180

## Introduction

181 The *Platform Level Data Model (PLDM) NIC Modeling document* defines the PLDM data structures for  
182 modeling a NIC using PLDM for Monitoring and Control semantics. Additional information related to  
183 modeling configuration options for NICs are also defined.

### 184 **Document conventions**

#### 185 **Typographical conventions**

186 The following typographical conventions are used in this document:

- 187 • Document titles are marked in *italics*.

188

# PLDM NIC Modeling

## 189 1 Scope

190 This document defines messages and data structures for modeling a NIC using PLDM for Monitoring and  
191 Control semantics. NIC modeling allows implementers of NIC and MC to better understand how to use  
192 PLDM for Monitoring and Control in a real system. Implementers using the model described in this  
193 document can assure interoperability at the system level. The model also provides for scalability in terms  
194 of the number of controllers, ports and connectors in the given NIC hardware. For model simplicity, entity-  
195 types are fabric-agnostic, and simplicity over accuracy is preferred where possible.

196 This specification is not a system-level requirements document. The modeling and messages which are  
197 stated in this document are implemented through PLDM messaging using PLDM for Platform Monitoring  
198 and Control semantics. PLDM NIC Modeling does not specify whether a given NIC is required to  
199 implement every property included in the model. For example, this model does not specify whether a  
200 given NIC shall support PLDM for Platform Monitoring and Control. However, implementing PLDM NIC  
201 Modeling per this document requires using messages and data model structures defined in PLDM for  
202 Platform Monitoring and Control.

203 Portions of this reference model specification rely on information and definitions from other specifications,  
204 which are identified in clause 2. Five of these references are particularly relevant:

- 205 • DMTF [DSP0240](#), *Platform Level Data Model (PLDM) Base Specification*, provides definitions of  
206 common terminology, conventions, and notations used across the different PLDM specifications  
207 as well as the general operation of the PLDM messaging protocol and message format.
- 208 • DMTF [DSP0245](#), *Platform Level Data Model (PLDM) IDs and Codes Specification*, defines the  
209 values that are used to represent different type codes defined for PLDM messages.
- 210 • DMTF [DSP0248](#), *Platform Level Data Model (PLDM) for Platform Monitoring and Control*  
211 *Specification*, defines the messages and data structures for discovering, describing, initializing,  
212 and accessing sensors and effecters within the management controllers and management  
213 devices of a platform management subsystem
- 214 • DMTF [DSP0249](#), *Platform Level Data Model (PLDM) State Set Specification*, defines the  
215 collection of state sets, each having a set of enumeration values. PLDM for Monitoring and  
216 Control uses the state set to report the discrete values from PLDM sensors.
- 217 • DMTF [DSP0257](#), *Platform Level Data Model (PLDM) FRU Data Specification 1.0*, defines a  
218 FRU data format that provides platform asset information including part number, serial number  
219 and manufacturer.

## 220 2 Normative references

221 The following referenced documents are indispensable for the application of this document. For dated or  
222 versioned references, only the edition cited (including any corrigenda or DMTF update versions) applies.  
223 For references without a date or version, the latest published edition of the referenced document  
224 (including any corrigenda or DMTF update versions) applies.

### 257 3 Terms and definitions

258 In this document, some terms have a specific meaning beyond the normal English meaning. Those terms  
259 are defined in this clause.

260 The terms "shall" ("required"), "shall not", "should" ("recommended"), "should not" ("not recommended"),  
261 "may", "need not" ("not required"), "can" and "cannot" in this document are to be interpreted as described  
262 in [ISO/IEC Directives, Part 2](#), Clause 7. The terms in parentheses are alternatives for the preceding term,  
263 for use in exceptional cases when the preceding term cannot be used for linguistic reasons. Note that  
264 [ISO/IEC Directives, Part 2](#), Clause 7 specifies additional alternatives. Occurrences of such additional  
265 alternatives shall be interpreted in their normal English meaning.

266 The terms "clause", "subclause", "paragraph", and "annex" in this document are to be interpreted as  
267 described in [ISO/IEC Directives, Part 2](#), Clause 6.

268 The terms "normative" and "informative" in this document are to be interpreted as described in [ISO/IEC](#)  
269 [Directives, Part 2](#), Clause 3. In this document, clauses, subclauses, or annexes labeled "(informative)" do  
270 not contain normative content. Notes and examples are always informative elements.

271 Refer to [DSP0240](#) for terms and definitions that are used across the PLDM specifications. For the  
272 purposes of this document, the following additional terms and definitions apply.

### 273 **3.1**

#### 274 **Cable**

275 one of: Active copper, Passive-Copper, Optical fiber of an AOC, optical fiber connected to an AOC  
276 module

### 277 **3.2**

#### 278 **Break-out Cable**

279 a set of physical cables which are connected to the same connector. Breakout cable is a physical cable  
280 type.

### 281 **3.3**

#### 282 **Communication channel**

283 a logical representation of a networking connection path that conveys information between physical  
284 entities as described in 6.6.5.

### 285 **3.4**

#### 286 **Connector**

287 a physical element which is part of the NIC. A pluggable Module is connected to the NIC by a physical  
288 connection to the connector.

### 289 **3.5**

#### 290 **Interconnect**

291 a physical connection between a pluggable module and a connector on the NIC

### 292 **3.6**

#### 293 **NIC**

294 Network Interface Card (NIC). A NIC is an entity in a system that provides network connectivity to the  
295 system. The network can be of any type, such as Ethernet, Fibre-Channel, InfiniBand or any other type.

### 296 **3.7**

#### 297 **Pluggable Module**

298 a module which is plugged into the NIC network connection connector. Pluggable modules may be  
299 integrated with a cable as one unit or may be separate elements. A pluggable module can be an active  
300 device with embedded active-components, or it can be a passive device with none. The type of a  
301 pluggable module depends on the type of the physical connector for which it is designed.

### 302 **3.8**

#### 303 **LOM**

304 LAN-On-Motherboard, a NIC which is embedded on the motherboard.

305 **3.9**  
306 **Network Controller**  
307 an active device which includes the equivalent of MAC and PHY of the specific network connection, this  
308 device typically connects to a host CPU over a bus such as PCIe

309 **3.10**  
310 **Network Port**

311 a physical interface on a network controller, used to convey network-communication. The type of a  
312 network port depends on the type of the communication network to which it is connected.

313 **3.11**  
314 **PHY**

315 an electronic circuit, usually implemented as a chip, required to implement physical layer interface  
316 function.

317 **3.12**  
318 **Record Handle**

319 an opaque numeric value used to access individual PDR within the PDRs repository.

320 **3.13**  
321 **TID**

322 Terminus ID as defined in [DSP0240](#).

## 323 **4 Symbols and abbreviated terms**

324 Refer to [DSP0240](#) for symbols and abbreviated terms that are used across the PLDM specifications. For  
325 the purposes of this document, the following additional symbols and abbreviated terms apply.

326 **4.1**  
327 **NIC**  
328 Network Interface Card

329 **4.2**  
330 **LOM**  
331 LAN On Motherboard

332 **4.3**  
333 **PHY**  
334 Physical layer interface

## 335 **5 Conventions**

336 Refer to [DSP0240](#) for conventions, notations, and data types that are used across the PLDM  
337 specifications.

### 338 **5.1 Reserved and unassigned values**

339 Unless otherwise specified, any reserved, unspecified, or unassigned values in enumerations or other  
340 numeric ranges are reserved for future definition by the DMTF.

341 Unless otherwise specified, numeric or bit fields that are designated as reserved shall be written as 0  
342 (zero) and ignored when read.

### 343 **5.2 Byte ordering**

344 Unless otherwise specified, as for all PLDM specifications byte ordering of multibyte numeric fields or  
345 multibyte bit fields is "Little Endian" (that is, the lowest byte offset holds the least significant byte, and  
346 higher offsets hold the more significant bytes).

## 347 6 PLDM NIC Modeling overview

348 This document describes a modeling scheme for a NIC using PLDM for Monitoring and Control [DSP0248](#)  
349 semantics. The model is scalable, allowing consistent modeling of NICs with different configuration  
350 options such as the number of network-controllers, number of ports, and number of connectors. PLDM  
351 NIC Modeling supports different types of networks, including devices supporting multiple network-types  
352 concurrently.

353 While PLDM for Platform Monitoring and Control is a public standard, using the model as defined in this  
354 document simplifies interoperability by establishing a consistent schema. The model is also intended to  
355 serve as a template for modeling other system hardware elements.

356 The basic format that is used for sending PLDM messages is defined in [DSP0240](#). The format that is  
357 used for carrying PLDM messages over a transport-layer protocol or medium is given in companion  
358 documents to the base specification. For example, [DSP0241](#) defines how PLDM messages are formatted  
359 and sent using MCTP as the transport. PLDM NIC Modeling defines the data structures and their  
360 relations which together describe a given NIC hardware configuration and state.

361 The model supports the following:

- 362 • Consistent modeling of a NIC regardless of the specific configuration and resources count
- 363 • NIC hardware structure description
- 364 • Defining the group of resources used to form a network connection
- 365 • Associating a network connection to a specific controller and cable
- 366 • Representing any type of physical connection, including cables, break-out cables and backplane  
367 connections
- 368 • Reporting of configuration changes

369 Unlike static systems, a NIC use external connections. For that reason, the same NIC can operate in  
370 different settings depending on the combination of NIC hardware and connected network cable. This  
371 dynamism requires dynamic modeling capability. For NIC hardware that supports pluggable modules, the  
372 model reflects both the NIC hardware as well as any connected pluggable modules. A NIC may support a  
373 backplane-connection; in this case, no pluggable module exists. The model equally supports these  
374 different hardware configurations.

375 The model is hierarchical, with each subgroup including elements grouped to form a physical element.

### 376 6.1 Model elements

#### 377 6.1.1 Terminus Locator(s)

378 PLDM for Platform Monitoring and Control defines a single root for every model, referred to as Terminus  
379 Locator.

380 In a typical implementation of PLDM for Platform Monitoring and Control, the network controller is the  
381 active component which communicates with the MC. The network controller is therefore serving as a  
382 terminus locator. When there are multiple Network controllers assembled on the same card, there is no  
383 single device which reports all the sensors of all the elements in the system to the MC.

384 PLDM for Platform Monitoring and Control does not allow associating components reported via different  
385 TIDs since every database is relative to a given TID. To overcome this constraint, the standard method  
386 allowing the MC to correctly associate multiple TIDs to the same NIC hardware requires the use of PLDM  
387 for FRU ([DSP0267](#)). When the MC reads multiple TIDs and observes the same board part number and

388 serial number and thus the same globally unique ID, it can recognize these TIDs as belonging to the  
389 same card.

390 All PLDM model IDs used in a given card shall be consistent across all TIDs. This avoids conflict from  
391 duplication of IDs in the combined model, generated by merging the TID-specific model elements  
392 reported as part of the overall model.

### 393 **6.1.2 NIC**

394 In this model, the NIC is the top-level element of the hierarchy.

395 When modelling a LOM (LAN On Motherboard) instead of a NIC, instead of being part of the system  
396 level, the NIC model will be defined as part of the system main board (Type-ID 64 in DSP0249). In this  
397 case, a NIC will not be a stand-alone card (Type-ID 68) but will rather be declared as a module (Type-ID  
398 62) which is part of the motherboard.

### 399 **6.1.3 Network controller**

400 The network controller is an active component which performs the networking control function of either  
401 MAC and PHY layers or only the MAC layer. A network controller always includes at least one network  
402 port.

403 A controller contains sensors for its health state, power-consumption, and temperature. The temperature  
404 of a network controller can be reported by one or more temperature sensors typically located in thermally  
405 sensitive areas on the card. In addition, state sensors for each of the MAC elements is monitored for link  
406 state, link speed, and link type.

407 Network controllers with more than one network interface port are modeled with a separate set of sensors  
408 for each port. In this case each port will be monitored independently through its set of sensors.,

409 The first network controller in a NIC reports all NIC level sensors under its terminus ID.

### 410 **6.1.4 Connector**

411 The connector is a physical component into which a cable or a pluggable module may be attached. In a  
412 typical use case, the connector is accessible through the system front or rear panel to allow the  
413 connection of a pluggable module. A connector is only included in the model of a NIC that is using that  
414 connector. Therefore connector is included in the model only when the network is physically connected  
415 via a [Pluggable module](#) or a [cable](#). When using a backplane connection there is no connector in the  
416 model.

### 417 **6.1.5 Pluggable module**

418 A pluggable module is the element which is plugged into the NIC network connector. Pluggable modules  
419 and the cables connected to them may be modeled as a single compound unit or be composed of  
420 separate elements. A pluggable module can be active or passive. When there is a pluggable module, the  
421 presence of the module is reported in the model via a state sensor. When active, supporting pluggable  
422 module reports, the power envelope and temperature of the module.

### 423 **6.1.6 Cable**

424 A cable is a passive element used to connect the network signal from a pluggable module or connector to  
425 the network. A cable can be electrical (such as copper) or optical (such as fiber-optic). Cables do not  
426 typically include any sensors and do not have presence indication; therefore, their state cannot be  
427 reported by any sensor. For this reason, when using a passive cable, such as RJ45, connected without a  
428 pluggable module, there is no way to report the cable presence, health, or temperature. Some DSP

429 based PHY devices may sense a cable presence allowing to report the presence state of a cable  
430 indirectly.

### 431 **6.1.7 Break-out cable**

432 A break-out cable is a group of network cables connected to the same pluggable module at one end with  
433 the other end of each cable is connected to a potentially separate pluggable module. When break-out  
434 cable is used, the model includes multiple cables which are all connected through the same pluggable  
435 module. When using a break-out cable, multiple communication channels are associated with the same  
436 break-out cable. Each of these channels is assumed to use a separate cable within the break-out cable.

### 437 **6.1.8 Backplane connection**

438 A backplane connection refers to a network connection that does not use a pluggable module or any  
439 physical cables. When using a backplane connection, the network connection signals are carried through  
440 a connector on the NIC to the system. When a backplane connection is used, there is no associated  
441 cable and there is no other sensor to reflect the physical connection state. As there is no additional  
442 monitor and control information in the connection to the backplane, there is no need to reflect this  
443 connector in the model.

## 444 **6.2 Model sensors**

445 Attributes are reported by means of sensors. Numeric sensors are used to report specific measured  
446 attribute. State sensors report operational and/or health state.

### 447 **6.2.1 NIC temperature sensor**

448 Temperature sensors in the NIC reports the card's physical temperature. There may be multiple  
449 temperature sensors installed on the PCB.

450 The temperature sensor is a numeric sensor. It is not included in the NIC container PDR as sensors are  
451 defined by directly referencing the entity being measured.

### 452 **6.2.2 NIC power sensor**

453 The power sensor in the NIC reports the estimated or measured aggregate power consumption of all the  
454 different elements included in the model. This includes mainly the network controller and the pluggable  
455 modules power. A NIC which cannot accurately report its real-time power shall report its expected  
456 maximal power at the respective operating mode. When there are multiple network controllers on the  
457 same NIC, there may be no visibility for any network controller to the real-time information of the other  
458 network controllers. For this reason, this sensor is only available when there is only one network controller  
459 in the NIC, or when there is a hardware sensor which does allow measuring and reporting the total power  
460 consumption. Note that network controllers which cannot report real-time information may report the  
461 expected maximal power for the operating mode in use.

### 462 **6.2.3 NIC FAN speed sensor**

463 The NIC FAN speed sensor reports the speed of an active cooling FAN. A NIC may have multiple FANs  
464 installed on the PCB, each with its own speed sensor. The thresholds reported for this numeric sensor  
465 shall be set by the hardware vendor.

#### 466 **6.2.4 NIC composite state sensor**

467 A composite state sensor is used to report the NIC thermal state, configuration state, and aggregate  
468 health state of all the components included in the reported database. The reported aggregate health state  
469 reflects the worst of the reported health states for each one of the elements monitored in the model.

470 When there are multiple network controllers, there may be no visibility from any network controller to the  
471 real-time information of other network controllers. For this reason, the composite state sensor is only  
472 available when there is only a single network controller in the NIC or when the reporting network  
473 controller has the needed visibility.

474 The configuration state reported in this sensor relates to the change of pluggable modules or to the  
475 network controller device. When a pluggable module is inserted or removed, the card configuration  
476 changes.

477 The NIC thermal state sensor, NIC configuration state sensor, and the NIC health state sensor are  
478 collected into the NIC composite state sensor.

#### 479 **6.2.5 Network controller temperature sensor**

480 The temperature sensor of the network controller reflects the device temperature at a physical location.  
481 The thresholds used by the sensor to define its normal, warning, critical, and fatal ranges are design  
482 specific and should be defined by the device manufacturer.

#### 483 **6.2.6 Network controller power sensor**

484 The network controller power sensor reflects the present value of the device power consumption. The  
485 thresholds which may be used by the sensor to define its normal, warning, critical, and fatal ranges are  
486 design specific and should be defined by the device manufacture.

487 Note that network controllers that cannot report real-time information may report the expected maximal  
488 power for the operating mode in use.

#### 489 **6.2.7 Network controller composite state sensor**

490 The network controller's composite state sensor reports the operational state of the network controller.  
491 The use of composite state sensor allows combining multiple metrics into a single sensor with a complete  
492 view of the operational and health state of the controller. The MC can use this sensor to identify issues  
493 with the controller and to identify the specific maintenance operations that need to perform. These  
494 operations may include network controller reset, system-level shut-down for thermal protection, and other  
495 system-level maintenance.

496 Using the configuration change indication, the network controller notifies the MC to retrieve PDRs  
497 updated by the configuration change.

498 When FW Update is detected, the composite state sensor can reflect this event to the MC, allowing the  
499 MC to take any action needed to respond to the update. Note that reading the new FW version shall be  
500 performed by the MC using protocols other than PLDM for Platform Monitoring and Control, such as  
501 [DSP0257](#) and/or [DSP0267](#). Please note that FW update only reflects the conclusion of the FW  
502 programming operation; it is device-specific whether this detection additionally implies that new FW is  
503 already active.

#### 504 **6.2.8 Network port link speed sensor**

505 The network port may operate at various communication speeds. This numeric sensor is used to report  
506 the actual operating link speed.

507 **6.2.9 Network port link state sensor**

508 A state sensor is used to reflect the operational state of the port. The MC uses the attributes reported by  
 509 this sensor to monitor the state of the port. Possible states for the link are Connected and Disconnected  
 510 as defined in [DSP0249](#).

511 **6.2.10 Pluggable module temperature sensor**

512 This sensor reflects the pluggable module temperature. The thresholds used to define the thermal  
 513 operating ranges are read from the module parameters. Note that due to some terminology gaps between  
 514 SFF and DMTF PLDM for Platform Monitoring and Control, some terms require translation as shown in  
 515 Table 1.

516 **Table 1 – SFF8636 and DSP0248 thresholds definitions**

<a href="#">SFF8636 / SFF8472</a>	DSP0248	Description
Warning	Warning	The reading is outside of normal expected operating range but the monitored entity is expected to continue to operate normally.
Alarm	Critical	The reading is outside of supported operating range. Monitored entities might operate abnormally, have transient failures, or propagate errors to other entities under this condition. Prolonged operation under this condition might result in degraded lifetime for the monitored entity.
N/A	Fatal	The reading is outside of rated operating range. Monitored entities might experience permanent failures or cause permanent failures to other entities under this condition.

517 **6.2.11 Pluggable module power sensor**

518 Power reporting for the pluggable module shall use the information from the module itself. As a reference,  
 519 [SFF8636](#) and [SFF8472](#) defines power classes that can be used to report the expected maximal power  
 520 consumption of the modules. If there is a module that can report its actual real-time power consumption,  
 521 this information should be used as it provides more accuracy.

522 **6.2.12 Pluggable module composite state sensor**

523 The composite state sensor within the pluggable module is used to report the overall operational state for  
 524 the pluggable module. This sensor reports the pluggable module’s presence as well as its temperature  
 525 operational state and the pluggable module health state.

526 **6.3 Hierarchy description of the NIC model elements**

527 PLDM NIC Modeling uses a hierarchical model. The hierarchy is described using two types of  
 528 associations as described in the following clauses. Associating entities is done hierarchically, by  
 529 associating the containing entities rather than associating all the contained entities within that container.

530 In PLDM modeling, except for the entity that represents an overall system, all entities are contained within  
 531 at least one other physical entity. Each level within the resulting hierarchy is an individual numeric space.

532 Identification of the numeric space in which a given element in the hierarchy is declared uses a parameter  
 533 called the container ID. Container ID is defined as an opaque number that identifies the containing Entity

534 that the Instance number is defined relative to. If this value is 0x0000, then the containing Entity is  
 535 considered to be the overall system.

536 An entity association PDR uses 3 references to container IDs:

- 537 • containerID – An opaque number that identifies a particular container entity in the hierarchy of  
 538 containment.
- 539 • containerEntityContainerID – a reference to the higher level that contains the declared  
 540 namespace. The top-level PDR shall always use containerEntityContainerID=0 (System)
- 541 • containedEntityContainerID – a reference to the numeric space at which a contained entity is  
 542 instantiated.

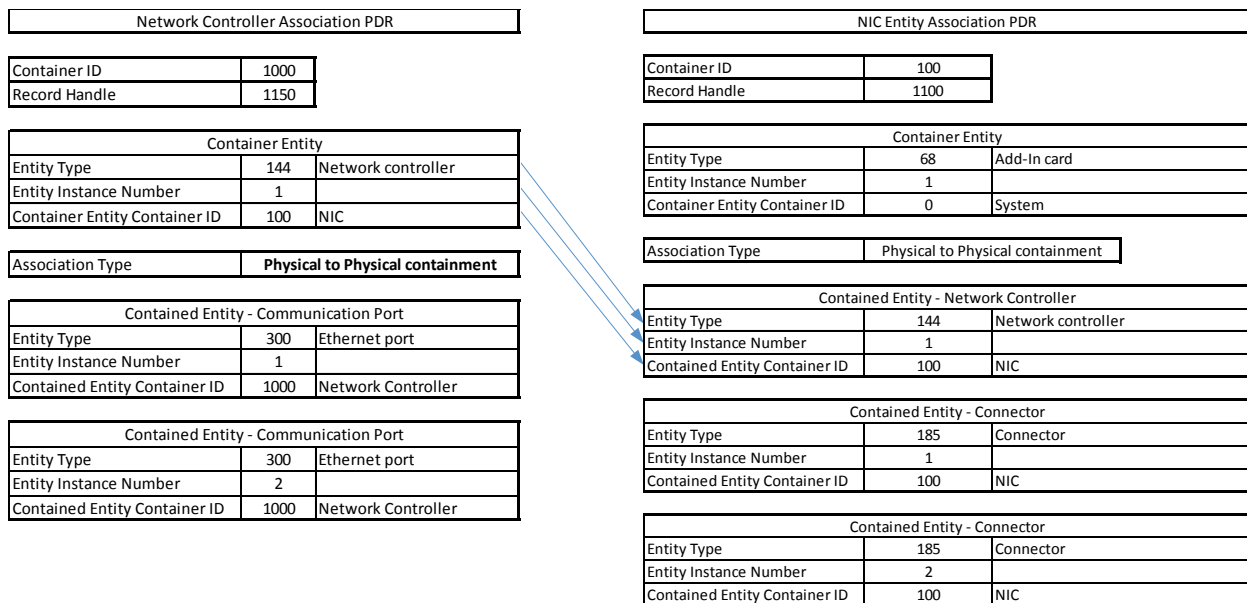

543 **6.3.1 Physical entities association**

544 Physical association is defined in DSP0248 as a method to associate components which are physically  
 545 connected to each other. The model uses this concept to describe the following structures:

- 546 • Content of the NIC PCB
- 547 • Content of the network controllers
- 548 • Content of a pluggable module, including the associated cable(s) of that module
- 549 • Association of a pluggable module with the connector into which it is plugged

550 A hierarchy entity is defined using an entity association PDR identified with a unique **containerID**  
 551 identifier parameter. The entity association PDR’s **containerEntityContainerID** references the PDR in  
 552 which the entity is contained.

553 Figure 1 shows how a contained entity PDR references its containing entity PDR:

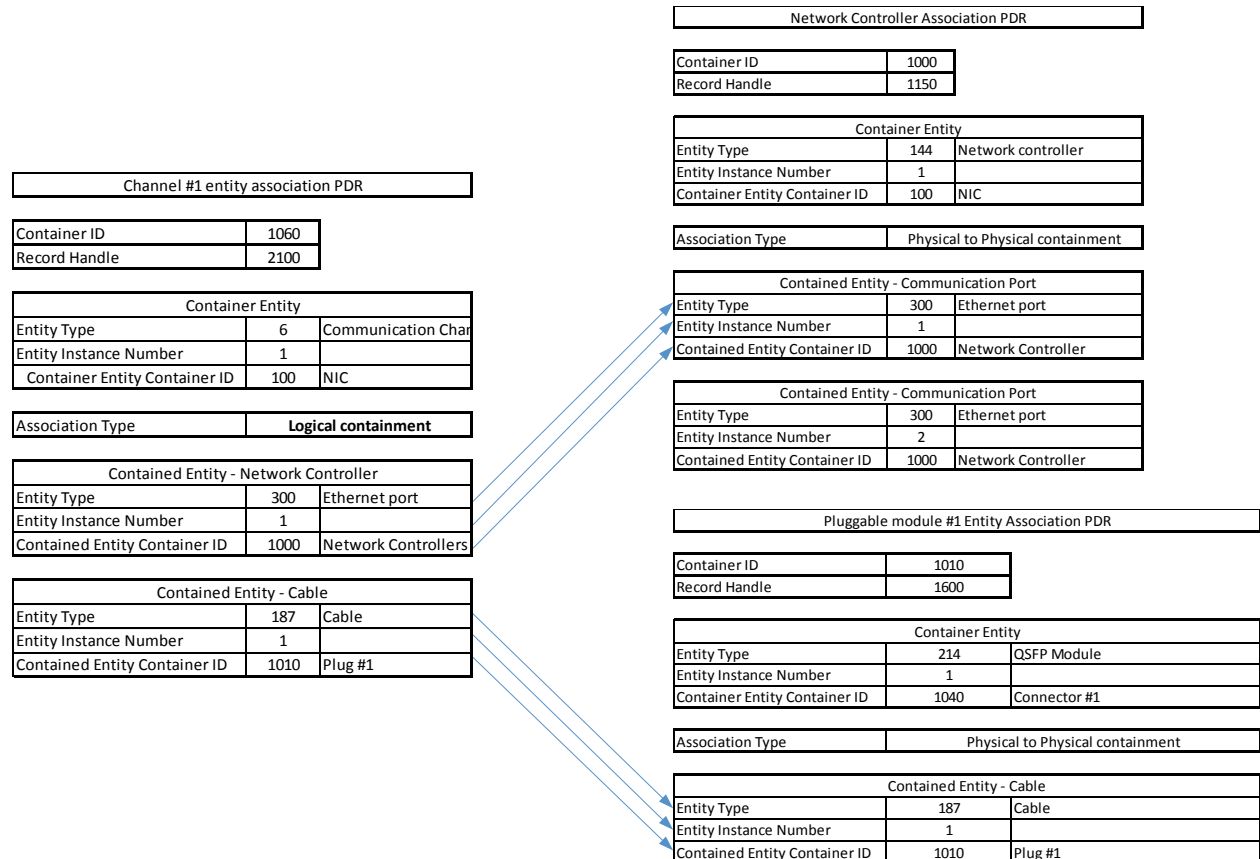

554  
 555 **Figure 1 – Hierarchy description using containerEntityContainerID referencing the**  
 556 **containedEntityContainerID**

557 **6.3.2 Logical entity association**

558 Logical association is defined in [DSP0248](#) as a method to associate components which collectively form  
 559 a shared property yet are not physically part of the same component. This model uses logical association  
 560 to describe the following structures:

- 561 • Sharing a MAC, PHY (if on a separate device than the MAC), and cable to form a network  
 562 connection

563 Figure 2 shows logical association between a network controller’s Ethernet network port and a cable  
 564 within a pluggable module:

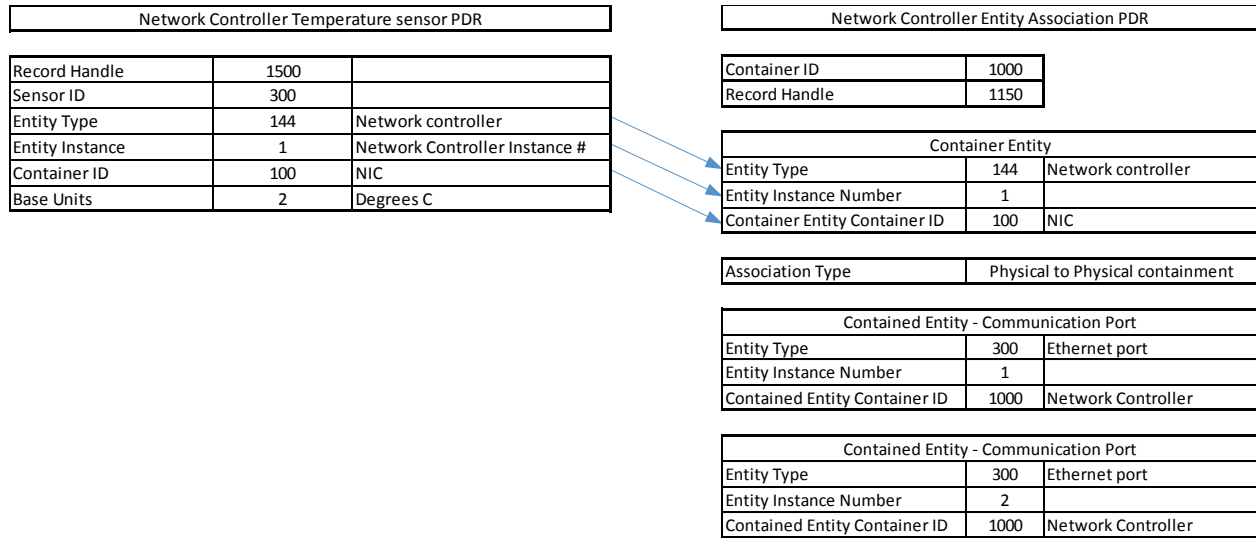

565

566 **Figure 2 – Defining a communication channel using logical association**

567 **6.3.3 Sensors association**

568 Associating a numeric sensor to the measured entity is done by directly referencing the measured entity  
 569 in an entity association PDR with its containedEntityContainerID, containedEntityType, and  
 570 containedEntityInstanceNumber. A sensor is identified by a unique Sensor ID value. In PLDM for Platform  
 571 Monitoring and Control, numeric and state sensors are not included in entity association PDRs.

572 Figure 3 illustrates the association of a temperature sensor to a network controller in the model:

573

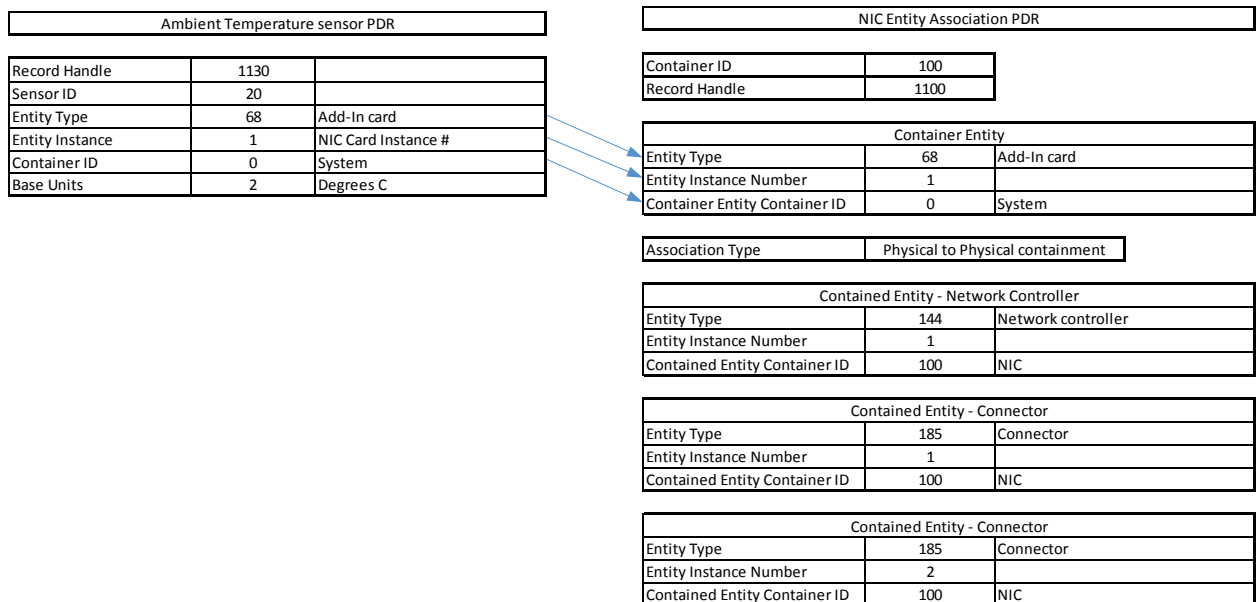

574

Figure 3 – Sensor association

575 **6.3.3.1 Associating a sensor at the top level**

576 When associating a sensor to the top-level entity which is the system the association uses the top-level  
 577 **containerEntityType containerEntityInstanceNumber** and **containerEntityContainerID** parameters.

578 Figure 4 illustrates the association of a temperature sensor to the NIC in the model.

579

580

Figure 4 – Top-level sensor association

581 **6.4 Element PLDM Type IDs**

582 The model uses the following Type ID for each component in the model, selected from the available types  
 583 defined in [DSP0249](#). The following table lists the chosen Type IDs used in the model:

584

**Table 2 – Type IDs used in the NIC model**

Component	Type ID
Communication channel	6
NIC <sup>1)1)</sup>	68/62
Network controller	144
Connector	185
Cable	187
QSFP Module <sup>1)3), 1)4)</sup>	214
Ethernet port <sup>1)2), 1)5)</sup>	300

585 Notes:

- 586 1) The Type ID for the NIC is 68. If the NIC is a LOM, then Type ID 62 shall be used, as described  
587 in 6.1.2.
- 588 2) The Type ID for the network controller ports shall match the type of network that is in use. The  
589 example in the above table relates to an Ethernet network.
- 590 3) The Type ID which identifies the pluggable module type, shall match the actual type of the  
591 pluggable module.
- 592 4) QSFP is used as an example. For additional types of pluggable modules types see [DSP0249](#)
- 593 5) Ethernet port is used as an example. For additional types of network port connection types see  
594 [DSP0249](#)

595 **6.5 Enumeration**

596 PLDM for Monitoring and Control uses enumerated IDs to define elements in the database. These IDs  
597 are labeled as:

- 598 • Container ID – unique for each container PDR in the model database
- 599 • Instance ID – unique for each entity type within a given hierarchy level
- 600 • Handle ID – unique ID for each PDR in the model database
- 601 • Sensor ID – unique for each sensor in the model database

602 The proposed model provides an example enumeration scheme for these IDs, allowing a reasonably  
603 scalable formulation.

604 **6.5.1 Enumeration scheme**

605 The model assumes some maximal limits to define the enumerated values. These limits were chosen  
606 based on industry practice, which restricts the number of network controllers, connectors, and sensors  
607 used in the same NIC hardware. These limits are provided as an example and can be adjusted according  
608 to the specific NIC requirements.

609 The example model enumeration is designed to support a NIC that does not exceed the following limits:

610

**Table 3 – Chosen enumeration limits in the model**

<b>Model Limit</b>	<b>Value</b>
Max network controllers	10
Max connectors count	20
Max board temperature sensors	10
Max temperature sensors/controller	10
Max temperature sensors/plug	10

611 **Note:**

612 If one of the above limits is insufficient for a NIC, only the enumerated values will be affected; the model  
 613 structure will not have to change.

614

615 Table 4 illustrates the enumeration scheme, calculated based on the above limits.  
616

617

**Table 4 – Example Enumeration Scheme with Type IDs**

Item	Max count	Container ID	Container ID	Base Handle	Max Handle	Base Sensor ID	Max Sensor-ID	Base Instance	Max instance	Type-ID
NIC	1	100		1100				1	1	68
Card Composite State Sensor	1			1101	1101	5	5	1	1	68
NIC Power Sensor	1			1102	1102	6	6		1	68
Connectors	20	1040	1059	1110	1129			1	4	185
NIC Temp sensors	10			1130	1139	20	29		10	68
NIC FAN speed sensor	10			1140	1149	30	39		10	68
Network Controllers	10	1000	1009	1150	1159			1	10	144
Network Controller power	1			1160	1169	50	59	1	1	144
Network Controller State	1			1170	1179	60	69	1	1	144
Ports of Network Controller	10			1200	1299			1	2	300
Link speed of network controller	10			1300	1399	100	199		2	300
Port State of network controller	10			1400	1499	200	299		2	300
Temp sensors per network controller	10			1500	1599	300	399		10	144
Plugs	20	1010	1029	1600	1619			1	2	214
Plug Power Sensor	20			1700	1719	400	419			214

**620 6.6 Model illustration**

621 The PLDM NIC model is hierarchical model. The following subclauses describe the model for each of the  
 622 hierarchy levels:

623

624

Figure 5 – NIC PLDM model diagram

625 **6.6.1 NIC**

626 The NIC level contains the PCB card, network controllers, connectors, and one or more thermal sensors.  
 627 The PCB power consumption is represented with a power sensor. The NIC operational state is  
 628 represented by a composite state sensor. When there are multiple network controllers on the same card,  
 629 NIC sensors are typically only reported by the first network controller. Note that the top-level health state  
 630 sensor relates to card level sensors and may not reflect the health states of network controllers beyond  
 631 the first.

632 **6.6.2 Network controller**

633 The network controller hierarchy represents the active device (or one of multiple devices) that performs  
 634 the network control interface (such as the MAC and PHY layers). A network controller is represented as a  
 635 collection of ports and sensors associated with the controller as well as sensors associated with specific  
 636 network ports. Each port has its own set of sensors.

637 **6.6.3 Pluggable module**

638 Pluggable module is the element attached to the NIC connector that optionally includes the electronics of  
 639 the network cable. In single link module, a pluggable module is attached to one cable. When a breakout  
 640 cable is used, the same pluggable module is connected to multiple cables, each carrying an independent  
 641 network link.

642 The pluggable module is represented as a set of sensors, which reflect its operational state and power  
 643 consumption, and cables. Since the pluggable module is not part of the PCB, it may be attached or  
 644 detached from the NIC dynamically. The model reflects this occurrence with a PLDM configuration  
 645 change event. Configuration change events can be used to reflect both insertion and removal of a  
 646 pluggable module.

647 While a pluggable module is disconnected from the NIC, a query to the pluggable module numeric  
 648 sensors (power and temperature) shall be responded to with *sensorOperationalState* set to *unavailable*  
 649 as defined in [DSP0248](#). Note that when a pluggable module is (re-)inserted into a connector, a  
 650 configuration change event directs the MC to re-read the PDRs of the new module. This ensures that the  
 651 MC sees the parameter settings for the newly inserted module.

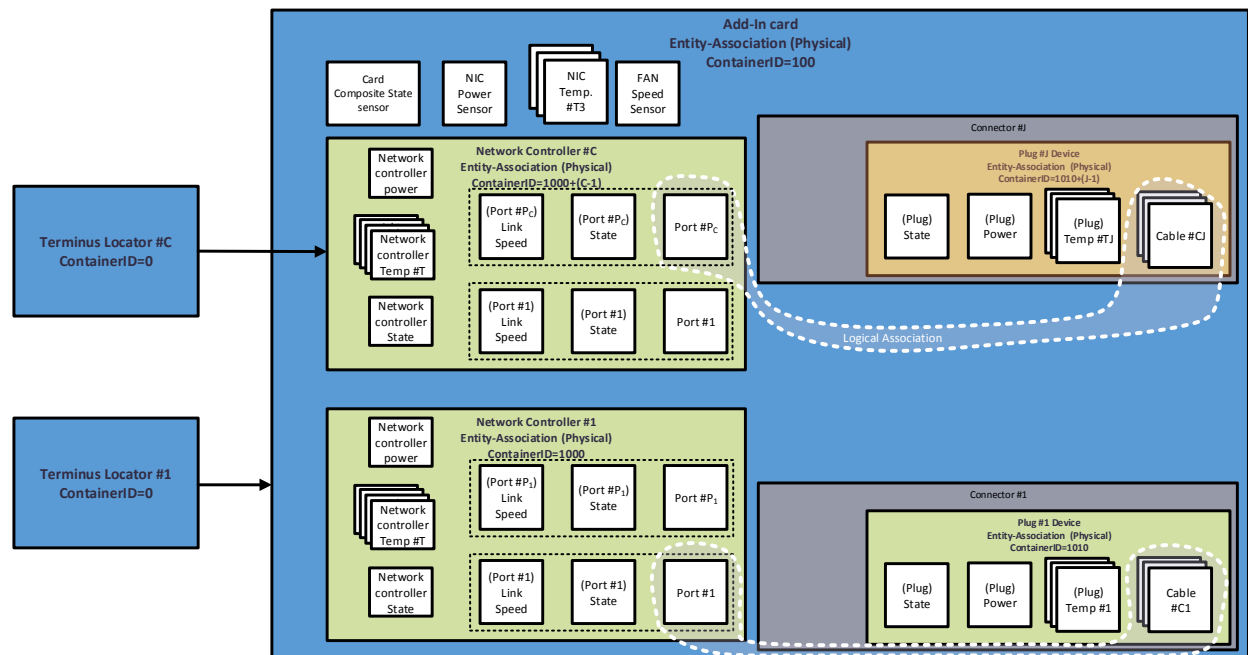

652 **6.6.4 Associating a pluggable module with connector**

653 A pluggable module is physically attached to a specific connector on the PCB. To reflect this physical  
 654 connection, the NIC model includes the pluggable module in the respective connector entity association  
 655 PDR using physical association.

656 **6.6.5 Associating a cable with a network port**

657 A given cable is used to carry the traffic of a specific port on a given network controller. The network port  
 658 is embedded within a given network controller, and the cable is attached to a given pluggable module. As  
 659 there is no physical direct connection between the network port and the cable, the logical connection  
 660 between the cable and the network port is declared as a communication channel. This declaration is  
 661 performed using a communication channel entity association PDR, with association type set to logical  
 662 association. As described in clause 6.1.8, cables are not included in the model when using a backplane  
 663 connection.

664 Figure 6 illustrates a logical association of a cable and a network port:

665

666 **Figure 6 – Cable and network port entity association**

667 The cable is a contained entity within the pluggable module. To associate the cable from a pluggable  
 668 module to the correct network port, the communication channel entity association PDR associates the  
 669 port entity in the network controller with the cable in the pluggable module.

670 Notes:

- 671 1) When a cable with no pluggable module is used (such as an RJ45 cable) there is no pluggable  
 672 module defined, and the cable is declared as directly attached to the connector. In this case, the  
 673 association of the cable to the network controller's network-port should be adjusted accordingly.

- 674 2) Even though every hierarchy is an independent numeric space, the example uses unique  
675 instances for the cables to allow matching the cable number to the marking on the NIC bracket.

## 676 6.7 Events

677 The model supports using PLDM events as a method to notify the MC upon changes to a model setting or  
678 to any of the model PDRs. The following events can be used with the model:

### 679 6.7.1 Network controller configuration change

680 This event indicates to the MC that some of the configuration parameters of the network controller have  
681 changed. Such changes could relate to link settings and/or enablement of a network port. The MC may  
682 use the *GetPDRRepositoryInfo* command and check if the *timestamp* parameter value has changed  
683 since it read the PDRs. The MC may update the whole PDRs repository by re-reading all the PDRs, or  
684 only update its repository. The value used for the *timestamp* shall be a virtual time value initialized by the  
685 network controller at device initialization.

686 An alternative approach for the MC to track PDRs change is using the newly defined  
687 *pldmNewPDRAdded*, *pldmExistingPDRDeleted* and *pldmPDRRepositoryChgEvent* platform events.

688 The MC should re-read any changed PDRs to get the new information.

### 689 6.7.2 Pluggable module insertion and removal notification

690 This event is important to notify the MC on pluggable module presence change. It is needed for both  
691 thermal threshold management as well as for module's presence indication. When the MC receives  
692 notification of new pluggable module insertion it shall read the parameters of the newly inserted pluggable  
693 module as it may have different power class information and/or thermal thresholds. Note that while the  
694 model reflects common sensors for pluggable modules, there could be additional sensors outside the  
695 scope of this document. Additionally, when changing from a single-cable pluggable module to one with a  
696 break-out cable, the whole NIC configuration may have to change accordingly. This may induce a change  
697 in the PDR repository.

698 As described in clause 6.1.8, pluggable modules are not included in the model when using a backplane  
699 connection.

### 700 6.7.3 Health and state sensors events notifications

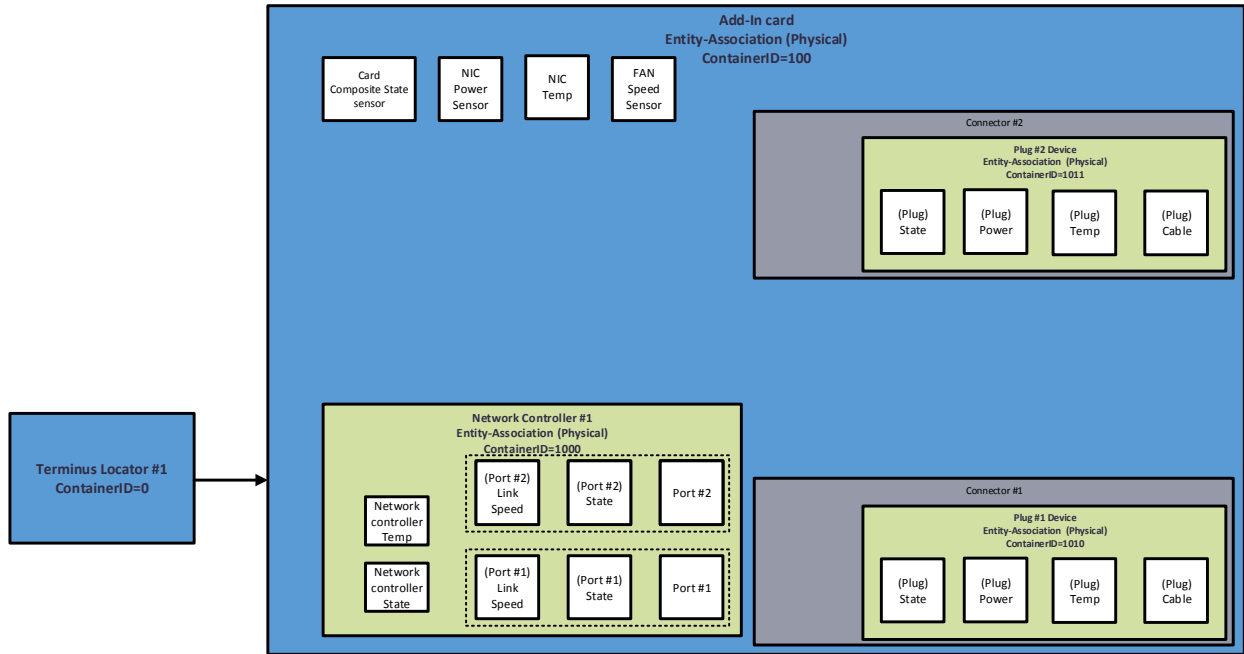

701 The NIC may report a change to any of its health or state sensors using a PLDM state or numeric sensor  
702 event. Providing such a notification can significantly shorten the response time, compared to waiting for  
703 the MC to poll the sensors, for an occurrence that requires the MC to take an action such as increasing  
704 the airflow from a cooling FAN.

705 **7 Model use example**

706 The following example for modeling a NIC using PLDM for Platform Monitoring and Control describes a  
 707 NIC with the following attributes:

- 708 • Dual-port NIC
- 709 • Single Network controller
  - 710 – Dual Ethernet port
  - 711 – Single on-chip temp sensor
- 712 • Single ambient temperature sensor on the PCB
- 713 • A QSFP pluggable module is attached to each network connector
  - 714 – The QSFP pluggable module has a single temp sensor and a single cable

715 Figure 7 illustrates the model which is used in the example.

716

717

**Figure 7 – Example model diagram**

718 **7.1 Model hierarchy**

719 The model PDRs identify the elements depicted in Figure 5. The hierarchies are illustrated in the following  
 720 diagram. For simplicity, Figure 8 does not show sensors. The physical connections between pluggable  
 721 modules and their corresponding connectors are modeled using physical entity association. The linkages  
 722 between cables and their corresponding network ports to form the communication channels are modeled  
 723 using logical entity association.

724

725

Figure 8 – NIC model hierarchy

726 **7.2 Top-level TID**

727 The terminus ID is identified by the terminus locator PDR. The TID defines the top-level entry point to the  
 728 PLDM model. Because there is only one network controller on the NIC, there is only one TID in this  
 729 example.

730

Table 5 – TID PDR

Field name	Value	Description
Container ID	0	System
TID		Assigned by System
Record Handle	10	Opaque number
Terminus Locator Size	1	Size of(EID) or size of(UUID)
Terminus Locator Type	1/0	MCTP EID/RBT UID
EID	EID	MCTP assigned EID Value
UID	UID	Vendor provided UUID format value

731 The TID value is assigned to the terminus by the system controller. When the transport layer is MCTP  
 732 then the identification of the terminus is performed using the Endpoint ID (EID) value. When using PLDM  
 733 over RBT the terminus locator PDR shall use the UID (instead of EID). The UID value in the terminus  
 734 locator PDR uses the device UUID value as the termini UID, for more information regarding terminus  
 735 locator PDR see [DSP0248](#).

736 **7.3 NIC**

737 The top level of the model is the NIC level. The NIC includes the physical elements which are the network  
 738 controller (only one controller in this example) and the connectors.

739

Figure 9 – NIC level elements

740

741 The sensors in the NIC level are described using a reference to the measured entity, independently of the  
 742 container that includes all the physical elements on the NIC.

NIC Entity Association PDR		
Container ID	100	
Record Handle	1100	
Container Entity		
Entity Type	68	Add-In card
Entity Instance Number	1	
Container Entity Container ID	0	System
Association Type		
	Physical to Physical containment	
Contained Entity - Network Controller		
Entity Type	144	Network controller
Entity Instance Number	1	
Contained Entity Container ID	100	NIC
Contained Entity - Connector		
Entity Type	185	Connector
Entity Instance Number	1	
Contained Entity Container ID	100	NIC
Contained Entity - Connector		
Entity Type	185	Connector
Entity Instance Number	2	
Contained Entity Container ID	100	NIC

**Figure 10 – NIC container PDR**

743

744 Note that the NIC's ID, 100, will be referenced by the sensors not included in the entity association PDR.  
 745 The enumeration model shown in

746 Table 4 includes the container ID for every hierarchy level.

747 **7.3.1 NIC power sensor**

748 The NIC power sensor is a numeric sensor. It is not included in the NIC container PDR as sensors are  
749 defined by directly referencing the entity being measured.

750 Using a Container ID value of 100 implies that this PDR is reporting a sensor that is part of the container  
751 ID 100, which in this model relates to the NIC level shown in Figure 7.

752

NIC Power sensor PDR		
Field	Value	Description
Record Handle	1102	
Sensor ID	6	
Entity Type	68	Add-In card
Entity Instance	1	NIC Instance #
Container ID	0	System
Base Units	7	Watt
Unit Modifier	-1	0.1Watt resolution

753

Figure 11 – NIC power sensor PDR

754 **7.3.2 NIC temperature sensor**

755 The NIC temperature sensor reports the card’s temperature. While it is possible to have multiple  
756 temperature-sensors installed on the PCB, this example has only one.

757 The temperature sensor is a numeric sensor. It is not included in the NIC container PDR as sensors are  
758 defined by directly referencing the entity being measured.

759

Ambient Temperature sensor PDR		
Field	Value	Description
Record Handle	1130	
Sensor ID	20	
Entity Type	68	Add-In card
Entity Instance	1	NIC Instance #
Container ID	0	System
Base Units	2	Degrees C

760

Figure 12 – Ambient Temperature sensor PDR

761 Using a Container ID value of 100 implies that this PDR is reporting a sensor that is part of container ID  
762 100, which in this model relates to the NIC level shown in Figure 7.

763 **7.3.3 NIC FAN speed sensor**

764 The FAN speed sensor in the NIC reports the fan speed of an active cooling FAN. While it is possible to  
765 have multiple FANs installed on the PCB, each with its own speed sensor, this example has only one.

766 The FAN speed sensor is a numeric sensor. It is not included in the NIC container PDR as sensors are  
767 defined by directly referencing the entity being measured.

768

NIC FAN speed sensor PDR		
Field	Value	Description
Record Handle	1140	
Sensor ID	30	
Entity Type	68	Add-In card
Entity Instance	1	NIC Instance #
Container ID	0	System
Base Units	19	RPM
Unit Modifier	0	no need for scaling

769

**Figure 13 – FAN speed sensor PDR**

770 Using a Container ID value of 100 implies that this PDR is reporting a sensor that is part of container ID  
 771 100, which in this model relates to the NIC level shown in Figure 7.

772 **7.3.4 NIC composite state sensor**

773 The configuration state change reported in this sensor relates to changes in pluggable modules or in the  
 774 network controller device. When a pluggable module is inserted or removed, the card configuration  
 775 changes. In this example, there is a single network controller device, which allows complete visibility of  
 776 configuration changes from the NIC level. Invalid configuration is applicable to cases where the pluggable  
 777 module cannot be supported for any reason such as installing a pluggable module with breakout cable to  
 778 a card which does not support a breakout cable.

779 When there are multiple network controllers, it may not be possible to report an overall NIC configuration  
 780 state. In this case, the NIC configuration change and configuration state sensors should not be included  
 781 in the NIC composite state sensor.

782 The state sensor is not included in the NIC container PDR as sensors are defined by directly referencing  
 783 the entity being measured.

NIC composite State Sensor PDR		
Record Handle	1101	
Entity Type	68	Add-In card
Entity Instance Number	1	
Container Entity Container ID	0	System

Terminus Handle	0
Sensor ID	5
Composite Sensor Count	4

Sensor Type	1	Health state
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 4=Fatal	

Sensor Type	15	Configuration
Possible States	1=Valid Configuration, 2=Invalid Configuration	

Sensor Type	16	Configuration Change
Possible States	1=Normal, 2=Change in Configuration	

Sensor Type	21	Thermal Trip
Possible States	1=Normal, 2=Over-Temp Shutdown	

**Figure 14 – NIC composite state sensor PDR**

784

785 Using a Container ID value of 0 implies that this PDR is reporting a sensor that is part of the top level  
 786 container ID 0, which relates to the NIC level.

787 **7.3.5 NIC connectors**

788 The connectors in the model represent the physical elements into which pluggable modules are installed.  
 789 It is assumed that the instance IDs of the connectors will be set to match the port number as marked on  
 790 the hardware bracket. This ensures consistency between the physical marking and the logical reporting of  
 791 the PLDM model.

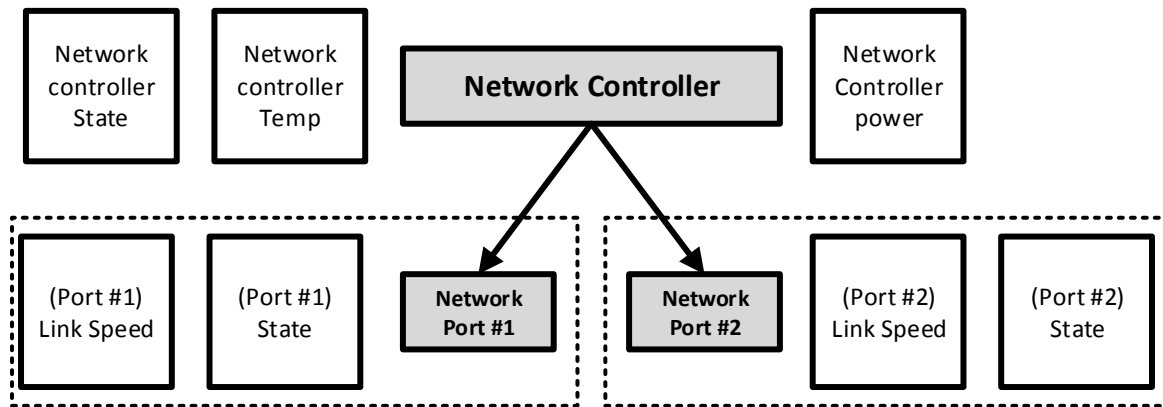

792 The connector type reflects one of the possible types of pluggable modules that can be used with the  
 793 specific NIC. The enumerated values used for connector types are defined in [DSP0249](#) in the PLDM  
 794 Entity ID Code Tables.

795 The connectors are part of the NIC physical elements and are thus included within the NIC container  
 796 PDR.

797 **7.4 Network controller**

798 The network controller is the active device in charge of the network connection. In the given example of  
 799 an Ethernet NIC the network controller device includes the MAC and PHY layers of the network ports.

800 Being a physical entity, the network controller is already declared within the NIC container PDR. The  
 801 content of the network controller includes a set of sensors related to the network ports, as well as a set of  
 802 device-level sensors. The following diagram illustrates the model elements for the network controller in  
 803 the example model:

804

805

**Figure 15 – Example model network controller**

806 The network controller content is declared using an entity-association PDR that includes the hierarchical  
 807 description of the network controller. The device-level sensors as well as the network port sensors are  
 808 declared with separate PDRs using direct references to the measured entities. The dotted lines in the  
 809 diagram are used to illustrate the association of the link and state sensors to their network port. In this  
 810 example use case the network port is an Ethernet port; for different network port types, the corresponding  
 811 port type ID should be used.

Network Controller Association PDR		
Container ID	1000	
Record Handle	1150	
Container Entity		
Entity Type	144	Network controller
Entity Instance Number	1	
Container Entity Container ID	100	NIC
Association Type		
Association Type	Physical to Physical containment	
Contained Entity - Communication Port		
Entity Type	300	Ethernet port
Entity Instance Number	1	
Contained Entity Container ID	1000	Network Controller
Contained Entity - Communication Port		
Entity Type	300	Ethernet port
Entity Instance Number	2	
Contained Entity Container ID	1000	Network Controller

812

**Figure 16 – Network controller association PDR**

813 The network controller is contained within the NIC level (ID 100) and has ID 1000. This creates a  
 814 hierarchy that allows sensors to be associated with the network controller, as described in the clauses  
 815 7.4.1, 7.4.3 and 7.4.4.

816 **7.4.1 Network controller temperature sensor**

817 The network controller temperature sensor reflects the device’s temperature. The thresholds that define  
 818 its normal, warning, critical and fatal ranges are design specific and should be defined by the device  
 819 manufacturer.

820

Network Controller Temperature sensor PDR		
Field	Value	Description
Record Handle	1500	
Sensor ID	300	
Entity Type	144	Network controller
Entity Instance	1	Network Controller Instance #
Container ID	100	NIC
Base Units	2	Degrees C

821

**Figure 17 – Network controller temp sensor PDR**

822 In this example there is only one temperature sensor on the device. There may be more than 1  
 823 temperature sensor in a given device. It is recommended that every network controller device contain at  
 824 least one temperature sensor to allow the MC to perform thermal monitoring and system control.

825 The container ID in this case is 100 which references the NIC, as defined in 7.4.

826 **7.4.2 Network controller power sensor**

827 The network controller power sensor reflects the present value of the device’s power consumption. The  
 828 thresholds which may be used by the sensor to define its normal, warning, critical and fatal ranges are  
 829 design specific and should be defined by the device manufacture.

830

Field	Value	Comment
Record Handle	1160	
Sensor ID	50	
Entity Type	144	Network controller
Entity Instance	1	Network Controller Instance #
Container ID	100	NIC
Base Units	7	Watt
Unit Modifier	-1	0.1Watt resolution

831

**Figure 18 – Network controller power sensor PDR**

832 Network controllers that cannot report real-time information may report the expected maximal power for  
 833 the present operating mode.

834 **7.4.3 Network controller composite state sensor**

835 The network controller’s composite state sensor reports the operational state of the network controller.  
 836 Composite state sensors aggregate multiple metrics into a single sensor that provides an overview of the

837 operational and health state of the controller. The MC can use this sensor to identify issues with the  
838 controller, as well as to identify which maintenance operations are required to be performed by the MC.  
839 Such operations may include reset to the network controller, system-level shut-down for thermal  
840 protection and other system-level maintenance operations.

841 Using the configuration change indication, the controller can trigger notification to the MC so that it can  
842 retrieve the updated PDRs which are affected by the configuration change.

843 When FW Update is detected, the composite state sensor can reflect this event to the MC, so that the MC  
844 can take the needed action to respond to the update. Note that reading the new FW version should be  
845 performed by the MC using protocols other than PLDM for Platform Monitoring and Control, such as  
846 [DSP0257](#) and/or [DSP0267](#). Please note that FW update only reflect the conclusion of the FW  
847 programming operation. It is device-specific dependent if this detection also implies that the new FW is  
848 already active or not.

849

Network Controller composite State Sensor PDR		
Record Handle	1170	
Entity Type	144	Network controller
Entity Instance Number	1	
Container Entity Container ID	100	NIC

Terminus Handle	0

Sensor Type	15	Configuration
Possible States	1=Valid Configuration, 2=Invalid Configuration	

Sensor Type	16	Configuration Change
Possible States	1=Normal, 2=Change in Configuration	

Sensor Type	21	Thermal Trip
Possible States	1=Normal, 2=Over-Temp Shutdown	

Sensor Type	18	Firmware Version
Possible States	1=Normal, 2=Version change detected - Compatible, 3=Version change detected Incompatible	

850

**Figure 19 – Network controller composite state sensor PDR**

851

The container ID in this case, 100, references the network controller defined in clause 7.4.

852

**7.4.4 Network controller Ethernet port**

853

The Ethernet network port is declared as an entity within the network controller. The sensors within the network controller that monitor a given channel are declared by directly referencing the corresponding port ID.

854

855

856 **7.4.4.1 Network controller port state**

857 A state sensor is used to reflect the operational state of the port. The following diagrams show composite  
 858 state sensors for the two network controller ports in the example NIC:

859

Network Controller Port #1 State Sensor PDR		
Record Handle	1400	
Entity Type	300	Ethernet port
Entity Instance Number	1	
Container Entity Container ID	1000	Network Controllers

Terminus Handle	0
Sensor ID	200
Composite Sensor Count	1

Sensor Type	33	Port State
Possible States	1=Connected, 2=Disconnected	

860

**Figure 20 – Network port 1 state sensor PDR**

861

Network Controller Port #2 State Sensor		
Record Handle	1401	
Entity Type	300	Ethernet port
Entity Instance Number	2	
Contained Entity Container ID	1000	Network Controllers

Terminus Handle	0
Sensor ID	201
Composite Sensor Count	1

Sensor Type	33	Port State
Possible States	1=Connected, 2=Disconnected	

862

**Figure 21 – Network port 2 state sensor PDR**

863 As can be seen from the PDR diagrams, links can be characterized as either connected or disconnected.  
 864 Note that the disconnected link state implies simply that the link operation is not enabled; in particular, it  
 865 does not imply that the physical link connection is disconnected.

866 The container ID in this case, 1000, references the network controller defined in clause 7.4.

867 **7.4.4.2 Network controller port speed**

868 The network port may operate at various communication speeds. This numeric sensor reports the actual  
 869 operating link speed.

870 The following diagrams show the link speed PDRs of the two network ports in the example:

871

Network controller link speed sensor Port #1 PDR		
Field	Value	Description
Record Handle	1300	
Sensor ID	100	
Entity Type	300	Ethernet port
Entity Instance	1	Port instance #1 in controller
Container ID	1000	Network Controller
Base Unit	60	Bits
Unit Modifier	6	Mbits
Rate Unit	3	Per Second

872

**Figure 22 – Network port 1 link speed sensor PDR**

873

Network controller link speed sensor Port #2 PDR		
Field	Value	Description
Record Handle	1301	
Sensor ID	101	
Entity Type	300	Ethernet port
Entity Instance	2	Port instance #2 in controller
Container ID	1000	Network Controller
Base Unit	60	Bits
Unit Modifier	6	Mbits
Rate Unit	3	Per Second

874

**Figure 23 – Network port 2 link speed sensor PDR**

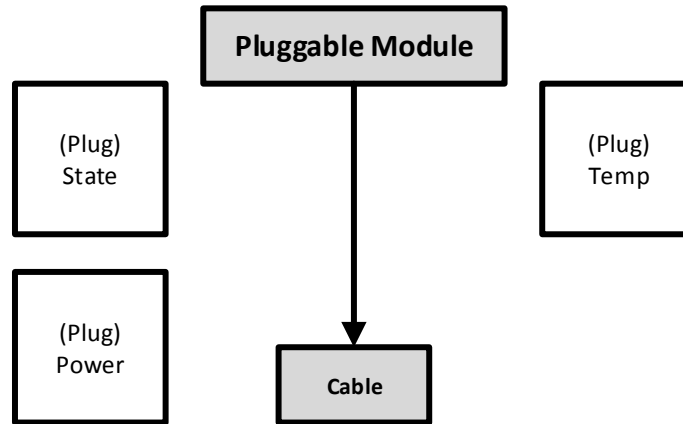

875 PLDM numeric sensor PDRs require specification of both the units of measure and the scaling method of  
 876 the reported value. In this case, the units of measure are bits/second and the scaling multiplier of the  
 877 measured value is 1,000,000. Together, these yield a reported value in Mbps.

878 The container ID in this case, 1000, references the network controller defined in clause 7.4.

879 **7.5 Pluggable module**

880 As defined in clause 6.6.3, the pluggable module includes one or more cables as well as some sensors.  
 881 The following diagram shows the content of the first pluggable module in the example model. The  
 882 pluggable module type in the model matches the network interface connector type; in this example,  
 883 QSFP. Note that the numeric sensors and the composite state sensor in the pluggable module are not

884 described in the pluggable module hierarchy itself: these sensors are only declared by referencing the  
 885 measured entity.

886

887

**Figure 24 – Example pluggable module structure**

888 The following PDR defines the content of the pluggable module device using physical association  
 889 between the cables and the pluggable modules.

890

Pluggable module #1 Entity Association PDR		
Container ID	1010	
Record Handle	1600	
Container Entity		
Entity Type	214	QSFP Module
Entity Instance Number	1	
Container Entity Container ID	1040	Connector #1
Association Type	Physical to Physical containment	
Contained Entity - Cable		
Entity Type	187	Cable
Entity Instance Number	1	
Contained Entity Container ID	1010	Plug #1

891

**Figure 25 – Pluggable Module #1 entity association**

<b>Pluggable module #2 Entity Association PDR</b>		
Container ID	1011	
Record Handle	1601	
<b>Container Entity</b>		
Entity Type	214	QSFP Module
Entity Instance Number	1

<b>Association Type</b>		
Association Type	Physical to Physical containment	
<b>Contained Entity - Cable</b>		
Entity Type	187	Cable
Entity Instance Number	1	
Contained Entity Container ID	1011	Plug #2

892

**Figure 26 – Pluggable Module #2 entity association**

893 The pluggable modules are part of their respective connectors; this is indicated because they point to  
 894 their connectors' container ID values. Each of the pluggable modules has its own content and its own  
 895 hierarchy ID. In the example, these are 1010 for the 1<sup>st</sup> pluggable module and 1011 for the 2<sup>nd</sup> pluggable  
 896 module.

897 **7.5.1 Pluggable module temperature sensor**

898 The pluggable module temperature sensor reports the pluggable module temperature. As with the other  
 899 sensors, the sensor is declared by referencing the measured entity.

900

<b>Plug #1 Temperature sensor PDR</b>		
<b>Field</b>	<b>Value</b>	<b>Description</b>
Record Handle	1800	
Sensor ID	500	
Entity Type	214	QSFP Module
Entity Instance	1	Temp sensor #1 in Plug
Container ID	1040	Connector #1
Base Units	2	Degrees C

901

**Figure 27 – Plug #1 temperature sensor PDR**

902

Plug #2 Temperature sensor PDR		
Field	Value	Description
Record Handle	1801	
Sensor ID	501	
Entity Type	214	QSFP Module
Entity Instance	1	Temp sensor #1 in Plug
Container ID	1041	Connector #2
Base Units	2	Degrees C

903

**Figure 28 – Plug #2 temperature sensor PDR**

904 Note that as the instance ID of each element is enumerated within its hierarchy, both sensors can have  
 905 instance ID of 1 as they are in different pluggable modules, while both are uniquely defined. The  
 906 container ID of each of the sensors matches the corresponding pluggable module Container ID.

907 If a pluggable module is turned off by the network controller - for thermal protection or for any other  
 908 reason -- the reported temperature shall reflect the last measured value read before the pluggable  
 909 module was turned off.

910 **7.5.2 Pluggable module power sensor**

911 The pluggable module power sensor reports the pluggable module’s expected or measured power  
 912 consumption. As with other sensors, the sensor is declared by referencing the measured entity.

913

Plug #1 Power sensor PDR		
Field	Value	Description
Record Handle	1700	
Sensor ID	400	
Entity Type	214	QSFP Module
Entity Instance	1	Power sensor #1 in Plug
Container ID	1040	Connector #1
Base Units	7	Watt
Unit Modifier	-1	0.1Watt resolution

914

**Figure 29 – Pluggable module #1 power sensor**

915

Plug #2 Power sensor PDR		
Field	Value	Description
Record Handle	1701	
Sensor ID	401	
Entity Type	0	#N/A
Entity Instance	1	Power sensor #1 in Plug
Container ID	1041	Connector #2
Base Units	7	Watt
Unit Modifier	-1	0.1Watt resolution

916 **Figure 30 – Pluggable module #2 power sensor**

917 The unit of measure in this case is Watts and the multiplication scaling factor is 0.1; therefore, the  
 918 reported value will use tenths of a Watt.

919 **7.5.3 Pluggable module composite state sensor**

920 The pluggable module’s composite state sensor reports the overall operational state of the pluggable  
 921 module.

922

Plug #1 composite State Sensor PDR		
Record Handle	2000	
Entity Type	214	QSFP Module
Entity Instance Number	1	
Container Entity Container ID	1040	Connector #1

Terminus Handle	0	
Sensor ID	700	
Composite Sensor Count	3	

Sensor Type	1	Health state
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 4=Fatal	

Sensor Type	13	Presence

Entity Instance Number	2	
Container Entity Container ID	1041	Connector #2

Terminus Handle	0
Sensor ID	701
Composite Sensor Count	3

Sensor Type	1	Health state
Possible States	1=Normal, 3=Critical, 5=Upper_Non_Critical, 4=Fatal	

Sensor Type	13	Presence
Possible States	1=Present, 2=Not_Present	

Sensor Type	21	Thermal Trip
Possible States	1=Normal, 2=Over-Temp Shutdown	

**Figure 32 – Pluggable Module #2 composite state sensor PDR**

924

925 The composite state sensor uses temperature thresholds detailed in Table 1 to report the health state and  
 926 the thermal state rating. When there is no pluggable module in the NIC, the presence sensor will report  
 927 the module’s absence.

928 If a module is turned off by the network controller for thermal protection or for any other reason, the  
 929 reported health state shall reflect the last known state of the module prior to being turned off.

930 **7.6 Connector association to a Pluggable module**

931 Pluggable modules are defined within the Connector hierarchy level. The association of pluggable  
 932 modules with their connectors is done using entity association PDRs as described in Figure 34 and  
 933 Figure 35. The following diagram illustrates the entity association in the example model:

934

935

936 **Figure 33 – Pluggable module association with connectors**

937 The corresponding entity association PDRs are shown below:

938

Connector #1 entity association PDR		
Container ID	1040	
Record Handle	1110	
Container Entity

	Physical containment	
Contained Entity - Cable		
Entity Type	214	QSFP Module
Entity Instance Number	1	
Contained Entity Container ID	1041	Connector #2

941

**Figure 35 – Connector #2 entity association PDR**

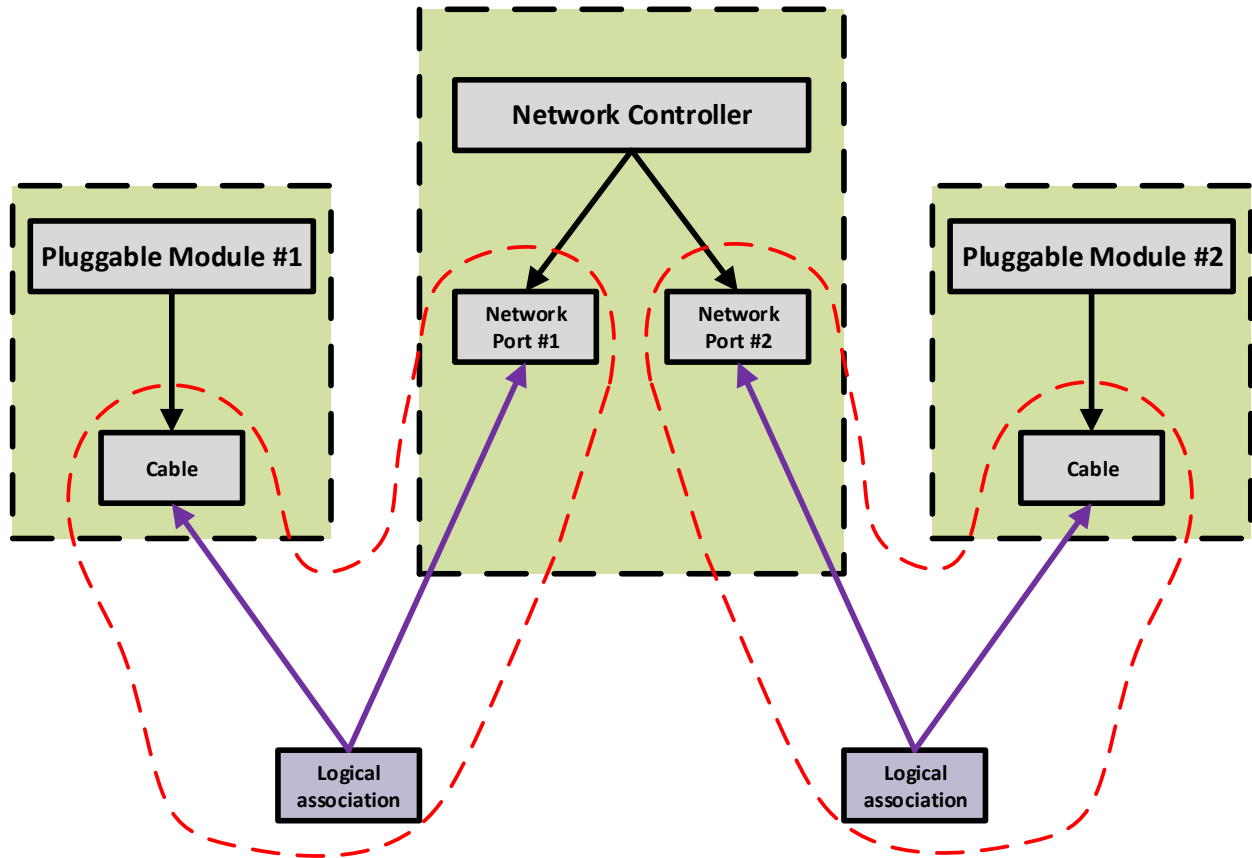

942  
943  
944  
945

As can be seen from the provided PDRs, Connector 1 is used with pluggable module 1 and connector 2 is used with pluggable module 2. It is strongly recommended to match pluggable module instance numbers and connector numbers to the port numbers physically marked on the PCB card and/or bracket to ensure coherent database enumeration.

946 **7.7 Logical association of a cable with a network port**

947 The PLDM NIC model associates cables with network ports in a network controller via logical association  
 948 as described in clause 6.6.5. The following diagram illustrates entity association in the example model:

949

950

951 **Figure 36 – Logical association of cables with network controller ports**

952 The logical associations of the network ports to the cables are shown by the dashed red lines. Different  
 953 NIC implementations may map their network ports to the physical connectors and to the associated  
 954 cabled in different ways. Entity association PDRs allows modeling any NIC implementation. For example,  
 955 note the different associations of the cables here in Figure 36 as compared to in Figure 6, above.

956 The corresponding entity association PDRs are shown below:

Channel #1 entity association PDR

958

**Figure 38 – Cable #2 entity association with controller network port #2**

959 The Cable instance number is 1 for both PDRs. The reasoning for this is that the enumeration for every  
 960 entity is performed within its hierarchy. As there is only 1 cable in each pluggable module, in our example,  
 961 both are having the same instance ID value of 1, but each is referenced within a different hierarchy. If a  
 962 breakout cable were in use, the component cables within it would be numbered with instance numbers 1,  
 963 2, 3, etc.
