12 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems manage-  
13 ment and interoperability. Members and non-members may reproduce DMTF specifications and documents for uses  
14 consistent with this purpose, provided that correct attribution is given. As DMTF specifications may be revised  
15 from time to time, the particular version and release date should always be noted.

16 Implementation of certain elements of this standard or proposed standard may be subject to third party patent rights,  
17 including provisional patent rights (herein "patent rights"). DMTF makes no representations to users of the standard  
18 as to the existence of such rights, and is not responsible to recognize, disclose, or identify any or all such third party  
19 patent right, owners or claimants, nor for any incomplete or inaccurate identification or disclosure of such rights,  
20 owners or claimants. DMTF shall have no liability to any party, in any manner or circumstance, under any legal the-  
21 ory whatsoever, for failure to recognize, disclose, or identify any such third party patent rights, or for such party's  
22 reliance on the standard or incorporation thereof in its product, protocols or testing procedures. DMTF shall have no  
23 liability to any party implementing such standard, whether such implementation is foreseeable or not, nor to any  
24 patent owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is  
25 withdrawn or modified after publication, and shall be indemnified and held harmless by any party implementing the  
26 standard from any and all claims of infringement by a patent owner for such implementations.

27 For information about patents held by third-parties which have notified the DMTF that, in their opinion, such patent  
28 may relate to or impact implementations of DMTF standards, visit

36 **Abstract**

37 The Desktop and mobile Architecture for System Hardware (DASH) is a DMTF Management Initiative  
38 that represents a suite of specifications which standardize the manageability interfaces for mobile and  
39 desktop hardware. The DASH suite of specifications defines the interfaces for management in the form of  
40 protocols and profiles for representing mobile and desktop hardware.

41 This document is an architectural white paper and describes the concepts used in managing mobile and  
42 desktop platforms which adhere to the DASH Implementation Requirements [2].

43 **Acknowledgments**

44 The following persons were instrumental in the development of this white paper:  
45 Bob Blair – AMD, Jon Hass – Dell, Jeff Hilland – HP, David Hines, - Intel, Hemal Shah - Broadcom.

# 126 **1 Introduction**

127 This document is an introduction into the architectural framework required for managing desktop  
128 and mobile systems hardware in the enterprise environment. This document lays forth the basic  
129 principles required for understanding and implementing the DMTF Web Services for Manage-  
130 ment (WS-Management) interface as applied to this environment. The framework is composed  
131 of technologies defined in multiple standard specifications, including the WS-Man Specification  
132 [1], the DASH Implementation Requirements Specification [2], and a variety of profiles (Section  
133 7) which are applicable to this environment.

134 The focus of this architecture is to enable the management of desktop and mobile computing re-  
135 sources in a standard manner across any Manageability Access Point implementation, independ-  
136 ent of operating system state.

## 137 **1.1 Target Audience**

138 The intended target audience for this document is readers interested in understanding manage-  
139 ment through Web Services of desktop systems, mobile systems, thin clients and bladed PCs as  
140 well as desktop and mobile systems management architecture in general.

### 165 1.3 Terminology

Term	Definition
Administrator	A person managing a system through interaction with management clients, transport clients and other policies and procedures.
Autonomous Profile	An autonomous profile defines an autonomous and self-contained management domain. This includes profiles that are standalone, or have relationships to other profiles
Common Information Model	The DMTF Common Information Model (CIM) is an approach to the management of systems and networks that applies the basic structuring and conceptualization techniques of the object-oriented paradigm. The approach uses a uniform modeling formalism that— together with the basic repertoire of object-oriented constructs—supports the cooperative development of an object-oriented schema across multiple organizations.
CIM Profile	A profile is a specification that defines the CIM model and associated behavior for a management domain. The CIM model includes the CIM classes, associations, indications, methods and properties. The management domain is a set of related management tasks. A profile is uniquely identified by the name, organization name, and version.
Client	Any system that acts in the role of a client to a MAP.
Common Information Model Object Manager	A CIM-capable implementation.
Component Profile	A component profile describes a subset of a management domain. A component profile includes CIM elements that are scoped within an autonomous profile (or in rare cases, another component profile). Multiple autonomous profiles may reference the same component profile.
Encapsulating Security Payload	An IPSec extension header that provides origin authenticity, integrity, and confidentiality protection of a packet.
Extensible Markup Language	Extensible Markup Language (XML) is a simple, very flexible text format derived from SGML (ISO 8879). Originally designed to meet the challenges of large-scale electronic publishing, XML is also playing an increasingly important role in the exchange of a wide variety of data on the Web and elsewhere.
Hypertext Transfer Protocol	The Hypertext Transfer Protocol (HTTP) is an application-level protocol for distributed, collaborative, hypermedia information systems. It is a generic, stateless, protocol which can be used for many tasks beyond its use for hypertext, such as name servers and distributed object management systems, through extension of its request methods, error codes and headers.
HTTP over TLS	The Hypertext Transfer Protocol (HTTP) encapsulated in the Transport Layer Security Protocol.

Term	Definition
In-Band	Management that operates with the support of hardware components that are critical to and used by the operating system
In-Service	Management that operates with the support of software components that run concurrently and are dependent on the operating system.
Internet Protocol	The Internet Protocol is designed for use in interconnected systems of packet-switched computer communication networks. The internet protocol provides for transmitting blocks of data called datagrams from sources to destinations, where sources and destinations are hosts identified by fixed length addresses. The internet protocol also provides for fragmentation and reassembly of long datagrams, if necessary, for transmission through "small packet" networks.
IP Security	A suite of protocols for securing Internet Protocol (IP) communications.
Manageability Access Point (MAP)	A collection of services of a system that provides management in accordance to specifications published under the DMTF Server Management Architecture for Server Hardware initiative.
Managed Element	The finest granularity of addressing which can be the target of commands or messages, or a collection thereof.
Managed Element Access Method	The method by which a Managed Element performs a unit of work.
Managed System	A collection of Managed Elements that comprise a Computer System for which a MAP has management responsibilities.
Out-of-Band	Management that operates with hardware resources and components that are independent of the operating systems control
Out-of-Service	Management that operates with the support of software components that require the operating environment to be put out-of-service and the system be placed into an alternate management environment. In this state, the operating system is not available
Remote Management and Control Protocol	A protocol used for client control and discovery functions.
SOAP	A lightweight protocol intended for exchanging structured information in a decentralized, distributed environment.
Transmission Control Protocol	The Transmission Control Protocol (TCP) is a connection-oriented, end-to-end reliable protocol designed to fit into a layered hierarchy of protocols which support multi-network applications.
Transport	The layers of the communication stack responsible for reliable transportation of commands and message from the Client to the MAP
Transport Layer Security	The TLS protocol provides communications privacy over the Internet. The protocol allows client/server applications to communicate in a way that is designed to prevent eavesdropping, tampering, or message forgery.

Term	Definition
User	The set of human users and Management Clients which interact with the Transport Client in order to manage a Managed System through a Manageability Access Point. Human users include Administrators, Operators, and Read-Only Users.
WS-CIM Mapping	A specification that provides the normative rules and recommendations that describe the structure of the XML Schema, WSDL fragments and metadata fragments corresponding to the elements of CIM models, and the representation of CIM instances as XML instance documents.
WS-Management	A general SOAP-based protocol for managing systems such as PCs, servers, devices, Web services and other applications, and other manageable entities.
WS-Management CIM Binding	A specification that describes how transformed CIM resources, as specified by the WS-CIM specification, are bound to WS-Management operations and WSDL definitions.
Web Services	A Web service is a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-processable format (specifically WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards.
WS-Addressing	WS-Addressing provides transport-neutral mechanisms to address Web services and messages. Specifically, it defines XML elements to identify Web service endpoints and to secure end-to-end endpoint identification in messages. It enables messaging systems to support message transmission through networks that include processing nodes such as endpoint managers, firewalls, and gateways in a transport-neutral manner.
WS-Enumeration	A general SOAP-based protocol for enumerating a sequence of XML elements that is suitable for traversing logs, message queues, or other linear information models.
WS-Eventing	A protocol that allows Web services to subscribe to or accept subscriptions for event notification messages.
WS-Transfer	A general SOAP-based protocol for accessing XML representations of Web service-based resources.

## 1.4 Acronyms and Abbreviations

Term	Definition
ASF	Alert Standard Format
CIM	Common Information Model
CIMOM	Common Information Model Object Manager
DASH	Desktop and mobile Architecture for Systems Hardware
ESP	Encapsulating Security Payload
HTTP	Hypertext Transfer Protocol
HTTPS	Hypertext Transfer Protocol over TLS
IP	Internet Protocol

<b>Term</b>	<b>Definition</b>
IPSec	IP Security
MAP	Manageability Access Point
RMCP	Remote Management and Control Protocol
SMASH	Systems Management Architecture for Server Hardware
SOAP	Simple Object Access Protocol
TCP	Transmission Control Protocol
TCP/IP	See TCP and IP
TLS	Transport Layer Security
XML	Extensible Markup Language

## 167 **2 Architecture Overview**

168 Desktop and mobile systems management in today's enterprise environments is comprised of a  
169 disparate set of tools and applications which administrators can use to manage the multitude of  
170 networked desktop and mobile computers. In many cases, these tools are specialized and adapted  
171 to each individual environment, installation and product in the environment.

172 Currently, the CIM Schema provides a feature-rich systems management environment. In its cur-  
173 rent form, it also places a burden on those vendors attempting to implement the CIM Schema and  
174 CIM-XML Protocol to support systems hardware management. This has resulted in lack of inter-  
175 operability and acceptance of solutions in the desktop and mobile systems hardware management  
176 solution space, particularly in the out-of-band and out-of service cases. In addition, the resulting  
177 Out-of-Band and Out-of-Service management solutions are different from the operating system's  
178 representation and management of the system.

179 The Desktop and mobile Architecture for System Hardware (DASH) Management Initiative  
180 supports a suite of specifications which include architectural semantics, industry standard proto-  
181 cols and a set of profiles to standardize the management of desktop and mobile systems inde-  
182 pendent of machine state, operating platform or vendor. By creating industry standard protocols,  
183 interoperability is facilitated over the network and the syntax and semantics of those protocols  
184 are facilitated to be interoperable by products which adhere to those standards. Because it is  
185 based on the CIM Schema, the DASH Management Initiative (hereafter referred to as DASH)  
186 leverages the richness of CIM. By creating industry standard profiles, the richness of the CIM  
187 Schema can be applied in a consistent manner by all vendors.

188 Extra emphasis has been placed in the development of DASH to enable lightweight implementa-  
189 tions which are architecturally consistent. This has been done to enable a full spectrum of im-  
190 plementations without sacrificing the richness of the CIM heritage. This includes software-only  
191 solutions and small footprint firmware solutions. Emphasis has been placed on ensuring that  
192 these implementations will be interoperable, independent of implementation, CPU architecture,  
193 chipset solutions, vendor or operating environment.

### 194 **2.1 Principal Goals**

195 One goal of DASH is to enable the same interfaces independent of system state. To this end, a  
196 Service Model is referenced in Section 2.2 to illustrate that, independent of Service Access Point  
197 or operating system state, the same protocols can be used for systems management.

198 Another goal of DASH is to enable the same tools, syntax, semantics and interfaces to work  
199 across a full range of products – traditional desktop systems, mobile and laptop computers,  
200 bladed PCs as well as “thin clients”. Therefore, we have encompassed considerations for these  
201 products in our initial architecture and plan to include support for them in the on-going profile  
202 development effort.

### 203 **2.2 Service Model**

204 Fundamental to the DASH is the underlying goal to unify the experience achieved through out-  
205 of-band mechanisms with those available via the operating system. To achieve this goal, DASH  
206 has adopted the Service Model as Described in the SMASH White Paper [3]. The definitions,  
207 terms and model for In-Band, Out-of-Band, In-Service and Out-of-Service documented in the  
208 SMASH White Paper [3] apply to DASH.

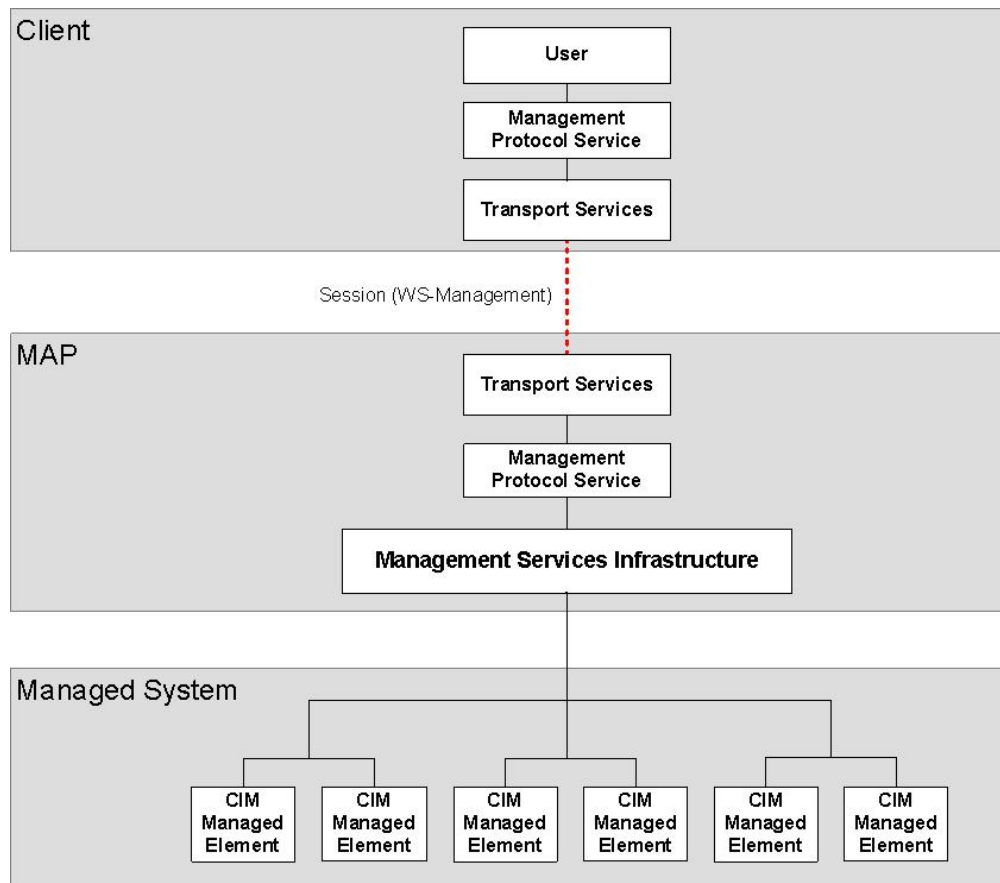

209 **3 Desktop and Mobile Management Architecture Model**

210 In order to provide systems management standardization, it is necessary to develop an abstract  
211 model that describes systems management independent of the actual implementation. This is  
212 necessary to provide a common vocabulary and to provide a common base of understanding. It is  
213 also used to illustrate the access points where interoperability is facilitated as well as to show  
214 semantically visible components and interfaces.

215 The goal of the architecture is also to describe systems management in abstract terms for all  
216 desktop and mobile systems. This means it is implementation agnostic and spans the spectrum of  
217 the supported platforms.

218 **3.1 Architectural Model**

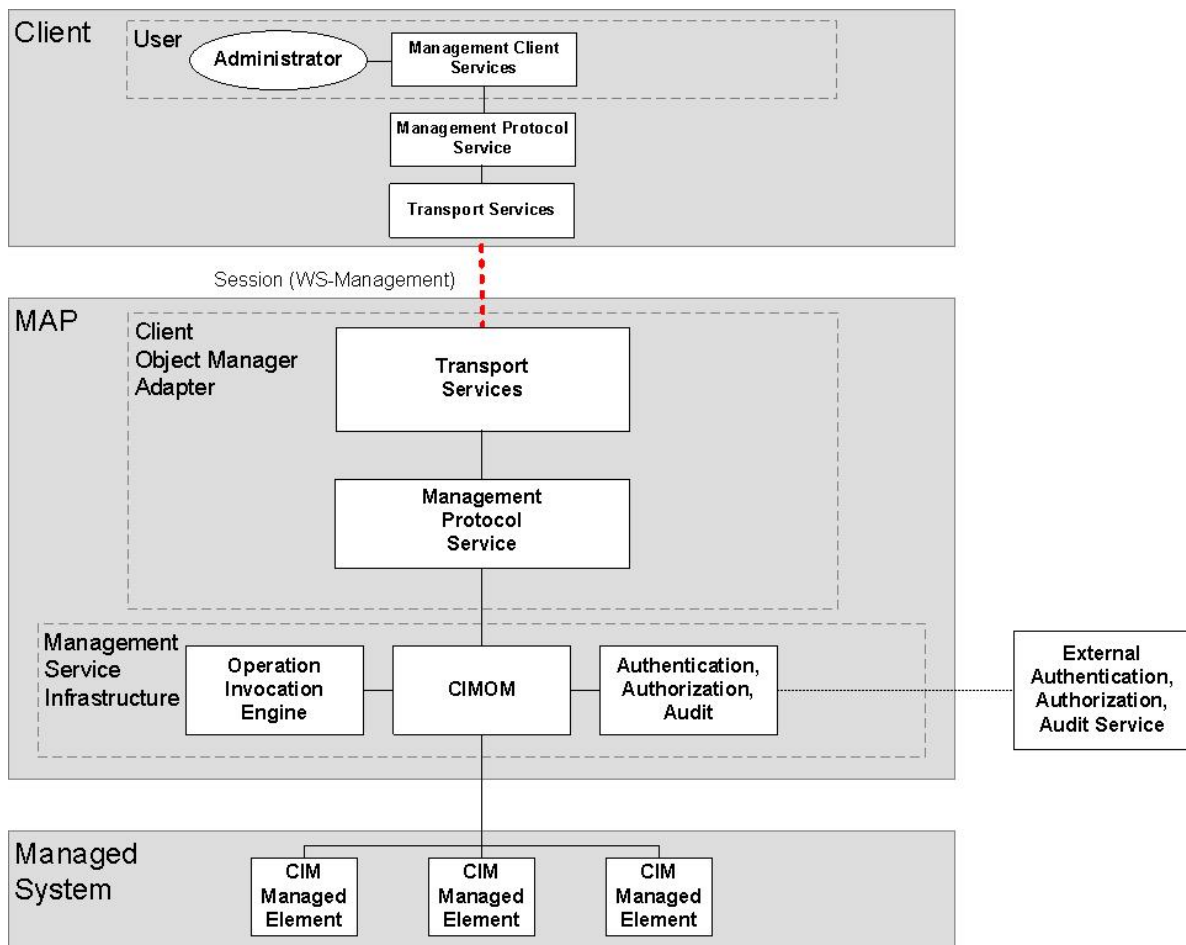

219 This section introduces the overall DASH Architecture Model (see Figure 1). The terms used in  
220 this model are defined in the following sections. The dotted lines in this model indicate the pro-  
221 tocols and transports that are externally visible. These are the communication interfaces between  
222 the Manageability Access Point (MAP) and the Client and represent data that flows across the  
223 network, for example. The solid lines indicate semantically visible interfaces. The packets, trans-  
224 ports, and interfaces are not externally visible but the fact that they are separate components with  
225 their own semantics is visible. The functional implications which are noticeable by the Client  
226 need to be accounted for in order to have a complete model.

227

228 **Figure 1 - DASH Management Initiative Architecture Model**

229 Figure 2 depicts an example implementation that emphasizes the components within the MAP  
 230 which are noticeable when implemented within a WBEM context. While the entities described  
 231 are not required to exist as independent entities, their existence is evident from the syntax and  
 232 semantics of the interface between the MAP and the Client. This figure expands on the architec-  
 233 ture model, exposing the detailed, identifiable portions of the Client and the MAP. This includes  
 234 the Transports and a detailed User model to indicate support by DASH of a human Administrator  
 235 interacting with Management Client Services. It also includes Authentication, Authorization and  
 236 Audit components within the MAP that are expected to be accessible through the protocols. In  
 237 addition, the Operation Invocation Engine indicates that the operations within the MAP are dis-  
 238 tinct with their own operational semantics. Note that while only one Managed System is shown,  
 239 managing multiple Managed Systems from one MAP is supported by DASH.

240

241

**Figure 2 - Example MAP Implementation Architecture**

242

The following sections describe the components found in Figure 1 and Figure 2.

### 243 3.2 Client

244

A Client is a logical component that manages a system via a Manageability Access Point (MAP).

245

A Client may run on a management station or other system.

246

A Client is responsible for:

- 247 • Providing an interface to the functionality provided by the MAP in a form consistent with  
248 DASH Implementation Requirements [2].
- 249 • Accessing a MAP using the DASH defined management protocol. This entails interacting  
250 with the MAP through the following process:
- 251 – Initiating a session with a MAP.
- 252 – Transmitting protocol-specific messages to the MAP.
- 253 – Receiving protocol-specific output messages from the MAP.
- 254 – Terminating a session with a MAP.

### 255 **3.2.1 User**

256 The User in this model represents an instance of a Management Client Services and an Adminis-  
257 trator.

#### 258 **3.2.1.1 Management Client Services**

259 A Management Client Services represents a program of some type, such as an application, that  
260 initiated management requests to the Transport Client and handles responses from the Transport  
261 Client. Interaction between the Management Client and the Transport Client is in the form of  
262 WS-Management messages. Interaction between the Administrator and the Management Client  
263 Services is outside the scope of this document.

#### 264 **3.2.1.2 Administrator**

265 This represents the human interacting with the Management Client.

### 266 **3.2.2 Transport Services**

267 The Transport Services in the Client represents the endpoint of the transport and lower layer pro-  
268 tocols with which the User interacts. It initiates and maintains the transport session with the  
269 Transport Service in the MAP. This includes transport session establishment, authentication, and  
270 authorization.

271 The DASH Implementation Requirements Specification [3] contains mappings for HTTP and  
272 HTTPS. Other transports are not precluded but are outside of the scope of DASH.

## 273 **3.3 MAP**

274 The Manageability Access Point (“MAP”) is a network-accessible service for managing a Man-  
275 aged System. A MAP can be instantiated by a Management Process, a Management Processor, a  
276 Service Processor or a Service Process.

277 The MAP is responsible for:

- 278 • Managing the Session between the MAP and the Client. The MAP is considered the end-  
279 point for the transport protocol.
- 280 • Interpreting the incoming protocol-specific messages and seeing that a response is trans-  
281 mitted.
- 282 • Returning protocol-specific output messages to the Client containing status and result  
283 data.

284 The MAP fulfils these responsibilities by utilizing components contained within the MAP. Note  
285 that the interface between the Managed Elements (ME) and the MAP is outside of the scope of  
286 DASH. The interfaces within the MAP are outside of the scope of DASH.

287 The MAP contains the following major components, which are discussed in the following sec-  
288 tions:

- 289 • The Management Service Infrastructure, which provides management access to the in-  
290 strumentation of the Managed Systems.
- 291 • A Client Object Manager Adapter that adapts the WS-Management Messages into CIM  
292 operations that the Management Service Infrastructure can act upon.

### 293 **3.3.1 Management Service Infrastructure**

294 The Management Service Infrastructure is a logical entity that contains the core services set of  
295 the MAP that implement a CIM Server. It is primarily comprised of the functions described be-  
296 low.

#### 297 **3.3.1.1 CIMOM**

298 The Common Information Model Object Manager (CIMOM) represents the components of the  
299 Management Service Infrastructure that handles the interaction between the Client Object Man-  
300 ager Adapter and the Providers. It supports services such as the Operation Invocation Engine and  
301 the Authentication, Authorization and Audit components.

#### 302 **3.3.1.2 Operation Invocation Engine**

303 The Operation Invocation Engine is responsible for understanding the management requests and  
304 tracking the initiation, interim status and completion of operations resulting from those requests  
305 on Managed Elements. A major component of the Operation Invocation Engine is the Operation  
306 Queue. This is the queue of all of the operations submitted to the MAP. Operations are discussed  
307 in more detail in Section 4.1.

#### 308 **3.3.1.3 Authentication, Authorization, Audit**

309 This entity is responsible for coordinating the authentication, authorization and auditing within  
310 the MAP. This includes coordination of transport session establishment, local account informa-  
311 tion and the access permission required for MAP operations. It also is responsible for coordina-  
312 tion of audit information of the operations and tasks taking place within the MAP. Note that this  
313 is a service internal to the MAP and interaction or coordination with any external service com-  
314 ponents is outside the scope of this architecture.

### 315 **3.3.2 Client Object Manager Adapter**

316 This represents the collection of entities required to process the WS-Management messages and  
317 ensure responses are generated and, as required by the messages, interact with the Management  
318 Service Infrastructure to accomplish the requests and produce the information contained in the  
319 responses. It consists of the Transport Service and the Management Protocol Service.

#### 320 **3.3.2.1 Transport Services**

321 This represents the transports and lower layer protocols over which the Management Protocol  
322 Service is carried. This includes transport session establishment, authorization, and authentica-  
323 tion.

324 It also represents the entity which encrypts/decrypts the data stream. This happens as part of the  
325 transport mechanism in this architecture. The two defined transport services for DASH are HTTP  
326 [6] and HTTPS [7].

327 Note that the DASH Implementation Requirements Specification [2] is the definitive reference  
328 for requirements on the Transport Service.

### 329 **3.3.2.2 Management Protocol Service**

330 This represents the endpoint of the Management Protocol within the MAP. The Management  
331 Protocol for DASH is WS-Management. WS-Management messages will be received here and  
332 turned into internal operations within the MAP. This entity is responsible for receiving messages  
333 and transmitting responses which are compliant with the WS Management Specification [1].

334 The interface between the Management Protocol Service and the Management Service Infra-  
335 structure is implementation-dependent and thus the interface itself is out-of-scope of DASH.

### 336 **3.3.3 External Authentication, Authorization, Audit Service**

337 The External Authentication, Authorization, Audit Service represents the entity which estab-  
338 lishes and coordinates the authentication, authorization and auditing information outside of the  
339 MAP. Examples of services that it may coordinate are keys, certificates, user accounts, pass-  
340 words and privileges. The instantiation of any global Authentication, Authorization, Audit Ser-  
341 vice is outside of the current scope of DASH. In addition, the interface between the MAP and the  
342 Security Service is outside of the current scope of the DASH. Note that this is distinct from the  
343 Authentication, Authorization, Audit component of the MAP itself since (see Section 3.3.1.3) it  
344 is an external service and not contained within the MAP.

## 345 **3.4 Managed System**

346 A Managed System is a collection of Managed Elements that comprise a Computer System for  
347 which the MAP has management responsibilities. The Managed System may sometimes be re-  
348 ferred to as a host, node, system, or platform. Managed System types include desktop, work-  
349 station, laptop, tablet, thin client, bladed, and virtual systems.

350 One or more Managed Elements and/or Resources – or collections thereof – are managed by a  
351 single MAP. There may also be more than one Managed System within the domain of a MAP.

352 Each Managed Element within the Managed System could contain subcomponents, sub-targets  
353 or resources within that individual Managed Element.

### 354 **3.4.1 Managed Element**

355 Managed Elements are the targets, components, resources, collections, physical or logical enti-  
356 ties within a Managed System which the operations will manipulate.

357 Direct interfaces for Managed Element access are outside of the scope of DASH.

## 358 **4 Management Models**

359 This section contains the models which are useful in understanding DASH.

### 360 **4.1 Operation Model**

361 This section contains information relevant to operation handling within the MAP. It covers MAP  
362 responsibilities, operation handoff, queue depth issues, issues on multi-session support, operation  
363 visibility, communication between MAPs and resource handling.

364 It is important to understand that in the MAP operation model, the term operation is often used.  
365 In CIM, operations correspond to property accesses using intrinsic methods and extrinsic method  
366 invocations. The reader should understand the class CIM\_ConcreteJob (Core Schema), which  
367 can be used to make operations visible to management clients.

#### 368 **4.1.1 MAP Responsibilities**

369 The Manageability Access Point (MAP) has several responsibilities to the Client. Some of these  
370 may appear intuitive to some readers, but for purposes of clarity they are included here.

371 MAPs are responsible for managing the elements for which they claim responsibility. This does  
372 not imply that they will actually execute the method or modify the property included in the op-  
373 eration, but MAPs are responsible for dispatching, tracking, ensuring the completion of, and de-  
374 livering the results of the operation.

375 The MAP is responsible for ensuring the message is syntactically correct. It may pass the parsing  
376 to one of its subcomponents or another system component, but it is the MAP that has the respon-  
377 sibility for ensuring that the implementation complies with the protocol.

378 The MAP is responsible for operation handling. It may delegate the actual operation but it is re-  
379 sponsible for handling messages, turning them into jobs or operations, tracking operations and  
380 manipulating the operations (including completing, canceling, removing, or logging).

381 The MAP is responsible for determining if the specified ME is in its scope. Operations which  
382 target MEs which are not within the MAP's scope should result in the appropriate error syn-  
383 drome.

384 The MAP is responsible for determining if access to the ME is allowed. This includes, but is not  
385 limited to, authorization determination (to ensure that the user account and access right combina-  
386 tion will allow access to the ME) and determination that the ME is in a state where the operation  
387 can be initiated.

388 The MAP is also responsible for determining if the operation or property modification is valid  
389 for this Managed Element and if the operation or property modification is a valid request. It is  
390 the MAP's responsibility to ensure that any such request takes place as indicated. The MAP en-  
391 sures that the request is properly formed and conveyed, but relies on the feedback from the ME  
392 for the assessment of operation validity.

### 393 **4.2 Operation Handoff**

394 Operations within the MAP are not directly visible to the Client. The fact that they exist, are ini-  
395 tiated, can be cancelled, can complete and can be deleted can be made visible by the implementa-  
396 tion if it supports CIM\_ConcreteJob, which is returned when a CIM method will complete asyn-  
397 chronously. In addition, their status can be retrieved.

398 Operations can only be created using messages. The MAP exposes one and only one identifiable,  
399 traceable operation for any single, valid message. If an implementation spawns multiple activi-  
400 ties in order to process a single message, then all of the activities are related to the message  
401 and/or single job identifier created when the operation was initiated and it is the responsibility of  
402 the MAP to track the multiple activities and relate them to the single message.

403 When operations are modeled in CIM, they have identifiers. The CIM\_ConcreteJob class is used  
404 to represent operations, so the identifier is that of a CIM\_ConcreteJob instance. The term Job ID  
405 represents the identifier of that CIM\_ConcreteJob instance. The status of the job can be retrieved  
406 with a command or message using the Job ID. The MAP keeps track of all active operations.

407 When an operation modeled by CIM\_ConcreteJob is complete, the properties of the instance of  
408 CIM\_ConcreteJob determine if the instance persists or is immediately recycled. Specifically, the  
409 TimeBeforeRemoval property in CIM\_ConcreteJob is used to determine the amount of time that  
410 the instance persists.

411 Operations which result in a Job being spawned are able to handle a cancellation request. Some-  
412 times the response to the cancellation will be an error, such as in the case of an operation that  
413 cannot be undone, an operation that has already taken place or that cannot be stopped part of the  
414 way through, such as turning the power off or resetting a system.

415 The Client can then determine the status of the operation and whether or not the operation is  
416 complete. This can be done through a query operation on the operation queue using the Job ID.  
417 The operation queue can also be queried to find out the maximum operation queue depth, or if  
418 the queue is full.

### 419 **4.3 Operation Queue**

420 In the architecture, the MAP implements an Operation Service which logically contains an Op-  
421 eration Queue. This is a FIFO queue which contains all of the operations to be processed within  
422 the MAP. All current sessions submit operations to this single queue. The MAP provides access  
423 to the capabilities of this queue and the profiles. The properties of the Operation Queue are ex-  
424 pected to vary from implementation.

425 Ordering is with respect to operation initiation and is implied by the queue. Ordering of opera-  
426 tion initiation is guaranteed but no such guarantee is made on operation completion.

427 The MAP's operation queue depth varies from MAP to MAP. The minimum acceptable opera-  
428 tion queue depth is equal to one operation or message. Some implementations may support mul-  
429 tiple outstanding operations; others may not. Should the queue become full, the MAP is respon-  
430 sible for communicating this resource constrained condition.

431 Implementations that support asynchronous operation completion support the class  
432 CIM\_ConcreteJob, which provides detailed information about the operation, including status. A  
433 reference to an instance of CIM\_ConcreteJob is returned by a CIM method when it will complete  
434 asynchronously. A Client that receives such a reference can use it to query this information.

### 435 **4.4 Multi-session capabilities**

436 An important aspect of MAP operations management is to be able to support simultaneous man-  
437 agement sessions through the MAP. Implementations are not required to support more than one  
438 session simultaneously. However, implementations are expected to exist that support many si-

439 multaneous management sessions. Therefore, DASH supports multiple concurrent management  
440 sessions.

441 The number of ports offered to transports from the Management Services Core for each protocol  
442 supported is one per transport supported. The MAP utilizes the error syndromes of the transport  
443 and subsequent layers when handling out of resource conditions (such as no more ports avail-  
444 able), attempting to connect to the wrong port, or not supporting the requested transport.

445 Another aspect of multi-session capabilities is the ability for operations to be visible independent  
446 of the transport that initiated them. This implies that there is one global operations (job) queue  
447 per MAP. The MAP is responsible for routing the results of operations to the appropriate session.  
448 But if the command or message spawns a job, then any session should be able to discover the  
449 details about the job in question, by querying the job using its ID. This is helpful for a number of  
450 reasons. For example, if an operation is spawned, the Client may disconnect and then query the  
451 status of that operation at a later time, provided the Client has retained or can discover the identi-  
452 fier for that operation.

## 453 **5 Protocol Support**

454 DASH uses a CIM-based data model for representing managed resources and services. The  
455 Management Services Infrastructure and protocols are used to exchange the management infor-  
456 mation in a platform-independent and resource-neutral way. This is done by encapsulating CIM  
457 Operations in a Management Protocol, which (in turn) is encapsulated in a Transport Protocol.  
458 This section describes the management protocol and transport protocol selected by DASH.

### 459 **5.1 Management Protocol**

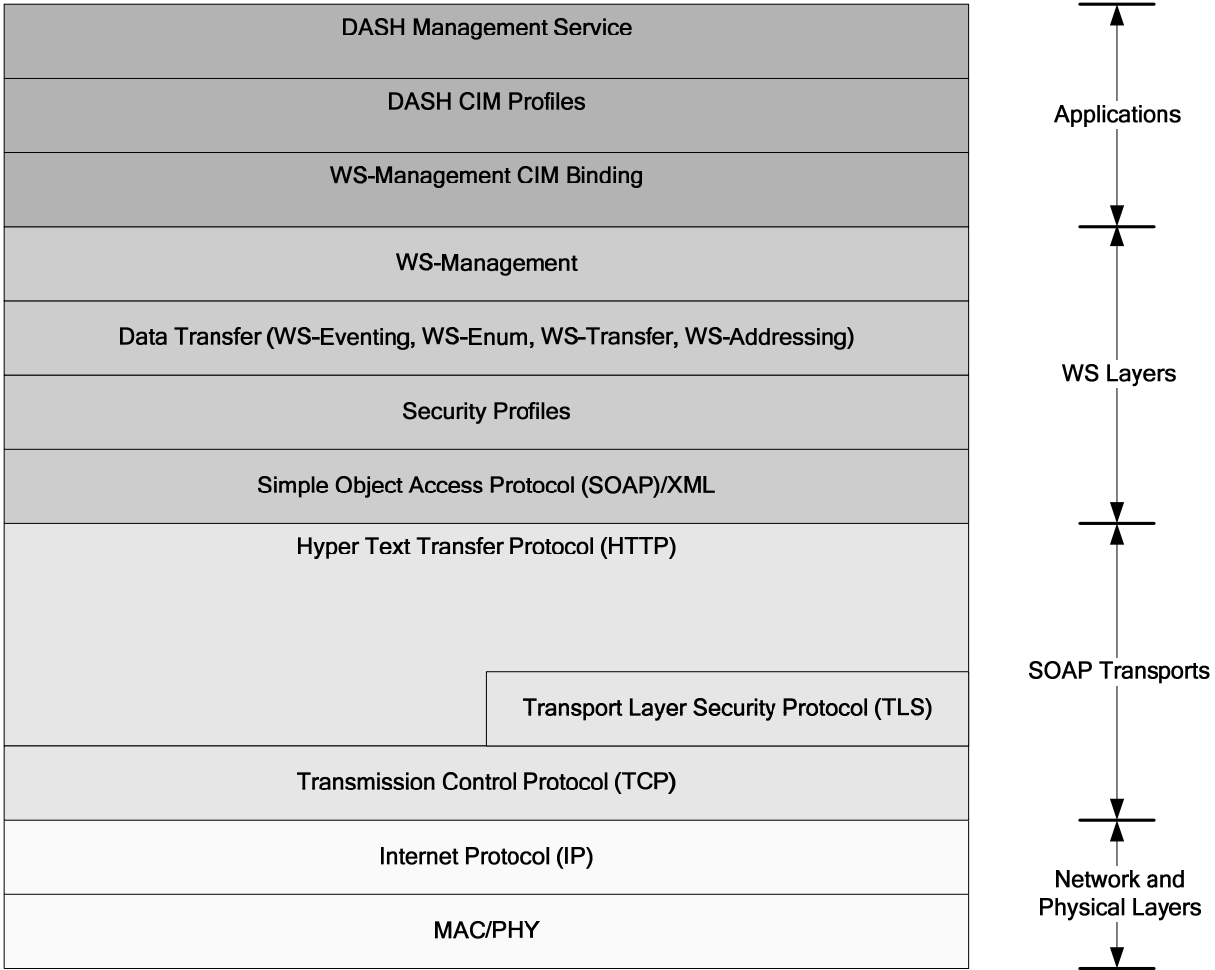

460 DASH supports the Web Services for Management Protocol, as defined in the WS-Management  
461 Specification [1], as the management protocol for transporting DASH messages. WS Manage-  
462 ment is a specification of a core set of Web Services to expose a common set of system man-  
463 agement operations. The specification comprises the abilities to:

- 464 • Discover and navigate management resources.
- 465 • Manipulate management resources (create, destroy, rename, get, put).
- 466 • Enumerate the content of containers or collections (logs or tables).
- 467 • Subscribe/unsubscribe to events.
- 468 • Execute specific management methods.

469 The WS-Management protocol stack for DASH is shown in Figure 3. The WS Management  
470 stack is based on the Web Services. The network and physical layers are the two bottommost  
471 layers in the stack.

472 The transport layers that carry SOAP messages are next in the stack. These layers include TCP,  
473 which provides reliable, stream-oriented data transport; TLS, which provides various security  
474 attributes, and HTTP 1.1, which provides user authentication and request-response semantics.  
475 TCP and HTTP 1.1 are required by DASH. TLS support is conditional on support for security  
476 profiles that require it. Section 9 describes DASH security profiles in more detail.

477 At the next layer, SOAP/XML messaging is handled. The security profiles specified in the  
478 DASH Implementation Requirements Specification [2] define the security mechanisms required.  
479 Above the SOAP/XML layer is the data transfer layer, which is based on multiple Web Services  
480 specifications. These are WS-transfer, WS-Enumeration, and WS-Eventing for transferring the  
481 management information. The top three layers represent the WS Management applications. The  
482 DASH profiles are mapped over the WS Management protocol stack using the WS Management  
483 CIM Binding [4] (which is defined in terms of WS-CIM [5]).

484

485

**Figure 3 – DASH Protocol Stack**

486 WS-Management defines a default addressing model based on WS-Addressing. WS-Addressing  
 487 defines a reference format using EndPointReference (EPR) that uses a ReferenceParameter field  
 488 to identify specific elements (ResourceURI and SelectorSet). WS-Addressing is used to identify  
 489 and access resources (CIM objects in the DASH Architecture).

490 The three data transfer models used by WS-management are briefly described below:

- 491 1. WS-Transfer: defines a mechanism for acquiring XML-based representations of entities.  
 492 It defines the following resource operation using SOAP messages.
  - 493 a. *Get*: is used to fetch a one-time snapshot representation of a resource.
  - 494 b. *Put*: is used to update a resource by providing a replacement representation.
  - 495 c. *Create*: is used to create a resource and provide its initial representation.
  - 496 d. *Delete*: is used to delete a resource.
  - 497 e. WS-Management in addition defines the rename operation and fragment level transfer  
 498 for fragment-level access of resources.
- 499 2. WS-Enumeration: is a SOAP-based protocol for enumeration. Using this protocol, the  
 500 data source can provide a session abstraction called the enumeration context. The con-

501 sumer can then request XML element information over a span of one of more SOAP  
502 messages using the enumeration context. The enumeration context is represented as XML  
503 data. The following operations (defined as SOAP request/response messages) are sup-  
504 ported using this model<sup>1</sup>:

- 505 a. *Enumerate*: to initiate an enumeration and receive an enumeration context.
  - 506 b. *Pull*: to pull a sequence of elements of a resource.
  - 507 c. *Release*: to release an enumeration context (graceful).
- 508 3. WS-Eventing: is a SOAP-based protocol for one web service to register interest and re-  
509 ceive messages about events from another web service. The operations supported by WS-  
510 Eventing include *Subscribe*, *Renew*, *GetStatus*, *Unsubscribe*, and *SubscriptionEnd*. WS-  
511 management defines heartbeats as pseudo-events. WS-Management also defines a book-  
512 mark mechanism for keeping a pointer to a location in the logical event stream. The de-  
513 liverly modes defined for events are: Push, Push with Acknowledgement (PushWithAck),  
514 Batched, and Pull.

## 515 **5.2 Transport Protocol**

516 The WS-Management protocol is transport-independent but it specifies HTTP 1.1 [6] and  
517 HTTPS [7] as the common transports for the interoperability.

518 DASH uses HTTP 1.1 as the SOAP transport for WS-Management. HTTP 1.1 is consistent with  
519 existing transports used by the web servers and Web Services. HTTP 1.1 is widely supported,  
520 deployed, tested, and enhanced. HTTP provides 2-way authentication in the form of basic and  
521 digest authentication (RFC 2617) [8]. HTTP digest authentication exchanges are confidential,  
522 but HTTP does not provide general-purpose confidentiality. There is a well known SOAP bind-  
523 ing for HTTP. Transport Layer Security (TLS) 1.0 (RFC 2246) [9] can be used to add encryp-  
524 tion, message integrity, message origin authentication, and anti-replay services to HTTP-based  
525 communications. HTTPS supports HTTP communications over TLS [9].

## 526 **5.3 WS-Management – CIM Binding**

527 The WS-Management CIM Binding specification defines the binding between the Web Services  
528 representation of CIM (defined in the WS-CIM Mapping Specification [5]) and WS-  
529 Management. This binding encompasses:

- 530 1. WS-Addressing based addressing to identify and access CIM objects that are accessed  
531 over the protocol.
  - 532 2. Retrieving and updating instances of a class using WS-Transfer.
  - 533 3. Enumerating instances of classes using WS-Enumeration.
  - 534 4. Invoking an extrinsic method using action URIs and messages.
  - 535 5. Performing generic operations using WS-Management equivalent operations.
- 536

---

<sup>1</sup> The WS-Enumeration operations *Renew*, *GetStatus*, and *EnumerationEnd* are omitted here because their use is not recommended by the WS-Management specification.

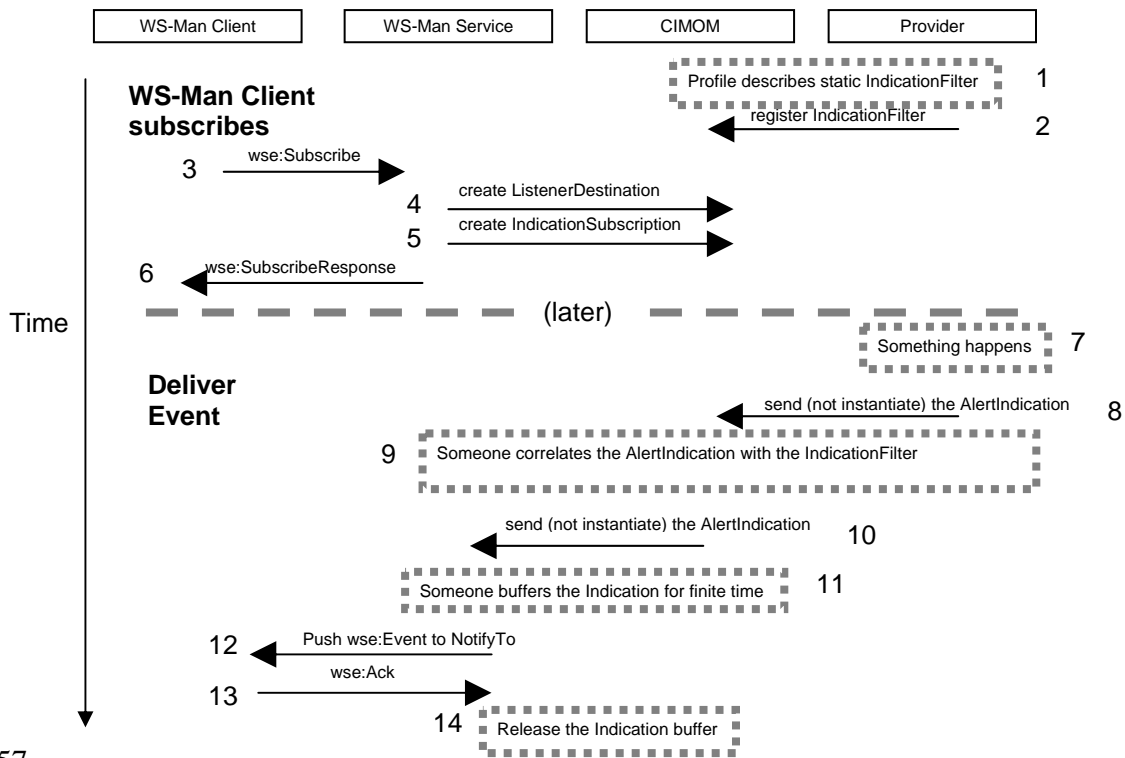

537 **6 Eventing**

538 This section provides an overview of the DASH eventing model. This model encompasses a  
 539 definition of indications, methods for subscribing to and delivering indications, and a standard  
 540 alert indication message format.

541 DASH targets the use of WBEM-based event notification mechanisms in conjunction with  
 542 greater standardization of event message content. Traditionally, Simple Network Management  
 543 Protocol (SNMP) [10] network messages have been used to communicate event related informa-  
 544 tion from the Managed System to a listener console or application. With the advent of CIM-  
 545 based management interfaces, more robust event delivery and more granular control of event  
 546 message traffic is enabled. The DASH Implementation Requirements Specification [2], in con-  
 547 junction with WS-Management [1], WS-Management CIM Bindings [4], Profiles and related  
 548 Message Registry specifications, defines a new level of Web Services based event management  
 549 and notification.

550 **6.1 Eventing Overview**

551 The CIM model contains indication class designs that represent events (described below). The  
 552 DASH approach to event management combines the WS-Eventing event subscription model,  
 553 specific requirements for generating indications and a standardization of alert indication message  
 554 content. Figure 4 provides an example of the sequence of activities that take place when instru-  
 555 mentation generates an indication filter, an application subscribes to the indication filter and the  
 556 instrumentation generates an indication based on an underlying event.

557

558

**Figure 4 – Indication Activity Diagram**

559 The first sequence of events in Figure 4 provides an example of how instrumentation indicates  
560 that it would make a filter available. In step 1, the provider has a static description of at least one  
561 IndicationFilter, for which support was probably created when the provider was developed. In  
562 step 2, the provider indicates to the CIMOM that it has an Indication Filter by registering the In-  
563 dicationFilter with the CIMOM. Now the CIMOM adds this information into the repository.

564 When a WS-Management based Client subscribes to an indication, it sends a WS-Management  
565 Subscribe message to the implementation (step 3). The WS-Management service, in turn, creates  
566 the ListenerDestination and IndicationSubscription instances in the CIMOM (steps 4 and 5) to  
567 represent the client and creates the appropriate associations. This information is then returned to  
568 the Client in the SubscribeResponse message (step 6).

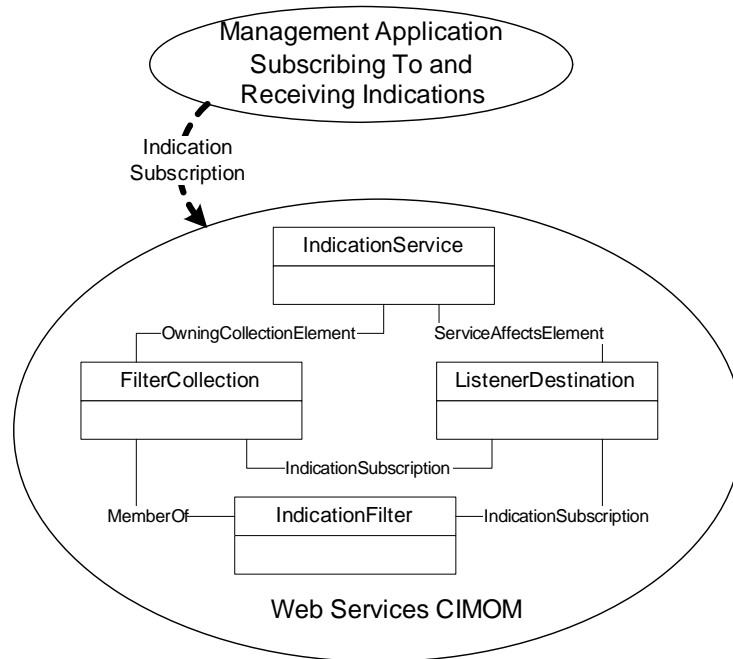

569 When an event occurs (step 7), the instrumentation has the responsibility of communicating the  
570 event to applications that have subscribed to that particular information. The WS-Eventing ap-  
571 proach to communicating event information involves generating an instance of the appropriate  
572 CIM Indication Class and sending the instance information, along with other information, as the  
573 payload of an event delivery message to subscribing listeners. Specifics of the CIM to event de-  
574 livery message mapping are defined in the WS-Management CIM Binding specification [4]. A  
575 synopsis of that process is as follows: when an event occurs (step 7), the provider sends the  
576 AlertIndication to the CIMOM (step 8). Then one of the implementation components correlates  
577 the AlertIndication from the provider with the IndicationFilter from the Client (step 9). Then the  
578 CIMOM sends the AlertIndication to the WS-Management Service (step 10). The service then  
579 pushes the Event (step 12) to the Client, which acknowledges the message (step 13) resulting in  
580 the Indication buffer being released (step 14). Note that the instance of the indication will be  
581 buffered for a finite amount of time by the MAP, implying that the Client should acknowledge  
582 the receipt of the message in an expedient fashion. Future versions of DASH may also use life  
583 cycle indications to convey other observations for an event.

## 584 **6.2 Alert Indications**

585 The content of an Alert Indication consists of a Message ID/string oriented class design. The  
586 content includes a reference pointing to the alerting Managed Element and support for specifying  
587 recommended actions. The content includes a Message ID, which correlates to a Message Regis-  
588 try entry. The content may also other identifying information in the form of MessageArgs. These  
589 will be indicated in the Message Registry as well. Note that the underlying event and its data  
590 may or may not be modeled in the CIM class hierarchy representing the managed system.

## 591 **6.3 CIM Modeling of Events**

592 The CIM event notification model is a subscription-based approach to configuring event indica-  
593 tion delivery. The MAP represents the subscription, listener destination and event filters as de-  
594 fined in DSP1054 – Indications Profile [11]. Figure 5 represents the actions and resultant repre-  
595 sentation of an event indication subscription. For a detailed explanation of the classes, please re-  
596 fer to DSP1054 – Indications Profile [11].

597

598

**Figure 5 – Event Indication Subscription**

599 **6.4 Standardized Message Content**

600 In order to foster greater interoperability between different implementations of management in-  
 601 strumentation and the applications that subscribe for and receive events, a set of standardized  
 602 event message content has been defined. The event message content is specified in XML docu-  
 603 ments according to the DMTF Message Registry Schema. Message Registry entries consist of  
 604 definitions for a message ID, message string, message arguments, perceived severity, and defin-  
 605 ing organization. Each Message in a registry represents a particular event type. DASH 1.1 uses  
 606 message registries for the Message IDs, perceived Severity and interpretations of MessageArgs  
 607 for each MessageID.

## 608 **7 Profiles**

609 This section discusses the topics of profiles. A brief overview of the purpose of profiles is in-  
610 cluded. Profiles specify standard support for manageability features, the list of which is in Sec-  
611 tion 7.2. The autonomous and component profiles are listed in the DASH Implementation Re-  
612 quirements Specification [2], but have been listed for convenience in Section 7.3.

### 613 **7.1 Overview**

614 DMTF profiles provide the object model definitions for manageability content and architecture  
615 models for mapping computer hardware to Common Information Model (CIM) object classes in  
616 a way that is consistent between different implementations. These autonomous and component  
617 profiles combine to ensure that individual implementations will contain the same object informa-  
618 tion as appropriate based on their hardware configuration and the elements they manage.

619 Autonomous and component profiles describe the classes and associations that are used to model  
620 a target desktop or mobile system and its manageable elements for DASH. These profiles com-  
621 bine to ensure that all CIM representations of the system are implemented in a consistent fashion  
622 across multiple vendor offerings and architectures. The profiles lay out the standard CIM-based  
623 modeling approaches defined for managed system elements. Profiles include object and associa-  
624 tion behavioral definitions that specify how system components are to be modeled in order to  
625 produce consistent implementations. Another benefit of profiles is that they effectively prune the  
626 many classes, associations, methods and properties in the CIM Schema to a base consensus  
627 model.

628 The use of the categories of "Mandatory", "Conditional" and "Optional" for classes, associations,  
629 properties and methods draws the distinction, both for the Manageability Access Point (MAP)  
630 Web Services implementation and the Client, as to what must be supported and what can be ex-  
631 pected with respect to interoperability. This results in not only consistent implementations but  
632 sets expectations on the levels of support within the industry.

### 633 **7.2 DMWG Targeted Manageability Features**

634 The following is the list of manageability features targeted in the 1.1 version of the DASH Im-  
635 plementation Requirements Specification [2]. These features are represented by using the pro-  
636 files listed in Section 7.3.

- 637 • Power Control
- 638 • Boot Control
- 639 • WS-Eventing Push Indications
- 640 • Correlatable System ID
- 641 • Software inventory
- 642 • Hardware inventory
  - 643 – Chassis model/serial, CPU, Memory, Fan, Power Supply, Sensor
- 644 • User account management
- 645 • Redirection

- 646                   • Text console redirection, USB redirection, Media redirection, and KVM redirection
- 647                    tion
- 648           • BIOS management
- 649           • Opaque data management or offline mailbox
- 650           • Software/firmware installation/update
- 651           • NIC Management

### 652   **7.3   DASH 1.1 Profiles**

653   This section contains the list of autonomous and component profiles in the DASH Implementa-  
654   tion Requirements Specification [2]. They have been listed for convenience in this section along  
655   with a description.

Profile Name	Description	Manageability Feature
Base Desktop Mobile	Autonomous profile for describing desktop or mobile systems	Hardware Inventory, Correlatable System ID
Physical Asset	Physical component, chassis, card, FRU representation	Hardware Inventory
Boot Control	Boot sequence representation and configuration	Boot Control
Power State Management	System power state representation and control	Power Control
Software Inventory	Representation of software/firmware identification and version information	Firmware Version Information
CPU	Processor representation and configuration	Hardware Inventory
System Memory	System memory representation	
Fan	Fan status and component representation	
Power Supply	Power supply status and component representation	
Sensor	Sensor status and component representation	
Role Based Authorization	Role and privilege representation and management	
Simple Identity Management	User identity representation and management	
Indications	Subscription, listener destination, event filter and indication representation and management	WS-Eventing Push Indications (functionally equivalent to PET alerts)
Battery	Battery status and component representation	Hardware Inventory
BIOS Management	BIOS configuration and control	BIOS Management
DHCP Client	DHCP client configuration and control	NIC Management
DNS Client	DNS client configuration and control	
Host LAN Network Port	Network port/LAN configuration and control	
Ethernet Port	Ethernet port configuration and control	
IP Interface	IP Interface configuration and control	
OS Status	OS representation and management	
Opaque Management Data	Opaque data representation and management	Opaque data management or offline mailbox
Software Update	Software/firmware installation and update	Software/firmware installation and up-

		date
KVM Redirection	KVM (Keyboard, Video & Mouse) console redirections management	Redirection
Media Redirection	Media redirections management	
Text Console Redirection	Text console redirections management	
USB Redirection	USB redirections management	

656  
657  
658

## 659 **8 Discovery**

### 660 **8.1 Discovery Overview**

661 Management clients make use of a variety of discoverable information about managed systems.  
662 These pieces of information are typically accumulated across multiple discovery stages. The fol-  
663 lowing is a list of stages involved in discovering managed systems and their management capa-  
664 bilities:

- 665 1. Network Endpoint Discovery Stage
- 666 2. Management Access Point Discovery Stage
- 667 3. Management Capabilities Discovery Stage

668 Each of these stages is described in more detail in this section.

### 669 **8.2 Network Endpoint Discovery Stage**

670 A Client may enumerate the participants in a network by finding the endpoints based upon net-  
671 work layer. When done, this step provides a list of network addresses for use in subsequent  
672 phases.

673 Because it is supported by all IP network stacks, ICMP Echo Request/Reply is one of the more  
674 common methods of network endpoint discovery.

675 DASH mandates that implementations support these methods. They are critical in discovering  
676 DASH Management Access Points (MAPs).

### 677 **8.3 Management Access Point (MAP) Discovery Stage**

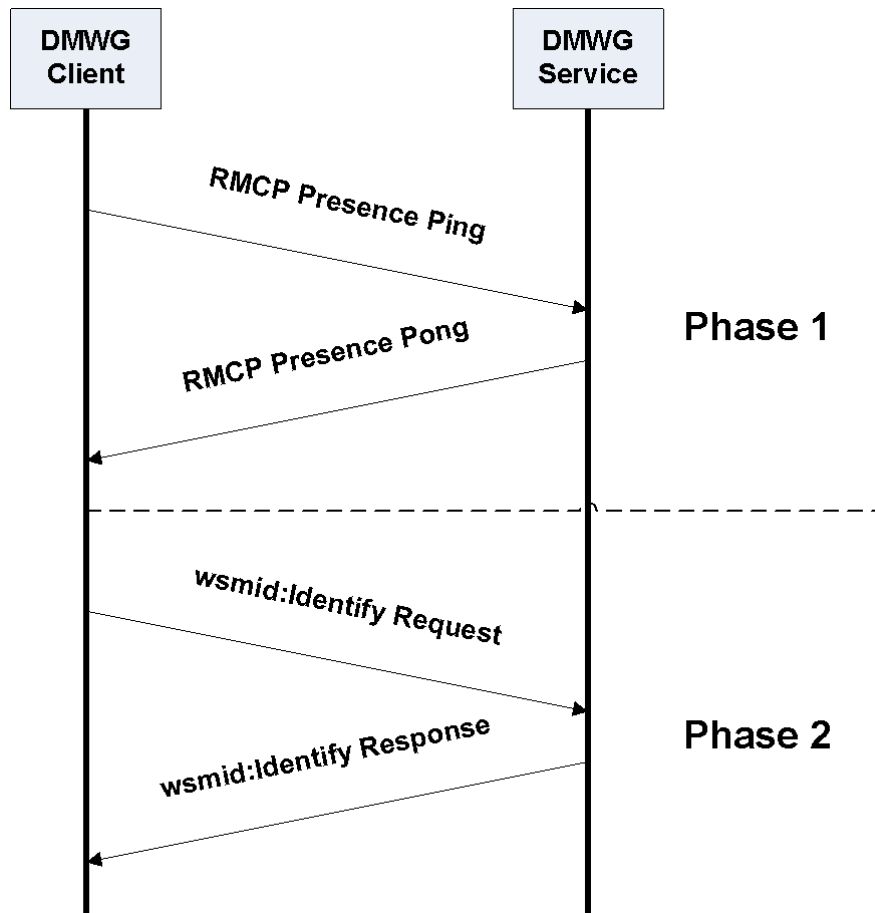

678 The MAP discovery phase involves discovering DASH MAPs in managed systems. It can be  
679 done either pursuant to or in lieu of network endpoint discovery.

680 DASH-compliant MAPs support the following two-phase process for MAP discovery:

681 Phase 1: RMCP Presence Ping/Pong. This provides information about the management pro-  
682 tocol(s) supported by the MAP. This can be done in a unicast, broadcast, or multicast fash-  
683 ion, as described below.

684 Phase 2: WS-Management Identify Method. This method provides detailed information  
685 about the WS-Management service, but it assumes a priori knowledge of the MAP's network  
686 address, and hence is not sufficient in and of itself as a discovery mechanism.

687 These steps are summarized in Figure 6 and described in more detail below.

688

689

**Figure 6 –Two-Phase Management Access Point Discovery**

690 **8.3.1 RMCP Presence Ping/Pong**

691 Presence Ping is an RMCP command defined in ASF [12]. It involves a request-response mes-  
 692 s- age exchange initiated by a management client (Ping) and completed by a management service  
 693 (Pong).

694 DASH implementations support this command on the asf-rmcp well-known UDP port (623).  
 695 Support of Presence Ping/Pong on the asf-secure-rmcp well-known UDP port (664) is not rec-  
 696 ommended for a DASH implementation discovery.

697 The DASH Implementation Requirements Specification [2] defines the ports used for the  
 698 Ping/Pong for phase 1 discovery. It also indicates the exact format of the Pong to determine if the  
 699 endpoint supports an out-of-band<sup>2</sup> WS-Management service. An existing bit in the Supported  
 700 Entities Field identifies support of ASF [12]. One of the key advantages of this method is that it  
 701 can be used in a heterogeneous environment to discover multiple types of management services.

702 Because the Presence Ping command is sent to a UDP port, it can be sent to broadcast and multi-  
 703 cast addresses as well as unicast addresses. The RMCP Presence Ping/Pong supports the follow-  
 704 ing models:

<sup>2</sup> The network endpoint may also support an in-band WS-Management service. Because the RMCP port was defined to describe out-of-band management services, it is not used to advertise support for in-band services.

- 705 1. Broadcast – A single Presence Ping message is sent to either the local or a network-  
706 directed broadcast address. All network endpoints that support RMCP Presence  
707 Ping/Pong respond with a Presence Pong message. Enterprise network policy may limit  
708 the applicability of this approach, in which case, one of the other methods should be used.  
709 Network-directed broadcast in particular is frequently disabled in enterprise networks.
- 710 2. Unicast sweep – A separate Presence Ping message is sent to each IP address in a range  
711 of IP addresses. Each network endpoint that supports RMCP Presence Ping/Pong re-  
712 sponds with a Presence Pong message. This approach should always be coordinated with  
713 any enterprise security policies designed to prevent Denial of Service (DoS) and other at-  
714 tacks that exhibit similar behavior.
- 715 3. Multicast – A single Presence Ping message is sent to a multicast group address. All net-  
716 work endpoints in the group that support RMCP Presence Ping/Pong respond with a  
717 Presence Pong message. The group may be defined expressly for discovery purposes, or  
718 may be more general-purpose in nature. The routers in the enterprise network need to  
719 have multicast delivery enabled, and the group needs to be established and managed.

### 720 **8.3.2 WS-Management Identify Method**

721 The Identify method is defined in WS-Management [1]. If Phase 1 indicates that the network  
722 endpoint supports an out-of-band WS-Management service, the management client can subse-  
723 quently send the *Identify* message to the DMTF registered TCP port to learn the protocol version,  
724 the product vendor, and product version of the service. These are provided in the *IdentifyRe-*  
725 *sponse* message in the *wsmid:ProtocolVersion*, *wsmid:ProductVendor*, and  
726 *wsmid:ProductVersion* elements, respectively.

727 A DASH MAP supports the Identify method on each registered access port that it supports. See  
728 the DASH Implementation Requirements Specification [2] regarding DMWG registered access  
729 ports.

730 DASH defines extension elements as children of the *IdentifyResponse* element in addition to the  
731 child element defined in WS-Management [1]. For details of these elements, see the DASH Im-  
732 plementation Requirements Specification [2].

### 733 **8.3.3 Enumeration of Management Capabilities Stage**

734 The DMTF Profiles Registration Profile [13] specifies methods for enumerating the management  
735 capabilities of a CIM-based management access point in a scalable manner. DASH Implementa-  
736 tions support the Profile Registration Profile and therefore provide a mechanism for enumerating  
737 the set of related management capabilities that is independent of the number of CIM instances  
738 supported by the management access point.

## 739 **9 Security**

740 Security is very important for systems management operations. DASH defines several aspects of  
741 security including transport level security, roles and authorizations, user account management,  
742 and authentication mechanisms. The transport level security provides machine-level authentica-  
743 tion and encryption of payloads contained within the transport messages. The user-level authen-  
744 tication and authorization mechanisms provide the second level of authentication and authoriza-  
745 tions for operations allowed for the specific roles.

### 746 **9.1 Transport Considerations**

747 DASH requires HTTP 1.1 [6] as the transport for the management protocol WS-Management  
748 [1]. The security at the transport or network layer provides the message integrity, data origin au-  
749 thentication, and encryption of transport messages. The transport or network layer security  
750 mechanisms protect the management protocol messages, management operations, and CIM-  
751 based resources/data accessed using the management protocol. DASH defines two classes of se-  
752 curity as described below for security at the transport layer and layers below it.

753 DASH defines two security classes for HTTP 1.1 transport.

- 754 1. Class A: The security class A requires HTTP digest authentication for the user authenti-  
755 cation. For this class, no encryption capabilities are required.
- 756 2. Class B: This class defines three security profiles that are based on either TLS or IPsec  
757 with specifically selected modes and cryptographic algorithms. For the class B compli-  
758 ance, the support for at least one the security profiles below is required. The definitions  
759 of the three security profiles defined for class B are as below.
  - 760 a. HTTP\_TLS\_1: For this security profile, TLS 1.0 is required for both authentication  
761 and encryption. This profile provides two-level authentication and encryption capa-  
762 bilities. The user-level authentication is provided by the HTTP digest authentication.  
763 The machine-level authentication is provided by the TLS server and client certificates  
764 (X.509 based) where the implementation of the client certification is optional. The  
765 encryption capabilities are provided by TLS 1.0. The required cipher suite for this se-  
766 curity profile is TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA.
  - 767 b. HTTP\_TLS\_2: For this security profile, TLS 1.0 is required for both authentication  
768 and encryption. This profile is based on providing two-level authentication and en-  
769 cryption capabilities. The user-level authentication is provided by the HTTP basic au-  
770 thentication. The machine-level authentication is provided by the TLS server and cli-  
771 ent certificates (X.509 based) where the implementation of the client certification is  
772 optional. The encryption capabilities are provided by TLS 1.0. The required cipher  
773 suite for this security profile is TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA. The only  
774 difference between HTTP\_TLS\_1 and HTTP\_TLS\_2 is the mechanism used for user  
775 authentication (HTTP digest authentication for HTTP\_TLS\_1 security profile and  
776 HTTP basic authentication for HTTP\_TLS\_2 security profile). For HTTP\_TLS\_2 se-  
777 curity profile, HTTP basic authentication used in conjunction with TLS avoids the  
778 transmission of credentials in clear text.
  - 779 c. HTTP\_IPSEC: This security profile is based on combining HTTP 1.1 over IPsec with  
780 the HTTP digest authentication. The user-level authentication is provided by the  
781 HTTP digest authentication. While, the machine-level authentication and encryption

782 is provided at the IPsec layer below the transport layer. For this security profile, IPsec  
783 ESP transport mode is required. This security profile requires the implementation of  
784 one of the cipher suites mentioned below:

- 785 i. AES-GCM (key size: 128 bits, ICV or Digest length: 16 bytes)
- 786 ii. AES-CBC (Key size: 128 bits) with HMAC-SHA1-96

787 A DASH implementation is required to support at least one of the above security classes. It is  
788 recommended that a DASH implementation be Class B compliant for privacy/confidentiality and  
789 additional security.

## 790 **9.2 Roles and Authorization**

791 The access control for the managed resources and management operations is an important aspect  
792 of the secure management for DASH. The authorization and access control is based on the roles  
793 assigned and privileges associated with the user accounts.

794 DASH defines the following operational roles.

- 795 1. Read-Only User. This is a role that allows a user to only perform query and read opera-  
796 tions on the managed elements. The read-only user is not allowed to modify  
797 data/properties, settings, and setting data. For the managed elements and objects, the  
798 read-only user can neither change the state of the managed elements/objects nor cre-  
799 ate/delete object instances or properties. The read-only user can not perform user account  
800 management.
- 801 2. Operator. This is a role that allows a user to perform read, write, and execute operations  
802 on the managed elements. An operator is allowed to change data/properties, settings, and  
803 setting data as well as change the state of the managed elements. The operator is not al-  
804 lowed to create/delete object instances or properties through direct manipulation of object  
805 instances or properties. Another restriction that applies to an operator role is the inability  
806 to perform user account management.
- 807 3. Administrator. This role is a superset of operator role with the additional capability to  
808 create/delete object instances or properties and perform user account management. Simi-  
809 lar to a user with the operator role, a user with the administrator role is allowed to per-  
810 form read, write, and execute operations; change data/properties, settings, and setting  
811 data; and change state of the managed elements. The administrator can perform user ac-  
812 count management (create/delete/modify user accounts) if supported by the implementa-  
813 tion.

814 A DASH compliant service is required to support the administrator role. In addition, an imple-  
815 mentation may support the operator and/or read-only user roles. DASH does not define any func-  
816 tionality-based roles but an implementation is free to support them. Also, DASH does not require  
817 a separate role for auditing the DASH operations.

## 818 **9.3 User Account Management**

819 The user account management is another important security aspect of the DASH architecture.  
820 The authentication and authorization mechanisms are tied with the user account management.  
821 DASH supports one or two-levels of authentications. The authorization model supported by  
822 DASH is role based.

823 Each user has the ability to modify his or her credentials. But only the administrator is allowed to  
824 perform account management for all users. The following are the operations supported for user  
825 account management.

- 826 1. Create an account
- 827 2. Delete an account
- 828 3. Enable an account
- 829 4. Disable an account
- 830 5. Modify the privileges of an account
- 831 6. Modify password of an account
- 832 7. Change the role of an account
- 833 8. Create a group of accounts
- 834 9. Delete a group of accounts
- 835 10. Add an account to a group
- 836 11. Remove an account from a group
- 837 12. Change the role of a group
- 838 13. Modify the privileges of a group

839 The modifications of privileges covers the changing of bindings between accounts/groups and  
840 roles. The privileges defined for DASH are static privileges. In other words, the bindings of  
841 privileges to roles can not be changed dynamically. For the administrator role, the following  
842 minimum set of operations is required to be supported for the user account management.

- 843 1. Create an account
- 844 2. Delete an account
- 845 3. Change the associations of roles and accounts

## 846 **9.4 Authentication Mechanisms**

847 The three different types of authentication mechanisms considered are:

- 848 1. Machine-level authentication. This is used to authenticate the machine that is accessing  
849 the service. The machine-level authentication uses machine-level credentials (keys, cer-  
850 tificates..) for the authentication. The machine-level authentication does not authenticate  
851 a particular user or a user session.
- 852 2. User-level authentication. This is used to authenticate a particular user. It is typically  
853 based on the usernames/passwords and it may involve a third-party which provides an  
854 identity for the user. User-level authentication is performed on a per operation basis.  
855 However, this authentication is typically visible to the user only on the first operation; the  
856 user's credentials are cached for use in subsequent operations.
- 857 3. Third-party authentication. This is typically an out-of-band authentication mechanism  
858 where the third-party is used to verify the user credentials. The credentials used for the  
859 authentication are issued by the third-party (like a certificate authority). The user pro-  
860 vides these credentials during the authentication process. The third-party is involved in

861 authenticating a user (third-party verifies user credentials). Typically, the third-party au-  
862 thentication is performed using a separate channel and it does not involve the managed  
863 system. Typically, the authentication is asserted in the credential and the MAP authenti-  
864 cates the credential.

865 DASH requires user-level authentication support at minimum. The machine-level authentication  
866 is optional. Note: If class B security compliance is needed, then the machine-level authentication  
867 is required for the defined security profiles. The third-party authentication is optional. So, any  
868 configuration for third-party authentication happens outside of the CIM profiles defined in  
869 DMWG. But, the identity can be incorporated in the model. A DASH implementation can  
870 choose to support multiple levels of authentication.

## 871 **9.5 Authorization**

872 DASH uses a role-based authorization model. The scope of the authorization is within an authen-  
873 ticated session. For a TLS session, the HTTP digest authentication may happen multiple times  
874 within a session. Each operation performed by the user is authorized prior to the execution of the  
875 operation. An unauthorized operation (the operation which fails the authorization) does not  
876 change any state or data of the managed resources.

## 877 **10 Use Cases**

878 These Use Cases describe representative common tasks that can be performed using DASH 1.1.

### 879 **10.1 User Accesses the DASH Service as an Administrator**

880 The user presents credentials to the DASH service using one of the DASH-mandated WS-  
881 Management mechanisms. Whether the credentials allow him to use the service as an administra-  
882 tor depends on steps taken earlier to establish an association between the instance of  
883 CIM\_Identity that corresponds to the credentials and the instance of CIM\_Role that corresponds  
884 to the Administrator role. Use cases for establishing identities, roles and privileges are described  
885 in DSP1039 (Role Based Authorization Profile). DASH-specific values for the authorization  
886 classes are described in <DASH Wrapper Spec>. A general discussion of authentication and au-  
887 thorization in DASH is found in section 9 above. Note that DASH 1.1-compliant services are not  
888 required to implement the Role Based Authorization Profile.

### 889 **10.2 Client discovers the capabilities of the DASH Service**

890 There are three sets of discoverable capabilities in DASH 1.1.

891 The first is simply whether there is a DASH service at a particular network endpoint. This can be  
892 done using the RMCP Presence Ping mechanism described in section 8.3.1 above.

893 The second is the set of capabilities advertised in the response to a WS-Identity query.

894 The WS-Identity query is described in the WS-Management specification; DASH-specific capa-  
895 bilities are described in detail in <DASH Wrapper Spec>.

896 A general discussion of DASH discovery is found in section 8 above.

897 A third set of capabilities discoverable in DASH 1.1 is the list of supported profiles. The Profile  
898 Registration Profile (DSP1033) describes how to find the Profiles that are supported in an im-  
899 plementation. The “Scoping Class” described in the Profile Registration Profile is  
900 CIM\_ComputerSystem for the DMTF Service. The “Central Class” is also  
901 CIM\_ComputerSystem, so either the Scoping Class Methodology or the Central Class Method-  
902 ology may be used to find the list of supported profiles.

### 903 **10.3 PC Needs to be woken up remotely on a wired network**

904 PCs that have Wake On LAN configured will awake on receipt of the Magic Packet. DASH pro-  
905 vides a similar capability through the Out Of Band DASH Service. An administrator, using a  
906 SOAP client program which perhaps has been extended for DASH, formulates a query to locate  
907 the computer systems at a Management Access Point accessible through a WS-Management Ser-  
908 vice transport address. If the target computer is located, the Administrator fetches the associated  
909 CIM\_PowerManagementCapabilities instance, and examines the PowerChangeCapabilities and  
910 property.

911 If the computer supports setting its enabled state to 2 (enabled), the Administrator executes the  
912 extrinsic method RequestStateChange() on the computer instance.

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile

Step	Actor	Action	Notes
2	Client	Navigate from the target instance of CIM_ComputerSystem to the instance of CIM_PowerManagementService using the CIM_AssociatedPowerManagementService association.	See Power State Management Profile
3	Client	Using the instance of CIM_PowerManagementService, navigate to the instance of CIM_PowerManagementCapabilities through the CIM_ElementCapabilities association.	Ditto
4	Client	If the PowerChangeCapabilities property array contains the value 3 (Power State Settable) and PowerStatesSupported contains the value 0 (On), then waking the computer is supported by the MAP.	Ditto
5	Client	Invoke the RequestPowerStateChange( ) method of the instance of CIM_PowerManagementService with the PowerState argument set to 2 (Power On).	Ditto
4	DASH Service	Using internal interfaces, effect the requested state change and return the appropriate response to the Client.	
5	Client	Examine the returned values to determine if the PC was woken.	

## 913 10.4 PC needs to be woken up remotely on a wireless network

914 Wake On LAN is not commonly implemented on wireless NICs because of the power require-  
915 ments of keeping the radio on, but some systems can be configured to periodically wake up and  
916 listen for traffic on the wireless connections. While the wireless NIC is powered, the DASH Ser-  
917 vice can act as described in use case 10.3.

## 918 10.5 PC will not boot

919 An administrator can be notified of a PC boot failure if he subscribes to these alert indications:

MessageID	Event
20	Preboot User password violation
23	Network Boot password violation
175	No Bootable Media
176	Non-bootable Media
177	PXE Server Not Found
178	User-timeout on boot

920 In DASH 1.1 can expose the following capabilities to help an administrator diagnose the prob-  
921 lem and fix it remotely:

- 922 • Examine the Boot Control settings to see if the boot parameters, including boot source,  
923 are correct.
- 924 • Examine the Software Inventory to make sure there is an appropriate BIOS installed. If  
925 the installation tracks it, this can also be used to check that there is an OS locally in-  
926 stalled.
- 927 • Examine the Physical Asset inventory.
- 928 • Check to see that the CPUs and memory are recognized as present and are compatible.
- 929 • Make sure that the system environmental and power will allow a boot.
- 930 • Examine a record of indications sent from the PC if it ever was operational.

- 931 • Set the boot source to a different image using the Boot Control settings. Note: In DASH  
932 1.1, the boot configuration can be changed using three different profiles: boot control,  
933 text console redirection, and BIOS management. The boot control profile is the preferred  
934 profile for the boot configuration changes.
- 935 • Reset the system.

## 936 10.6 PC will boot, but OS hangs

937 An administrator can be notified when an OS fails to load by subscribing to indication message  
938 178 (User Timeout on Boot).

939 The administrator has all the same tools and capabilities available to diagnose OS hangs as he  
940 does to investigate boot failures (see section 10.5). In addition, OS-managed log records may  
941 also be accessible.

## 942 10.7 Query PC assets while OS hung or absent

943 An administrator can query the DASH service for information about Software assets.

944 Depending on the implementation, some information that is available when the OS is running  
945 may not be available while an OS is absent. A number of use cases are described in detail in the  
946 Software Inventory Profile, but the following steps will return all available software information.

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Locate the packaging of the Computer by following the ComputerSystemPackage association.	See Software Inventory Profile
3	Client	Find each instance of CIM_SoftwareIdentity associated through the CIM_InstalledSoftwareIdentity association. Each instance represents a piece of software or firmware installed on the computer. To find all software whether or not it is installed, get the instance associated with the computer through the CIM_ElementSoftwareIdentity association.	Ditto
4	Client	To find information about the software, get properties like CIM_SoftwareIdentity.Name CIM_SoftwareIdentity.MajorVersion CIM_SoftwareIdentity.MinorVersion Etc.	Ditto
5	Client	Examine the returned values to determine if the FRU data was successfully retrieved.	

947 The administrator can also get hardware information from the DASH Service. The following  
948 steps allow him to get FRU information about the system chassis:

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Locate the packaging of the Computer by following the ComputerSystemPackage association. The Platform GUID is a property of this association.	See Physical Asset Profile
3	Client	To find if FRU information is available for the packaging, follow the ElementCapabili-	Ditto

		ties of the package to its CIM_PhysicalAssetCapabilities instance. If CIM_PhysicalAssetCapabilities.FRUInfo is "TRUE", then there is some FRU information.	
4	Client	To find FRU information, get properties like CIM_PhysicalPackage.PartNumber CIM_PhysicalPackage.SerialNumber CIM_PhysicalPackage.Model etc.	Ditto
5	Client	Examine the returned values to determine if the FRU data was successfully retrieved.	

949 These steps allow the administrator to get FRU information about other devices:

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Follow the SystemDevice associations of the computer until the desired device is found	See Physical Asset Profile
3	Client	Follow the Realizes association of the device to locate the instance of CIM_PhysicalPackage that describes its physical aspects.	Ditto
4	Client	Follow the ElementCapabilities association of the PhysicalPackage to an instance if CIM_Capabilities. If CIM_Capabilities.FRUInfo is "TRUE", then there is some FRU information	Ditto
5	Client	To find FRU information, get properties like CIM_PhysicalPackage.PartNumber CIM_PhysicalPackage.SerialNumber CIM_PhysicalPackage.Model etc.	Ditto
6	Client	Examine the returned values to determine if the FRU data was successfully retrieved.	

## 950 10.8 Detect overheat or a broken fan

951 An administrator who wants to be notified of events such as fan failures and high temperatures  
952 on DASH-enabled computers will use WS-Eventing support in DASH to subscribe to alert indi-  
953 cations issued by the DASH infrastructure. After locating the target computer, the administrator  
954 creates a WS-Management Subscribe message. As illustrated in [1], the Subscribe message com-  
955 bines the WS-Management Subscribe Action; an End Point URI representing the computer or  
956 perhaps the CIM\_NumericSensor class; and a filter that identifies the events of interest. If the  
957 administrator's SOAP client is capable of receiving WS-Eventing messages, the target DASH  
958 implementation will send indication alerts to it as triggering events occur.

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Subscribe to threshold events using the Endpoint URI and filter as described in <DASH Wrapper Spec>.	See Sensor Profile
3	DASH Service	Watch for events that trigger the indications specified by the EPR and filter. Send matching alert indications to the SOAP end point specified in the subscription.	

4	Client	Take action as appropriate. This may be to gather more information or to shut down the computer where the event occurred.	Ditto
---	--------	---	-------

959 **10.9 Query health sensors for overheat or a broken fan**

960 To find all the fan and temperature sensors in the computer and determine which indicate a prob-  
 961 lem, an administrator uses a DASH-enabled SOAP client to find the target computer instance,  
 962 then find and examine the fan sensors. If only a single sensor or a small number of known sen-  
 963 sors are suspect, the administrator might request each of them by name.

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Locate each fan speed sensor by finding all the instances of class CIM_NumericSensor associated with the Computer through the SystemDevice association where CIM_NumericSensor.SensorType="Tachometer".	See the Sensor Profile
3	Client	To find the state of the sensor (and by implication the state of the fan), examine CIM_NumericSensor.CurrentState. If the state is not "OK", take appropriate action.	Ditto
4	Client	Examine the returned values to determine if the query operations worked.	

964 **10.10 Detect chassis intrusion**

965 The steps in this use case are the same as in section 10.8, except that the Administrator will  
 966 watch for these alert indication messages:

MessageID	Event
1	Chassis Open
3	Drive Bay Open
6	I/O Card Area Open
8	Processor Area Open
14	Fan Area Open

967 **10.11 Add, Remove or Edit a DASH Service User remotely.**

968 DASH 1.1-compliant services are required to implement user account management.

969 An Administrator adds an account in this way:

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Find an instance of CIM_AccountManagementService associated with the computer instance through CIM_HostedService. If there is no such instance, user management is not implemented.	See the Simple Identity Management Profile
3	Client	Find an instance of CIM_AccountManagementCapabilities associated with the service through CIM_ElementCapabilities	Ditto
4	Client	Examine the value of the OperationsSupported property. If it contains the value 2(Create), then adding a user is supported.	Ditto
5	Client	Create a template instance of CIM_Account	Ditto
6	Client	Execute the CreateAccount() method of the service	Ditto

970 To remove an account, follow the first three steps above, then

Step	Actor	Action	Notes
4	Client	Examine the value of the OperationsSupported property. If it contains the value 4 (Delete), then removing a user is supported.	See the Simple Identity Management Profile
5	Client	Execute the DeleteInstance intrinsic operation specifying the instance of CIM_Account corresponding to the user.	Ditto

## 971 10.12 Install System Firmware

972

973 The table below describes a use case of installing system firmware (or BIOS) on a system. The  
 974 software update profile is used for installing the system firmware on the computer system. The  
 975 software inventory profile is then used to query the installed version of the system firmware.  
 976

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Find an instance of CIM_SoftwareInstallationService associated with the CIM_ComputerSystem instance through CIM_HostedService. If there is no such instance, then software installation service is not implemented.	See Software Update Profile
3	Client	Find an instance of CIM_SoftwareInstallationServiceCapabilities associated with the service through CIM_ElementCapabilities. Examine the SupportedSynchronousActions property. If it contains value 4(Install From Byte Stream), then the system firmware can be installed using InstallFromByteStream() method.	Ditto
4	Client	Execute the InstallFromByteStream() method of the service using the appropriate parameters including the system firmware image as the byte stream and CIM_ComputerSystem as the managed element.	Ditto
5	Client	Find an instance of CIM_SoftwareIdentity for the system firmware associated with the CIM_ComputerSystem instance through CIM_InstalledSoftwareIdentity.	See Software Inventory Profile

977

## 978 10.13 Check Installed OSes and Running OS

979

980 The table below describes a use case of checking installed OSes and running OS on the system.  
 981

Step	Actor	Action	Notes
1	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
2	Client	Find all instances of installed OSes (CIM_OperatingSystem) associated with the CIM_ComputerSystem instance through CIM_InstalledOS. If there is no such instance, then no OS has been installed on this system.	See OS Status Profile
3	Client	If there are one or more OSes installed on this system, then find an instance of the running OS (CIM_OperatingSystem) associated with the CIM_ComputerSystem instance through CIM_RunningOS. If there is no such instance, then no OS is currently running on this system.	See OS Status Profile

## 982 10.14 Remote BIOS Configuration and Remediation

983

984 The table below describes a use case of remotely booting from a redirected media by changing  
 985 the BIOS configuration using text console redirection profile. The system is repaired using the  
 986 USB redirection and text console redirection. After the system is repaired, it boots normally.

Step	Actor	Action	Notes
1	DASH Service	Service advertises to BIOS/OS redirected USB mass storage device	
2	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
3	Client	Find an instance of CIM_USBRedirectionService associated with the computer instance through CIM_HostedService. If there is no such instance, USB redirection is not implemented.	See USB Redirection Profile
4	Client	Find an instance of CIM_USBRedirectionCapabilities. If found, see whether SAPCapabilitiesSupported array contains value of 1 (Pre-Configured SAPs).	Ditto
5	Client	Enumerate the instances of CIM_USBRedirectionSAP that are associated through an instance of CIM_ServiceAccessBySAP	Ditto
6	Client	For each instance of CIM_USBRedirectionSAP, enumerate the instances CIM_USBDevice associated to the CIM_USBRedirectionSAP through an instance of CIM_SAPAvailableForElement. Find an instance of USB mass storage device that is being redirected.	Ditto
7	Client	Find an instance of CIM_TextRedirectionService associated with the computer instance through CIM_HostedService. If there is no such instance, text console redirection is not implemented.	See Text Console Redirection Profile
8	Client	Enumerate the instances of CIM_TextRedirectionSAP that are associated through an instance of CIM_ServiceAccessBySAP	Ditto
9	Client	Start at the instance of the CIM_TextRedirectionSAP that is a component of the Text Console Redirection of interest	Ditto
10	Client	Invoke the RequestStateChange() method with the RequestedState parameter set to 2 (Enabled)	Ditto
11	Client	Verify that the CIM_TextRedirectionSAP.EnabledState property is set to a value of 2 (Enabled). The Text Console Redirection is now active	Ditto
12	Client	Navigate from the target instance of CIM_ComputerSystem to the instance of CIM_PowerManagementService using the CIM_AssociatedPowerManagementService association.	See Power State Management Profile
13	Client	Using the instance of CIM_PowerManagementService, navigate to the instance of CIM_PowerManagementCapabilities through the CIM_ElementCapabilities association.	Ditto
14	Client	If the PowerChangeCapabilities property array contains the value 3 (Power State Settable) and PowerStatesSupported contains the value 0 (On), then waking the computer is supported by the MAP.	Ditto
15	Client	Invoke the RequestPowerStateChange() method of the instance of CIM_PowerManagementService with the PowerState argument set to 2 (Power On).	Ditto
16	Client	Use the text console redirection session and change the BIOS settings to have the system boot from the redirected USB mass storage device.	
17	Client	The managed system boots from the redirected USB mass storage device. Remediate and repair the system.	
18	Client	Invoke the RequestPowerStateChange() method of the instance of CIM_PowerManagementService with the PowerState argument set to 5 (Power Cycle Off-Soft).	See Power State Management Profile
19	Client	Use the text console redirection session and change the BIOS setting to have the system boot from the local devices.	See Text Console Redirection

20	Client	Invoke the RequestStateChange() method on CIM_TextRedirectionSAP with the RequestedState parameter set to 3 (Disabled)	Ditto
21	Client	Verify that the CIM_TextRedirectionSAP.EnabledState property is set to a value of 3 (Disabled). The Text Console Redirection is now inactive and the system boots normally.	Ditto

988 **10.15 Programmatic BIOS Configuration Changes**

989  
 990 The table below describes a use case of programmatically changing BIOS configurations on mul-  
 991 tiple systems using the BIOS management profile.

992

Step	Actor	Action	Notes
1	Client	Discover all the systems running DASH services on the network. For each system, perform the steps 2-11 below.	
2	Client	Locate the target instance of CIM_ComputerSystem	See Base Desktop Mobile Profile
3	Client	Find an instance of CIM_BIOSService associated with the computer instance through CIM_HostedService. If there is no such instance, then the BIOS management is not implemented.	See BIOS Management Profile
4	Client	Enumerate the instances of CIM_BIOSAttribute that are associated with CIM_BIOSService through an instance of CIM_ServiceAffectsElement.	Ditto
5	Client	For each BIOS attribute of interest, change the BIOS attribute by invoking the method SetBIOSAttribute().	Ditto
6	Client	Navigate from the target instance of CIM_ComputerSystem to the instance of CIM_PowerManagementService using the CIM_AssociatedPowerManagementService association.	See Power State Management Profile
7	Client	Using the instance of CIM_PowerManagementService, navigate to the instance of CIM_PowerManagementCapabilities through the CIM_ElementCapabilities association.	Ditto
8	Client	If the PowerChangeCapabilities property array contains the value 3 (Power State Settable) and PowerStatesSupported contains the value 5 (Power Cycle Off-Soft) that performs the soft reset of the computer, then continue with Steps 9-11 described below.	Ditto
9	Client	Invoke the RequestPowerStateChange( ) method of the instance of CIM_PowerManagementService with the PowerState argument set to 5 (Power Cycle Off-Soft).	Ditto
10	DASH Service	During POST, the DASH service communicates all the BIOS attribute changes to the BIOS. The BIOS attribute changes are accepted or rejected by the BIOS and the system boots.	
11	Client	Enumerate the instances of CIM_BIOSAttribute that are associated with CIM_BIOSService through an instance of CIM_ServiceAffectsElement. Verify the BIOS attribute changes that were accepted by the BIOS.	BIOS Management Profile

## 993 **11 Conclusion**

994 DASH contains the models, mechanisms and semantics necessary to manage mobile and desktop  
995 computers in use today, independent of service state. This includes the architectural, service and  
996 operations models, and covers boot and firmware update as well as service discovery. The pro-  
997 files contain the required classes, instances, properties and methods necessary to manage sys-  
998 tems. The transport and management protocols allow implementers to determine the communica-  
999 tion requirements for compliant systems. Discovery and security requirements described help to  
1000 understand their aspects in relation to the profiles and protocols. And the use cases should help  
1001 implementers understand the communications that take place in certain circumstances. All of  
1002 these combine in DASH to deliver the syntax and semantics necessary to manage desktop and  
1003 mobile computer systems.
