LERI: A measure of Land Surface Dryness

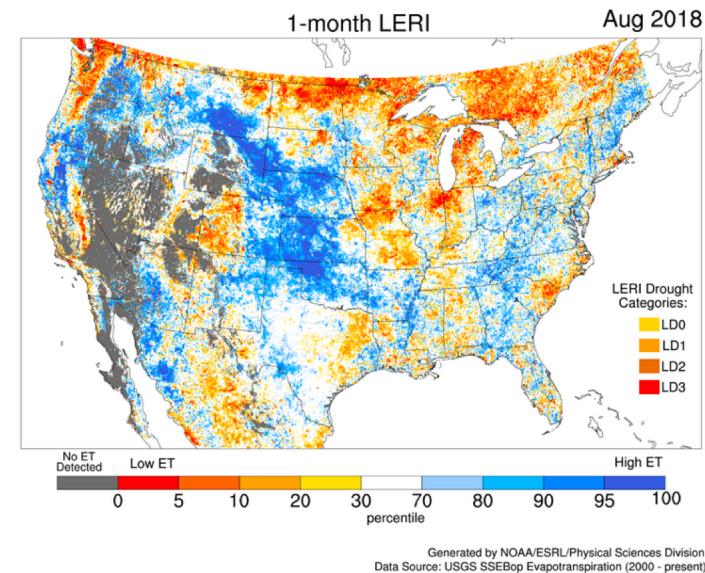

[About](#) [LERI \(Monthly\) Maps](#) [LERI \(8-day\) Maps](#) [LERI Time-Series](#) [Team](#) [Resources](#)

About

What is LERI?

The **Landscape Evaporative Response Index (LERI)** is an experimental drought-monitoring and early warning guidance tool that measures the anomaly in the actual evapotranspiration (ET_a) from the land surface. This webpage provides LERI plots based on accumulated monthly, seasonal, growing season, and annual ET_a for the contiguous United States and northern Mexico at a 1-km spatial resolution. LERI data are available from January 2000 to the present — a period that corresponds to the availability of MODIS satellite data on which it depends.

ET_a is the sum of transpiration from vegetation and evaporation from soil (and water bodies), and is accumulated over a given time period for a given location. The ET_a data on which LERI is based are produced by the U. S. Geological Survey using the operational Simplified Surface Energy Balance (SSEBop) model ([Senay et al., 2013](#)). SSEBop combines evapotranspiration fraction (i.e., the ability of the land surface to meet the atmospheric demand for water vapor, expressed as a proportion of that demand) generated from remotely sensed [MODIS thermal imagery](#), acquired every 8 days, with climatological atmospheric evaporative demand as represented by reference evapotranspiration derived using the Penman-Montieth formulation and driven by from University of Idaho's Gridded Surface Meteorological Data for that period.

[How To Read these LERI Maps](#)

University of Idaho's Gridded Surface Meteorological Data for that period.

What is LERI?

- ❖ An experimental drought-monitoring and early warning guidance tool based on a high-resolution, remotely-sensed (MODIS) evapotranspiration response from the land
- ❖ LERI represents the relative evaporative response from the land at 1-km
- ❖ By its design, **LERI largely reflects the anomalous state of land-surface moisture (i.e., soil moisture)** that is readily accessible to plants (for transpiration) and the atmosphere (for evaporation from bare soils and water bodies)
- ❖ LERI is available from January 2000 to the present
- ❖ LERI is available as maps (and associated data) and historical time series for a user selected domain

Strengths of LERI

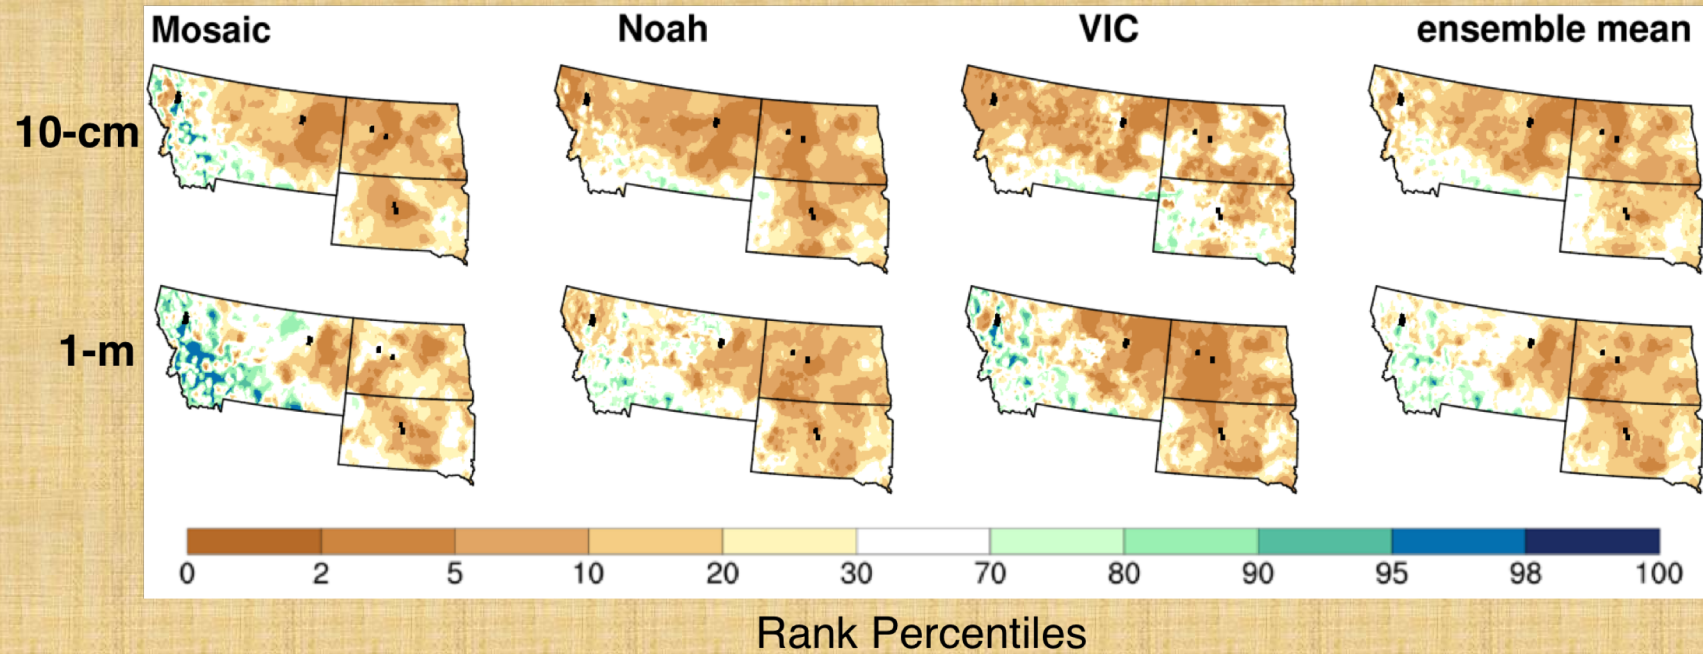

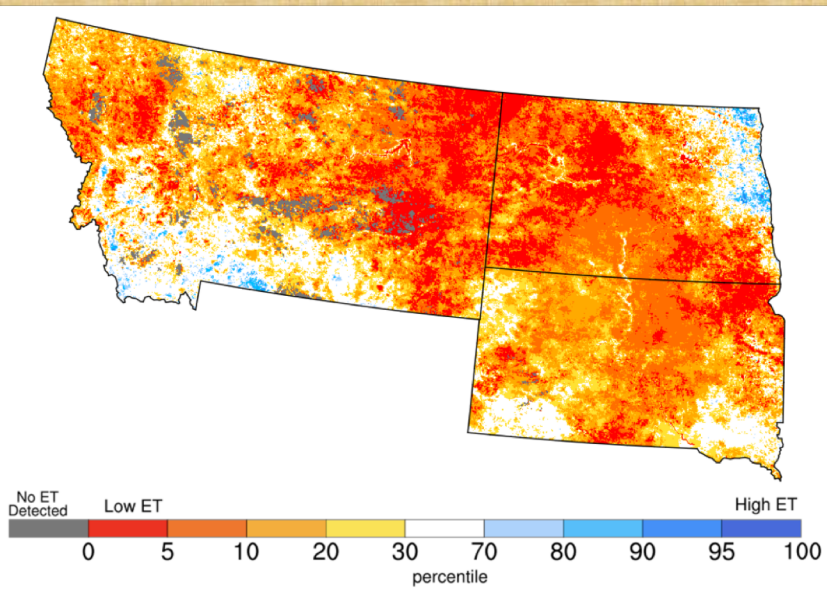

- ❖ Direct Observations
- ❖ High Resolution (1km)
- ❖ Monitoring/Situational Awareness ability with with 1 week latency – Drought Early Warning potential
- ❖ Gets us “relative” soil moisture anomalies

... and potential limitations

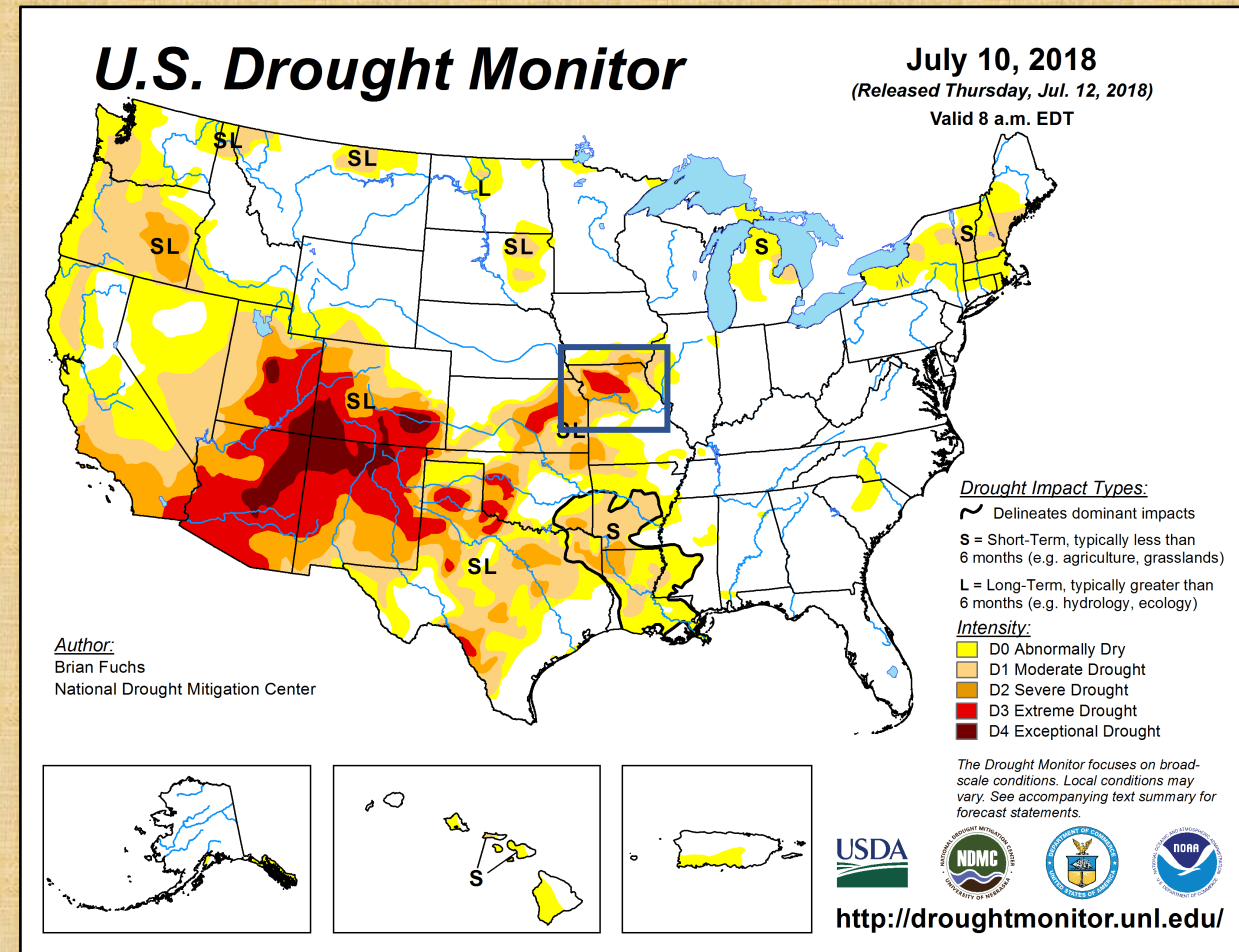

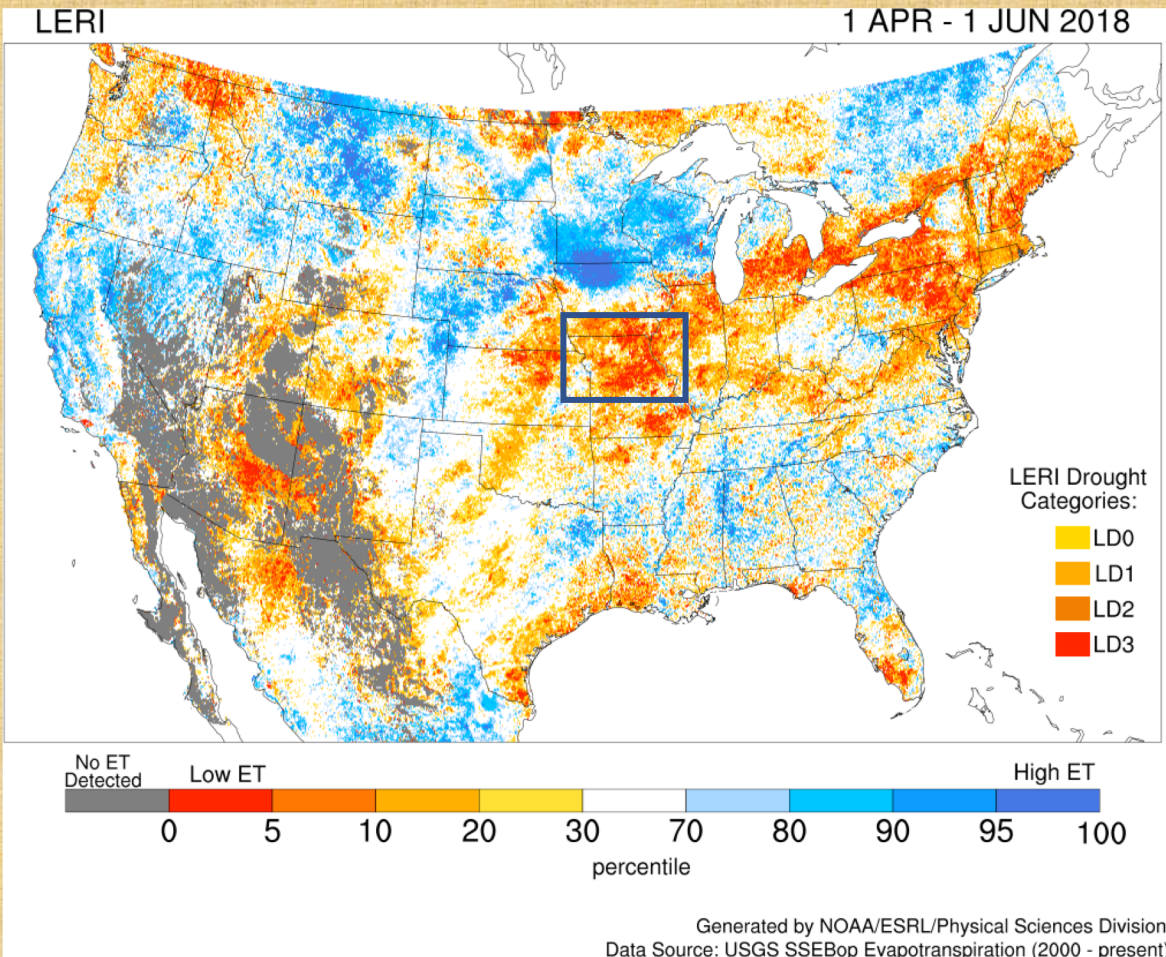

- ❖ Shorter record (2000-present) to assess relative anomalies
- ❖ Possibility of missing data from Remote Sensing
- ❖ Temperature calibration could be enhanced
- ❖ New --- needs more verification of the tool

LERI is found to more closely track moisture anomalies in top soil layers

Map Below: LERI compared to NLDAS 10-cm and 1-m (modeled) soil moisture for July 2017

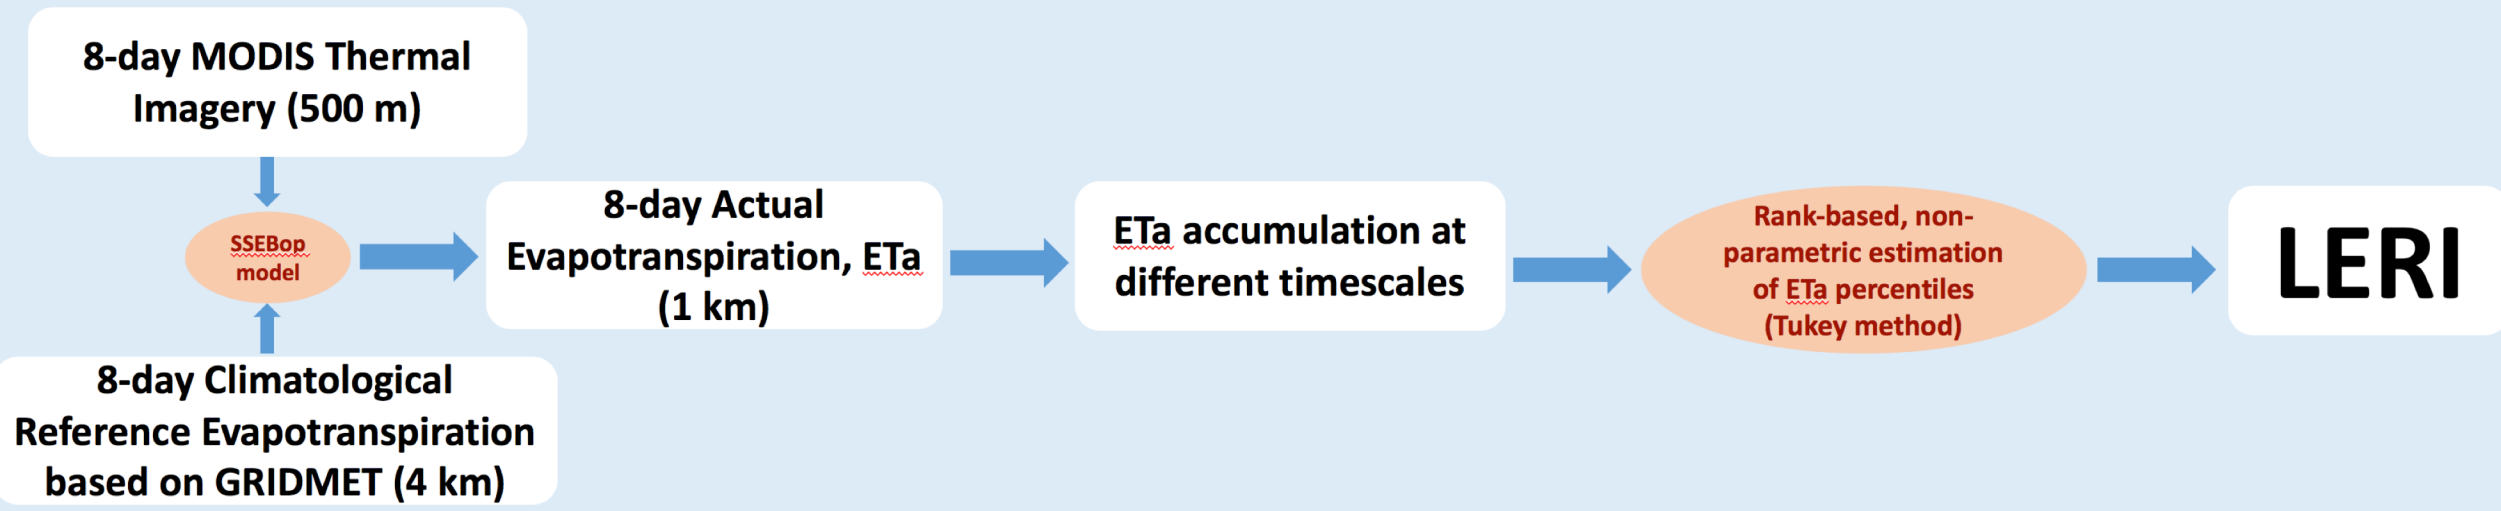

LERI: Drought Early Warning Potential

Example: LERI identifying extreme drought stress in northern Missouri in the summer of 2018 more than a month earlier before it get reported in the U.S. Drought Monitor

How is LERI calculated?

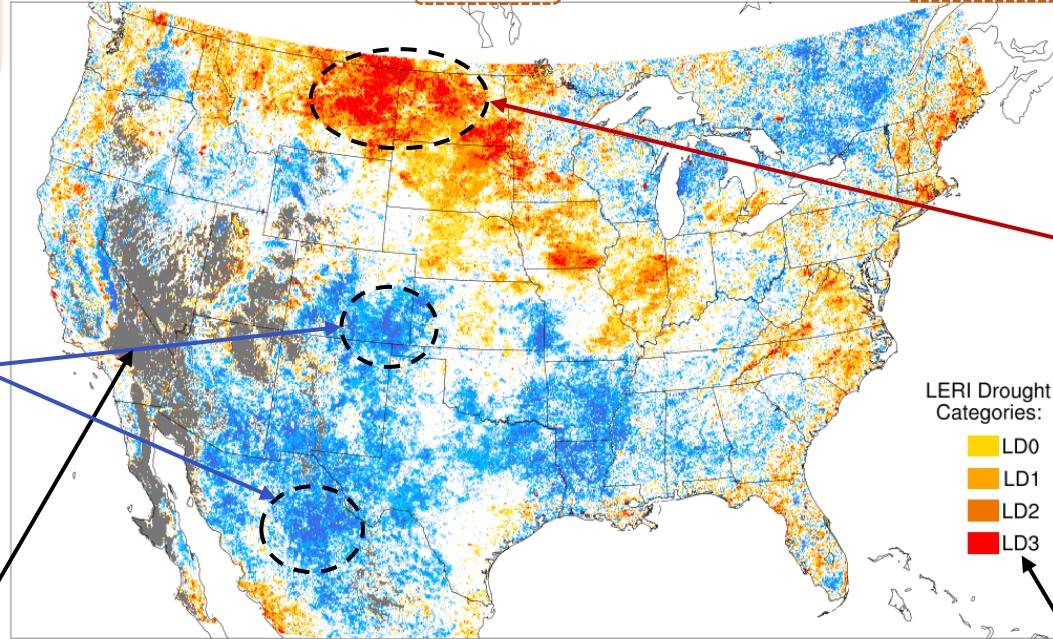

Reading a LERI map

Time length of ET_a accumulation. This map shows the percentiles for a 3-month accumulated ET_a (Jun 1 - Aug 31, 2017) relative to the period of record (Jan 2000-present)

Date or month & year for which the LERI map is generated

3-month LERI

Aug 2017

Unusually low evaporative response as accumulated between Jun 1 – Aug 31 signifying unusually dry land-surface conditions. LD3 means that this dryness is expected less than 5% of the time

Unusually high evaporative response as accumulated between Jun 1 – Aug 31 signifying unusually wet land-surface conditions

These categories are analogous to D0-D3 categories in the US Drought Monitor. There is no LD4 category because of the short period of the SSEBop ET_a record

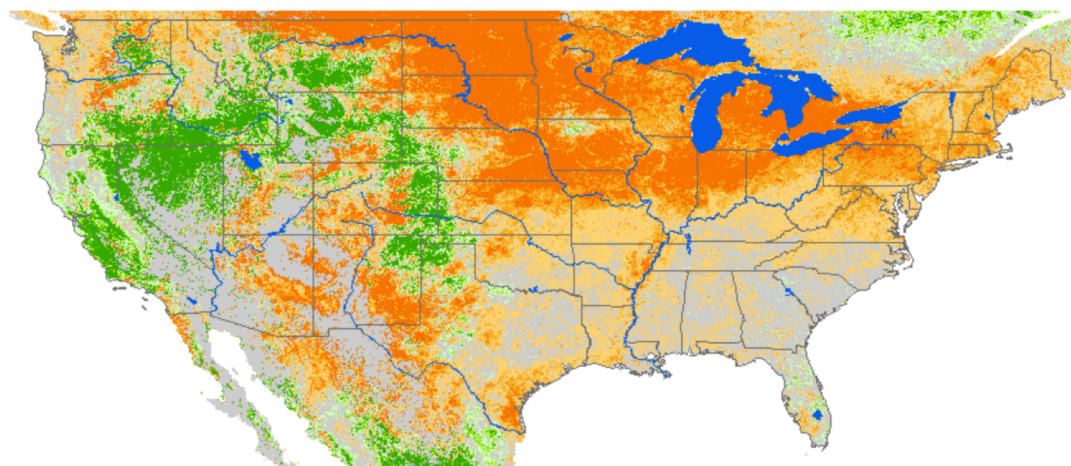

The gray shading shows that no ET_a is detected using the SSEBop method

Data Source: USGS SSEBop Evapotranspiration (2000 - present)

LERI (right) is an improvement on the USGS actual ET anomaly maps (left) produced by USGS EROS. The rank-based non-parametric method used to calculate percentiles for LERI makes it more equally sensitive to both water-limited and energy-limited regions. LERI maps also further distinguish regions where no ET is detected (using the gray shading). Lastly, LERI operates as a drought indicator and identifies drought categories analogous to the US Drought Monitor.

EDDI and LERI

EDDI Evaporative Demand Drought Index

[About](#) [Current Conditions](#) [EDDI Map Archive](#) [Time Series](#) [Team](#) [Resources](#)

About

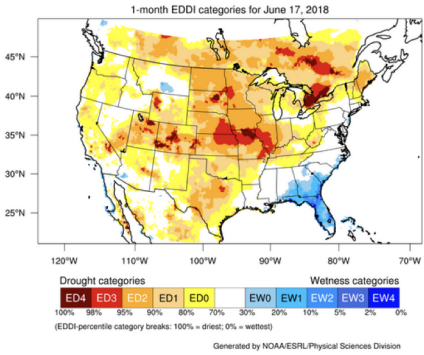

What is EDDI?

The **Evaporative Demand Drought Index (EDDI)** is an experimental drought monitoring and early warning guidance tool. It examines how anomalous the atmospheric evaporative demand (E_0 ; also known as "the thirst of the atmosphere") is for a given location and across a time period of interest. EDDI is multi-scalar, meaning that this period—or "timescale"—can vary to capture drying dynamics that themselves operate at different timescales; we generate EDDI at 1-week through 12-month timescales.

This webpage offers a frequently updated assessment of [current conditions](#) across CONUS, southern parts of Canada, and northern parts of Mexico; a tool to generate historical [time series](#) of EDDI for a user-selected region; introductions to the [EDDI team](#); and a list of [resources](#) for users to explore EDDI and its applications further.

Why use EDDI?

EDDI can offer early warning of agricultural drought, hydrologic drought, and fire-weather risk by providing near-real-time information on the emergence or persistence of anomalous evaporative demand in a region. A particular strength of EDDI is in capturing the precursor signals of water stress at weekly to monthly timescales, which makes EDDI a strong tool for preparedness for both flash droughts and ongoing droughts.

[How To Read a LERI Map](#)

A measure of Land Surface Dryness

Relationship between E_0 and ET changes as land surface dries out

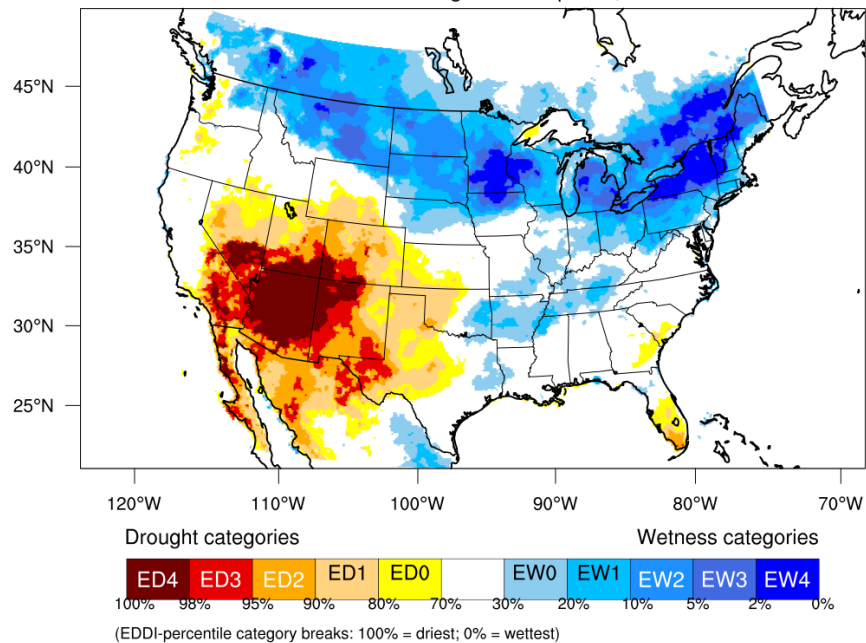

- When surface moisture is sufficient, rising E_0 leads to rising ET
- When moisture is limited, ET declines, while E_0 rises even more steeply

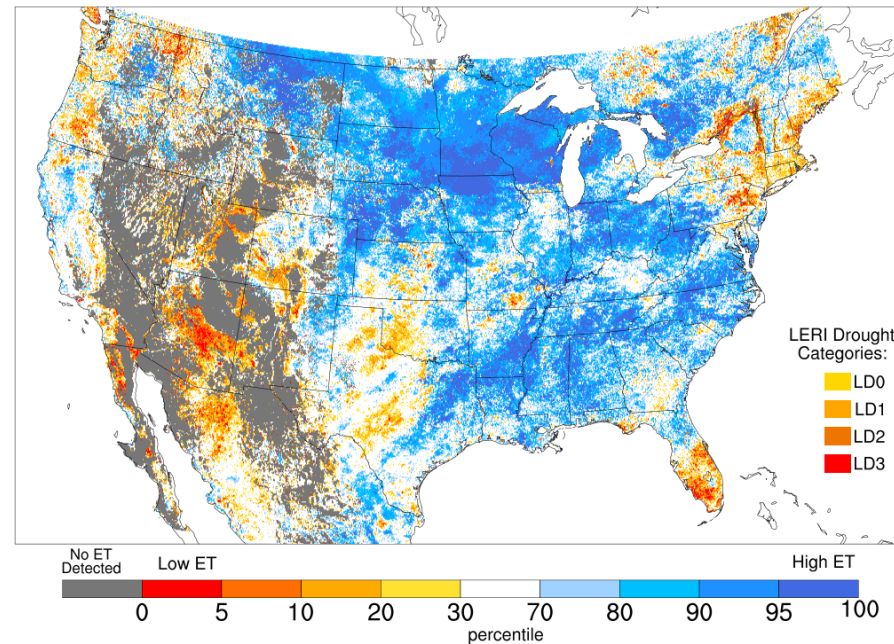

E_0 always increase as drought intensifies

Plot LERI Time Series

This webtool allows a user to generate historical (2001-latest complete year) timeseries data of the Landscape Evaporative Response Index (LERI) for a specified region in the Contiguous United States or northern Mexico. The time series is generated as a table for different timescales, i.e. 1 to 12 months of integrated evaporative demand at the end of a given month. This tool also allows users to generate time series plots with user specified timescales.

U.S. Drought Monitor

August 1, 2017
(Released Thursday, Aug. 3, 2017)
Valid 8 a.m. EDT

Drought Impact Types:

- ~ Delineates dominant impacts
- S = Short-Term, typically less than 6 months (e.g. agriculture, grasslands)
- L = Long-Term, typically greater than 6 months (e.g. hydrology, ecology)

Intensity:

- D0 Abnormally Dry
- D1 Moderate Drought
- D2 Severe Drought
- D3 Extreme Drought
- D4 Exceptional Drought

The Drought Monitor focuses on broad-scale conditions. Local conditions may vary. See accompanying text summary for forecast statements.
