
```

```
599     <List of constant definition> (Optional)
```

```
600     <List of macro definitions> (Optional)
```

```
601 }
```

```
602 Policy { ... } : Priority; (Optional)
```

```
603 Policy { ... } : Priority; (Optional)
```

```
604 Policy { ... } : Priority; (Priority is required)
605 ...
606 PolicyGroup:[Association Name(Property1,Property2)] { ... } : Priority;
607 (Optional)
608 PolicyGroup:[Association Name(Property1,Property2)] { ... } : Priority;
609 (Optional)
610 PolicyGroup:[Association Name(Property1,Property2)] { ... } : Priority;
611 (Optional)
612 ...
```

613 At least one policy rule or one policy group shall be part of a policy group. The priorities are positive
614 integers. The order of policies and policy groups is immaterial; they can be intermixed, but all priorities
615 shall be different.

616 8.1.1 Suggested Mechanisms of Invocation: Import Statements and Indications

617 The Import statement in a policy group plays the same role as the Import statement in a single policy rule.
618 This Import statement indicates the class of the object instance under consideration to each policy rule in
619 the group. How the Import statement affects the evaluation of a policy group that is contained in another
620 policy group is described later in this section.

621 A policy (rule or group) is evaluated on a *target set* of managed elements. All these managed elements
622 shall be instances of the import class. This set defines instances of the PolicySetAppliesToElement
623 association in the CIM Policy Model.

624 The method used for an evaluator of a policy rule to get access to the managed elements in the target set
625 of the policy rule is outside the scope of the language definition and is an implementation issue. This
626 allows different policy invocation methods to be applied in different systems environments.

627 In one situation, a policy enforcement point may directly request (probably from a CIM Object Manager
628 (CIMOM) the evaluation of all policies relevant to the resource with which it is associated. The time of
629 invocation is decided by the policy enforcement point. This evaluation mechanism is often designated as
630 *solicited policy evaluation*. For a solicited evaluation of a policy, the target set may consist of all instances
631 of the import class that match the simple Boolean condition of the Import statement of the policy. If the
632 simple Boolean condition is not specified in the Import statement, the target set consists of all instances
633 of the import class. CIM-SPL does not define how the instances of the import class are gathered; that is, it
634 does not describe the scope of the operation that gathers instances. For example, the scope of gathering
635 data could be limited to a particular CIMOM or to all locations in the world-wide IT infrastructure of an
636 enterprise. At the time of activating or installing a policy, the scope of data gathering should be explicitly
637 or implicitly specified for the policy. Thus, this issue falls outside the CIM-SPL language definition.

638 In another situation, policy evaluation may be triggered by an event in the system. This mechanism is
639 often designated as *unsolicited policy evaluation*. For an unsolicited evaluation of a policy, the *target set*
640 for evaluation can be provided implicitly by the instances of CIM_InstIndication subclasses that are
641 *consistent* with the Import statement of the policy. The SourceInstance parameter of a CIM_InstIndication
642 instance points to a managed element that was the source of the CIM_InstIndication. A
643 CIM_InstIndication instance is consistent with the Import statement of a policy if the class of the managed
644 element to which the SourceInstance parameter of the CIM_InstIndication points is a subclass of the
645 class in the Import statement. CIM-SPL does not define which compatible instances of CIM_InstIndication
646 initiate an unsolicited evaluation of a policy. For example, when a policy is installed or is activated, a
647 policy server may require that an instance of CIM_IndicationFilter be specified. Such a requirement would
648 be sufficient for the policy server to generate a CIM_IndicationSubscription to CIM_InstIndications that
649 trigger evaluations of the policy. Subsequently, when the policy server receives a CIM_InstIndication
650 instance, the policy server evaluates the corresponding policy on the managed element to which the
651 SourceInstance parameter of the received CIM_InstIndication instance points.

652 8.1.2 Strategy Statement

653 A policy is applicable if its condition part evaluates to TRUE. A policy group is applicable if at least one of
 654 the policies belonging to the group is applicable. Any CIM-SPL implementation shall support at least two
 655 evaluation strategies: *Execute_All_Applicable* and *Execute_First_Applicable*. The strategy shall be
 656 specified in the strategy statement of a policy group. The *Execute_All_Applicable* strategy goes one by
 657 one over all the policies and policy subgroups, evaluating all applicable policies. The
 658 *Execute_First_Applicable* strategy proceeds in the order indicated by the priorities and examines policies
 659 and policy subgroups until one that is applicable is evaluated. Implementations may handle other
 660 evaluation strategies. If a policy mentions a strategy not supported by the CIM-SPL implementation the
 661 evaluation shall return a CIM_ERR_NOT_SUPPORTED error.

662 8.1.3 Policy Evaluation

663 Assuming that a set of managed elements have been collected for evaluation by a policy group, the
 664 evaluation shall proceed as follows. Consider a policy group **P** whose constituent policy rules and policy
 665 groups are given by $P_1, P_2, P_3, P_4, \dots$ and so on. For each managed element **M** for which the policy group
 666 **P** needs to be evaluated, the evaluation of **P** proceeds in two steps (regardless of whether the triggering
 667 of the evaluation was solicited or unsolicited): an *Applicability* step and an *Action Evaluation* step. The
 668 *Applicability* step returns a set of action blocks (see Section 7.1.3.4). The *Action Evaluation* step takes the
 669 set of action blocks output by the *Applicability* step and evaluates the actions. The *Applicability* step
 670 proceeds as follows:

671 First, if the evaluation strategy is *Execute_All_Applicable*, each P_i is processed as follows:

672 If P_i is a policy rule, the rule is checked if it is applicable on **M**. If during the evaluation of any
 673 condition to determine the applicability of a policy rule, the evaluation fails, the policy evaluations fails
 674 and returns CIM_ERR_POLICY_EVALUTION.

675 If P_i is a policy group, a new target set **S** is created as follows:

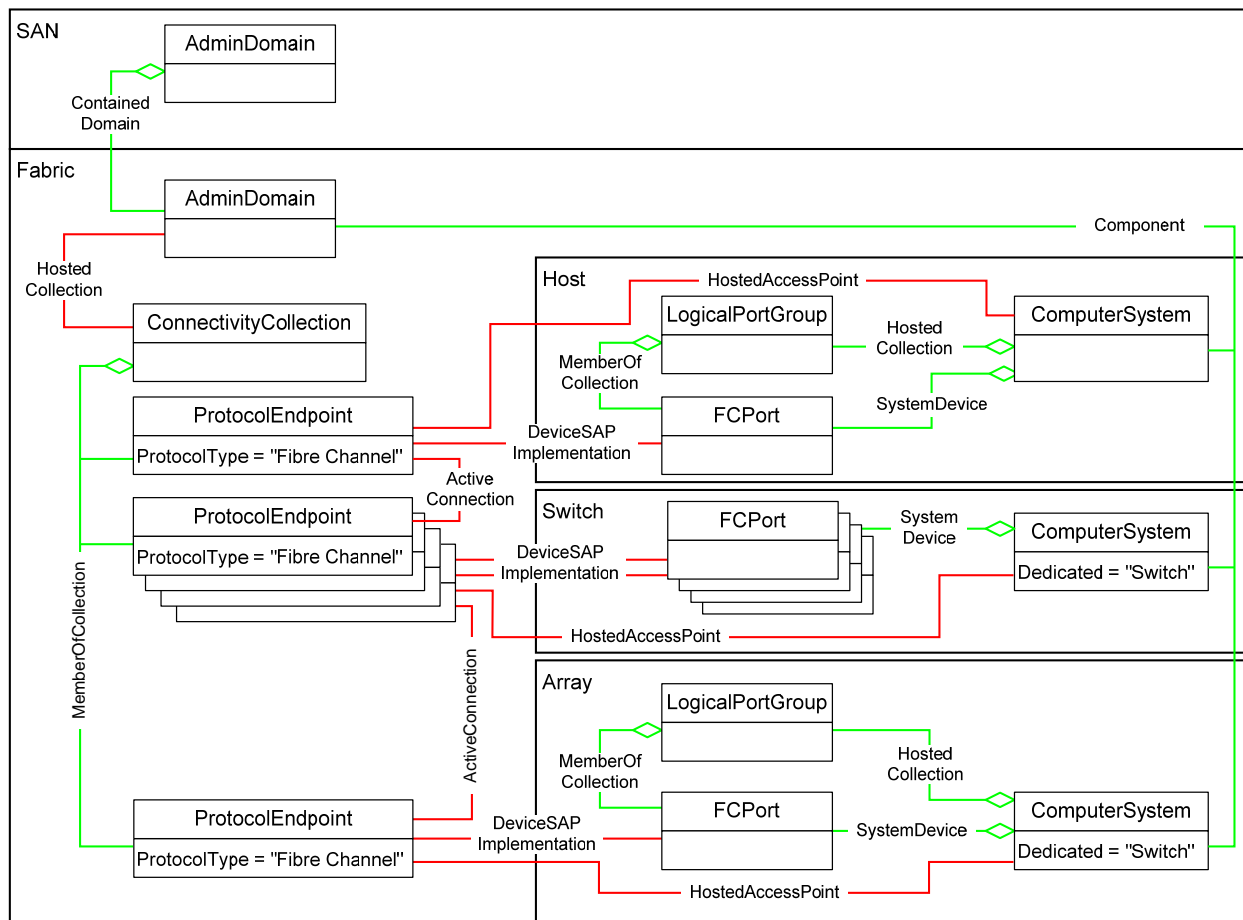

- 676 • If the policy group P_i has the optional association specification *Association Name(P1,P2)*
 677 specified with P_i (indicated following the keyword *PolicyGroup*), the target set **S** has
 678 managed elements that are associated with **M** through instances of the named association
 679 in such a way that **M** is referenced in the instance by property *P1* while the elements in the
 680 target set are referenced in the instances by property *P2*. If there is no association with
 681 specified name associated with the object the policy evaluation fails and returns
 682 CIM_ERR_POLICY_EVALUTION.
- 683 • If the optional association is not specified with P_i , the association is assumed to be the
 684 association CIM_Component, *Property1* the property GroupComponent, and *Property2* the
 685 property PartComponent. As a consequence, the target set **S** consists of all Components
 686 of the managed element **M**. If there is no association CIM_Component the policy
 687 evaluation fails and returns CIM_ERR_POLICY_EVALUTION.
- 688 • Then recursively the *Applicability* step is applied to the policy group P_i for each managed
 689 element in **S**. Each evaluation returns a set of action blocks
- 690 • If the evaluation strategy is *Execute_First_Applicable*, the P_i s shall be processed in the
 691 order specified by the priority (lower numbers first), but the processing shall stop at the first
 692 time either a policy rule is applicable or the *Applicability* step applied to a policy group
 693 returns a non-empty set of action blocks.
- 694 • Next, all action blocks of policy rules that have been processed and have been found
 695 applicable and all action block sets returned by the processing of policy groups are
 696 collected together in a single set of action blocks and the set is returned as the result of the
 697 *Applicability* step. If no policy rule has been found applicable and no group has returned a
 698 non-empty set of action blocks, the *Applicability* step will return an empty set of action
 699 blocks.

- 700 • Next the *Action Evaluation* step is applied. In this step each action block in the set shall be
701 processed according to the action execution schema described in Section 7.1.3.4.

702 The evaluation of a policy group for a managed element works recursively — policy rules in the policy
703 group are applied to the managed element, and, by default, policy subgroups in a policy group are
704 applied to the *components* of the managed element. The default behavior can be changed and the policy
705 subgroups in a policy group can be applied to other managed elements that are associated with the
706 managed element through an association other than CIM_Component. Section 8.2 shows how this
707 evaluation provides a powerful mechanism for specifying and applying policies in a hierarchical manner.

708 8.2 Policy Group Example

709 Figure 2 shows a diagram from the SNIA specification SMI-S 1.1.0. It shows a SAN Fabric that has Host,
710 Switch, and Array instances (distinguished by the value of the Dedicated property) as its components.

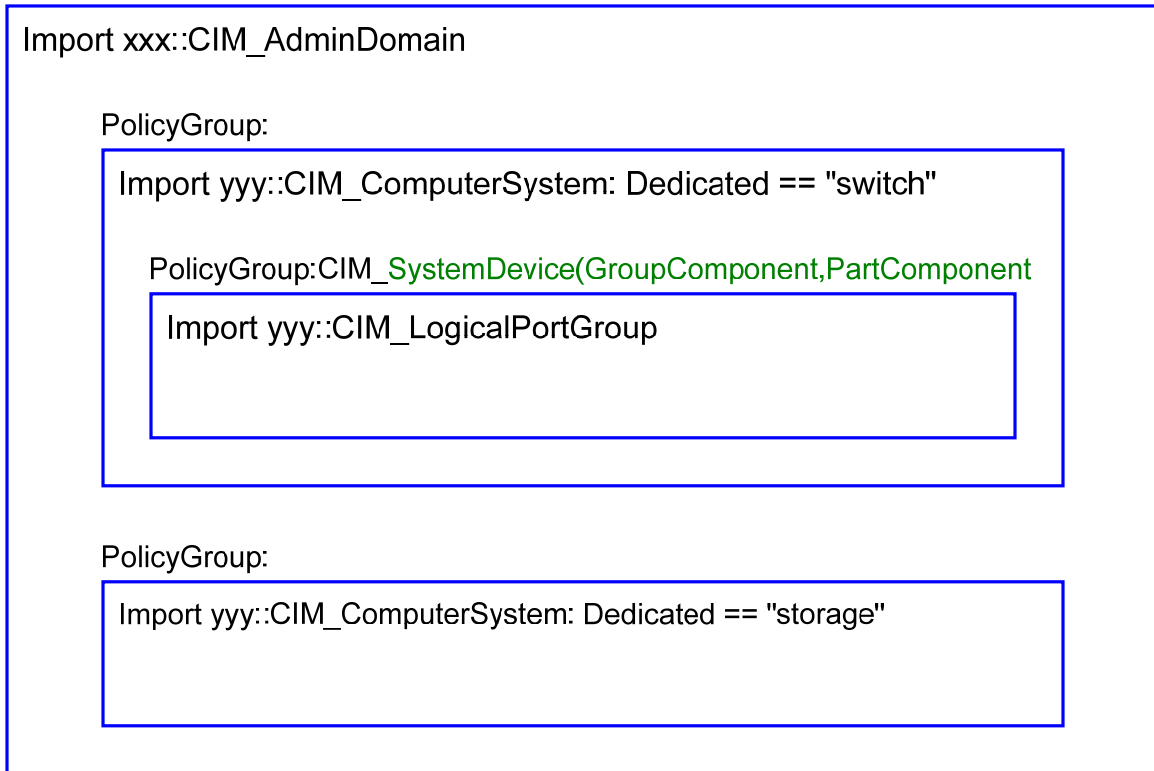

711

712

Figure 2 – Fabric Instance Diagram

713 A policy group for a SAN fabric can comprise two policy subgroups, one for the Switch and the other for
 714 the Array. Inside the policy group for the Switch, a policy group can exist for fiber channel ports (FCPort).
 715 Schematically, the policy group for the SAN fabric is shown in Figure 3.

<Name="System1"> ← Object associated with the initial call

716

717

Figure 3 – PolicyGroup Schema

718 When this policy group is evaluated for a SAN fabric, the first policy subgroup is evaluated for all switches
 719 in the fabric (components of type ComputerSystem with the Dedicated property set to “switch”). Similarly,
 720 the second policy subgroup is evaluated for all storage arrays in the fabric (components of type
 721 ComputerSystem with Property Dedicated set to “storage”). For each switch in the fabric, the innermost
 722 policy group is evaluated for all fiber channel ports (FCPort instances that are reached by traversing the
 723 association GroupComponent from the switch instance).

724 When specifying a policy group, certain policies are applicable only to a particular component of the
 725 managed element. Or, certain policies within a policy group may be applicable only to managed elements
 726 that are associated in a specific manner with the managed element. Such policies can be conveniently
 727 collected within a subgroup to ease the specification of a policy group.

728 9 Expressions

729 The expression language of CIM-SPL shall support all CIM intrinsic data types, arrays of these data
730 types, references to instances of CIM classes, and arrays to instances of CIM classes. This section
731 describes required operators supported by CIM-SPL.

732 Unless specified otherwise, a CIM-SPL function shall have the following syntax: **operator**(*operand1*,
733 *operand2*, *operand3*, ...). The syntax phrase shows the required operator in **bold**. Items that are required
734 arguments are shown in italics, like *<expression>*. Italicized values inside square brackets are optional.
735 These operators shall not be case-sensitive. Spacing between operands, operators, and parentheses is
736 optional. If one of the operands were to evaluate to NULL, then the operator shall evaluate to NULL.

737 9.1 Abs

738 Shall return the absolute value of the required numeric argument

739 **abs**(*<expression>*)

740 **Examples:**

741 abs(nbr1)

742 abs(4)

743 9.2 Logical And

744 Shall return a Boolean value corresponding to the logical AND operation on the required Boolean
745 arguments

746 (*<expression>* **&&** *<expression>*)

747

748 **Examples:**

749 (a **&&** b)

750 ((stringLength(alpha) >9) **&&** (5<c))

751 9.3 StartsWith

752 Shall return TRUE if the first required string argument begins with the second required string argument

753 **startsWith**(*<expression1>*, *<expression2>*)

754 where *<expression1>* is the given string, and *<expression2>* is the substring

755 **Example:**

756 startsWith("just a test", "just")

757 9.4 Ceiling

758 Shall return the smallest integer that is greater than or equal to the required numeric argument

759 **ceiling**(*<expression>*)

760 where *<expression>* is the numeric value

761 **Example:**

762 ceiling(nbr1)

763 9.5 Concatenate

764 Shall return the concatenation of two or more required string arguments

765 **concatenate**(*<expression1>*, *<expression2>*, ..., *<expressionN>*)

766 **Examples:**

767 concatenate(alpha, beta)

768 concatenate("Entered ", aValue, " in field")

769 9.6 Contains

770 Shall return TRUE if the first required string argument contains the second required string argument

771 **contains**(*<expression1>*, *<expression2>*)

772 where *<expression1>* is the given string, and *<expression2>* is the substring

773 **Example:**

774 contains("just a test", "t a t")

775 9.7 ContainsOnlyLettersOrDigits

776 Shall return TRUE if the required string argument is all letters or digits

777 **containsOnlyLettersOrDigits**(*<expression>*)

778 where *<expression>* is the string

779 **Example:**

780 containsOnlyLettersOrDigits("one4theroad")

781 9.8 ContainsOnlyDigits

782 Shall return TRUE if the required string argument is all digits

783 **containsOnlyDigits**(*<expression>*)

784 where *<expression>* is the string

785 **Example:**

786 containsOnlyDigits('12345')

787 9.9 ContainsOnlyLetters

788 Shall return TRUE if the required string argument is all letters

789 **containsOnlyLetters**(*<expression>*)

790 where *<expression>* is the string

791 **Example:**

792 containsOnlyLetters("onefortheroad")

793 9.10 Division

794 Shall return the result of the first required numeric argument divided by the second required numeric
795 argument with standard convention casting

796 (*<expression>* / *<expression>*)

797 Examples:

798 (a/b)

799 (5/c)

800 9.11 EndsWith

801 Shall return TRUE if the first required string argument ends with the second required string argument

802 **endsWith**(*<expression1>*, *<expression2>*)

803 where *<expression1>* is the given string, and *<expression2>* is the substring

804 Example:

805 endsWith("just a test", "test")

806 9.12 Equal

807 Shall return TRUE if the first required argument and the second required argument do not evaluate to the
808 same value

809 Equality Operator

810 (*<expression>* == *<expression>*)

811 Examples:

812 (a == b)

813 (stringLength(alpha) == 5)

814 (string1 == string2)

815 9.13 Exp

816 Shall return the value of *e* (Euler's number, the base of natural logarithms) raised to the power of the
817 value of the required numeric expression

818 **exp**(*<expression>*)

819 where *<expression>* is the value of the power

820 Examples:

821 exp(nbr1)

822 exp(2)

823 9.14 Floor

824 Shall returns the largest integer that is less than or equal to the required numeric argument

825 **floor**(*<expression>*)

826 where *<expression>* is the numeric value

827 Example:

828 floor(nbr1)

829 9.15 GetDayOfMonth

830 Shall return the day of the required DATETIME argument as a numeric value, for example, the first day of
831 the month has a value of 1, and so on.

832 **getDayOfMonth(<expression>)**

833 where <expression> is the DATETIME value

834 **Example:**

835 getDayOfMonth(aDate)

836 9.16 GetDayOfWeek

837 Shall return the day of the week of the required DATETIME argument as a numeric value, for example,
838 Sunday = 1, Monday = 2, and so on

839 **getDayOfWeek(<expression>)**

840 where <expression> is the DATETIME value

841 **Example:**

842 getDayOfWeek(aDate)

843 9.17 GetDayOfWeekInMonth

844 Shall return the day of the week in month of the required DATETIME argument as a numeric value, for
845 example, the DAY_OF_MONTH 1 through 7 always correspond to DAY_OF_WEEK_IN_MONTH 1; 8
846 through 14 correspond to DAY_OF_WEEK_IN_MONTH 2, and so on. DAY_OF_WEEK_IN_MONTH 0
847 indicates the week before DAY_OF_WEEK_IN_MONTH 1. Negative values count back from the end of
848 the month, so the last Sunday of a month is specified as DAY_OF_WEEK = SUNDAY,
849 DAY_OF_WEEK_IN_MONTH = -1.

850 **getDayOfWeekInMonth(<expression>)**

851 where <expression> is the DATETIME value

852 **Example:**

853 getDayOfWeekInMonth(aDate)

854 9.18 GetDayOfYear

855 Shall return the day within the year of the required DATETIME argument as a numeric value

856 **getDayOfYear(<expression>)**

857 where <expression> is the DATETIME value

858 **Example:**

859 getDayOfYear(aDate)

860 9.19 GetHour12

861 Shall return the hour of the required DATETIME argument in a 12-hour clock as a numeric value

862 **getHour12(<expression>)**

863 where <expression> is the DATETIME value

864 **Example:**

865 getHour12(aDate)

866 **9.20 GetHour24**

867 Shall return the hour of the required DATETIME argument in a 24-hour clock as a numeric value

868 **getHour24**(<expression>)

869 where <expression> is the DATETIME value

870 **Example:**

871 getHour24(aDate)

872 **9.21 GetMillisecond**

873 Shall return the millisecond within the second of the required DATETIME argument as a numeric value

874 **getMillisecond**(<expression>)

875 where <expression> is the DATETIME value

876 **Example:**

877 getMillisecond(aDate)

878 **9.22 GetMinute**

879 Shall return the minute within the hour of the required DATETIME argument as a numeric value

880 **getMinute**(<expression>)

881 where <expression> is the DATETIME value

882 **Example:**

883 getMinute(aDate)

884 **9.23 GetMonth**

885 Shall return the month within the year of the required DATETIME argument as a numeric value

886 **getMonth**(<expression>)

887 where <expression> is the DATETIME value

888 **Example:**

889 getMonth(aDate)

890 **9.24 GetSecond**

891 Shall return the second within the minute of the required DATETIME argument as a numeric value

892 **getSecond**(<expression>)

893 where <expression> is the DATETIME value

894 **Example:**

895 getSecond(aDate)

896 **9.25 GetWeekOfMonth**

897 Shall return the week within the month of the required DATETIME argument as a numeric value

898 **getWeekOfMonth**(<expression>)

899 where <expression> is the DATETIME value

900 **Example:**

901 getWeekOfMonth(aDate)

902 **9.26 GetWeekOfYear**

903 Shall return the week within the year of the required DATETIME argument as a numeric value

904 **getWeekOfYear**(<expression>)

905 where <expression> is the DATETIME value

906 **Example:**

907 getWeekOfYear(aDate)

908 **9.27 GetYear**

909 Shall return the year of the required DATETIME argument as a numeric value

910 **getYear**(<expression>)

911 where <expression> is the DATETIME value

912 **Example:**

913 getYear(aDate)

914 **9.28 Greater**

915 Shall return TRUE if the first required argument is greater than (or comes later in lexicographical order
916 based on UTF-8) the second required argument; returns FALSE otherwise

917 (<expression> > <expression>)

918 **Examples:**

919 (a > 4)

920 (stringLength(alpha) > stringLength("beta"))

921 **9.29 Greater or Equal**

922 Shall return TRUE if the first required argument is greater than (or comes later in lexicographical order
923 based on UTF-8) or equal to the second required argument; returns FALSE otherwise

924 (<expression> >= <expression>)

925 **Examples:**

926 (a >= 4)

927 (stringLength(alpha) >= stringLength("beta"))

928 9.30 IsWithin

929 Shall return TRUE if the IsWithin checks whether a DATETIME is inside a time period. When taking three
930 DATETIME expressions, the first is the DATETIME, and the remaining two define the start and end of the
931 time period.

932 **isWithin**(*<expression1>*, *<expression2>*, *<expression3>*)

933 where *<expression1>* is the DATETIME value to check, *<expression2>* is the start DATETIME
934 value, and *<expression3>* is the end DATETIME value

935 Examples:

936 isWithin(aDate1, aDate2, aDate3)

937 isWithin(2005-01-29T09:40:00 TZ=America/Chicago, aDate1, aDate2)

938 isWithin(2005-01-29T09:40:00 TZ=America/Chicago, 2006-01-29T09:40:00
939 TZ=America/Chicago, 2006-01-29T09:40:00 TZ=America/Chicago)

940 isWithin(aDate, aDate, 2006-01-29T09:40:00 TZ=America/Chicago)

941 9.31 Less

942 Shall return TRUE if the first required string or numeric argument is less than (or comes earlier in
943 lexicographical order based on UTF-8) the second required string or numeric argument; returns FALSE
944 otherwise. Both arguments shall be of the same datatype.

945 (*<expression>* < *<expression>*)

946 Examples:

947 (a < 4)

948 (stringLength(alpha) < stringLength("beta"))

949 9.32 Less or Equal

950 Shall return TRUE if the first required string or numeric argument is less than (or comes earlier in
951 lexicographical order based on UTF-8) or equal to the second required string or numeric argument;
952 returns FALSE otherwise. Both arguments shall be of the same datatype.

953 (*<expression>* <= *<expression>*)

954 Examples:

955 (a <= 4)

956 (stringLength(alpha) <= stringLength("beta"))

957 9.33 Ln

958 Shall return the natural logarithm of the given required numeric expression (logarithm base e)

959 **ln**(*<expression>*)

960 where *<expression>* is the numeric value

961 Example:

962 ln(nbr1)

963 **9.34 Max**

964 Shall return the maximum value of the required numeric or string arguments. All arguments shall be either
 965 numeric type or string type.

966 **max**(*<expression>*, *<expression>*, [*<expression>*...])

967 where *<expression>*s are the numeric values to compare

968 **Examples:**

969 max(nbr1, nbr2)

970 max(aNbr, 4, ToSINT16("2"))

971 **9.35 Min**

972 Shall return the minimum value of the required numeric or string arguments. All arguments shall be either
 973 numeric type or string type.

974 **min**(*<expression>*, *<expression>*, [*<expression>*...])

975 where *<expression>*s are the numeric values to compare

976 **Examples:**

977 Min(nbr1, nbr2)

978 min(aNbr, 4, ToSINT16("2"))

979 **9.36 Subtraction**

980 Shall return the result of the first required numeric argument minus the second optional numeric argument
 981 if two arguments are present; otherwise, returns the unary minus of the first required numeric argument.
 982 The data type of the result value shall follow standard JAVA casting conventions.

983 (*<expression>* - *<expression>*)

984 **Examples:**

985 (a - b)

986 (stringLength(alpha) - 5)

987 **9.37 Not Equal**

988 Shall return TRUE if the first required argument and the second required argument do not evaluate to the
 989 same value

990 (*<expression>* != *<expression>*)

991 **Examples:**

992 (a != b)

993 (stringLength(alpha) != c)

994 **9.38 Logical Not**

995 Shall return a Boolean value that corresponds to the logical NOT operation on the required Boolean
 996 argument

997 **!**(*<expression>*)

998 **Examples:**

999 !(alpha)

1000 !(true)

1001 9.39 Logical Or

1002 Shall return a Boolean value that corresponds to the logical OR operation on the required Boolean
1003 arguments

1004 (*<expression>* || *<expression>*)

1005 **Examples:**

1006 (a || b)

1007 ((stringLength(alpha) < 5) || (5+b))

1008 9.40 Addition

1009 Shall return the sum of the required numeric arguments. The data type of the result value shall follow the
1010 standard JAVA casting conventions.

1011 (*<expression>* + *<expression>*)

1012 **Examples:**

1013 (a + b)

1014 (stringLength(alpha) + 5)

1015 9.41 Power

1016 Shall return the value of the first required numeric argument raised to the power of the second required
1017 numeric argument.

1018 **power**(*<expression1>*, *<expression2>*)

1019 where *<expression1>* is the value raised to the power of *<expression2>*

1020 **Examples:**

1021 power(nbr1, nbr2)

1022 power(2, 4)

1023 9.42 Product

1024 Shall return the product of the required numeric arguments. The data type of the result value shall follow
1025 the standard JAVA casting conventions.

1026 (*<expression>* * *<expression>*)

1027 **Examples:**

1028 (a * b)

1029 (stringLength(alpha) * c)

1030 9.43 Mod

1031 Shall return the remainder from an operation of dividing the first required numeric argument by the
1032 second required numeric argument

1033 **mod**(*<expression1>*, *<expression2>*)

1034 where *<expression1>* is the value divided by *<expression2>*

1035 **Examples:**

1036 mod(nbr1, nbr2)

1037 mod(aNbr, 4)

1038 9.44 Round

1039 Shall return the closest SINT32 value to the required numeric argument. The return type of the result shall
1040 follow Java conventions for rounding and unary numeric promotion.

1041 **round**(*<expression>*)

1042 where *<expression>* is the value to round

1043 **Examples:**

1044 round(nbr1)

1045 round(ToREAL32(aNbr))

1046 9.45 SquareRoot

1047 Shall return the square root of the required numeric argument

1048 **squareRoot**(*<expression>*)

1049 where *<expression>* is the numeric value

1050 **Example:**

1051 squareRoot(nbr1)

1052 9.46 StringLength

1053 Shall return the number of characters in the required string argument

1054 **stringLength**(*<expression>*)

1055 where *<expression>* is the string

1056 **Examples:**

1057 stringLength(alpha)

1058 stringLength("hello world")

1059 9.47 MatchesRegExp

1060 Shall return TRUE if the required first string argument matches the regular expression defined by the
1061 required second string argument. The second string argument shall be interpreted as a regular
1062 expression.

1063 **matchesRegExp**(*<expression1>*, *<regExp>*)

1064 where *<expression1>* shall return a string and *<regExp>* shall be a regular expression that shall
1065 follow the syntax and semantics of regular expressions in the Pattern class of the java.util.regex
1066 core package in Java 2 SE 5.0.

1067 **Example:**

1068 matchesRegExp(IP, "\d{1,3}+\.\d{1,3}+\.\d{1,3}")

1069 9.48 Substring Operations

1070 The following set of string operations can be implemented using the MatchesRegExp operator. However,
1071 CIM-SPL provides for these additional substring operations for readability and possibly more efficient
1072 implementations.

1073 **9.48.1 Substring**

1074 The substring operator takes either two or three arguments. The first and second arguments of this
 1075 operator are required while the third argument is optional. The first argument of this operator shall be a
 1076 string argument, while the second and third argument shall be integer argument.

1077 This operator shall return the substring of the first string argument, starting at the position indicated by the
 1078 second numeric argument and going to the end of the string or the position indicated by the third numeric
 1079 argument - 1. The position of a character is determined as follows: The first character is at position 0, the
 1080 second character is at position 1, and so on.

1081 The second numeric argument shall be greater than or equal to 0. The third numeric argument shall be
 1082 greater than the second numeric argument if the third argument is present. If the starting position given by
 1083 the second numeric argument is greater than the length of the string, an empty string shall be returned. If
 1084 the third numeric position is not present, the string starting at the second numeric position until the end of
 1085 the string shall be returned.

1086 **substring**(*<expression1>*, *<expression2>*, [*<expression3>*])

1087 where *<expression1>* is a string argument, and *<expression2>* and *<expression3>* are integers
 1088 (UINT32) argument.

1089 **Examples:**

1090 substring("Robert Hancock", 2, 8) returns "bert H".

1091 **9.48.2 LeftSubstring**

1092 The LeftSubstring operator returns a prefix of a given string argument by taking three arguments. How to
 1093 compute the prefix is determined by the arguments. The first argument shall be a string and it indicates
 1094 the given string, the second argument shall be either an integer or a string indicating an offset, and the
 1095 third argument shall be a string indicating a direction and is either "LeftToRight" or "RightToLeft".

1096 When the offset is given by a number, the prefix is determined by counting the character position by the
 1097 offset from either left to right (from the beginning of the string) or from right to left (from the end of the
 1098 string). In particular, if the direction is "LeftToRight", the offset indicates the number of characters to return
 1099 from the beginning of the string. If the direction is "RightToLeft", the offset indicates the number of
 1100 characters to skip from the end of the string.³ For example, leftSubstring("Mississippi", 4, "LeftToRight")
 1101 returns "Miss", and leftSubstring("Mississippi", 4, "RightToLeft") returns "Mississ".

1102 When the offset is given by a string, the prefix is determined by searching for the offset string in the
 1103 original string in the direction specified by the third parameter. The returned substring consists of the
 1104 characters on the left side of the offset string. For example, leftSubstring("Mississippi", "ss",
 1105 "LeftToRight") returns "Mi", and leftSubstring("Mississippi", "ss", "RightToLeft") returns "Missi".

1106 **leftSubstring**(*<expression1>*, *<expression2>*, *<expression3>*)

1107 where *<expression1>* is a string, *<expression2>* is an integer, and *<expression3>* is a string
 1108 constant that indicates either "LeftToRight" or "RightToLeft"

1109 **leftSubstring**(*<expression1>*, *<expression2>*, *<expression3>*)

1110 where *<expression1>* and *<expression2>* are strings, and *<expression3>* is a string constant
 1111 that indicates either "LeftToRight" or "RightToLeft"

³ If the offset value is a negative number, the entire string is returned in either case.

1112 **Examples:**

1113 leftSubstring(StateSymbolAndZip, 2, "LeftToRight") // to get the state symbol
 1114 leftSubstring(FirstAndLastName, " ", "LeftToRight") // to get the first name

1115 **9.48.3 RightSubstring**

1116 The RightSubstring operator returns a suffix of a given string argument by taking three arguments. How to
 1117 compute the suffix is determined by the arguments. The first argument shall be a string and it indicates
 1118 the given string, the second argument shall be either an integer or a string indicating an offset, and the
 1119 third argument shall be a string indicating a direction and is either "LeftToRight" or "RightToLeft".

1120 When the offset is given by a number, the suffix is determined by simply counting the character position
 1121 by the offset from either left to right (from the beginning of the string) or from right to left (from the end of
 1122 the string). In particular, if the direction "RightToLeft", the offset indicates the number of characters to
 1123 return as a suffix. If the direction is "LeftToRight", the offset indicates the number of characters to skip
 1124 from the beginning of the string. For example, rightSubstring("Mississippi", 4, "LeftToRight") returns
 1125 "issippi", and rightSubstring("Mississippi", 4, "RightToLeft") returns "ippi".

1126 When the offset is given by a string, the suffix is determined by searching for the offset string in the
 1127 original string in the direction specified by the third parameter. The returned substring consists of the
 1128 characters on the right side of the offset string. For example, rightSubstring("Mississippi", "ss",
 1129 "LeftToRight") returns "issippi", and rightSubstring("Mississippi", "ss", "RightToLeft") returns "ippi".

1130 **rightSubstring**(<expression1>, <expression2>, <expression3>)

1131 where <expression1> is a string, <expression2> is an integer, and <expression3> is a string
 1132 constant that indicates either "LeftToRight" or "RightToLeft"

1133 **rightSubstring**(<expression1>, <expression2>, <expression3>)

1134 where <expression1> and <expression2> are strings, and <expression3> is a string constant
 1135 that indicates either "LeftToRight" or "RightToLeft"

1136 **Examples:**

1137 rightSubstring(StateSymbolAndZip, 5, RightToLeft) // to get the zip code
 1138 rightSubstring(FirstAndLastName, " ", "LeftToRight") // to get the last name

1139 **9.48.4 MiddleSubstring**

1140 The MiddleSubstring operator returns a middle portion of a given string using various arguments as filters.
 1141 How to compute the suffix is determined by the arguments. MiddleSubstring takes four arguments:
 1142 original string, first offset, second offset, and direction string. The first and second offsets shall be
 1143 specified either by a number or a string. The direction string can be either "LeftToRight" or "RightToLeft".
 1144 The meaning of the first offset is similar to that in the rightSubstring: it indicates where the resulting
 1145 substring starts scanning, either from the left or from the right based on the direction string. The meaning
 1146 of the second offset is as follows: if it is a number, it simply indicates the number of characters to return; if
 1147 it is a string, it specifies where the substring should end. For example:

1148 **middleSubstring**(<expression1>, <expression2>, <expression3>, <expression4>)

1149 where <expression1> is a string, <expression2> and <expression3> are integers, and
 1150 <expression4> is a string constant that indicates either "LeftToRight" or "RightToLeft"

1151 **middleSubstring**(<expression1>, <expression2>, <expression3>, <expression4>)

1152 where <expression1> is a string, <expression2> is an integer, <expression3> is a string, and
 1153 <expression4> is a string constant that indicates either "LeftToRight" or "RightToLeft"

1154 **middleSubstring**(*<expression1>*, *<expression2>*, *<expression3>*, *<expression4>*)
 1155 where *<expression1>* is a string, *<expression2>* is a string, *<expression3>* is an integer, and
 1156 *<expression4>* is a string constant that indicates either "LeftToRight" or "RightToLeft"

1157 **middleSubstring**(*<expression1>*, *<expression2>*, *<expression3>*, *<expression4>*)
 1158 where *<expression1>* is a string, *<expression2>* and *<expression3>* are strings, and
 1159 *<expression4>* is a string constant that indicates either "LeftToRight" or "RightToLeft"

1160 **Examples:**

1161 middleSubstring("Mississippi", 4, 5, "LeftToRight") = "issip"
 1162 middleSubstring("Mississippi", 4, 5, "RightToLeft") = "ippi"
 1163 middleSubstring("Mississippi", "ss", 5, "LeftToRight") = "issip"
 1164 middleSubstring("Mississippi", "ss", 5, "RightToLeft") = "ippi"
 1165 middleSubstring("Mississippi", 4, "ss", "LeftToRight") = "i"
 1166 middleSubstring("Mississippi", 4, "ss", "RightToLeft") = ""
 1167 middleSubstring("Mississippi", "ss", "ip", "LeftToRight") = "iss"
 1168 middleSubstring("Mississippi", "ss", "ip", "RightToLeft") = "Missi"

1169 **9.48.5 ReplaceSubstring**

1170 The ReplaceSubstring operator shall take two or three string arguments. It replaces one substring with
 1171 another substring in a given string. The first argument specifies the given string, the second argument
 1172 specifies a from-string, and the third argument specifies a to-string. Note that it is a purely functional form
 1173 with no side-effect — that is, none of the string arguments are modified.

1174 **replaceSubstring**(*<expression1>*, *<expression2>*, [*<expression3>*])
 1175 where *<expression1>*, *<expression2>*, and *<expression3>* are strings

1176 **Example:**

1177 replaceSubstring(Name, "Jim", "James")

1178 **9.49 ToBoolean**

1179 Shall return Boolean TRUE if the required argument is a string argument that equates to "true" ignoring
 1180 the case; shall return Boolean TRUE if the required argument is a numeric argument that evaluates to a
 1181 non-zero; otherwise, it shall return FALSE.

1182 **Note:** toBoolean(1) returns TRUE. toBoolean("1") returns FALSE, because this is passing in a string.

1183 **toBoolean**(*<expression>*)
 1184 where *<expression>* is the value to be converted

1185 **Examples:**

1186 toBoolean("true")
 1187 toBoolean(1)

1188 9.50 ToREAL32

1189 Shall return a Real32 value corresponding to the one required argument. The required argument shall be
1190 either of type string or numeric. The conversion shall be done according to the Java conventions.

1191 **ToREAL32(<expression>)**

1192 where <expression> is the string

1193 **Examples:**

1194 ToREAL32("25.")

1195 ToREAL32(alpha)

1196 9.51 ToSINT32

1197 Shall return a SINT32 value corresponding to the one required argument. The required argument shall be
1198 either of type string or numeric. The conversion shall be done according to the Java conventions.

1199 **ToSINT32(<expression>)**

1200 where <expression> is the string

1201 **Examples:**

1202 ToSINT32("257")

1203 ToSINT32(alpha)

1204 9.52 ToSINT16

1205 Shall return a SINT16 value corresponding to the one required argument. The required argument shall be
1206 either of type string or numeric. The conversion shall be done according to the Java conventions.

1207 **ToSINT16(<expression>)**

1208 where <expression> is the value to convert

1209 **Examples:**

1210 ToSINT16("25")

1211 ToSINT16(alpha)

1212 9.53 ToSINT64

1213 Shall return a SINT64 value corresponding to the one required argument. The required argument shall be
1214 either of type string or numeric. The conversion shall be done according to the Java conventions.

1215 **ToSINT64(<expression>)**

1216 where <expression> is the value to convert

1217 **Examples:**

1218 ToSINT64("2556")

1219 ToSINT64(255)

1220 ToSINT64(alpha)

1221 9.54 ToLower

1222 Shall return the required string argument converted into lowercase

1223 **toLowerCase(<expression>)**

1224 where <expression> is the string

1225 **Examples:**

1226 toLowerCase(alpha)

1227 toLowerCase("Hello World")

1228 9.55 ToMilliseconds

1229 Shall return the number of milliseconds since the standard base time known as "the epoch," namely
1230 January 1, 1970, 00:00:00 GMT, corresponding to the required DATETIME argument.

1231 **toMilliseconds(<expression>)**

1232 where <expression> is the DATETIME value

1233 **Example:**

1234 toMilliseconds(aDate)

1235 9.56 ToSINT8

1236 Shall return a SINT18 value corresponding to the one required argument. The required argument shall be
1237 either of type string or numeric. The conversion shall be done according to the Java conventions.

1238 **ToSINT8(<expression>)**

1239 where <expression> is the value to convert

1240 **Examples:**

1241 ToSINT8("25")

1242 ToSINT8(25)

1243 ToSINT8(alpha)

1244 9.57 ToString

1245 Shall return a String value corresponding to the one required argument. The required argument shall be
1246 either of type Boolean or numeric. The conversion shall be done according to the Java conventions.

1247 Converts the numeric and the Boolean arguments into a string value

1248 **toString(<expression>)**

1249 where <expression> is the value to convert

1250 **Examples:**

1251 toString(nbr1)

1252 toString(1)

1253 toString(true)

1254 9.58 ToUINT32

1255 Shall return a UINT32 value corresponding to the one required argument. The required argument shall be
1256 either of type string or numeric. The conversion shall be done according to the Java conventions.

1257 **ToUINT32(<expression>)**

1258 where <expression> is the value to convert

1259 **Examples:**

1260 ToUINT32("2556")

1261 ToUINT32(2550)

1262 ToUINT32(alpha)

1263 9.59 ToUINT16

1264 Shall return a UINT16 value corresponding to the one required argument. The required argument shall be
1265 either of type string or numeric. The conversion shall be done according to the Java conventions.

1266 **ToUINT16(<expression>)**

1267 where <expression> is the value to convert

1268 **Examples:**

1269 ToUINT16("2556")

1270 ToUINT16(2550)

1271 ToUINT16(alpha)

1272 9.60 ToUINT64

1273 Shall return a UINT64 value corresponding to the one required argument. The required argument shall be
1274 either of type string or numeric. The conversion shall be done according to the Java conventions.

1275 **ToUINT64(<expression>)**

1276 where <expression> is the value to convert

1277 **Examples:**

1278 ToUINT64("2556")

1279 ToUINT64(2550)

1280 9.61 ToUINT8

1281 Shall return a UINT8 value corresponding to the one required argument. The required argument shall be
1282 either of type string or numeric. The conversion shall be done according to the Java conventions.

1283 **ToUINT8(<expression>)**

1284 where <expression> is the value to convert

1285 **Examples:**

1286 ToUINT8("25")

1287 ToUINT8(25)

1288 9.62 ToUpper

1289 Shall return an uppercase version of the required string argument.

1290 **toUpperCase**(*<expression>*)

1291 where *<expression>* is the string

1292 **Examples:**

1293 toUpperCase(alpha)

1294 toUpperCase("hello world")

1295 9.63 Word

1296 This operator shall take three arguments. The first two arguments shall be of type string, and the third
1297 argument shall be of type number. This operator shall extract *n* words from the first string argument where
1298 the third argument specifies the number *n*. Words are defined as text between the separator substring
1299 given by the second argument.

1300 **word**(*<expression1>*, *<expression2>*, *<expression3>*)

1301 where *<expression1>* is the given string, *<expression2>* is the separator substring, and
1302 *<expression3>* is the number

1303 **Example:**

1304 Word(alpha, " ", 3)

1305 9.64 Logical XOR

1306 Shall return a Boolean value that corresponds to the logical XOR operation on the bit representation of
1307 the two required numeric arguments

1308 (*<expression>* ^ *<expression>*)

1309 **Examples:**

1310 (a ^ b)

1311 (Netmask ^ (IP))

1312 9.65 StringConstant

1313 Values inside double quotes are converted to StringConstants.

1314 **Example:**

1315 alpha == "22"

1316 9.66 LongConstant

1317 UINT32 (unquoted) values that do not contain decimals are converted to UINT64 constants.

1318 **Example:**

1319 alpha == 22

1320 9.67 DoubleConstant

1321 Numeric (unquoted) values that contain decimal points are converted to Real64 constants. This includes
1322 numeric values ending in a decimal point (for example, 22).

1323 **Example:**

1324 alpha == 22.25

1325 9.68 DATETIMEConstant

1326 Unquoted values in the format "yyyy-mm-ddThh:mm:ss TZ=javaTimezoneID" are interpreted as a
1327 DATETIMEConstant following the XML standard semantics.

1328 **Example:**

1329 alpha > 2004-01-29T09:40:00 TZ=America/Chicago

1330 9.69 BooleanConstant

1331 Unquoted strings 'true' or 'false' inside the clauses are converted to BooleanConstants in the resulting
1332 XML.

1333 **Example:**

1334 alpha == true

1335 9.70 Identifier

1336 Identifier can be either simple or multi-level. A **simple identifier** shall be any of the following values:

- 1337 • Name of a named constant. It evaluates to the value of the named constant as defined in the
1338 declaration sections.
- 1339 • Name of a named macro. It evaluates to the value of the named macro as defined in the
1340 declaration sections.
- 1341 • <classname.propertyname>, where classname is the class name of the Import statement or any
1342 super class of that class, and propertyname is the name of a property of the classname. The
1343 prefix "classname." is optional. It is required only to disambiguate the name of a property if the
1344 same name is used in any super class and it is not overridden. It evaluates to the value of the
1345 property of the class instance under consideration.
- 1346 • Any of the preceding three values followed by an index enclosed in square brackets. In this
1347 case, the type of the named constant, macro, or property should be an array of an intrinsic CIM
1348 data type or CIM references. The index can only be an expression that evaluates to an integer
1349 (UINT32) value. The first index is always 0. If any of these conditions is not true, the policy
1350 parser returns an error; otherwise, the expression evaluates to the value of the data in the
1351 position indicated by the index in the array identified by the named constant, macro, or property.
- 1352 • A qualifier that is an expression that evaluates to a reference of an instance of a CIM class. This
1353 can be the reserved word *Self* that refers to the object instance under consideration or the
1354 member of a collect operator that returns collections of references (see section 11.2).

1355 A **multi-level identifier** has the form <qualifier.simpleIdentifier>, where simpleIdentifier is a simple
1356 identifier that is not a qualifier.

1357 A simple identifier that is not prefixed by a qualifier shall be evaluated under the scope of the managed
1358 element that is made available to the rule based on the Import statement. If the qualifier appears, the
1359 scope of the simple identifiers shall be the object referenced by the evaluation of the qualifier.

1360 10 Simple Boolean Condition

1361 A simple Boolean condition shall be a CIM-Expression with the following two properties:

- 1362 • The expression evaluates to a Boolean constant.
- 1363 • Any identifier that appears in the expression is a simple identifier that is not a qualifier.

1364 11 Collection Operations

1365 In addition to operators that apply to the CIM intrinsic data types, CIM-SPL also supports operations over
 1366 arrays. In addition to handling arrays of basic CIM intrinsic types, CIM-SPL operations also manipulate
 1367 arrays of references to CIM object instances. All the arrays returned by a CIM-SPL operation behave as a
 1368 CIM Indexed array. These operations are referred to as collection operations, and they are described in
 1369 the following subsections.

1370 11.1 Basic Collection

1371 Shall return an array of intrinsic CIM data type objects, all of the same type

1372 [<expression1>, <expression2>, ... , <expressionN>]

1373 where the N <expressions> are of the same type. At least one expression is required.

1374 **Example:**

1375 [2 , 2, 3+StringLength("abc")]

1376 11.2 Collect

1377 Shall return an array of an intrinsic CIM data type or references to object instances all of the same class.
 1378 This operator has two signatures:

1379 **collect**(<RefExpression>, <association>, <role>, <resultRole>, <CIM class Name>, <expression>)

1380 **collect**(<RefExpression>, <association>, <role>, <resultRole>, <CIM class Name>, <CIM class
 1381 property name>, <expression>)

1382 where <RefExpression> shall be an expression that evaluates to an object reference,
 1383 <association> shall be the name of a CIM association, <role> and <resultRole> shall be
 1384 reference names in the <association>, <CIM class Name> shall be the class of the <resultRole>
 1385 (this argument can be null if there is no ambiguity on the possible classes of the <resultRole>),
 1386 <CIM class property name> shall be the name of a property of objects that might be referenced
 1387 by the <resultRole> reference in instances of the <association>, the <expression> is a Boolean
 1388 expression, and the <identifiers> appearing in the <expression> are evaluated under the scope
 1389 of the objects referenced by the <resultRole> reference in instances of the <association>.

1390 In the first signature, any instance of the <association> in which the reference returned by the
 1391 evaluation of the <RefExpression> appears as the value of the <role> reference, the object
 1392 reference by the <resultRole> is inspected and, if the expression evaluated under the scope of
 1393 this object evaluates to TRUE, the object is returned in the collection. In the second signature,
 1394 instead of returning a reference to the object, only the value of the property identified by the
 1395 <CIM class property name> is returned. If this property is an array, this operation returns an
 1396 array with the first values of all collected object properties.

1397 **Examples:**

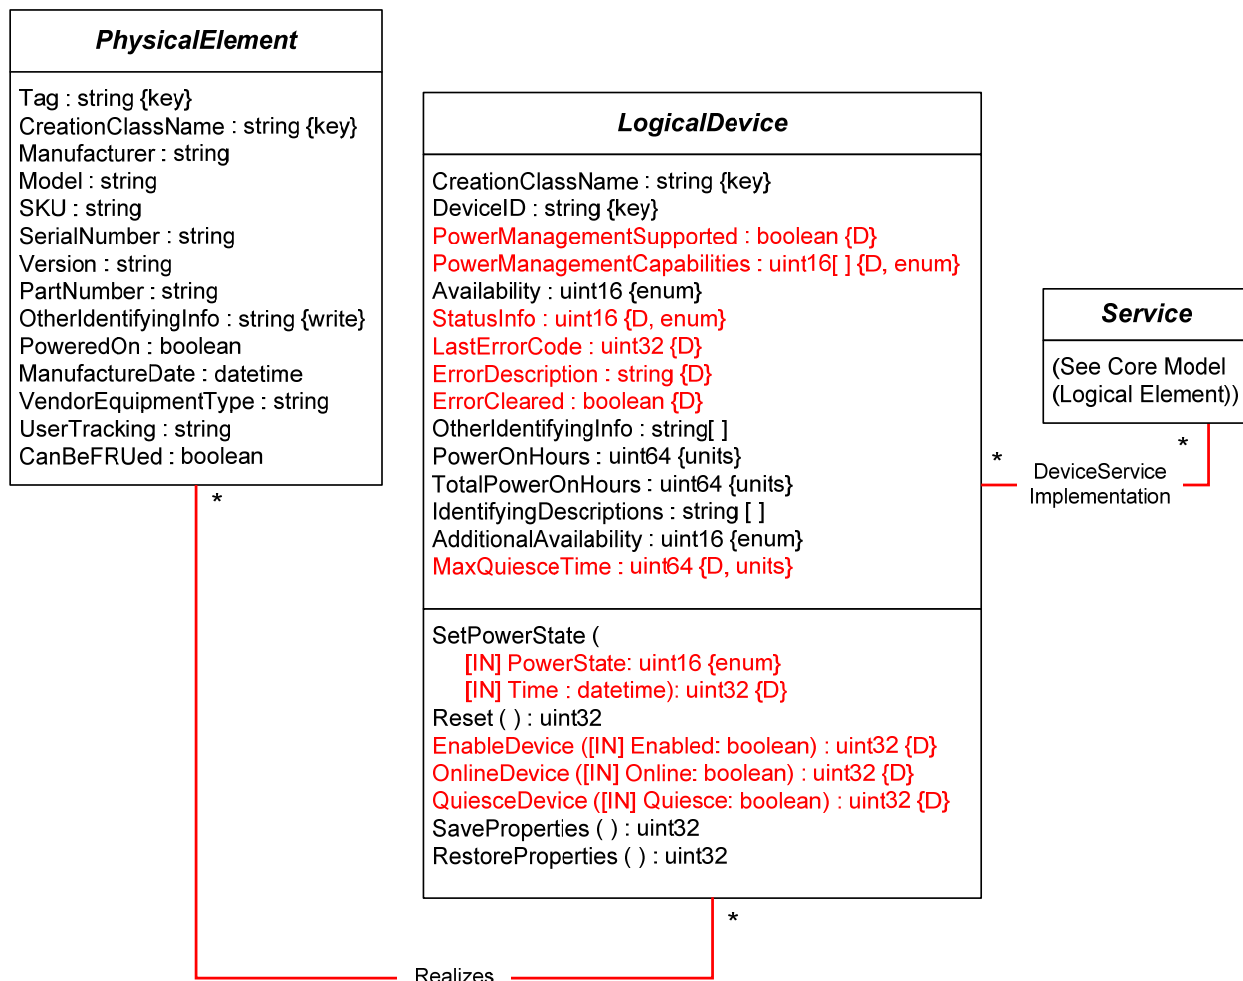

```
1398           collect(Self, Realizes, PhysicalElement, LogicalDevice, CIM_LogicalDevice,  
1399           TotalPowerOnHours > 5)
```

```
1400           collect(Self , Realizes, PhysicalElement, LogicalDevice, CIM_LogicalDevice,  
1401           TotalPowerOnHours, TotalPowerOnHours > 5)
```

1402 Self references an instance of the CIM_PhysicalElement class. To traverse multiple associations, collect
1403 operators can be nested, as in the following example:

```
1404 collect(  
1405     collect(Self , Realizes,  
1406         PhysicalElement, LogicalDevice, CIM_LogicalDevice,  
1407         true)[0],  
1408     DeviceServiceImplementation,  
1409     LogicalDevice,  
1410     CIM_Service,  
1411     True)[1].Started
```

1412 Starting in a PhysicalElement (see Figure 4), the Realizes association is traversed to get a collection of
 1413 LogicalDevice elements. Using one of these logical devices as an anchor (the first one in the collection),
 1414 the DeviceServiceImplementation association is traversed to get a collection of Service elements. The
 1415 expression takes the second element in this collection ([1]), and the value of the Started property is
 1416 returned.

1417

1418

Figure 4 – Example of CIM Associations

1419 **11.3 InCollection**

1420 Checks whether an object is a member of a collection

1421 **inCollection(<expression>, <collection>)**

1422 Shall returns TRUE if the value returned by <expression> appears in <collection>. The type of the
 1423 <expression> shall the same type as the arguments in the <collection>.

1424 **Example:**

1425 inCollection(100, collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
 1426 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1427 11.4 Union

1428 Shall results in a new collection that is the union of the two required collections in the arguments. Object
1429 repetitions are preserved.

1430 **union**(*<collection>*, *<collection>*)

1431 **Example:**

1432 union([100],collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1433 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1434 11.5 SubCollection

1435 Checks whether a collection is a subcollection of another collection

1436 **subCollection**(*<collection1>*, *<collection2>*)

1437 Shall return TRUE if every member in *<collection1>* appears in *<collection2>*

1438 **Example:**

1439 subCollection([100,150],collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1440 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1441 11.6 EqCollections

1442 Checks whether two collections are equal

1443 **eqCollections**(*<collection1>*, *<collection2>*)

1444 Shall return TRUE if *<collection1>* is a subcollection of *<collection2>*, *<collection2>* is a subcollection
1445 of *<collection1>*, and the repetitions of objects in both collections is identical

1446 **Example:**

1447 eqCollections([100,150],collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1448 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1449 11.7 AnyInCollection

1450 Checks whether an object with a given property exists in a collection

1451 **anyInCollection**(*<expression>* *<op>* *<collection>*)

1452 where *<op>* shall be either a Boolean or relational operator. If *<op>* is a Boolean operator,
1453 *<expression>* shall be Boolean. If *<op>* is relational, *<expression>* shall be of a type compatible with
1454 the operator. The operation shall return TRUE if there is an object *<oj>* in *<collection>* such that
1455 *<expression>* *<op>* *<oj>* is true.

1456 **Example:**

1457 anyInCollection(240 > collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1458 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1459 11.8 AllInCollection

1460 Checks whether all objects in a collection have a given property

1461 **allInCollection**(*<expression>* *<op>* *<collection>*)

1462 where *<op>* shall be either a Boolean or relational operator. If *<op>* is a Boolean operator,
1463 *<expression>* shall be Boolean. If *<op>* is relational, *<expression>* shall be of a type compatible with
1464 the operator. The operation shall return TRUE if for every object *<oj>* in *<collection>*, *<expression>*
1465 *<op>* *<oj>* returns TRUE.

1466 **Example:**

1467 anyInCollection(240 > collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1468 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1469 11.9 ApplyToCollection

1470 Applies an arithmetic operation to each element in a collection and shall return a numeric collection

1471 **applyToCollection**(*<expression>* *<op>* *<collection>*)

1472 where *<op>* shall be a binary numeric operator and *<expression>* is a numeric expression. The
1473 operation shall return a collection similar to *<collection>* but in which every object *<oj>* in
1474 *<collection>* is replaced by the result of the expression *<expression>* *<op>* *<oj>*.

1475 **Example:**

1476 applyToCollection(1024 + collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1477 CIM_LogicalDevice, TotalPowerOnHours, TotalPowerOnHours > 5))

1478 11.10 Sum

1479 Shall return the sum of a collection of numeric CIM data elements. The *<collection>* shall be a collection
1480 of numeric values.

1481 **sum**(*<collection>*)

1482 **Example:**

1483 sum(collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice, CIM_LogicalDevice,
1484 TotalPowerOnHours, TotalPowerOnHours > 5))

1485 11.11 MaxInCollection

1486 Shall return the maximum object from a collection of totally ordered CIM data objects

1487 **maxInCollection**(*<collection>*)

1488 **Example:**

1489 maxInCollection(collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1490 CIM_LogicalDevice, TotalPowerOnHours, true))

1491 Strings are ordered lexicographically based on UTF-8.

1492 11.12 MinInCollection

1493 Shall return the smallest object from a collection of totally ordered CIM data objects

1494 **minInCollection**(<collection>)

1495 **Example:**

1496 minInCollection(collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1497 CIM_LogicalDevice, TotalPowerOnHours, true))

1498 11.13 AvrgInCollection, MedianInCollection, sdInCollection

1499 Shall return the average/median/standard deviation in a double from a collection of numeric CIM data
1500 objects. The <collection> shall be a collection of numeric values.

1501 **avrgInCollection**(<collection>) / **medianInCollection**(<collection>) / **sdInCollection**(<collection>)

1502 **Example:**

1503 avrgInCollection(collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1504 CIM_LogicalDevice, TotalPowerOnHours, true))

1505 11.14 CollectionSize

1506 Shall return the size of a collection in a UINT32

1507 **collectionSize**(<collection>)

1508 **Example:**

1509 collectionSize(collect(PhysicalElement.Self , Realizes, PhysicalElement, LogicalDevice,
1510 CIM_LogicalDevice, TotalPowerOnHours, true))

1511 12 Policy Example

1512 The following example shows a policy that is invoked when a file system is 85 percent full. The policy
1513 expands the storage pool by 25 percent.

```
1514 Import    CIM_X_XX_XXXX::CIM_LocalFileSystem;
1515 Strategy Execute_All_Applicable;
1516 Policy {
1517   Declaration { /* Macros to traverse HostedService associations to get */
1518                   /* to FileSystemConfigurationService for ModifyFile and */
1519                   /* StorageConfigurationService for CreateOrModify... */
1520     computer_system = collect(Self, CIM_HostedFileSystem,
1521                               PartComponent, GroupComponent, null, true)[0];
1522     storage_config_service =
1523       collect(computer_system, CIM_HostedService, Antecedent,
1524               Dependent, CIM_StorageConfigurationService,
1525               true)[0];
1526     logical_disk = collect(Self, CIM_ResidesOnExtent,
1527                             Dependent, Antecedent, null, true)[0];
1528     storage_pool = collect(logical_disk, CIM_AllocatedFromStoragePool,
```

```

1529             Dependent, Antecedent, null, true)[0];
1530     fs_goal = collect(Self, CIM_ElementSettingData, ManagedElement,
1531         SettingData, CIM_FileSystemSetting true)[0];
1532 }
1533 Condition {
1534     (AvailableSpace / FileSystemSize) < 0.25
1535 }
1536 Decision {
1537     storage_conf_service.CreateOrModifyElementFromStoragePool("LogicalDisk",
1538         /* ElementType Volume */
1539         8, job, fs_goal,
1540         1.25 * FileSystemSize,
1541         storage_pool,
1542         logical_disk)
1543     // CreateOrModifyElementFromStoragePool defined in pp. 1024
1544     // of SMI-S 1.1.0 SNIA Standard document
1545     // ElementType value list can be found in pp. 1116
1546     | DoSomethingOnFailure()
1547 }
1548 }:1;

```

1549 **13 CIM-SPL Grammar**

1550 In the following grammar, non-terminal symbols are represented by sequences of uppercase letters in
 1551 boldface. Alternatives in the production rules are represented by "|", except for the use of "||" in Boolean
 1552 expressions and "|||" and "|" in action blocks. All blanks but one are ignored in the rules. Blanks do not
 1553 appear in any of the terminal symbols.
