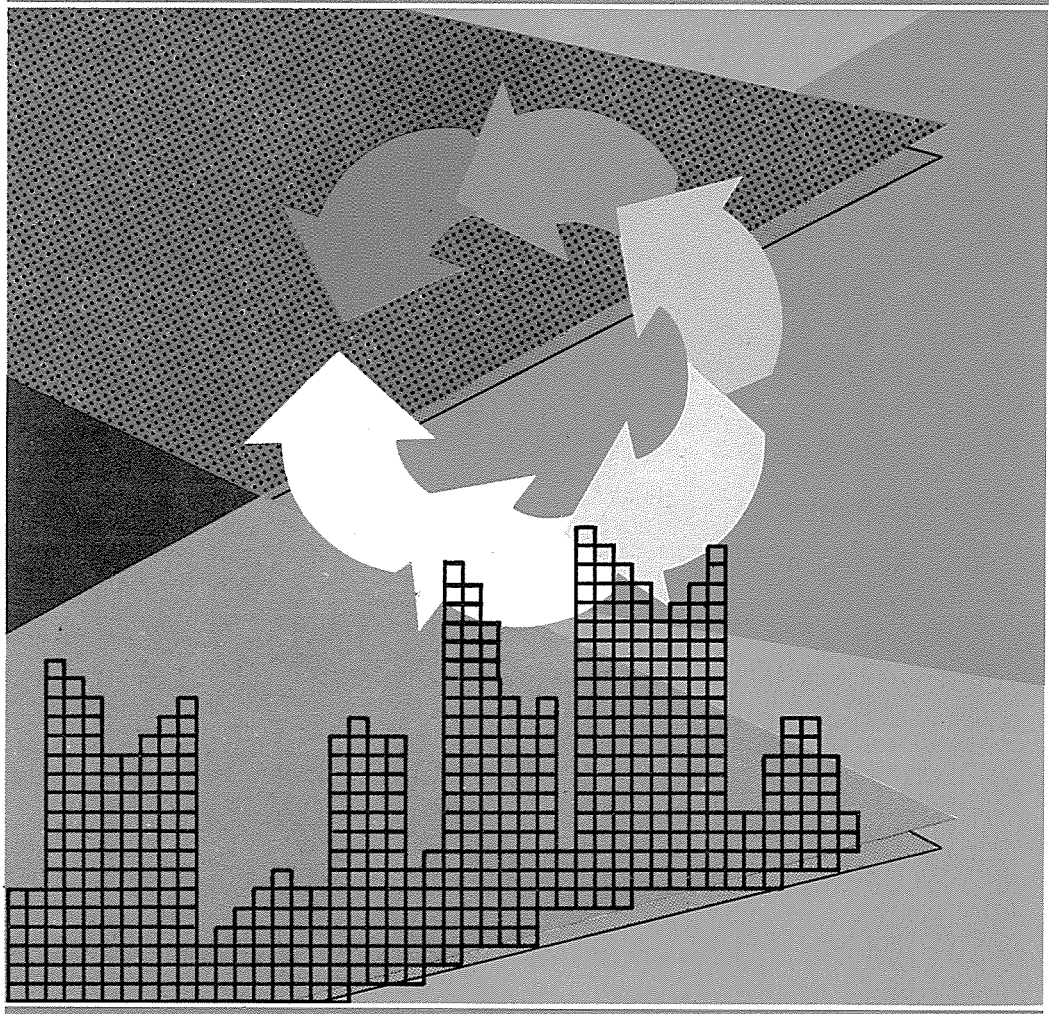
THE STATE OF FOOD AND AGRICULTURE



40 YEARS OF SERVICE

World review: the ten years since the World Food Conference

Urbanization, agriculture and food systems

1984

SPECIAL CHAPTERS

In addition to the usual review of the recent world food and agriculture situation, each issue of this report from 1957 has included one or more special studies of problems of longer-term interest. Special chapters in earlier issues have covered the following subjects:

1957 Factors influencing the trend of food consumption
Postwar changes in some institutional factors affecting agriculture

1958 Food and agricultural developments in Africa south of the Sahara
The growth of forest industries and their impact on the world's forests

1959 Agricultural incomes and levels of living in countries at different stages of economic development
Some general problems of agricultural development in less-developed countries in the light of postwar experience

1960 Programing for agricultural development

1961 Land reform and institutional change
Agricultural extension, education and research in Africa, Asia and Latin America

1962 The role of forest industries in the attack on economic underdevelopment
The livestock industry in less developed countries

1963 Basic factors affecting the growth of productivity in agriculture
Fertilizer use: spearhead of agricultural development

1964 Protein nutrition: needs and prospects
Synthetics and their effects on agricultural trade

1966 Agriculture and industrialization
Rice in the world food economy

1967 Incentives and disincentives for farmers in developing countries
The management of fishery resources

1968 Raising agricultural productivity in developing countries through technological improvement
Improved storage and its contribution to world food supplies

1969 Agricultural marketing improvement programmes: some lessons from recent experience
Modernizing of institutions to promote forestry development

1970 Agriculture at the threshold of the Second Development Decade

1971 Water pollution and its effects on living aquatic resources and fisheries

1972 Education and training for development
Accelerating agricultural research in the developing countries

1973 Agricultural employment in developing countries

1974 Population, food supply and agricultural development

1975 The Second United Nations Development Decade: mid-term review and appraisal

1976 Energy and agriculture

1977 The state of natural resources and the human environment for food and agriculture

1978 Problems and strategies in developing regions

1979 Forestry and rural development

1980 Marine fisheries in the new era of national jurisdiction

1981 Rural poverty in developing countries and means of poverty alleviation

1982 Livestock production: a world perspective

1983 Women in developing agriculture

THE STATE OF FOOD AND AGRICULTURE 1984

FAO Agriculture Series *No. 18*

the state of food and agriculture 1984

World review: the ten years since the World Food Conference
Urbanization, agriculture and food systems

FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS
ROME 1985

The statistical material in this publication has been prepared from the information available to FAO up to 1 March 1985.

The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of the Food and Agriculture Organization of the United Nations concerning the legal status of any country, territory, city or area, or of its authorities, or concerning the delimitation of its frontiers or boundaries. In some tables, the designations "developed" and "developing" economies are intended for statistical convenience and do not necessarily express a judgement about the stage reached by a particular country or area in the development process.

Chapter 2, Urbanization: a growing challenge to agriculture and food systems in developing countries was prepared by the Policy Analysis Division in collaboration with the Agricultural Services Division, the Food Policy and Nutrition Division, the Statistics Division and members of the Population Programme of FAO.

Foreword

We marked in 1984 the 10th Anniversary of the World Food Conference, which was convened to cope with the global shortage of cereals that erupted in the early 1970s. It was inevitable that on the anniversary, we should recall the Conference's brave, well-intentioned pledge that by 1984, "no man, woman or child should go to bed hungry". We note grimly, however, how far that pledge has yet to be met, in that in 1984 well over 30 million men, women and children, in 21 African countries, were directly threatened by starvation.

Paradoxically, 1984 was also a year of agricultural abundance. World production of cereals rose between 9% and 10%, boosting estimated supplies, at the beginning of the 1984/85 season, to an all-time record level, while the skeletal figures of starvation victims in Africa became a recurring feature on television screens.

More than ever before, it was obvious that increased global production alone would not automatically secure access to available food for those in greatest need.

In terms of human anguish and the prospects of famine-sparked instability, Africa continued to be the focus of world attention in 1984. As early as mid-1983, FAO's Global Information and Early Warning System had issued its first alert, calling attention to the initial signs of an emerging crisis in Africa.

It was then that I promptly established a FAO/World Food Programme task force, to carry out surveillance, to provide regular reports, and to help in the mobilization of the necessary resources and assistance.

In the course of the year, the worst drought of the century reached its peak, searing 21 countries, mostly in the Sahel, southern and eastern Africa. In some cases, the disruptions caused by crop failures were exacerbated by civil strife. Famine engulfed an estimated 20% of the population of Ethiopia, and entire ways of traditional living, which had endured for centuries in the Sahel, were on the verge of collapse.

Hundreds of thousands of people died in these countries. The precise number will never be known. Those who survived formed lines of destitute refugees that made their way to feeding camps pitched on what were once fertile farms. Meanwhile, the world registered the largest production increases in coarse grains, edible oil and root crops, and warehouses were crammed with surplus sugar and dairy products.

Faced with this situation, I urgently addressed appeals to the international community at the FAO Conference, at the United Nations' General Assembly and elsewhere, using every available occasion to draw the attention of donors to the desperate plight of the African farmers and their families.

The response has been generous. We saw, in 1984, an historically unprecedented outpouring of food aid to stricken areas. If aid deliveries are now falling short of needs, it is due in many cases to problems of logistics and administration, at the ports and in inland transport.

The hard, costly lessons of the 1984 emergency are now better appreciated. Food supplies must be procured early. They must be pre-positioned, so they can be shipped rapidly. Recipient countries must clear logistical bottlenecks to ensure prompt delivery of food aid. Early and thorough action is needed on these and other measures to find and speed food to the hungry.

The world community's response and the lessons of the emergency prompted me to propose the adoption of a World Food Security Compact by FAO member countries. This statement of principles would articulate the spirit of a civilized community rededicating itself to the ideal of a world freed from hunger. The thrust of the compact is to make every effort to uproot the causes of hunger. This has special relevance to the food crisis in Africa, where neglect of agriculture for too long, as well as external factors, now threaten the economic and political integrity of many countries of the continent. If this crisis is to be defused, agriculture must be rebuilt.

At the FAO Regional Conference on Africa, held in September 1984, African ministers responsible for food, agriculture and rural development issued the Harare Declaration. In this important document, they accepted the basic responsibility for adopting the difficult policy decisions needed to build the productive capacity of their devastated food and agricultural sectors. This move towards self-reliance lays a foundation for practical measures of internal reforms to prevent future famines.

Yet the acceptance of responsibility for the necessary policy decisions can achieve little without adequate resources. FAO has striven to make a contribution to this resource mobilization, not merely through exhortation to donors and preparing concrete projects for them to finance, but also by refocusing part of its modest Regular Programme and devoting savings in support of efforts aimed at rehabilitating Africa's agricultural sector. In March 1985, FAO prepared a package of 108 projects for donors to help African countries restart agricultural production.

FAO is also undertaking, for consideration at the 1986 FAO Regional Conference for Africa, an in-depth review of long-term development to remedy Africa's agricultural and food problems. The Organization continues to execute its large extra-budgetary investment and development programmes for that continent, as well as for other developing regions where the precarious balance between population and food production growth does not permit any sparing of effort.

The magnitude of this crisis and its implications for the future may be appreciated better if seen in the context of the state of food and agriculture world-wide.

In terms of output, 1984 proved a better year for agriculture than 1983. Global food production in 1984 recovered from the setback of the previous year by achieving an overall increase of more than 4%--one of the best performances in recent years. Record cereal crops were produced in much of Europe; production recovered well in North America; and Asia consolidated the remarkable progress in grain production it had made in the previous year.

Weak demand failed, however, to match the rich harvests, as the lingering effects of the recession, combined with widespread poverty, held back increases in purchasing power. The economic recession, the worst in 50 years, reduced the capacity of people to pay for the food they needed, in many cases for their sheer survival. The trend towards increased protectionism also inhibited trade flows. As a consequence, stocks of several major food products rose while many went hungry.

Prices fell, at least in terms of the strengthening U.S. dollar. Interest rates remained relatively high in real terms and financial distress spread rapidly among farmers, particularly in the United States, and among developing countries struggling to service burdens of external debt.

The recession also eroded export earnings. And in many countries, it led to budgetary cutbacks for essential programmes aimed at alleviating rural poverty and redressing social inequities.

Development assistance, needed precisely at a time of economic stress, continued to shrink. Available data shows that concessional multilateral assistance to agriculture, which can build food security and reduce reliance on food aid, suffered a sharp reduction of more than 15% in 1983.

Partly in response to the starvation in Africa, food aid and emergency food assistance expanded. Large stocks of cereals and other foods, and their relatively low prices, helped this expansion.

Technically, the recession ended in 1984, with economic growth resuming strongly in some developed countries. But it dealt such harsh blows to low-income countries struggling to raise the living standards of their people above the poverty level, that it will take considerable time for countries to recover from the setback to their development programmes.

The strains appearing at the international level, such as difficulties in maintaining the flows of multilateral assistance to agriculture and overcoming protectionism in trade, will require collaborative efforts in the years ahead to design and implement practical measures that will reinforce the world community. Alleviation of hunger offers a universally accepted common ground for this task.

The paradox of hunger festering in the midst of abundance prompted the State of Food and Agriculture 1984 to mark the 10th Anniversary of the World Food Conference by devoting a part of its World Review chapter to an analysis of trends and developments in global food supplies during the past decade.

The review shows that there had been heartening progress in many developing countries in their efforts to increase food supplies, but there were also worrying setbacks. In fact, in the early 1980s, there were 28 countries with a total of more than 350 million people where per caput food supplies deteriorated during the previous decade.

The review also shows that food supplies increased most frequently in countries that achieved the most rapid rates of economic growth, either through their own production or through increased capacity to finance imports of food. However, increased availability of food supplies needed more than ever to be equitably distributed.

In some ways, institutional developments since the World Food Conference have increased global food security. Commitments under the Food Aid Convention have risen to 7.6 million tons of cereals, providing a greater volume of food aid. The 10-year old International Emergency Food Reserve has exceeded the minimum target replenishment of 500 000 tons of cereals for the last two years. The International Monetary Fund's food facility has provided a safety net for some countries confronted by balance of payment problems due to food imports, although its conditions have restricted its wider use.

The Undertaking on Plant Genetic Resources will help to conserve and better utilize the productive base for increasing agricultural output by the next century. Another FAO initiative--the International Code of Conduct on the Distribution and Use of Pesticides--will ensure that future abundance is not purchased at the cost of a poisoned environment.

At national levels, 1984 saw more countries adopting cereal stock policies and national food security systems; while innovative regional arrangements have evolved to cover emergency food needs. Still, much remains to be done.

FAO's broadened concept of World Food Security defines the complex interrelated tasks that challenge our international community and is committed to ensure that famines will ultimately become historical footnotes. The basic elements of the concept are to ensure adequate food production, maximize stability of food supplies, and secure access to these supplies for those who need them most. In the years ahead, achievement of these objectives will demand our utmost attention and dedication.

Reshaping the global system of fisheries, embodied in the United Nations Convention on Law of the Sea, will also have an impact on achieving food security. Thus, the FAO World Conference on Fisheries Management and Development, organized by FAO in Rome in mid-1984, endorsed a strategy and an integrated package of five practical Programmes of Action to assist developing countries boost the productivity and lives of fishermen and thus make a vital contribution to the battle against malnutrition.

The United Nations Conference on Population in Mexico drew attention to the need of world agriculture to feed a population set to increase to over six billion by the year 2000. The State of Food and Agriculture 1984 includes a special chapter on one of the serious consequences of this population growth--the effects of urbanization on agriculture in developing countries.

Urbanization may have been seen in the past as a desirable manifestation of overall economic development. But now it is realised that rapid urbanization, particularly the high concentration of population in huge, ill-prepared, ill-serviced cities, also poses serious challenges to the means of producing, marketing and distributing adequate supplies of food.

In far too many cities, the food supply lines today are no longer rooted in the hinterland. Instead, they stretch across oceans to suppliers of staples that the consuming countries traditionally cannot or do not grow.

A resurgent agriculture can help slow down and reverse the flow of people fleeing the desperate poverty of rural areas for the equally desperate penury of urban slums.

SOFA's chapter examines measures that planners and policymakers can take to help pace urbanization with other development objectives and help food systems adjust to the increasing burdens.

We are faced with enormous problems and challenges. Hunger can, however, be conquered through in-depth internal reform within developing countries, and international reforms in the major sectors of indebtedness and trade. A global approach is required.

It is my hope that this document will contribute to the creation of the necessary measures to break the vicious circle in which the economies of developing countries are caught up and to resolve the grim paradox of our day--intractable food surpluses confronting unprecedented hunger and malnutrition.

WMO	World Meteorological Organization

Explanatory note

The following symbols are used in statistical tables:

- none, or negligible
... not available

"1981/81" signifies a crop, marketing or fiscal year running from one calendar year to the next; "1979-81" signifies the average for three calendar years.

Figures in statistical tables may not add up because of rounding. Annual changes and rates of change have been calculated from unrounded figures. Unless otherwise indicated, the metric system is used throughout. The dollar sign ($) refers to U.S. dollars.

PRODUCTION INDEX NUMBERS 1/

The FAO index numbers have 1974-76 as the base period. The production data refer to primary commodities (for example, sugar cane and sugar beet instead of sugar) and national average producer prices are used as weights. The indices for food products exclude tobacco, coffee, tea, inedible oilseeds, animal and vegetable fibres, and rubber. They are based on production data presented on a calendar-year basis.

TRADE INDEX NUMBERS 2/

The indices of trade in agricultural products also are based on 1974-76. They include all the commodities and countries shown in the 1983 issue of the FAO Trade Yearbook. Indices of total food products include those edible products generally classified as "food".

All indices represent the changes in the current values of export (f.o.b.) and imports (c.i.f.), all expressed in U.S. dollars. If some countries report imports valued at f.o.b., these are adjusted to approximate c.i.f. values. This method of estimation shows a discrepancy whenever the trend of insurance and freight diverges from that of the commodity unit values.

Volumes and unit value indices represent the changes in the price-weighted sum of quantities and of the quantity-weighted unit values of products traded between countries. The weights are respectively the price and quantity averages of 1974-76, which is the base reference period used for all the index number series currently computed by FAO. The Laspeyres formula is used in the construction of the index numbers.

1/ For full details, see FAO Production Yearbook 1983, Rome, 1984.
2/ For full details, see FAO Trade Yearbook 1983, Rome, 1984.

REGIONAL COVERAGE

The regional groupings used in Chapter 1 follow the "FAO country classification for statistical purposes." The coverage of the groupings is in most cases self-explanatory. The term "developed countries" is used to cover both the developed market economies and the centrally planned economies of Eastern Europe and the USSR, and "developing countries" to cover both the developing market economies and the Asian centrally planned economies. Israel, Japan and South Africa are included in the totals for "developed market economies." Western Europe includes Yugoslavia, and the Near East is defined as extending from Cyprus and Turkey in the northwest to Afghanistan in the east, and including from the African continent, Egypt, Libya and the Sudan. Totals for developed and developing market economies include countries not elsewhere specified by region.

In Chapter 2, the regional groupings used are based on the UN, Estimates and Projections of Urban, Rural and City Populations, 1950-2025: The 1980 Assessment, New York, 1982 (see Annex 2-1).

DEFINITIONS OF "NARROW" AND "BROAD"

The OECD definitions of agriculture are generally used in reporting on external assistance to agriculture. The "narrow" definition of agriculture now referred to as "directly to sector" includes the following items:

appraisal of natural resources
development and management of natural resources
research
supply of production inputs
fertilizers
agricultural services
training and extension
crop production
livestock development
fisheries
agriculture, sub-sector unallocated

The "broad" definition includes, in addition to the above items, activities that are defined as "indirectly to sector". These activities are:

forestry
manufacturing of inputs
agro-industries
rural infrastructure
rural development
regional development
river development

INTRODUCTION

In late 1974, the World Food Conference marked international recognition of a series of events that became known as the world food crisis. Attention was focused during the crisis on fears that the world had entered into a phase that would be marked by periodic surpluses and shortages, and high volatility of world food supplies and prices. There was widespread concern that the demand of developing countries for food would far outstrip their domestic production capacities. Concerted action was sought at both national and international levels to expand food production, particularly in developing countries, to enhance food security, and to strengthen international support for the domestic efforts of developing countries.

This year's State of Food and Agriculture reviews some of the developments that have occurred since the early 1970s as a background for its yearly assessment of the current food and agricultural situation. It focuses on selected issues that have evolved from the time of the food crisis of the early 1970s, with particular reference to the food situation in developing countries.

Although the economic recovery continued to gain momentum in industrial countries in 1984, it was unevenly distributed. Its beneficial effects on agriculture have yet to be determined. Agricultural trade did not recover in 1983 and remained well below the levels of 1981.

Flows of external assistance to agriculture continued to be affected by budgetary stringency in donor countries, and their concessional element appears to have declined in 1983. World agricultural production in 1984 was, however, reasonably good, this being particularly true for cereals in North America and Europe. Confronting rather weak demand, a consequence of the economic recession, these high levels of cereal production have resulted in increased stocks. Although these stock levels are not exceptionally high in relation to consumption, they have led to depressed world market prices in recent months. The continued strength of the U.S. dollar against most other currencies also has contributed to low market prices in dollar terms. The gain in agricultural output in developing countries in 1984 was less than the average for the previous five-year period (1980-84), but exceeded population growth. Regional progress was uneven and differences in output gains were less than in 1983.

Despite some improvement in the food situation in some West African countries, a large number continue to face food emergencies in 1985, particularly in East Africa and the Sahel. The situation in Ethiopia and Chad assumed critical proportions in 1984. Emergency assistance will continue to be required if catastrophic famine is to be averted.

Turning to long-term developments, global progress has been made in agricultural and rural development since the early 1970s. Per caput dietary energy supplies (DES) have improved in two-thirds of the 90 developing countries reviewed. Yet food production increases in developing countries have failed to meet the production targets established at the time of the World Food Conference. Regional performances have been very uneven. Asia has shown improvement, but Africa, in particular, has slipped back. There is an even more marked polarization among countries in the average availability of food.

A major feature in the evolution of food supply patterns is that food imports have provided the major share of the additional calorie availability in those countries where significant nutritional improvements have been achieved.

Relatively high-income developing countries have accounted for most of the increase in food imports. Nevertheless, it is in low-income countries that food imports represent a higher proportion of per caput incomes. A majority of developing countries have been spending an increasing amount of their export earnings on food imports since the early 1970s, and many of them simply cannot afford to import more food on commercial terms.

The dilemma facing many food policymakers is that the demand for food, fuelled by population and income growth, may exceed the domestic capacity to satisfy it. Unless food imports are allowed to rise in these situations, people's food needs will not be met. Yet rising food imports may be detrimental to domestic food production and foreign exchange balances.

The experience of the 1970s has underlined the growing interdependence of food production and trade and the international policies affecting them. Institutional developments that reflect this greater interdependence, have taken place since the food crisis. For example, the Food Aid Convention (FAC) has been enlarged; the International Emergency Food Reserve (IEFR) and the International Monetary Fund (IMF) cereal import facility has been established; the importance of international action in supporting and strengthening equitable rights for people in agriculture recognized by the World Conference on Agrarian Reform (WCARRD); the New Law of the Sea put into operation; and a programme of action on new and renewable sources of energy prepared.

While achievements are only modest relative to needs, they do at least demonstrate wider recognition of the need for international negotiation and action related to food and agriculture. One major challenge is the articulation of a coherent vision of how to promote and sustain equitable growth and welfare. Another is how to muster the political will to face the necessary costs of fulfilling this vision domestically and internationally. The mustering of political will, in particular, has been made more difficult by the economic and financial difficulties that have beset developed as well as developing countries.

A special chapter in The State of Food and Agriculture 1984 focuses on the implications of urbanization trends and rural-urban migration on food production and marketing. Urbanization and associated rural-urban migration pose a challenge to agriculture, forcing it to adjust to new market conditions under changing systems of production. In so doing, it creates both opportunities and problems. Furthermore, it is not a self-adjusting process, and measures may be needed to adjust the rate of urbanization to allow other socio-economic objectives to be achieved.

Urbanization, agriculture and rural development are interdependent, and policies covering a wide range of areas such as health care, education, transport, food and agriculture, must be integrated. More direct actions are also possible. First, planners can modify the rate of rural-urban migration, perhaps most effectively by making living in rural areas more worthwhile. Second, they can help food systems--production and marketing--to adjust to the opportunities and challenges created by urbanization. Third, they can affect the balance of competition for water and other natural resources by ensuring that consumers bear the cost of using them.

It is appropriate that this long-term assessment by The State of Food and Agriculture should address these important issues because 1984 also marked the occasion of the United Nations World Population Conference held in Mexico.

CHAPTER 1 WORLD REVIEW

1. THE ECONOMIC, FINANCIAL AND TRADE ENVIRONMENT

Developments in the Last Decade

The early 1970s introduced a period of economic and financial turbulence and a slower growth in economic activity (Table 1-1). With the collapse of the Bretton Woods system of fixed exchange rates in 1971, rapid shifts in the competitive position of trading countries occurred that introduced an element of uncertainty into international transactions. The 1972-74 food crisis and the surge in commodity prices, particularly the 1973-74 quadrupling of oil prices, contributed to a short but deep recession in 1974-75. After an adjustment in the world economy the following three years, there entered another, more prolonged period of recession in 1979-80. This caused a faltering growth in production and trade combined with strong inflation, unusually volatile exchange and interest rates, and a massive international debt problem. By 1984 the external debt of developing countries had reached $827 000 million and was expected to expand further to $863 000 million in 1985.

For most developing countries, the consequences of these events, particularly the post-1979 recession, were severe economic blows. Although their actual experience depended on how well their economies were able to adjust to the changing economic situation, many faced serious repayment problems because of the decline in export earnings and a sharp increase in interest rates. The external debt of non-oil developing countries rose to a peak of 150% of export earnings in 1983, and this share was expected to decline only moderately in 1984 and 1985. As a result, debt issues have dominated the international economic and financial scene as well as North-South economic relations. A rescheduling of official and private debts has been concluded by several debtor countries with their creditors. Rescheduling operations were accompanied by the implementation of economic adjustment programmes aimed at redressing the economies of debtor countries. These programmes introduced serious austerity measures and included policy reforms as well as cuts in public expenditure, consumption and imports.

External financial resources available to developing countries declined drastically. New lending on commercial terms to developing countries was at an annual rate of only $10 000 million in the first nine months of 1983, only one-fifth of the amount for 1981. As a consequence, in 1983 there was an unprecedented net outflow from developing countries estimated at $11 000 million. Total official development assistance (ODA) also declined in real terms since 1981, after an annual growth of over 5% in the 1970s. This development has been particularly damaging to low-income developing countries that rely heavily on ODA to maintain their investment levels and is thus jeopardizing their future economic growth.

The Agricultural Sector

Nor have these events left the agricultural sector untouched. Agriculture was adversely affected by low commodity prices and weak markets that have characterized the recent years, while it benefited from the commodity price boom of 1977-78. Marked downturns in prices have had a serious impact on farm incomes in many countries. Incomes also have been affected by a weakening of agriculture's productive capacity by a slackening of rural investment from commercial and official sources. Agriculture had to adjust to rapidly rising costs of inputs such as fuel, fertilizer (at times), and interest rates on capital. In some cases, supplies of inputs have faltered because foreign exchange has not always been available to import them.

TABLE 1-1. ANNUAL CHANGES IN SELECTED ECONOMIC AND FINANCIAL INDICATORS, 1973-84

Protectionism in Agricultural Markets

Another consequence of the major economic shifts that took place after 1974 was the increase in trade protectionism. While protectionism has become a permanent feature of agricultural trade, pressures intensified considerably with the two major economic downturns of 1974-75 and particularly 1980-82. Faced with the problems posed by growing pressures for agricultural adjustment, deteriorating farm incomes and limited opportunities for alternative jobs outside agriculture, many major trading countries resorted to more market intervention and import restrictions. High interest rates and depressed world market prices, particularly between 1980 and 1983, resulted in heavy financial losses in rural areas and intensified domestic calls for agricultural protection. Exchange rate uncertainties compounded the difficulties of planning long-run sectoral adjustments. Wide exchange rate fluctuations also had the side-effect of rendering the practical results of painfully negotiated tariff concessions often irrelevant.

The effects of these factors on agricultural trade are difficult to quantify. The evidence does support, however, the claim that agricultural protectionism in the major trading zones has remained generally high. 1/ Moreover, the economic recovery under way does not offer much encouragement, at least in the short run. In many large trading countries, highly protected agriculture has permanently lost its competitiveness and the ongoing economic recovery is not expected to alleviate the problems of excess agricultural capacity in the near future. Agricultural trade policies in many major importing countries have become inextricably linked to domestic policies developed in response to internal socio-economic problems. Experience has also shown that protection measures, such as export subsidies and restraints on imports, cannot be easily dismantled once they have been introduced.

The accentuation of agricultural support and trade-restricting measures has not been limited to the major importing countries. Many developing countries adopted tighter restrictions on trade as an inevitable reaction to formidable debt-servicing problems, difficulties of market access for their exports and a limited capacity to introduce adjustment measures and austerity programmes. The losers to agricultural protectionism have not been confined to developing countries with agricultural export potential or to traditional developed country exporters. Indeed, the fact that the developed countries have become increasingly dependent on export markets as outlets for excess supplies of food products has exposed them more to the effects of trade protectionism in agriculture. A willingness to discuss these measures has therefore become more pronounced.

Present Situation and Outlook

According to estimates by the IMF and the Organization for Economic Cooperation and Development (OECD), the world economy made better progress in 1983 and 1984 than it had in the several preceding years. GNP in the OECD increased by 2.6% in 1983 and by 4%-5% in 1984, with increasing employment and a reduction in inflation rates to their lowest average level in 15 years in the seven largest economies. The output of OECD countries is expected to decelerate, however, in 1985 and early 1986. Inflation was forecast to increase slightly in the United States and Japan, but to decline further in Europe. The increase in the volume of world trade, around 2% in 1983, accelerated to more than 6% in 1984.

1/ See FAO, The State of Food and Agriculture 1982; and Protectionism in Agricultural Trade: Review of Action Taken on Conference Resolution 2/79, Rome, CCP 83/19, August 1983.

The economic recovery, though hesitant, has provided some relief to developing countries. The export prices of some major commodities have increased but not strongly nor uniformly, and interest rates have eased compared with peak levels, even though they remain high in real terms.

Developing countries as a whole, however, continued to face slow economic growth in 1983 (between 1% and 2% average growth in non-oil developing countries). Accelerated economic expansion in industrial countries, increased trade and lower oil prices were expected to favourably influence the economic performance of most developing countries in 1984. Their per caput incomes are likely to have increased again in 1984, having stagnated in 1983 and declined in 1982.

Although the current account deficit of non-oil developing countries is being reduced significantly (from a peak of $108 000 million in 1981 to $52 600 million in 1983, and possibly $45 000 million in 1984 and 1985), it is at the cost of severe economic adjustments and emergency financing arrangements. Unlike industrial nations, developing countries generally have failed to reduce price inflation. Among regions, only Asia has had reduced inflation rates.

As recovery proceeded in 1984, growth spread to most industrial countries, inflationary pressures eased and some progress was achieved in reducing unemployment. However, the recovery is still vulnerable and many uncertainties remain. Prospects for sustained growth depend very much on the overall macro-economic policies of developed countries and on the ability of developing countries to benefit from a continuing and broadening economic recovery in the industrialized countries.

Two examples quantify this developed-developing country interdependence. According to the IMF:

- An increase of 1 percentage point in the average annual rate of economic growth of industrial countries between 1984 and 1986 could result in an increase of about 3% in the average annual growth rate in the value of exports of non-oil developing countries, equivalent to $35 000 million by 1986.

- Each increase of 1 percentage point in world interest rates adds $3 500 million to $4 000 million to the cost of servicing the debt of non-oil developing countries.

Developing countries need to expand their exports not only to service their debt, but also to earn the foreign exchange necessary for the import of capital goods and production inputs. Therefore, it is of utmost importance that the access of their export commodities and products to developed country markets be assured, if they are to benefit from and contribute to the world economic recovery. Trade liberalization is indeed an important factor for growth and development of both developed and developing countries. The efforts being made to check protectionism and eliminate other trade distortions and restrictions could lead to the expansion of agricultural trade and create favourable conditions for sustained and dynamic economic growth.

Developing countries have been diverting considerable resources to service their burgeoning debt, with the result that the investment necessary to expand or at least maintain a productive base has been reduced, in some cases very drastically. Soaring interest rates and the strengthening of the U.S. dollar (the currency in which most international debt is denominated) against their currencies have contributed to increasing their debt-servicing burden and to diverting resources from productive sectors such as agriculture. This situation has worsened since commercial lending to developing countries has been reduced drastically, primarily because of the decline in the credit-worthiness of developing countries. Indeed, the

over indebtedness of these countries impedes any further large-scale borrowing on commercial terms. What is needed in the short term is a large transfer of resources under concessional terms to rehabilitate the productive sectors of developing countries and to enable them to participate in the economic recovery that is under way.

The prospects for increased concessional assistance are bleak, however, if recent events in this area continue. Total external assistance of official commitments to agriculture (OCA) decreased in 1983 in current and constant prices. The International Development Association's (IDA) seventh replenishment was limited to $9 000 million rather than the $12 000 million expected or the $16 000 million hoped for. The proposed supplementary funding arrangement for IDA has not materialized. The replenishment of the International Fund for Agricultural Development (IFAD) for 1985-87 also has faced serious difficulties. It is hoped that some progress will be made on these issues as well as the special financing facility established by the World Bank to address developmental and financial needs of sub-Saharan Africa.

Few significant recent policy measures can be reported for major trading countries in the area of price support or export subsidization that would lead to less restricted trade, such as the proposed cuts in U.S. government support to farm prices under the 1985 Farm Bill, which is under active discussion. In the field of multilateral negotiations, some results in checking tariff escalation have continued to be made under the follow-up to the Tokyo Round negotiations. However, little progress can be recorded in the far more evasive non-tariff front beyond the establishment of 'codes of conduct' for trading partners. Some expectations arise from work under way by the GATT Committee on Trade in Agriculture, which aims, among other things, at bringing export subsidies and other forms of export assistance within the purview of strengthened and more operationally effective GATT rules and disciplines. As regards preferential treatment to developing country exports, the narrow agricultural coverage of existing schemes in relation to that for industrial products, remains. Moreover, the trend in industrial countries has been to impose low quotas on competitive suppliers and extend more liberal treatment to those countries that are less able to benefit from it.

2. CURRENT SITUATION AND OUTLOOK

Food and Agricultural Production

Estimates for 1984 indicate that world food and agricultural production was more than 4% higher than in 1983, thus recovering from the setback suffered in 1983 (Table 1-2). The 4.5% increase in agricultural production is the highest registered since the 4.8% increase of 1973. World crop production is expected to increase by more than 6%, one of the best results achieved in the last decade. However, livestock production will increase by less than 2% because of less favourable conditions and incentives for milk production, and cyclical and demand factors affecting meat production.

Agricultural output of developing countries increased by 2.9%, less than the average of the last five years (1980-84) during which the annual growth was 3.6%, but above a population growth of about 2%. In Asia the large production increase of 1983 was consolidated; the combined increase of 1983 and 1984 was between 9% and 10%. Latin America and the Near East had more favourable weather and production recovered somewhat. Some recovery in food and agricultural production was also recorded in Africa, but this was owing mainly to improved production in the coastal countries of western Africa.

Source: FAO, Statistics Division

Many countries in southern and eastern Africa were afflicted by drought. Fifteen countries that were already affected in 1983/84 are again facing serious food supply problems in 1984/85, and food supplies in another six countries are threatened. The problems are most acute in Chad, Ethiopia, Mali, Mauritania, Mozambique, Niger and Sudan.

In developed countries food and agricultural production has gone up between 5% and 5.5%. Much of this increase is a consequence of the North American recovery from the sharp decline of 1983, reflecting both increased plantings and favourable weather. Western Europe also had exceptionally good harvests of cereals, and some progress was made in the USSR and Eastern Europe. Crop production in the Southwest Pacific fell back a little from the very good results achieved in 1983.

Cereal production, including rice in paddy equivalent, is estimated to have achieved a new record of at least 1 780 million tons in 1984, an increase of 138 million tons, or more than 8% (Table 1-3). Production of oil-bearing crops is expected to have increased by nearly 10%, but those of sugar and pulses by only very small amounts. Among non-food crops, cotton lint production should have gone up by 20% and tea by nearly 7%. Tobacco output is estimated to have been between 4% and 5% higher than in 1983, while coffee production is likely to have declined by more than 3%.

Outlook for Cereals in 1984/85

Large supplies of cereals in exporting countries resulting from record levels of production in 1984 are not expected to be completely absorbed by domestic and export demands. As a result, world cereal stocks at the end of 1984/85 are expected to recover significantly from the sharp fall of 1983/84. At a level of 295 million tons, cereal carry-over stocks are forecast to be 28 million tons (10%) larger than in 1983/84. This volume of stocks represents 18% of expected world consumption compared with 17% in 1983/84.

Cereal stocks by the close of 1984/85 are expected to be composed of the following commodities:

Wheat:	142 million tons, nearly 8% more than the year's beginning stocks
Course grains:	105 million tons, nearly 17% more
Rice (milled):	47 million tons, 7% more.

As of early March 1985, the world imports of cereals in 1984/85 are forecast to be 211 million tons, 11 million more than in 1983/84 and a quantity exceeded only in 1981/82 (212 million tons):

Wheat:	103 million tons, 4% more than in 1983/84
Coarse grains:	96 million tons, 8% more than in 1983/84
Rice:	12 million tons, no change from 1983.

Imports of wheat by developing countries in 1984/85 are forecast at 64 million tons, less than 1 million tons above the previous year's level. However, excluding China and India where domestic supplies are abundant, wheat imports by developing countries are expected to increase by almost 3 million tons, all of which would be in low-income food-deficit countries, mainly in Africa. Developed countries are expected to increase their wheat imports by 3 million tons to 39 million tons, reflecting record imports by the USSR (24 million tons).

Imports of course grains are expected to increase by 11% to 61 million tons in developed countries, again reflecting larger shipments to the USSR (at least 21 million tons), while those by developing countries may increase a little having remained almost unchanged in the two previous

years. The overall increase is expected to be nearly 8% (96 million tons). Imports in Western Europe are forecast to be sharply lower owing to record barley crops and are expected to decline a little also in Eastern Europe. Japanese purchases, however, are expected to be larger (21 million tons). The drought-affected production of South Africa will again have to be supplemented by imports of coarse grain and feed wheat.

On 14 September 1984, the U.S. government published its acreage reduction programmes for 1985. A minimum 30% acreage reduction has been introduced for wheat. For feed grain, because its projected carry-over for 1984 was below a trigger level of 1 100 million bushels (just under 30 million tons), a much more modest 10% acreage reduction programme has been put in force. This action should ensure greater continuity of supplies of coarse grains in 1985/86. There will be no 'payment-in-kind' (PIK) provision for either wheat or feed grains in 1985.

Fertilizer Prices

The downward trend in the export prices of major fertilizers that started in 1980 was reversed from mid-1983. Particularly pronounced price rises affected urea and Western European ammonium sulphate (around 40%) and potassium chloride (around 15%) between October 1983 and 1984. The prices of diammonium phosphate and triple superphosphate rose strongly through 1983 only to fall back in the first-quarter of 1984. By October 1984, following another recovery, the prices of these two materials were 11% below or approximately equal, respectively, to the prices of the preceeding year.

Prices in the last months of 1984 were relatively stable because, although demand was strong, supplies were relatively abundant. However, most importing countries will be paying significantly more for fertilizers in 1985 because the U.S. dollar has strengthened considerably--about 9%-10%--against the currencies of its major trading partners during 1984.

Fertilizer Consumption and Production

World consumption of the three primary nutrients--nitrogen (N), phosphate (P) and potash (K)--combined declined for the second consecutive year in 1982/83 to nearly 115 million tons. However, the latest decline was only marginal compared with that of 1981/82 (Table 1-4). The fall in consumption was mainly accounted for by the developed market economies (particularly the United States) where consumption declined by about 12% in the three years 1980/81 to 1982/83 and by the latter year was below the level of 1977/78. Overall consumption resumed its upward trend in the developing market economies and recovered in the centrally planned economies, although the rates of increase recorded were well below those of the previous five years.

The fall in consumption in the Unitd States in 1981/82 and 1982/83 was a reflection of ample stocks of several products (especially cereals), weak product prices, the implementation of policies designed to reduce output and save production costs, and high interest rates. Drought also affected consumption in Australia.

In developing countries the declines in fertilizer consumption (15% in Latin America in 1981/82 and 10% in Africa in 1982/83), or the rather low rates of growth in consumption (in Asia) were due to a variety of factors such as poor weather, low product prices, problems with balance of payments and hence, restrictions on imports and, in Latin America particularly, changes in credit and pricing policies.

Production of the three major nutrients increased a little in 1982/83 to reach 121 million tons, but still failed to regain the level of 1980/81 (125 million tons). The modest increase of about 1% was due to a

considerable expansion in the developing market economies, mainly those in the Near and Far East regions. Production declined by 3%-4% in the developed market economies, however.

Preliminary estimates indicate that fertilizer consumption recovered in 1983/84, but mainly in North America and the centrally planned economies. There were only slight increases in Africa and Asia and a further decline in Latin America.

Meeting in February 1985, the Commission on Fertilizers noted with concern that the present growth rate in fertilizer use in developing countries was far below what was required to achieve self-reliance in food and food security. An appeal was made for increased bilateral and fertilizer aid channeled through the International Fertilizer Supply Scheme (IFS). The commission also expressed concern that the reduction in the rate of expansion in additional manufacturing capacity for nitrogenous fertilizers in the developed market economies would result in a possible deficit between supply and demand by the late 1980s.

Outlook for Fertilizer, Supply and Demand

The supply-demand balance for nitrogenous fertilizer was rather tight in 1983/84 (which explains the rapid strengthening of prices since mid-1983), but the situation is tending toward a small surplus for the next two to three years and, as indicated above, will possibly revert to excess demand by the late 1980s. The situation for phosphatic and potassic materials appears to be more toward a continuing excess supply although the surplus balances at the global level could be reduced toward the late 1980s.

TABLE 1-4. FERTILIZER CONSUMPTION, BY MAJOR NUTRIENTS, 1981-83

BOX 1-1. ABNORMAL FOOD SHORTAGES AND EMERGENCY FOOD AID

By the end of 1984, 34 countries were reported to be experiencing abnormal food shortages, 26 in Africa, five in Asia and three in Latin America.* The situation had changed little from 1983 when 35 countries faced food shortages, 24 of them in Africa. At that time, in both years, 16 countries were reported as having unfavourable crop conditions.

The steadily rising amount of emergency food aid in recent years is shown in the table below. The IEFR has made increasing contributions to meet these needs, enabling allocations from the World Food Programme's (WFP) regular resources for such emergencies to be limited to $45 million annually. In 1982 less than one-half this amount had been allocated, freeing a corresponding amount for WFP's development programme. However, in 1984 the rising costs of funding 63 emergency operations meant an allocation of over $54 million to supplement the IEFR, despite record contributions to the reserve. It is estimated that currently about one-quarter of total food assistance is used for emergency needs.

In 1984, commitments to IEFR were 648 000 tons, comprising 608 000 tons of cereals and 40 000 tons of other food products, such as milk powder and vegetable oil. In 1983, the figures were 501 000 tons and 36 000 tons for cereals and other food products, respectively. These past two years have been the only ones when the IEFR annual replenishment target of 500 000 tons of cereal equivalent has been surpassed. The increase in 1984 was due partly to additional contributions of 64 000 tons made by a number of countries in response to a special appeal by the Director-General of FAO for emergency assistance to Africa.

* The countries listed in Section 2, "Food Situation in Africa," (24 or 21 depending on the date referred to) are those suffering from severe drought in 1983 and 1984 and are included in the list of countries receiving assistance to rehabilitate their food and agricultural sectors.

WFP EMERGENCY OPERATIONS APPROVED ANNUALLY, 1981-84 a/

Agricultural Trade

Main features in 1983 and 1984. According to GATT estimates, the volume of world merchandise trade in 1983 recovered by about 2% and regained the level of 1980-81. At least half of this growth in world trade in 1983 was accounted for by the increased import demand by the United States. Indeed, the seven largest economies of the OECD increased the volume of their imports by more than 6% in 1983, having reduced this volume in each of the years 1980-82. This increase is close to the annual average for the 1970s, but far below the increase of nearly 15% recorded in 1976 following the recession of 1974-75. Although there has appeared to be an acceleration in the volume and value of world trade since the last quarter of 1983 (GATT was expecting an increase in the volume of trade of 5%-6% in 1984), the overall response of world trade to the current recovery has been thus far relatively weak.

While manufactured goods recovered by more than 4% in volume terms in 1983, agricultural trade rose only 1%, far below the average rates of growth of the 1960s and 1970s. In value terms, world trade in agricultural products in 1983 failed to recover from the sharp downturn of the previous year. Exports of agricultural, fishery and forestry products declined further by approximately 1% in 1983, resulting in an overall 10% reduction in the value of these exports since 1981 (Table 1-5).

The reduction in agricultural trade in 1983, at a time of ample international supplies, reflected a number of economic and market factors:

- Improved domestic supply conditions and reduced import requirements in such large importing countries as the USSR, China, Brazil and Saudi Arabia;

- Inability to finance food import costs in many import developing countries facing balance of payment and debt problems; and

- A reduction in demand caused by the appreciation of the U.S. dollar, which implied for many importing countries higher prices in their own currencies.2/

The overall decline in world agricultural trade in 1983 reflected a reduction of about 2% in the export value of crop and livestock products, which account for over three-quarters of the total trade in agricultural, fishery and forestry products. There was a moderate increase in the trade of fishery products, which brought the value of world exports back to the 1981 level. Exports of forestry products rose by 2%, representing a partial recovery from the 9% decline of the previous year.

Trade in food products in 1983 was more depressed than that of other main groups of agricultural commodities (Table 1-6). World food exports stagnated at the previous year's level in volume terms. Cereal trade increased only marginally. In terms of value, food exports in 1983 were 3% smaller than the previous year and 15% smaller than in 1981. The increase in export earnings from raw materials and beverages, of major importance to many developing countries, was insufficient to compensate for the losses incurred in recent years.

2/ For a fuller discussion of agricultural commodity trade, see FAO, Commodity Review and Outlook 1984-85, Rome, 1985.

The reversal in the net trade position of developing regions was a significant development in the regional pattern of agricultural trade in 1983. After having shown a net trade deficit for the first time in 1981 and further in 1982, developing countries as a whole emerged again as net agricultural exporters in 1983, but by a very slender margin (Table 1-7). However, this resulted from a further decline in their imports of agricultural products, which were 13% below the level of 1981 and only a 3% increase in their agricultural exports. Imports declined in China, several large importing countries in the Near East, including Saudi Arabia, Iran, Iraq, and some countries in Africa.

The improvement in the agricultural trade balances of developing countries appeared, therefore, precarious and narrow-based. The modest increase in their agricultural export earnings in 1983 only partially offset the heavy losses of 1982. Moreover, most of the increase was concentrated in a few large exporting countries in Latin America (Argentina, Brazil, Cuba and Mexico).

World agricultural trade is expected to be boosted in 1984/85, in particular by the increased import requirements of the USSR, although Western Europe, normally a large importer, has ample domestic supplies of cereals this year. Export earnings from the principal agricultural products of developing countries may improve only moderately in 1984 following the poor export performances of 1982 and 1983, judging from preliminary indications of trade. Export earnings from fats and oils are estimated to have increased over their levels of 1983 because of higher prices. While trade in tea is up only moderately because India has curbed its exports caused by high domestic demand and prices, world market prices are exceptionally high. Cocoa bean shipments were depressed in 1983/84 because of supply constraints. Coffee trade expanded in 1983 and prices remained firm, mostly within the range of the International Coffee Agreement. Banana trade was at a rather low level, the result of supply losses due to poor weather. Trade prospects are poor for sugar as demand and prices are low, and competition from alternative sweeteners remains keen. Jute trade has been below normal because of low production in Bangladesh and strong competition from synthetic fibres.

Agricultural export prices. International U.S. dollar prices of most agricultural commodities showed a substantial upward trend during much of 1983 and the first-quarter of 1984, but have tended to slacken more recently. 3/ Between the third-quarter of 1983 and the third-quarter of 1984, export prices of food declined by 7% and those of non-food agricultural products by 2% (Fig. 1-1).

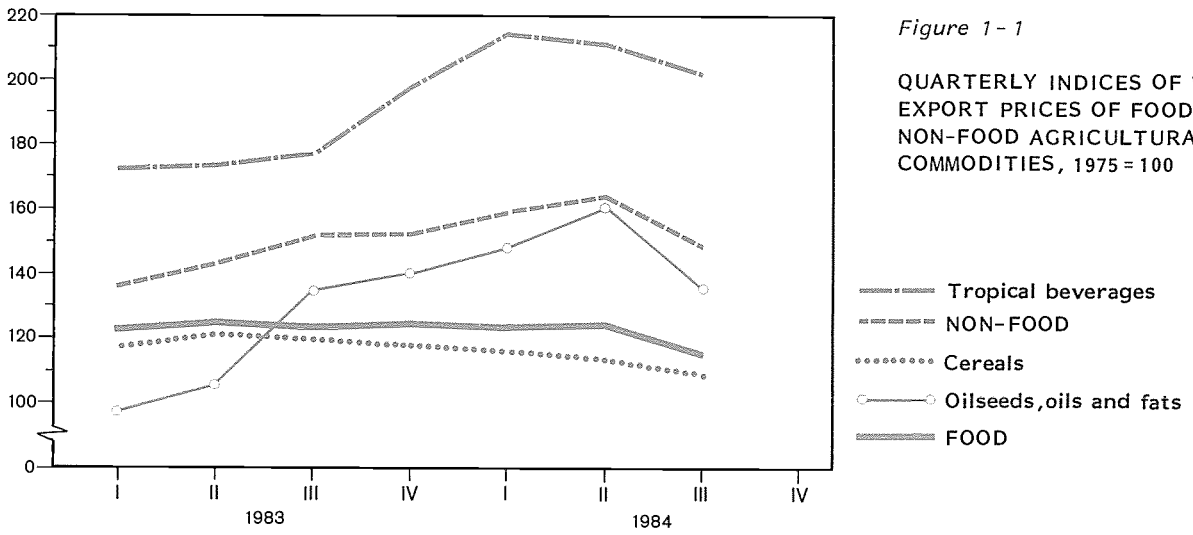

Figure 1-1

QUARTERLY INDICES OF WORLD EXPORT PRICES OF FOOD AND NON-FOOD AGRICULTURAL COMMODITIES, 1975 = 100

Source: UN, Monthly Bulletin of Statistics, December 1984.

Prices of the main groups of commodities exported primarily by developed countries (cereals and livestock products) stagnated or declined throughout most of 1983 and 1984. By the third-quarter of 1984 the prices of cereals as a whole were approximately 8% lower than a year earlier. The prices of cereals have tended to slacken further recently reflecting: large market supplies (particularly in the United States and the EEC); the

---

3/ Changes in dollar prices should be considered in the light of the continous strengthening of the U.S. dollar against most currencies (See Box 1-2).

prospects of a suspension of the long-term grain import agreements by China, which entered the market as a maize exporter; and the continued strengthening of the U.S. dollar (Table 1-8). These factors have largely offset price-raising influences, in particular, the large grain purchases by the USSR. The decline was less pronounced in the case of wheat, the quotations of which remained relatively stable throughout 1984. As regards livestock products, the prices of both dairy products and meat generally remained depressed.

Prices of non-food commodities and many food products exported by developing countries increased steadily throughout 1983 and into the first- and second-quarters of 1984. Subsequently, they have tended to fall back. Price increases between early 1983 and early 1984 were particularly pronounced for tropical beverages (24%), although they have declined markedly since then. Sugar prices declined further in 1984 to their lowest level in 13 years, reflecting a continuing situation of world oversupply. By late 1984, sugar prices were less than one-half of those prevailing a year earlier. There was a boom in prices of most vegetable oils, with the notable exception of olive oil, reflecting a change from a period of ample supplies in the second-half of 1981 and 1982, to a situation of supply tightness during 1983 and the first-half of 1984. Prices of palm, coconut, palm kernel, groundnut, rapeseed, sunflower and soybean oils more than doubled. However, in anticipation of more adequate supplies in 1984/85, prices have tended to fall since July 1984, particularly of palm oil and soybeans. Soybean prices in the last months of 1984 had returned to the depressed levels of early 1983.

Quotations for natural fibres also rose considerably in 1983: cotton by 17% and jute by over 62%, reversing a period of several years of depression. However, while prices of jute continued to strengthen throughout 1984, those of cotton lint weakened, particularly during the second-half of the year.

BOX 1-2. PRICES OF COMMODITIES AND VALUE OF TRADE IN TERMS OF THE U.S. DOLLAR AND ECU

The U.S. dollar is the most widely used currency for international market transactions. The pronounced overall appreciation of the U.S. dollar against most other currencies since 1980 distorts any assessment of real change in commodity prices and the value of trade that have taken place since that time. Other things being equal, an appreciation of the U.S. dollar implies an equivalent increase in the price of a given commodity in terms of those currencies that experience a relative depreciation. Therefore, changes in the export performance of a given country, as measured in U.S. dollars, may appear grossly undervalued. For a commodity-exporting country, an appreciated U.S. dollar means larger export earnings in terms of the local currency price, and eventually, downward pressures on the U.S. dollar price of the commodity itself. Conversely, a food-deficit country may be facing far greater difficulties in financing imports than figures denominated in U.S. dollars suggest.

A more stable measurement of changes in international prices and in trade values is provided by Special Drawing Rights (SDRs). At the moment, however, the heavy dollar component of this 'basket' of currencies limits its validity as a deflator of U.S. dollar denominated prices and values for the purposes of comparison over time and between countries.

The European currency unit (ECU) provides an alternative. It comprises a basket of currencies of EEC members with weights determined by the relative economic sizes of the countries. Since the basket comprises strong currencies like the deutsche mark, as well as relatively weak ones, pronounced exchange rate fluctuations are greatly reduced.

The chart given here shows the strengthening of the U.S. dollar against the ECU since January 1983. The U.S. currency appreciated by 17% compared to the ECU during 1983 and by a further 13% during 1984.

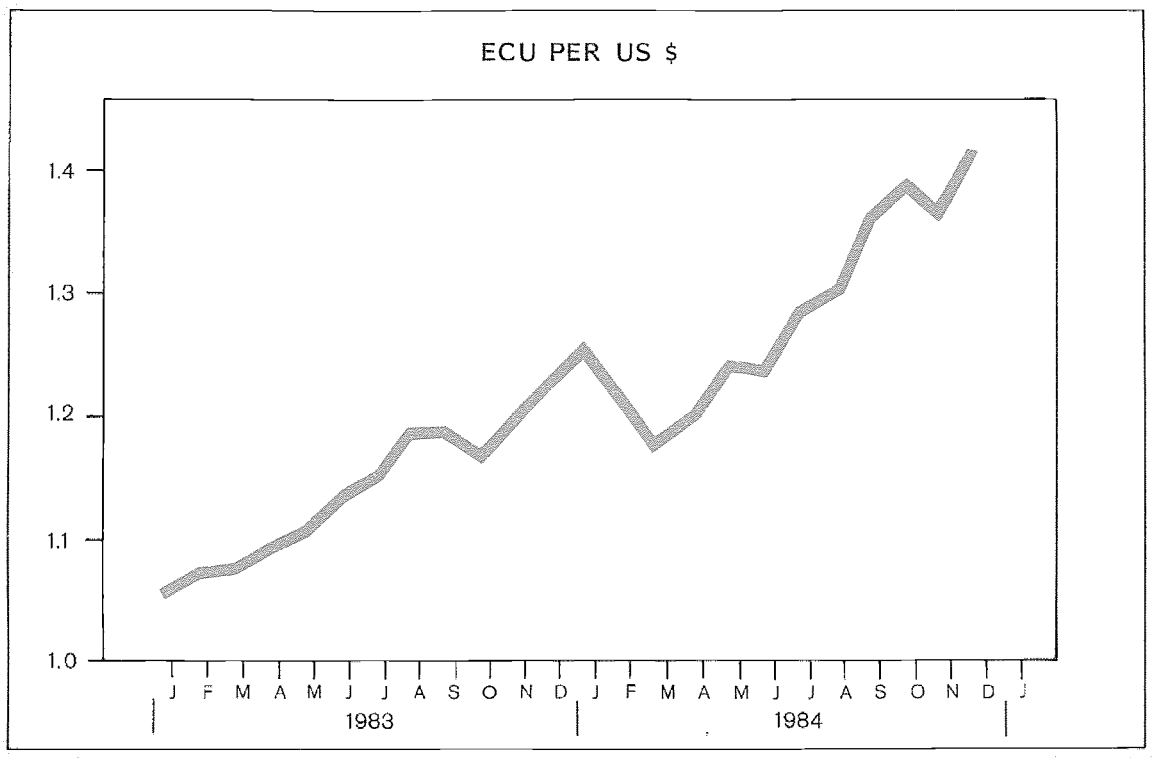
At the world level, the export value of agricultural products, which declined by nearly 1% a year in dollar terms between 1979 and 1983, actually increased by over 12% a year in ECUs.

The variations in export prices of selected commodities may also be compared in U.S. dollar and ECU terms (see table). It underlines the caution that should be used in interpreting the decline in dollar prices of many commodities that have taken place during much of 1984. While recent price declines have occurred in both U.S. dollar and ECUs for several commodities, including sorghum, sugar, soybeans and cocoa, the stagnation or decline in the U.S. dollar price of commodities such as wheat, maize, rice and coffee did not necessarily imply relief for importers. Although the appreciation of the U.S. dollar has exerted a depressing effect on U.S. dollar prices in international commodity markets, such effect is difficult to assess in view of such factors as the inflation differential among countries, taxes, subsidies, and the large weight of the United States in international trade.

Profound repercussions of the strengthening of the U.S. dollar for individual exporting countries can be illustrated by the example of two coffee-exporting countries, the Ivory Coast and Colombia. The U.S. dollar appreciated by 20% and 24% against their respective national currencies between January and December 1983. The dollar prices of coffee also increased by 9%-10% during this period, so that coffee prices, expressed in national currencies, rose by 29%-34%. Even allowing for the effects of domestic rates of inflation during this 12-month period, about 6% in the Ivory Coast and nearly 20% in Colombia, it appears that the prices of coffee rose appreciably in terms of the currencies of these exporting countries.



Source: EUROSTAT.

Terms of trade. Terms of trade of agricultural products in international markets improved in 1983. Developing countries were the main beneficiaries of the improvement, with dollar prices of manufactured goods declining by 4% and those of crude petroleum by 12%. Their agricultural exports appreciated in real terms by over 12% in 1983 (Table 1-9).

The benefits of higher real export prices of agricultural products were supplemented by the larger volumes of exports (4%) of developing countries. On balance, export earnings from agriculture in 1983 should have enabled them to purchase 16% more manufactured goods and petroleum than in the previous year.

TABLE 1-9. NET BARTER AND INCOME TERMS OF TRADE OF AGRICULTURAL EXPORTS FOR MANUFACTURED GOODS AND CRUDE PETROLEUM

Note: The index of net barter terms of trade is defined here as the true ratio of the index of export unit values of agricultural products to the index of world export prices of manufactured goods and crude petroleum. The index of income terms of trade is obtained by multiplying the index of net barter terms of trade (as defined above) by the index of export volumes of agricultural products.

Sources: FAO, Statistics Division and Policy Analysis Division.

Information available for the first nine months of 1984 shows a further improvement of about 5% in the terms of trade of developing country exports of food and nearly 12% for their exports of non-food agricultural commodities. The terms of trade of developed country agricultural exports declined by nearly 3% for food but improved by 10% for non-food commodities.

However welcome the recent improvements in the agricultural terms of trade of developing countries, they are subject to important reservations. First, the improvement comes after several years of deterioration and only partly compensates for the losses incurred since 1979. Second, they have mainly benefited large exporting countries in Latin America and the Far East. In Africa, where the purchasing power of agricultural exports has deteriorated most in recent years, the improvement in 1983 was minor. Third, the current sluggishness and uncertainties surrounding agricultural markets suggest that the improvement may be short-lived.

External Assistance to Agriculture

Total and concessional commitments in 1983. The most recent information available on external assistance to agriculture indicates a decline in 1983 in the levels of official commitments to agriculture (OCA) (narrow definition). This decline reflects budgetary constraints in major donor countries in the early 1980s. The decline in official development assistance (ODA) or the concessional part is of particular concern because it affects the low-income countries that rely heavily on such external assistance for expanding their investments in agriculture.

Commitments of multilateral and bilateral concessional assistance to agriculture, in current prices, decreased by more than 20% and by about 8%, respectively, between 1982 and 1983 (Table 1-10). As a result, the share of bilateral concessional assistance in total assistance to agriculture increased.

While multilateral concessional lending to agriculture has declined, non-concessional multilateral commitments increased from $2 351 million in 1982 to $2 836 million in 1983, indicating an overall hardening in terms of official lending to agriculture. This is due mainly to an increase of nearly 50% in commitments of the IBRD to agriculture in 1983. However, the share of lending to agriculture by regional development banks that was non-concessional decreased, except for the African Development Bank (ADB).

A similar picture appears to be developing with regard to multilateral and bilateral OCA (broad definition) (Table 1-11). Up to 1982, the pace of the expansion of these resources in current prices slackened,

with increases in 1982 of less than 5% and 2%, respectively, compared with increases of nearly 12% in 1980 and 8% in 1981.

- There was an abrupt decline in bilateral commitments in 1983 (more than 20%) following a recovery in these flows since 1980.

- There was also a marked slowdown of multilateral commitments between 1979 and 1983. After an expansion of nearly 30% in 1980, increases in 1981, 1982, and 1983 were only 6%, 3%, and less than 2%, respectively.

- There has been a steady decline in multilateral concessional commitments from 1980 to 1983 amounting to almost 22%, but a corresponding increase in non-concessional commitments of 50%. Therefore, between 1980 and 1983, the terms of multilateral commitments (broad definition) have significantly hardened: the concessional component falling from 54% to 38%. As this has been accompanied by a decline in bilateral commitments, most of which are concessional, the hardening of the terms of total commitments has been severe between 1980 and 1983, with the concessional share falling from 72% to 56%.

Most of the decline in multilateral concessional assistance in 1983 is accounted for by delays in replenishing IDA and reductions in its funding. The seventh replenishment of IDA ($9 000 million) is much smaller than its sixth (1979) replenishment. Under these circumstances, and because IDA assigns a major share of its resources to agriculture (40% in the early 1980s, equivalent to 20% of all concessional assistance to agriculture), it seems unlikely that IDA will be able to sustain the growth of its assistance to agriculture achieved since the late 1970s. Unless more resources are made available to this important lending institution, the disbursements of multilateral concessional assistance to the agricultural sectors of low-income countries will soon begin to flag.

The IDA is not the only concessional lending institution that has been forced to cut back its programmes. Commitments of IFAD also decreased in 1983. This situation reflected difficulties encountered in the negotiating of its first replenishment. The second replenishment of IFAD for 1985-87 also faced difficulties and negotiations that took place at the end of February 1985, while ensuring the fund's continued operation, were short of its first replenishment that covered 1981-84. On the other hand, regional development banks as a group increased their concessional commitments to agriculture by one-quarter between 1982 and 1983. Only the ADB decreased its concessional assistance to agriculture.

The impact of this reduction in multilateral concessional commitments has been particularly severe for the Asia and Pacific and African regions. They received 23% and 28% less, respectively, in 1983 than in 1980-82. However, on average, the Asia and Pacific region receives almost two-thirds of such commitments; thus, its absolute loss was greater--about $300 million. The decline for Africa was less than one-half this amount.

Food aid. Shipments of food aid in cereals are estimated to have been more than 9.8 million tons in 1983/84 compared with 9.2 million tons in 1982/83 (Table 1-12). It is expected that nearly 12 million tons will be provided in 1984/85, the largest quantity since 1971/72 and greater than the target of 10 million tons set by the World Food Conference.

a/ Estimated.

Source: FAO, Commodities and Trade Division.

Currently over 80% of shipments are consigned to low-income food-deficit countries and cover about 19% of these countries' estimated cereal imports, proportions that have not radically changed since 1979/80. 4/ The increase in shipments mainly reflect international concern over the serious food situation in sub-Saharan Africa.

As of the end of December 1984, pledges to the regular resources of the WFP for its 1983-84 biennium amounted to $982 million, or 82% of the pledging target of $1 200 million. Pledges for the 1985-86 biennium totalled almost $1 000 million or 74% of the new biennium's target of $1 350 million.

At its 18th session held in late October-early November 1984, the Committee on Food Aid Policies and Programmes (CFA) agreed that on an exceptional and ad hoc basis, $10 million in addition to the usual $45 million allocation, should be made to the 1984 emergency budget from the programme's regular resources. This decision was taken in light of the exceptional circumstances prevailing in Africa, the rapid utilization of IEFR's resources, and the regular allocation from WFP's regular resources for emergency needs.

Regional Highlights of Production and Trade, 1979-84

The current situation and outlook for some key aspects of agriculture have been examined. A following section examines long-term trends and issues, sometimes on the basis of unconventional country groupings. This linking section provides a summary of developments in food and agricultural production and trade in the medium term, according to more conventional, geographically based groups of countries (Table 1-13).

Developed countries as a whole achieved a moderate improvement in total agricultural and per caput food production. All developed regions except North America shared in this improvement. Larger food and agricultural supplies were, however, a mixed blessing for some developed countries already troubled by the excess capacity of their agricultural sectors. The problems of oversupply were made worse by the trade-depressing effects of a world recession. The dynamism that had characterized agricultural exports by developed countries during most of the 1970s gave way to a period of stagnation in terms of the U.S. dollar, with both Western and Eastern Europe actually experiencing a reduction in the dollar value of their exports between 1980 and 1984. The purchasing power of agricultural exports declined substantially during this period of depressed commodity prices, though to a lesser extent and with less critical consequences than in developing regions. There was also a marked reduction in the rate of growth of food imports compared to earlier periods.

As regards developing regions, aggregate food supplies increased substantially, with food production growth exceeding population growth and per caput food imports increasing by nearly 3% annually in volume terms. Larger supplies resulted in a sizable improvement in per caput calorie supplies, which had marginally exceeded minimum requirements in 1979-81. Agricultural export performances were on the whole less satisfactory, both in terms of absolute dollar values and in relation to purchasing power.

There were, however, wide regional divergences behind these aggregate figures. Improvements in domestic food supplies were concentrated in the regions of the Far East and ACPEs, the only developing areas that achieved

---

4/ Includes all food-deficit countries with per caput income below the level used by the World Bank to determine eligibility for IDA assistance ($805 in 1982) that, in accordance with the guidelines and criteria agreed to by the CFA, should be given priority in the allocation of food aid.

substantial growth rates in per caput food production. At the same time, they reduced further their already moderate dependence on food imports. Although the purchasing power of regional agricultural exports declined, particularly in ACPEs, this was compensated by greater export earnings from other sectors. As a result, food imports accounted for a considerably smaller share of the total value of merchandise exports than in the mid-1970s.

The economic difficulties that affected most Latin American countries during the early 1980s did not spare food and agriculture. Poor weather conditions and weather-related factors also had a depressing effect. Food output, which had barely kept pace with population growth during 1974-84, declined in per caput terms in the early 1980s. Stagnation and slow growth in production characterized most of this latter period, with the exception of 1981. At the same time, many heavily indebted countries in the region faced increasing difficulty in maintaining adequate levels of food imports. The annual increase in per caput food imports in volume terms decelerated from 6.5% during 1974-83 to less than 2% during 1979-83. This reduction in the pace of imports did not bring about any major improvements in the balance of payments, the proportion of total export earnings absorbed by food imports having remained practically unchanged at around 10%. External account imbalances were further aggravated by a significant erosion of the purchasing capacity of agricultural export earnings.

The agricultural situation in Africa appears even more serious. Agricultural production rose at insignificant rates, food production declined by over 1% a year in per caput terms, and nutritional standards remained well below minimum requirements, despite an increasing dependence on food imports and external aid. Not only did food imports absorb a high proportion of total export earnings--16% during 1981-83--but agricultural exports, critical for the economies of most countries in the region, were losing almost 10% of their purchasing power every year during 1979-83.

Though less critically dependent on agriculture, the Near East also suffered from sluggish production performances and declining per caput output during the early 1980s. Food imports continued to grow at very high rates, however, contributing to a major improvement in per caput calorie supplies. Although such an increase in food imports coincided with reduced export earnings, particularly from crude petroleum, food imports still absorbed a smaller share of total export earnings than in other developing regions. Unlike other regions, the Near East achieved fast growth rates in agricultural exports and a considerable improvement in the purchasing power of agricultural export earnings. However, this improvement was based on relatively few factors (e.g., the sharp increase in the volume of cotton exports by Egypt) and was of very limited significance for most economies of the region.

Food Situation in Africa

The Sixth Report of the Joint FAO/WFP Task Force, established in April 1983 to monitor the deteriorating food situation in nearly half the countries of Africa, was published in late October 1984. It showed that the aggregate cereal production in 1983 of the 24 countries in Africa identified by FAO as facing exceptional food needs in 1983/84 was 16.9 million tons, 9% below the poor crop level of the previous year and 15% less than the previous normal crop of 1981. The cereal import requirements of the 24 countries in 1983/84 were estimated at 5.3 million tons, some 2.1 million tons higher than the previous year. Of this total of 5.3 million tons, 2.9 million tons represented food aid requirements and 2.4 million tons the estimated commercial import capacity. This compared with actual food aid receipts of about 1.5 million tons and 1.8 million tons of commercial imports in 1982/83.

Although by late 1984, the cereal food aid pledged by donors was over 1 million tons more than shipped to the same 24 countries in 1982/83, there was still a shortfall of approximately 200 000 tons of cereals against the estimated food aid requirements of 2.9 million tons. The levels of commercial imports by these countries also increased by some 600 000 tons compared to 1983.

The situation in 1984/85. The African food emergency has continued into 1985. Poor main season crops of 1984 were harvested in a number of countries in southern, eastern and northern Africa, while most Sahelian countries harvested crops that were seriously reduced by drought. However, with the coastal countries of West Africa experiencing improved conditions, the number of seriously affected countries have been reduced to 21.

In eastern Africa the food supply situation deteriorated sharply in Ethiopia, following a poor main season harvest in 1983 and the failure of the secondary 'belg' harvest in early 1984. Moreover, the main cereal and pulse crops of 1984, the harvesting of which began late in the year, were also poor (about one-third below the 1980-82 average), so the food supply position will remain serious throughout the end of 1985. According to the Relief and Rehabilitation Commission of Ethiopia, 7.7 million people, or about one-fifth of Ethiopia's total population, are affected.

In Kenya, as a result of the worst drought in many years, the main cereal crop harvest of 1984 is estimated to have been some 30% below the previous year's level, resulting in cereal import needs of about 950 000 tons for 1984/85.

FAO estimates that in the eastern subregion, seven countries (Burundi, Ethiopia, Kenya, Rwanda, Somalia, Sudan and Tanzania) are facing exceptional food supply problems in 1984/85, with aggregate food production more than 20% below the average for 1979-83 and with food aid requirements of 3.8 million tons, 150% more than the aid received in 1983/84.

For the third consecutive year in most southern African countries, drought affected the main season's harvests (April/May) of 1984. Poor crops were again harvested in Angola, Botswana, Lesotho, Mozambique, Zambia and Zimbabwe. The 1984/85 cereal import requirements of these six countries were estimated by FAO at 2.1 million tons and their food aid requirements at 1.1 million tons, some 0.5 million tons higher than the previous year. The condition of crops to be harvested in 1985 is more favourable in most countries, but still depends crucially on the progress of the rains.

In West Africa, the main season's harvests of 1984 were much better than in 1983 in the countries bordering the Gulf of Guinea. The aggregate food supply position was considered to be back to normal in Ghana, Guinea, Guinea Bissau, Benin and Togo. However, harvests were again poor in 1984 in the Sahelian countries of the subregion. In the northern areas of these countries, widespread crop failures were reported and the final output was even worse than the drought-reduced crop of 1983. In the Sudanian zones of the same countries, the outcome was more mixed, particularly in Burkina Faso and Mali, but aggregate output was expected to be worse than 1983, leading to a continued need for substantial cereal imports and external assistance. Seven countries faced exceptional problems of food supply in 1984/85 (Burkina Faso, Cape Verde, Chad, Mali, Mauritania, Niger and Senegal). Their aggregate production was 25% below the annual average for 1979-83 and food aid needs for 1984/85, at 1.7 million tons, were double the level of 1983/84. Severe drought-affected crops in Morocco in 1984 for the second consecutive year, also requiring about 400 000 tons for emergency relief for that country.

In light of these developments, the aggregate cereal import requirements of the 21 drought-affected countries of Africa in 1984/85 were expected to exceed 12 million tons by February 1985 compared with actual imports of 7.1 million tons in 1983/84. Food aid needs at over 7 million were more than twice the amount donated in 1983/84. By late February 1985, only 40% of the known pledges of food aid to the affected countries (5.1 million tons) had been delivered.

By the end of February 1985 the food situation in Africa raised three issues of immediate concern:

- There remained an aggregate uncovered requirement of food aid of almost 2 million tons;

- Only about 40% of the known pledges of food aid had been delivered; and

- Logistical constraints, particularly in some land-locked countries, required special financial and technical assistance programmes.

Logistical problems. The problem of ensuring that people deprived of their normal sources of food have access to emergency food supplies is not solved by the identification of alternative sources of food, whether they are provided by donors or obtained through commercial channels. Most African countries are not well equipped with transport facilities and a substantial number of them are land-locked. Therefore logistical problems, always important in Africa, assume added significance when relatively large quantities of food supplies have to be moved quickly and reliably to people afflicted by famine.

The passage of bulk and bagged cereals, the most critical commodities, from ports overseas even to main distribution centres in affected countries face several potential bottlenecks.5/ Ports are frequently congested, and the unloading of ships can be delayed. Warehouses at ports are often full and open-air storage is therefore necessary with a likelihood of spoilage. For example, Mombasa will have to handle more than 1 million tons of imported food commodities in 1984/85 to meet Kenya's needs, as well as the food aid needs of Rwanda, amounting to another 65 000 tons. Both road and rail transport facilities are likely to be inadequate. The problems up-country may be even more daunting with poor road networks and a transport system suffering from a lack of fuel and maintenance.

Donors have responded generously to these challenges and, looking beyond the immediate provision of food, longer term remedial measures frequently include additional trucks or spare parts, port handling and storage facilities and other means of alleviating logistical constraints. However, the provision of additional equipment is not enough; improved logistical management is needed as well, such as the better scheduling of shipments to match the handling capacities of ports and the corresponding matching of port off-take rates with shipments up-country by different transport modes.

Bilateral external assistance for the procurement, transport and distribution of emergency food supplies includes EEC assistance amounting to the equivalent of nearly $6 million, the main recipients being Chad, Ghana and Senegal. Examples of multilateral logistical support is that provided by UNICEF to Burkina Faso, Cape Verde and Mali; by FAO to Chad; and by WFP (logistics officers posted to some major entry ports). FAO

5/ See The Critical Social and Economic Situation in Africa: Report by the UN Secretary-General, prepared for the 39th Session of the UN General Assembly, 1984.

also provides silos, vehicles, and management skills and training in staple food storage, handling and preservation through its Food Security Assistance Scheme. In the area of logistics management, FAO collaborates with UNDP and WFP on a project in Botswana.

Recovery and rehabilitation. While the provision of emergency food needs must take precedence over all other measures, steps to promote the rapid recovery and rehabilitation of affected zones also need attention. The 86th session of the FAO Council in November 1984 approved the allocation of $5 million of FAO's budget for 1984/85 to support such rehabilitation measures in Africa. The three areas of action focused on were: (1) improvements in food early warning systems, (2) seed supply, and (3) livestock.

(1) Extensions and improvements in food early warning systems and other components of preparedness

African governments need to establish or strengthen early warning systems related to weather, crop and pasture conditions. The system, usually based on agrometeorological information, can also monitor indicators describing the emerging food supply situation such as the stock situation and food prices in various markets.

FAO is continuing to assist many African countries in establishing and developing such systems at national and regional levels. The original AGRHYMET programme for meteorological forecasting in the Sahel is being supplemented by FAO in cooperation with the World Meteorological Organization (WMO) by similar projects for SADCC (Southern African Development Coordination Conference) countries as well as national projects for Sudan, Kenya, Rwanda, Ethiopia and Guinea Bissau. Requests for assistance have been made by several other African countries.

Countries exposed to acute and large-scale food shortages can make themselves better prepared to meet such emergencies by preparing contingency plans for food relief and planning the logistics of famine relief distribution. FAO is providing technical support in this area by arranging a programme of workshops for countries trying to develop such plans.

(2) Seed supply

Seed, almost invariably reserved by farmers from their own harvests in those African countries most frequently affected by drought, is often the only input to the production of basic food crops. Yet people afflicted by famine may be forced to consume their seed stocks before the new planting season begins. Poor, drought-affected crops may also result in poor seed quality and replanting needs may call for additional supplies of seed not easily available. Therefore, the following actions have to be supported:

- Ensuring the timely arrival of emergency food supplies so that seed is not consumed;

- Identifying, procuring, testing, storing and treating seed; and

- Holding emergency stocks of seed, possibly at the subregional level, to meet the situation where seed is unobtainable locally.

A number of countries have requested FAO to organize missions to assess their agricultural situations, including the supply and quality of seeds. Such missions are scheduled for Mali, Niger, Chad and Ethiopia.

Among international organizations, FAO and the United Nations Emergency Operation (UNEO) Trust Fund have been particularly active in

seed-supply activities in Botswana, Burkina Faso, Ghana, Gambia, Tanzania and Zambia. Chad has benefited from the joint support of several donors for the purchase of 3 500 tons of food crop seeds. Similarly, about 2 800 tons of food crop seeds have been procured in Ethiopia with the assistance of the EEC.

(3) Livestock

When drought strikes, the main problems facing livestock are shortages of forage and water. The latter two are linked because forage may be available but cannot be grazed because it lacks water, and watering points are almost certainly surrounded by overgrazed areas. In this situation, the livestock owner is doubly exposed because of losses in stock numbers and also because there are few or no buyers for livestock unless a government buying agency is at hand. Disease problems are worsened because of the animals' weakened condition and the greater movement of livestock.

International and technical support is needed in the form of programmes of disease control; animal nutrition to safeguard breeding stock; additional water sources to enable distant forage sources to be accessed; and in facilitating destocking through the funding of emergency buying operations.

Ongoing livestock programmes with external support include FAO's assistance in rinderpest control in Burkina Faso, the Central African Republic, the Gambia, Guinea, Mauritania, Togo and Zambia. The UNEO Trust Fund has also been involved in a large number of livestock protection programmes, including pasture and fodder crop production and vaccine supply. Other livestock protection operations are also being carried out on a bilateral basis, particularly with the participation of northern European countries.

Long-term situation. 6/ While FAO has recorded food emergencies in as many as 20-30 African countries each year since 1977, a group of 15 countries has recurrently suffered acute food shortages. These countries are listed in Table 1-14, together with some indicators of their food supply situation. The combined population of these countries represents 31% of the total for developing Africa.

In this group of countries, chronic food insecurity has resulted from a wide variety of factors. These include a poor endowment of agricultural resources, adverse weather conditions, civil disturbances and wars, and deteriorating export markets. Inappropriate government policies resulting in an inefficient use of resources have also played a role. A review of some of these factors reveals some common features of these countries:

- All but five countries of the group are low-income countries, with a per caput GNP of less than $410 in 1982. In all but one of these low-income countries, per caput incomes stagnated or declined during 1970-82.

- In all but three countries, the average per caput DES is below minimum nutritional requirements. Although DES improved in eight countries during the 1970s, this was achieved in most cases because in-

---

6/ Several papers have been prepared recently by FAO addressing the long-term deterioration in the food and agricultural situation in Africa and indicating possible measures to improve it. These papers include: Interim Report on Constraints on Food Production in Low-Income Food-Deficit Countries of Africa, CFS 83/6, February 1983; The State of Food and Agriculture 1983; and Delivery Systems for Small Farmers in Africa, CFS 84/5, January 1984.

a/ DES - Dietary energy supplies.

b/ PSC - Population supporting capacity or potential capacity of land to support the country's population. A figure of less than 1 shows that the country's land resources could not produce sufficient food to support the population at a low level of input use in 1975 (see FAO, Land, Food and Population, C 83/8 August 1983).

c/ Developing countries in Africa, excluding Egypt, Libya and Sudan. However, the PSC ratio includes these three countries.

Sources: FAO, IIASA, UNFPA, World Bank.

creased volumes of food imports more than offset declining domestic food output. On the other hand, six countries experienced large declines in DES. This reflects declines in both per caput food output and imports.

- In all countries food production per caput has either stagnated or declined throughout the 1970s. Production performances deteriorated further in recent years.

Poor production performances have been related to: a) poor resource endowments--in eight countries the productive potential of land has been inadequate to support the countries' populations at low levels of input use; b) unfavourable climatic conditions--many countries having suffered, in particular, from several consecutive years of drought; and c) civil disturbances or wars in some countries otherwise relatively well endowed for agriculture (Angola, Mozambique and Chad). In others (Ethiopia, Somalia and Uganda), the food crisis has been the result of a combination of all of the reasons cited.

All countries in the group are net food importers and have received increasing quantities of food aid in recent years. The volume of food imports rose considerably during the 1970s in most countries. In the case of cereals, they reached on average 52 kg per caput by the early 1980s, 60% more than the average for the other African countries. The increasing dependence on food imports is indicated by the growing import content of total calorie consumption in all countries of the group. Imported food accounted for 16% of total calorie supplies in the late 1970s compared with 11% in 1969-71. The shares for Africa as a whole were 6% in 1969-71 and 13% in 1979-81. Though remaining generally high, food imports declined significantly in a number of countries, particularly since the late 1970s. Countries where food imports declined were by and large those with a decreasing per caput GNP, underlining the importance of overall economic performance in determining the level of food imports.

External payment problems, exacerbated by a growing imbalance in merchandise trade and the weakening of national currencies against the U.S. dollar, have been factors limiting food imports.7/ Nevertheless such imports have remained considerable in relation to the countries' purchasing capacity. With the exceptions of Chad, Uganda and Zambia, food imports have absorbed a large share of total merchandise export earnings.

Food aid has therefore constituted an invaluable, if precarious, supplement to domestic food supplies and commercial imports. Food aid in cereals in 1982 represented at least 20% of the domestic output of cereals in eight countries of the group and 20%-90% of the total cereal imports in 1980-82 in all 15 countries covered.

The Southern African Development Coordination Conference (SADCC): Agricultural Perspectives to 2000

SADCC is composed of Angola, Botswana, Lesotho, Malawi, Mozambique, Swaziland, Tanzania, Zambia and Zimbabwe. It was established in Lusaka in April 1980 and pursues the following four main goals: a) reduction of external dependence; b) progressive regional integration; c) the mobilization of resources; and d) joint action to secure international understanding and support for the SADCC development strategy.

7/ The external debt of 12 countries of the group for which data were available represented, on average, nearly half of their GNP in 1982.

At its highest executive level, the organization functions through an annual summit meeting of heads of state or governments of member states and a council of ministers to supervise the SADCC programme. A small permanent secretariat has operated in Gaborone (Botswana) since October 1982.

Programme development within SADCC is the responsibility of partner states. Each SADCC state is delegated responsibility for coordinating and implementating one or more sectors of the Lusaka Plan of Action. On agricultural matters, food security is handled by Zimbabwe; soil conservation and land utilization by Lesotho; agricultural research and animal disease control by Botswana; and fisheries, wildlife and forestry by Malawi.

The SADCC region is currently going through an extremely difficult period. Eight of the nine SADCC countries are on FAO's list of 24 African nations that faced acute food crises in 1983/84. While the current drought, world recession and, in some countries, civil and military strife are major reasons for the immediate difficulties facing the agricultural sector, the real causes lie much deeper. They are associated with long-term constraints such as deficiencies of infrastructure and the lack of a trained work-force and policies unattuned to promoting rural development. Corrective policies are needed without delay, but they should be conceived in a long-term perspective that leads to more adequate resources for agriculture and recognizes the long gestation period of many agricultural development activities.

In order to facilitate this action, FAO has prepared a perspective study, SADCC Agriculture: Toward 2000, which examines what would happen in the region in food and agriculture if past trends are allowed to continue and, alternatively, if well-planned and concerted efforts are made to rectify the situation.

The study indicates that a continuation of past trends would clearly spell disaster: negative growth rates in per caput agricultural production, a worsening situation in food crop supplies in both aggregate and per caput terms and a trade imbalance virtually impossible to finance. The cereal imports of SADCC countries, for example, would increase five-fold, from 1.5 million tons in 1979-81 to over 8 million tons in 2000, and would require (at 1980 prices) almost $4 000 million in foreign exchange. Even with these large imports, the nutritional situation in the region would continue to deteriorate. The study shows, through 'improved performance' (IP) and 'high performance' (HP) scenarios, that alternatives exist. Under the IP scenario, agricultural production would grow at 3.2% annually. The demand for basic foods would still exceed the projected supply, but the trend away from food self-sufficiency would be reversed. Under the HP scenario self-sufficiency in all food products would further increase except for livestock products. The SADCC region would remain a net exporter of agricultural commodities with a doubling of the export availability of non-food commodities and with manageable imports in the food sector.

The IP scenario and especially the HP scenario imply large efforts by national governments, requiring a massive concentration of human, financial and capital resources in agricultural development. The total gross investment in agriculture (narrow definition) by 2000 would amount to $2 400 million a year under the IP scenario and $4 000 million a year under the HP scenario (at 1980 prices). The requirements of external assistance under the IP scenario are estimated at $600 million annually (at 1980 prices) by the year 2000 or about 25% of the gross investment in agriculture. Accomplishment of this estimated requirement implies more than doubling, in real terms, the annual commitments made to SADCC countries in 1980-82.

FAO Regional Conferences in 1984

Every two years FAO holds its round of regional conferences that provide forums to discuss issues of regional interest or to give regional perspectives on more general topics. These discussions also help shape FAO's work programme at the regional and constituent country levels. While discussions in the 1984 sessions focused on topics of regional interest, themes common to all conferences were reviewed such as agricultural pricing policies, training and education.

The Regional Conference for Africa (Harare, Zimbabwe, July 1984) was held against a grim background of food shortages and the imminent starvation of millions of its people. Political strife, war, refugees, drought and debt problems complicated an already serious food and agricultural situation in sub-Saharan Africa. With these problems in mind, African ministers at the conference agreed that objectives set in the 1980 Lagos Plan of Action regarding food production and food losses had not been met. Responsibilities for this failure were accepted and pledges to correct the situation were included in the Harare Declaration.

Through this declaration, all members of the conference pledged to accord the necessary priority to agriculture in order to meet food problems and to monitor the progress of agricultural development. Emphasis was placed on the monitoring component that is considered essential to ensuring progress toward stated goals.

Conference members also recognized the responsibility placed on them by their countries to solve food problems and reaffirmed their determination for their countries to become more self-reliant by accepting the burden of developing their agriculture.

Significant attention was paid in the declaration to the importance of training and education in agricultural development as well as of agricultural price policies. It urged international bodies to provide technical assistance in these areas and exhorted African governments to use training institutions and personnel already available more effectively, both at national and regional levels, since large disparities exist among countries in the availability of training facilities. Workshops in management techniques were necessary in addition to short courses and seminars on technical matters.

The declaration also emphasized the need to intensify training for women at all levels since they have been and would continue to be responsible for a large share of food and agricultural production in the region.

Although the importance of the complex roles played by price policies were recognized, it was noted that improvements in Africa's food situation depended not only on prices but also on social, economic, technical, geographical and political factors influencing both production and consumption.

In reference to the role played by food aid, the conference pointed out that food aid could introduce distortions and fluctuations in prices and production and warned of a possible dependence on staple foods that could not be grown in Africa.

Emphasizing the importance of systems for monitoring agricultural progress, the conference recommended that member governments establish a monitoring system on the basis of appropriate socio-economic indicators for each country. FAO was requested to assist in the implementation of such monitoring systems as well as to provide guidance at national and regional levels.

Even though it was realized that African governments needed international and bilateral assistance to achieve agricultural and rural development, the conference pointed out that the major task was to be undertaken by the governments and the people of Africa.

The principal topic discussed at the Regional Conference for Latin America (Buenos Aires, Argentina, August 1984) was the debt problem that ultimately lead to the adoption of the Buenos Aires Declaration. This declaration called for the continued support of a new international economic order that would redress the economic grievances of developing countries. The conference, through the declaration, deplored the high interest rates that deprived the public and private sectors of these countries of the funds needed to import food and farm inputs to alleviate problems of food in security and malnutrition.

The declaration went on to point out the dangers of rising protectionism in agricultural trade that undermined developing countries' attempts to increase exports in order to service their debt and to finance imports needed for development. It also noted the cost to developing countries of the economic recovery of developed countries. This, it was pointed out, was mainly due to a deterioration in the terms of trade of developing countries, especially for agricultural products that resulted from trade protectionism and export subsidization by developed countries.

In reference to specific technical matters, the declaration agreed with FAO on the need to undertake a review of present rural education and training programmes in individual countries, to be followed by an exchange of findings and suggestions to improve programmes of basic education and training for peasants. Programmes should be implemented in coordination with a national development policy and strategy that should include economic, social, cultural and ethnic aspects so that living conditions in the countryside may be improved.

The declaration concluded with a plea for international financial institutions to take appropriate measures to ease the financial crisis of developing countries and with a request for developed countries to facilitate negotiations for new commodity agreements. The agricultural ministers at the meeting also pledged to give the food and agricultural sector the highest priority in their development programmes.

The Regional Conference for the Near East (Aden, Democratic Yemen, March 1984) focused on development issues in the region. It reviewed the consequences of policy formulation and implementation, forms of market interventions, consumer programmes and the role of FAO in the region.

The conference recognized the major role played by agricultural price policies in both agricultural and overall development. Thus, for effective policy formulation, it recommended that member governments take into consideration the limitations and linkages of agricultural price polices within the economy as a whole. At the same time, it suggested that each country should establish bodies at a high level to monitor and evaluate the impact of such policies.

Recognizing the need for more training, member countries were advised to improve education through practical courses and by raising the standard of teaching staff performance and student participation.

Member governments were urged to give high priority to agricultural investments selected according to national priorities, the availability of funds and the capacity for implementation. Moreover, if a country faced a serious debt problem, priority should be toward rehabilitation and the maintenance of the existing productive capacity.

The conference requested continuing support from FAO and other international bodies for the overall development of the region as well as for the full cooperation from member governments with these organizations.

By and large the major economic and financial problems that have assailed other developing regions were less serious in the Asia and Pacific region (Asia and Pacific Regional Conference, Islamabad, Pakistan, May 1984).

The main issue raised during the discussion of agricultural pricing policies was the need to integrate the agricultural policy fully and coherently with national plans and overall development strategies. Other issues discussed were whether it was necessary to raise price incentives to farmers, and, if necessary, in what ways.

The conference recognized the need for more effective marketing systems given that urbanization would continue and agriculture in the region would therefore become more market-oriented.

Concerning consumer programmes, it was noted that the food consumption of the poorest people must be protected by welfare schemes if producer prices are to be kept sufficiently high to act as production incentives.

Referring to policy implementation, it was stated that the confidence, continuity and credibility of programmes were essential. For this to be achieved, there is vital need for institutional coordination and data, as well as the availability of trained management and administrative personnel.

Adjustments in Agricultural Policies in Europe 8/

Agricultural policy reforms have been applied in both Eastern and Western Europe to reflect economic and social goals and conditions. The institutional bodies that have principal responsibility for coordinating or setting agricultural policies, the ten-member European Economic Community (EEC) in Western Europe and the seven-member Council for Mutual Economic Assistance (CMEA) in Eastern Europe, both share the goals of increasing farm income and food self-sufficiency.

Western Europe

The Common Agricultural Policy (CAP) of the EEC is being reformed for the first time since its inception over 20 years ago. High farm prices over the years have resulted in increasing budget deficits. Farm price supports accounted for 95% of the agricultural budget in 1983 and internal farm prices were considerably higher than world prices. For example, butter was 50% over the world price and wheat 33%, a situation relieved more recently by the strengthening of the U.S. dollar. Supply exceeds demand to the point where the cost of export subsidies and the storage of surplus commodities (7.5 million tons of grains and 1 million tons of butter) had to be reduced. Domestic agricultural prices were so high that imported grains had been substituted for domestic grains, which then had to be stored or exported with subsidy payments.

While reforms to the CAP introduced in 1984 were not severe, they did get to the heart of the problem: high prices and the overproduction of milk, grain and wine, and the ability of member countries to insulate

---

8/ This section draws on papers prepared for the 14th FAO Regional Conference for Europe (Reykjavik, 13-21, September 1984).

domestic producer prices from foreign exchange fluctuations. Production quotas for milk and grain were adopted, agricultural prices were cut by 5%, new vine planting was banned until 1990, and the agricultural monetary system was further integrated.

The production quota for milk is a significant step in controlling production in that over 103 million tons of milk were produced in 1983, but the 1984 quota was set at 99.2 million tons. From 1985 onwards, the quota will be 98.4 million tons. Member countries are free to allocate their quota among domestic producers as they see fit. However, in some instances there have been delays in introducing the quotas.

The quota on cereals is not as important since production has not yet reached the quota level, but lower prices should have an effect on production in the long run. In addition, the Monetary Compensatory Amount (MCA), a system of border taxes that allow member countries to maintain farm prices in the face of foreign exchange fluctations, will be phased out over a period of four years.

If the reforms are implemented, the EEC will not produce such large surpluses, thus relieving the downward price pressure on some commodities such as wheat and dairy products. On the other hand, lower internal EEC prices may result in a higher consumption of domestic grains, thus leading to greater imports and a smaller supply of feed grains in the world market.

The post-war push in Europe to high levels of agricultural production in order to increase self-sufficiency ratios and farm incomes was largely achieved through policies designed to reduce the number of farmers and consolidate land holdings. Price policies in particular led to increased yields and an intensified use of inputs. These policies have been so effective that the reverse problem now exists. Increasing total production is not the goal now. Rather, the emphasis is on adopting less intensive methods of production and use of inputs in order to decrease unit costs, becoming more competitive in world markets and alleviating environmental problems.

However, social and environmental concerns are likely to raise production costs. Unemployment in Western Europe is at historically high post-war levels so that a release of farm labour at former rates is not likely. Furthermore, large-scale mechanical and intensive farming methods are coming under increasing attack from environmental and consumer organizations. Many people feel that pollution and potential health problems resulting from the heavy use of pesticides and biological chemicals to increase crop and livestock growth have surpassed acceptable levels. Food quality is also questioned in that the taste and quality of products are not as appealing to many consumers as they were formerly.

Other concerns have also arisen such as the welfare of animals in large scale livestock agro-industrial production systems and the conservation of soil as a result of intensive growing methods. Thus opinion is gathering among scientists and the public to mitigate such problems by maintaining smaller farms that absorb more labour and use less capital intensive methods. The outcome is that unit production costs could increase, thus squeezing farm profits and raising consumer prices.

The agenda for agricultural research in EEC countries will have to shift to reflect these concerns. Ways will have to be pursued to decrease input use and cost while maintaining production at desirable levels and meeting social and environmental concerns as far as possible.

Eastern Europe

The goals of the socialist countries of Eastern Europe continue to be to increase the supply of agricultural products, to improve living standards for people in agriculture, and to improve the contribution of agriculture to their national economies. Agricultural production goals of the latest five-year plan have not been met by CMEA member countries and the high prices of industrial inputs to agriculture combined with low prices for agricultural products have squeezed farm incomes.

Adjustments in agricultural policy designed to meet goals generally centred on making agriculture more efficient. The central thrusts of the adjustments are to specialize production further based on the natural advantage of different regions and to improve incentives at all levels of the food chain. Special emphasis will also be directed to reduce wastage between the farm and the consumer.

Relatively higher producer prices will be granted to those regions where the production potential is low in order to distribute income more equally without jeopardizing production gains. Estate and collective farms are also being directed to provide inputs to private and household plots in order to increase production on these relatively efficient users of land. The private plots granted to workers in the USSR are particularly important as they provide nearly one-third of total perishable products.

Research efforts in Eastern European agriculture are directed toward exploiting the opportunities offered by improved plant breeding and introducing genetic characteristics adapted for the short growing season in the grain areas. Research has also shown that forage crops should replace cereals in some regions of the USSR since forage crops grow better, prevent erosion, and lessen food dependence on imported animal feeds. Underlining this latter trend, the USSR has again entered the world grain market in 1984 with large purchases of grain to meet the deficit created by low production.

3. LONG-TERM TRENDS AND ISSUES

Food Availability and Utilization

As measured by dietary energy supplies (DES), there has been an improvement in overall food availability in developing countries since the world food crisis of the early 1970s (Fig. 1-2). This overall dietary improvement (from 2 140 to 2 350 calories a day per caput) reflects the fact that, on the whole, food supplies have more than kept pace with population growth. However, this has not been universal. In 28 countries, with a total population of 357 million in 1980, supply availability and dietary levels have declined.

The reasons for the widely varying positive and negative experiences of developing countries are to be found in a complex interrelationship of supply and demand factors. In the following analysis, such factors are briefly reviewed for two groups of countries that were selected from a total of 90 developing countries on the basis of their experiences in changing their food situation. 9/

At one extreme, 28 countries with a population representing 16% of the 90 countries' total population showed declines in their DES between 1969-71 and 1979-81. Most of these are low-income countries and 11 of them are in Africa. At the other extreme, 27 countries (accounting for almost one-quarter of the 90 countries' total population) attained a

---

9/ The same group of countries as in FAO, Agriculture: Toward 2000. (China is excluded from this group).

significant improvement in DES of 10% or more during the same periods. Only three of these are low-income countries, but 11 are in Africa.

Supply factors. As might be expected, changes in domestic food production played a major role in the changes in DES (Table 1-15). In the group of countries with improving DES, per caput food production (calorie weighted) rose by 0.3% a year, while in the other group with worsening DES it declined by 1% a year.10/ Between 1969-71 and 1979-81, this represented a supplement of approximately 65 calories a day to the average per caput DES of countries in the first group, and a loss of about 230 calories a day in the second one.

The impact of food production on DES was limited by the difficulties encountered by a majority of countries in expanding rapidly food production as measured in calories. Most countries achieving a high rate of food production have increased their production of livestock products, which have a relatively low-calorie content, at even higher rates.

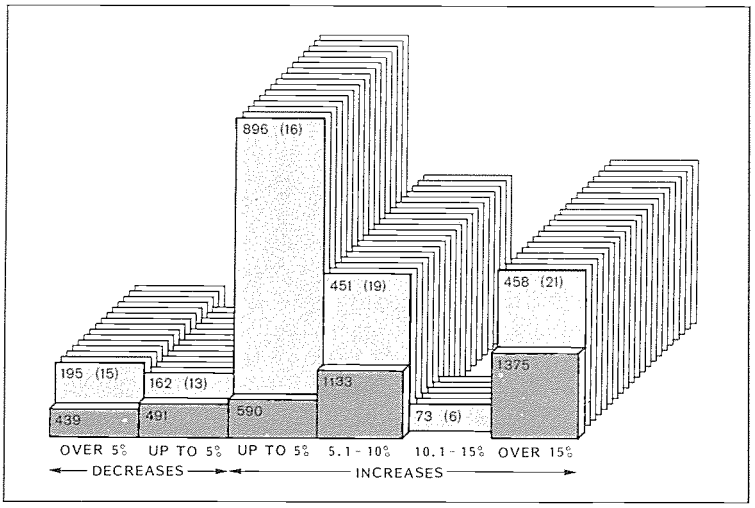

Figure 1 - 2

491 Per caput GDP (1982 $) : not available for all countries in 10.1 - 15% increase group.

Source: FAO, Statistics Division.

Examples of these countries are Indonesia, the Philippines, Korea DPR and Rwanda but, except for Korea DPR, this accomplishment was also associated with rising food imports. In fact, improvements in DES were largely associated with the countries' capacity to import food. Between 1969-71 and 1979-81, the import share of DES of countries with increasing DES rose from 19% to 31%, whereas it went from 5% to only 9% in countries with decreasing DES countries. 11/ Such an increase resulted in an addition of 400 imported calories a day per caput in 'successful' countries and 70 calories in the other group. In other words, imports contributed approximately 80%-90% of the net increase in average per caput DES in the group of countries with increasing DES and compensated by nearly one-third for the losses incurred from reduced output in the other group.

10/ These preliminary estimates have been derived from the background work for the FAO, Fifth World Food Survey (forthcoming) and are subject to change.

11/ For developing countries as a whole, gross food imports represented nearly 8% of total food supplies (in calorie equivalents) in 1979-81, almost twice as much as ten years earlier.

TABLE 1-15. PER CAPUT FOOD AVAILABILITY INDICATORS, SELECTED DEVELOPING COUNTRIES, 1970s

		27 countries increasing DES a/	28 countries decreasing DES b/

a/ Countries with dietary energy supplies (DES) increasing by 10% or more during the 1970s.
b/ Countries with decreasing DES during the 1970s.

Sources: FAO, Statistics Division and World Bank.

Such improvements in DES from external sources imply for some countries a potentially untenable dependence on imported food. For the group of countries that significantly raised their DES, rapid increases in imports usually have been associated with the capacity to finance them. However, for the countries with declining levels of DES, the increasing dependence on imports has represented a financially burdensome way to compensate for inadequate production performances. Food imports occupy a higher share of total export earnings in this comparatively poor group despite its much slower increase of food imports in absolute terms.

There is doubt that past levels of imports can be maintained, given current levels of indebtedness and capacity to earn foreign exchange. In the two groups of countries considered, debt servicing absorbed a substantial and increasing share of export earnings (11% and 14% in 1981 in the countries with significantly increasing and decreasing DES, respectively). The increase in the debt service ratio since 1973 was lower in the group of countries with increasing DES (22%) than in the other group (33%).

Income and price factors. Changes in DES appear to be strongly related to demand factors: per caput GDP (as an indicator of the capacity to purchase domestic and imported food) and the price of food relative to wage rates (as a measure of the real price of food).

The group of countries that significantly increased DES, a group that includes many oil exporters and newly industrializing countries, had much higher and more rapidly growing levels of per caput GDP than the countries with decreasing DES (Table 1-15).

Many countries have increased their DES through food imports that seem to be highly correlated with income levels; those countries that increased their DES had a per caput income growth rate of 3% annually from 1970 to 1980 compared with 0.2% for those countries that were unsuccessful in raising their DES (Table 1-15).

Changes in the consumer prices of food are also important factors in determining the structure of food demand and changes in nutritional levels. In a group of 25 developing countries (9 African, 10 Latir American and 6 Asian) selected on the basis of data availability, extremely wide variations were found in levels of consumer food prices. However, a close correspondence was evident between food price changes and levels of DES. The real price of food (as deflated by average wage rates) declined in 12 countries, all of which recorded improvements (on average 8%) in DES between 1971-73 and 1979-81. For example, Nigeria, El Salvador, Mexico, India and Republic of Korea, where particularly positive results were achieved in reducing food prices relative to wages, recorded increases from 9% to over 40% in their levels of DES. On the other hand, the group of 13 countries with rising real prices of food showed a stagnating nutritional situation during the same period.

Feed utilization. At the time of the World Food Conference there was some discussion on the use of what were, at times, scarce food supplies to feed livestock rather than hungry humans. This was in response to a greatly increased use of cereal as livestock feed by developed countries during the 1960s. However, from the early 1970s the increase has tended to level off. It is now in the developing countries, particularly those with higher incomes, where pressures for more livestock feed are strongest to sustain national livestock development plans.

Between 1969-71 and 1979-81 the global utilization of food commodities for livestock feed rose by 4% when measured in terms of calories a day per caput. A decline in feed use in some developed countries (mainly in North America and the Southwest Pacific) was more than offset by increases in developing countries (Africa 17%, Latin America 10%, Near East 36%, Far East 17% and ACPEs 100%). However, developing countries were still using only one-tenth as many calories from food used as livestock feed as developed countries by 1979-81.

On the whole, increasing feed use has resulted in an improvement in nutritional levels of developing countries, as measured by daily intake of animal protein. Again, however, wide differences among countries are found. Taking the two groups of countries described in Table 1-15, those with significantly increasing DES achieved an increase of 27% in daily intake of animal protein per caput during the 1970s, at the cost of increasing by 182% the calories used in livestock feed (Table 1-16). In contrast, those countries with decreasing DES hardly increased the use of calories for feed, but their per caput daily intake of animal protein declined.

TABLE 1-16. COMPARISON OF FEED USE, LIVESTOCK PRODUCTION AND CONSUMPTION OF ANIMAL PROTEIN, SELECTED COUNTRIES, 1970s

	Average increase in calories used in livestock feed	Average annual change in livestock production	Average change in intake of animal protein per day

Some aspects of food aid. One of the more serious aspects of the food crisis of the early 1970s was the decline in shipments of food aid precisely at the time when they were most needed (Fig. 1-3). The volume of food aid was reduced by one-half during 1972-74 although, with rising food prices, its value remained broadly unchanged. As a consequence of this reduced volume, the share of cereal imports of low-income food-deficit countries covered by food aid plunged by more than one-half to 13%. This share recovered for a few years as the level of food aid regained 9 million tons a year by 1976/77, but by the early 1980s it again approached the low level of 1973/74. The increase of commitments to the Food Aid Convention to a minimum of 7.6 million tons in 1980 from the 4.2 million ton level of 1973/74, while still below the objective set by the World Food Conference of 10 million tons, nevertheless provides some cushion against drastic reductions in food aid shipments.

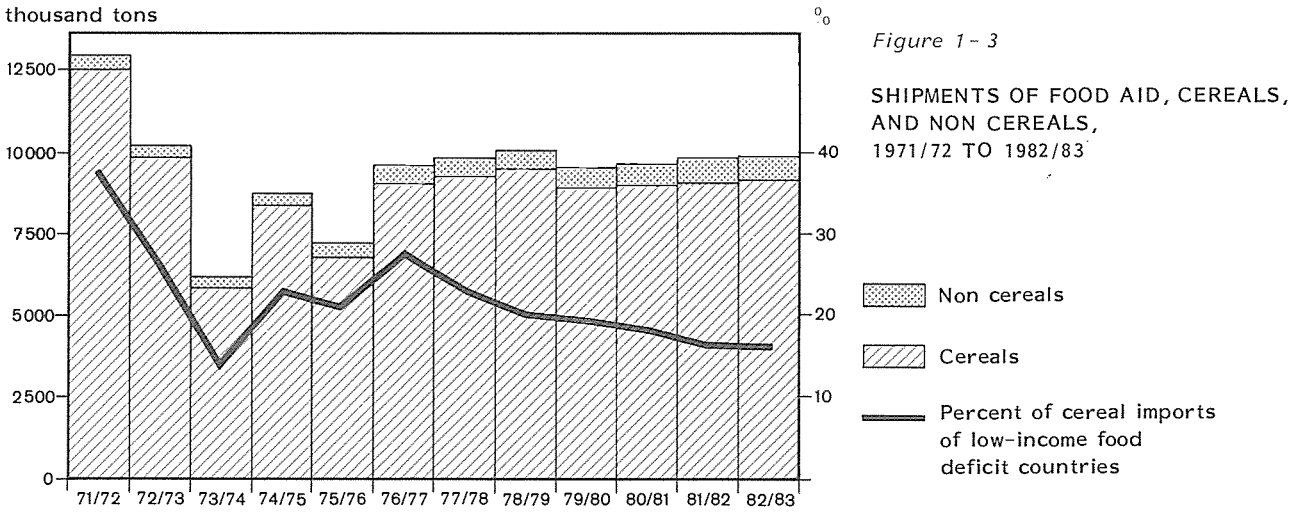

Figure 1-3

SHIPMENTS OF FOOD AID, CEREALS, AND NON CEREALS, 1971/72 TO 1982/83

Source: FAO, Commodities and Trade Division.

Food aid does not contribute greatly to overall calorie supply, but it is important for many individual countries. Low-income, food-deficit countries imported about 13% of their food supplies in terms of calories in 1979-81. Food aid covered approximately one-fifth of these countries' imports, so that the overall proportion of calories from food aid was 2%-3%.

The main benefit of food aid is to lower the foreign exchange costs of food imports for nutritionally precarious low-income countries.12/ As incomes rise, as has been pointed out, food imports tend to increase rapidly and, in the majority of cases, food aid is phased out.

The emergency component of food aid was covered more adequately after the World Food Conference by the establishment of the International Emergency Food Reserve (IEFR) in 1975. Since 1976, emergency operations funded from its resources have risen from $12 million to $172 million in 1982, equivalent to 24% to 89%, respectively of the total cost of WFP emergency operations. However, in the early years of the IEFR, at a time when the cost of emergencies was rising fast, its funding was not reliable. Its replenishment target of 500 000 tons of cereals has been achieved only in 1981, 1983 and 1984. In view of the increasing requirements for emergency assistance, the need to put the IEFR on a more reliable footing remains.

Cereal stocks. The rapid decline in the level of global stocks of cereals was one of the more alarming features of the world food crisis. However, the decline occurred in stocks held by the main exporters; those held by others (mainly cereal importers, particularly the EEC) in fact tended to increase during 1972-74 (Fig 1-4). Since the late 1970s, stocks have tended to be more evenly shared among the main exporters and others (mainly China and India), although recently cereals stocks have increased only in a few major exporting countries.

BOX 1-3. CONSUMER FOOD PRICES AND WAGES

Changes in the consumer price of food are important factors in determining the structure of food demand and changes in nutritional levels. In a group of 25 developing countries (9 African, 10 Latin American and 6 Asian) selected on the basis of data availability, extremely wide variations were found in levels of consumer food prices. However, a close correspondence was evident between food price changes and levels of dietary energy supplies (DES). Real prices of food (as deflated by average wage rates) declined in 12 countries, all of which recorded improvements (on average 8%) in DES between 1971-73 and 1979-81. For example, Nigeria, El Salvador, Mexico, India, and the Republic of Korea, where particularly positive results were achieved in reducing food prices relative to wages, recorded increases from 9% to over 40% in their levels of DES. On the other hand, the group of 13 countries with rising real prices of food showed a stagnating nutritional situation during the same period.*

This analysis can be further expanded by examining the time of work required for low-wage earners (unskilled workers in urban areas) to purchase selected food products that are major components of their daily diets. Because of statistical shortcomings, this analysis is confined to only 18 developing countries.

Rice is a staple food in nine of the 18 developing countries covered. In these, the time of work required to purchase 1 kg of rice ranged from 12 to 212 minutes in the early 1970s and from 12 to 154 minutes ten years later. Despite its greater relative importance for Far Eastern countries, rice was much more costly in relation to wages of unskilled workers in this region in the early 1980s (79 minutes of work), than in Latin America (43 minutes).

Wheat and wheat products provided most of the total calorie supply in nine other developing countries. In the early 1970s, 6 to 32 minutes of unskilled work were required to purchase 1 kg of wheat in these countries, as against 10 to 54 minutes in 1980-82. Considering the 18 developing countries selected in the latter period, it took 34 minutes of such work to purchase 1 kg of wheat in the Latin American countries and 108 minutes in the Far Eastern ones.

In eight countries where beef meat was found to contribute significantly to the total animal protein supply, the purchase of 1 kg of this product involved 82 to 700 minutes of work in the early 1970s compared with 124 to 554 minutes in the early 1980s. As may be expected, costs of beef meat in Latin America, a major producer of this commodity, were noticeably lower than in other regions (257 minutes, one-third less than in the Far East). In the three African countries reviewed, the average was 627 minutes.

In seven countries, mainly in the Far East, fish contributes significantly to total annual protein supply. In these countries an unskilled worker had to work between 117 to 670 minutes to purchase 1 kg of fresh fish in the early 1970s; and 114 to 896 minutes in the early 1980s. In Far Eastern countries, the decreasing per caput supply of food fish has contributed to an increasing competition with beef. In the early 1980s, beef has become cheaper than fresh fish in all Far Eastern countries reviewed.

---

* Wage and price data were those of ILO; food consumption patterns and calorie requirements were derived from FAO Food Balance Sheets 1979-81, 1984 and 1984 Country Tables.

The coordination of cereal stock-holding policies, in an attempt to stabilize global supplies, was a central element of FAO's International Undertaking on World Food Security endorsed by the World Food Conference. The conclusion of a new international wheat agreement with price and stocking provisions, which would be a major expression of support for the undertaking, has not yet been possible. Nevertheless, a few developing countries are beginning to hold larger stocks of cereals and use them for supply stabilization purposes. Furthermore, regional cooperation in the area of food security has been strengthened. Examples are the establishment of the Association of the Southeast Asian Nations' (ASEAN) Emergency Rice Reserve, the Southern Africa Development Coordination Committee (SADCC) in Africa, and the Committee for Action on Regional Food Security (CASAR) of SELA (Sistema Economico Latino Americano).

Food and Agricultural Production

Rates of increase in food production. From 1974--the year of the World Food Conference--to 1983, world food production, weighted by national prices, increased annually by 2.2%, nearly 0.5% above population growth (Table 1-17). In spite of their difficulties, developing countries (including China) expanded their food output at a rate approaching three times that of developed countries, but because of their much higher rate of population growth, the per caput growth rate was only a little more than double that of developed countries. Therefore, there has been an appreciable growth of over 10% in per caput food production of developing countries as a group since the World Food Conference.

The least developed countries (LDCs), most of which are in Africa, were a disappointing exception. Their per caput food production declined, and they remain a major cause for concern. Although food imports increased significantly during the 1970s, the importance of gains in domestic food production in sustaining dietary improvements in many developing countries, particularly the most populous among them, is clear.

The majority of developing regions have failed to achieve the minimum indicative goals of food production increases discussed by the World Food Conference (Table 1-18).13/ Only Asia and the Far East accomplished the

13/ The conference did not specifically adopt these regional goals but rather the overall and higher annual growth rate of 4%. United Nations Resolution 1, Report of the World Food Conference, E/CONF. 65/20, New York 1975.

goal of 3.4%. Indeed, ACPE exceeded it, but entirely because of China's progress. Africa achieved only one-half of the region's goal (1.9% against 3.8%); the Near East about 65% of its goal (2.6% against 4.0%); and Latin America about 80% of its goal (3.0% against 3.6%). In all regions except Africa, population actually increased at lower rates than had been projected. The actual production shortfalls in relation to the conference's targets were nonetheless significant.

The overall performance of food production in developing countries also conceals widely differing rates of production gains by country in relation to population growth (Fig. 1-5). Since 1974 food output has been rising by more than 3% a year in 28 countries (including China) with a total population of approximately 2 600 million people, out of the total of 105 countries shown. Furthermore, for almost all of these 28 countries, food production growth was faster than that of population growth. On the other hand, food production did not keep pace with population growth in 50 countries, which had a total population of 566 million people.

The stability of food production. An important issue concerns the stability of food production. Has production become more or less stable since the early 1970s, and have the cases of improved food production performances been associated with greater instability? Using data from 38 developing countries that represent about 80% of food production of all developing countries, the following observations can be made:

- In 19 countries, food production was more stable in 1971-80 than it had been in 1961-70; in 17 it was less stable; and in two it was unchanged.

- Higher rates of increase in food production in the 1970s do not seem to be associated with greater instability compared with the 1960s. In the 1970s, 19 countries of the 38 achieved higher rates of increase in food production than in the 1960s. Of these, only eight showed higher average deviations from the trend.14/

Production of food and non-food products. Another important issue relates to the relationship between the domestic production of food and non-food agricultural products. Some analysts believe that since the two groups of products compete for land and other resources, a disappointing performance in food production stems in part from an overemphasis on non-food production. An opposing view is that the improved technologies and husbandry adopted for non-food agricultural products--often cash or export crops--spill over into food crops as well. Improved cash flows also can help intensify the input use for food crops.

The evidence provided by the same 38 countries for the period 1974-83 appears to question both views. There was no significant correlation, either negative (that would support the first opinion) or positive (that would support the second), between the growth rates of food and non-food agricultural production.

The changing pattern of food production. The final issue dealt with here concerns the changing pattern of food production, largely in response to shifts in food demand. Between 1974-75 and 1982-83 there have been quite significant changes in what is normally a slowly shifting pattern (Table 1-19). There has been a clear shift to livestock production (and

---

14/ Other studies, for example, by the International Food Policy research Institute, which point to the increasing instability of production since the early 1970s, refer to cereals and not 'total' food.

* The figure refers to net food production, which represents disposable production minus domestically produced and imported seed and feed. Differences between net and gross production can be considerable in the cases of countries importing large quantities of feed. For instance, gross food production in Saudi Arabia rose by 9.5% annually between 1974 and 1984, but declined by 5.5% in net terms during the same period because much of the increase in food production was in livestock products based on imported feeds.

within that, to meat). This would be expected as per caput incomes rise. Within crops, there appears to have been a reduction in the share of cereals except in the case of the developed countries, Latin America and the developing oil exporters. The relative shift in agricultural production in Africa away from cereals is particularly striking. It may reflect the prolonged droughts in parts of the region that reduced cereal output.

Fertilizers. "In the present state of agricultural technology chemical fertilizers constitute one of the most important single means to increase food production."15/ This statement introduced the fertilizer section in the document discussed by the World Food Conference and remains true today.

A physical shortage of fertilizers and high world prices for fertilizer materials characterized the fertilizer sector at the time of the 1972-74 world food crisis. Consumption levelled off in developing countries and declined in developed ones for the first time since the end of World War II (Figures 1-6 and 1-7). These high prices, however, generated large new investments in fertilizer capacity, prices fell and consumption continued to expand during the 1970s. Since 1980, however, consumption has again levelled off as a consequence of another surge in prices resulting from the second oil shock of 1979, the effects of the recession on the agriculture sector, and international debt payment problems that curtailed imports. The effect of price increases on consumption since 1979 would have been even more severe if domestic fertilizer prices at the farmgate had closely followed world market prices. By and large they do not because of subsidies or because governments set domestic prices that are not fully linked to world prices.

Since mid-1980, fertilizer prices (expressed in U.S. dollars) dropped on world markets and fears were expressed by the FAO Commission on Fertilizers in early 1983 that sufficient investment would not be forthcoming to maintain adequate capacity in the industry.

15/ UN, The World Food Problem: Proposals for National and International Action, E/CONF. 65/4, Rome, August 1974, para 110.

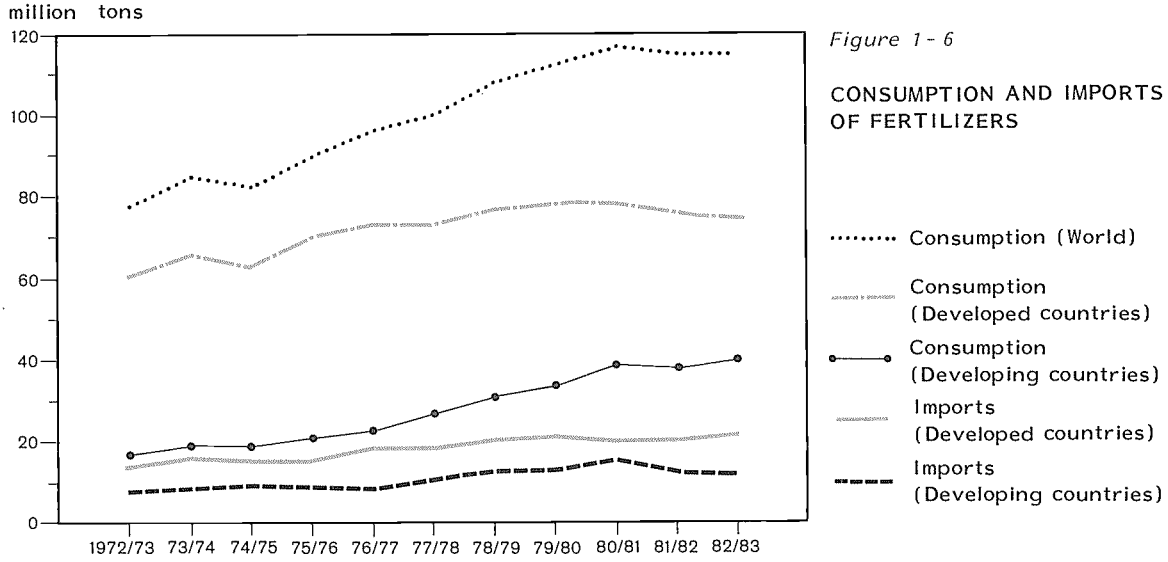

Figure 1 - 6

CONSUMPTION AND IMPORTS OF FERTILIZERS

Source: FAO, Statistics Division.

Two important current issues in the fertilizer sector are as follows:

a) Many developing countries, including some of those importing relatively large quantities of fertilizers, are facing severe debt financing problems. This situation, combined with low prices for agricultural commodities, has resulted in a decline in imports of fertilizers by developing countries. Only part of this decline can be explained by an expansion of their domestic fertilizer production capacity.

Nevertheless, for 21 of the 30 major developing country importers of manufactured fertilizers, expenditures on fertilizer imports constituted a declining share of total export earnings between 1974-75 and 1980-81. This share is relatively large in some countries such as Bangladesh, 16% in 1980-81, and 11%-12% for India and Pakistan. The means to allow such countries to maintain their supplies of fertilizers during periods of external payment problems have been considered, such as expanding the coverage of IMF's cereal import facility to include fertilizers. In some cases, the World Bank and regional development banks are financing fertilizer imports to maintain the impetus of agricultural development projects.

The International Fertilizer Supply Scheme (IFS) was established by the FAO Council in 1974 on the recommendation of the Commission on Fertilizers to channel fertilizer supplies to countries most seriously affected by the crisis of 1973-74. Unfortunately, its resources have dwindled in recent years, although contributions totalling over $5 million have been made by Italy, Ireland and Austria.

b) The supply-demand balance that has characterized the fertilizer sector in the past few years may deteriorate as a long-term result of low world dollar prices in 1982 and 1983 (for some kinds of fertilizers there was little increase in nominal terms in 10 years) and the consequent lack of investment in new fertilizer facilities.

Production of nitrogenous fertilizers involves high capital investment costs and depends on the availability and cost of natural gas, the preferred feedstock. Production of phosphatic and potassic fertilizers is less capital intensive, but depends more on the costs and location of raw materials.

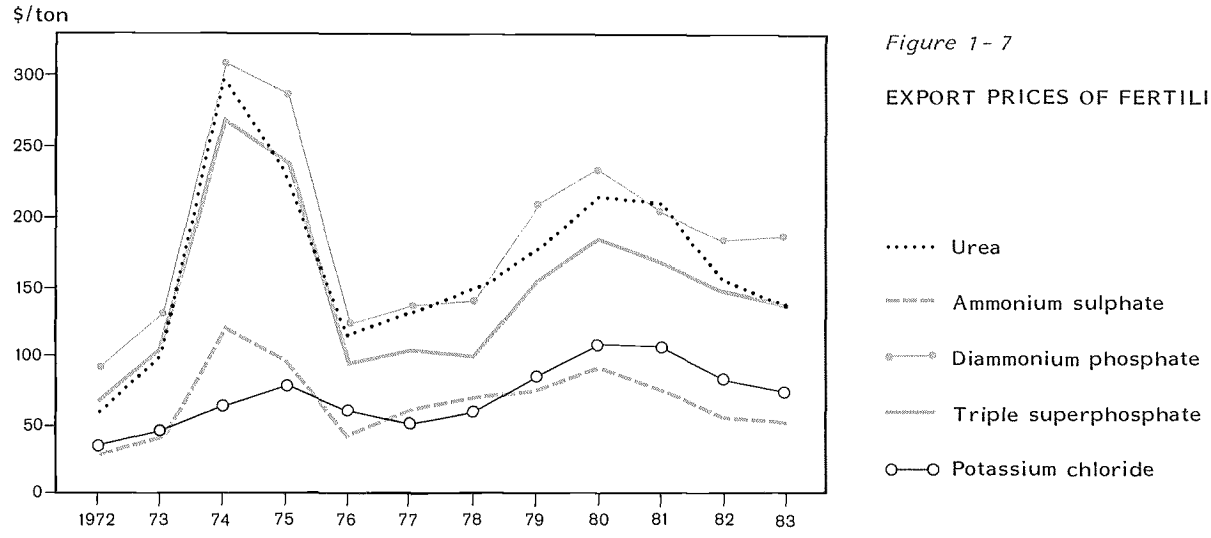

Figure 1-7

EXPORT PRICES OF FERTILIZERS

Source: FAO, Land and Water Development Division.

Taking these factors into consideration, the June 1984 forecast of the FAO/United Nations Industrial Development Organization (UNIDO)/World Bank Working Group on Fertilizers indicates a comfortable supply-demand balance for phosphatic and potassic fertilizers during the next five years. However, there is a potential supply constraint for nitrogenous fertilizers beyond this period unless the necessary investments are made soon. (See section on fertilizers in "Current Situation and Outlook").

Structural Changes in Agricultural Trade

The economic instability that characterized the international environment during the post-1973 period had profound repercussions on the magnitude, destination and composition of agricultural trade. 16/ The expansion in the volume of world merchandise trade slowed down from 8.5% in 1963-73 to 4% in 1973-80 and stagnated in 1981-82. While a small recovery was observed in 1983, it was only in 1984, when the recovery entered a more mature phase, that world trade regained its dynamism. In fact, GATT estimated that the volume of world trade in the first nine months of 1984 was 8.5% higher than the same period in 1983.

Declining role of agriculture in world trade. Despite the rapid increase in world agricultural exports (about 4.2% annually in constant value terms between 1970 and 1981 and significantly greater than the growth of world agricultural output of about 2.5%), the share of agriculture in total merchandise trade declined from 21% to 15%. The composition

16/ Unless otherwise stated, "agricultural trade" refers to trade in crops, livestock, fisheries and forestry products.

of world trade was radically altered by the emergence of petroleum as a major source of export earnings. The share of manufactures in world exports also declined, though less markedly than agriculture (Figure 1-8).

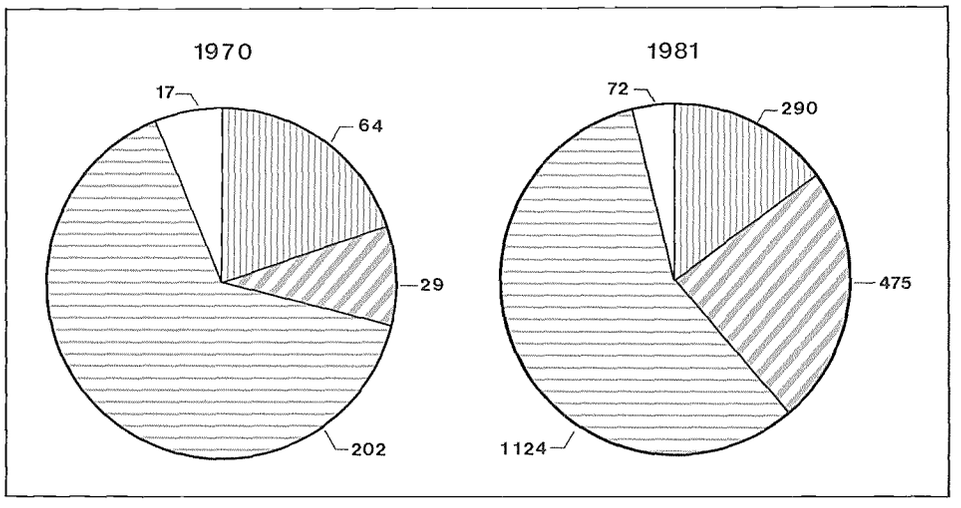

Figure 1-8

SECTORIAL STRUCTURE OF WORLD EXPORTS, 1970 AND 1981 (thousand million $)

Source: UN, Monthly Bulletin of Statistics, May 1983.

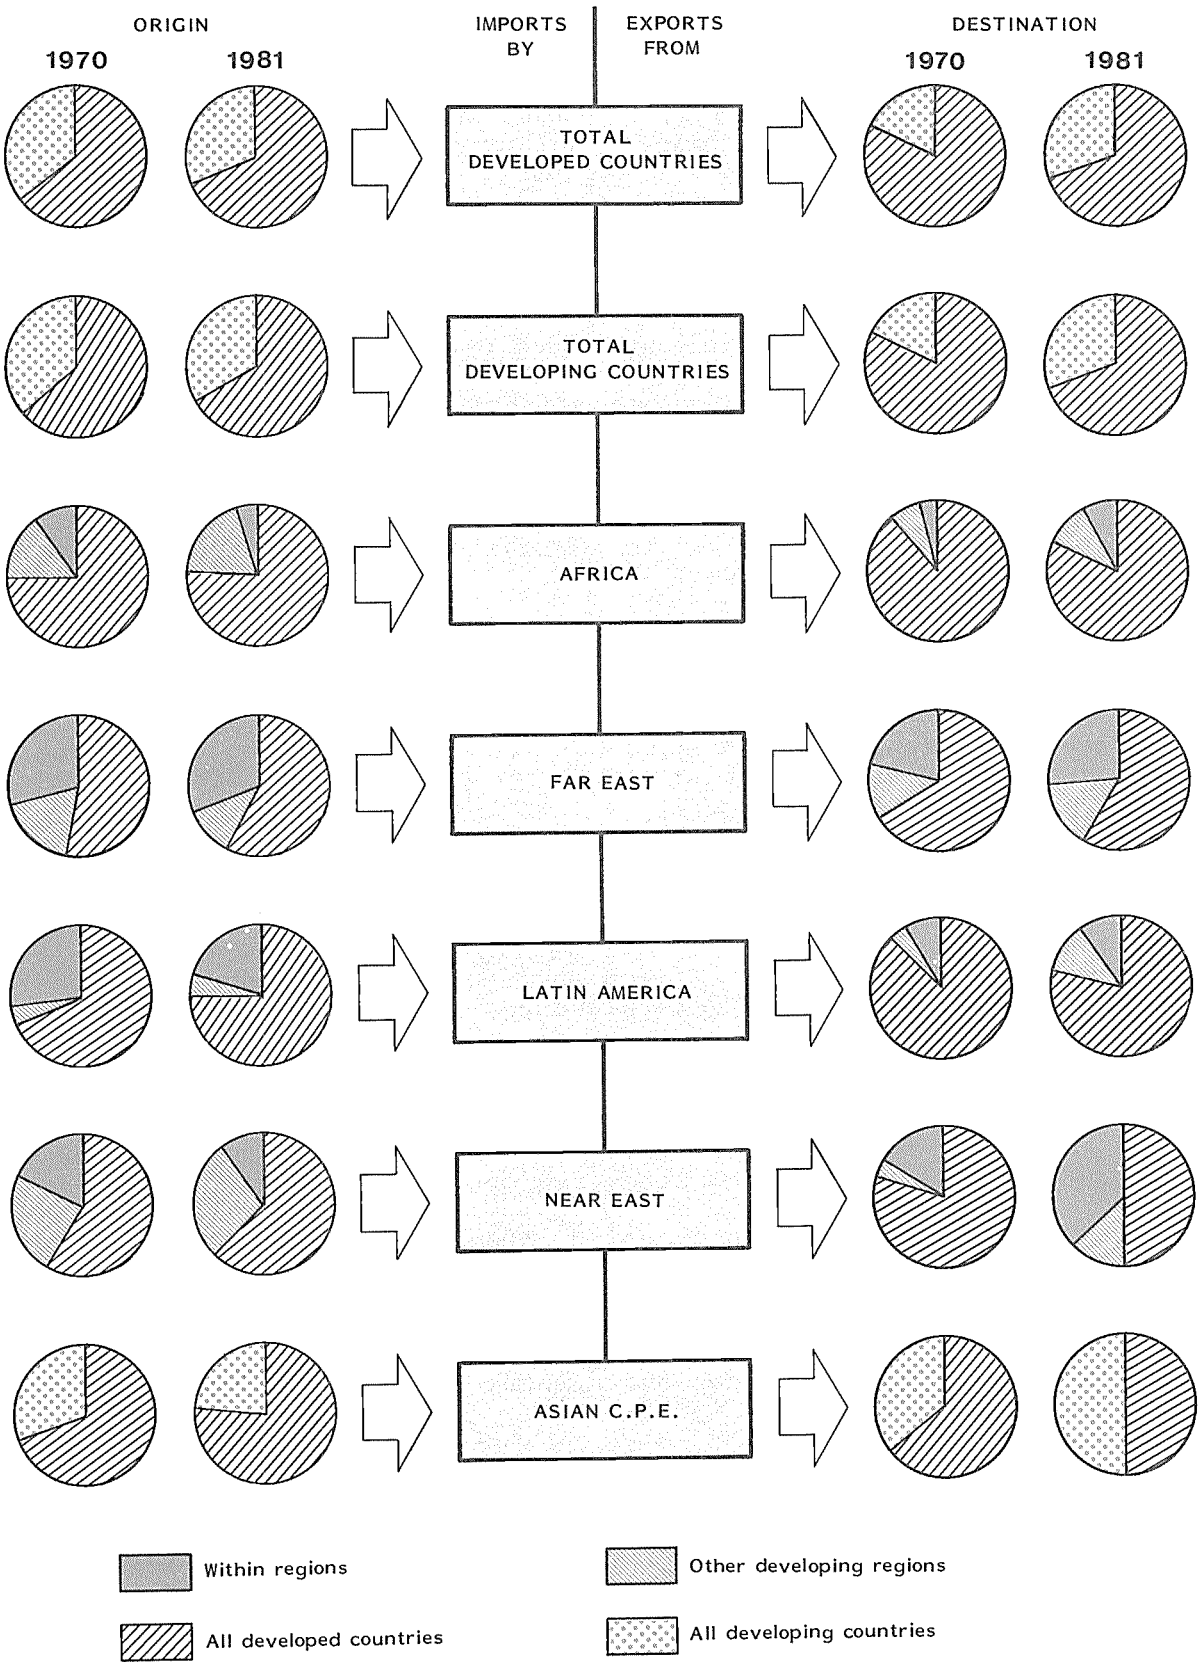
Agricultural trade flows. One major feature of the period reviewed was the change in the developing countries' position from net exporters to a net importers of crop and livestock products in 1981. Exports of developing countries rose 2.3% annually in constant value terms between 1970 and 1981, less than half the growth rate in developed countries. At the same time, agricultural imports of developing countries were expanding by nearly 9% annually in real terms, three times faster than imports developed countries.

On the side of agricultural imports, developed countries tended to rely more on supplies from other industrial areas. Among developing regions, only the Far East and Latin America succeeded in maintaining their shares of developed country total imports throughout the 1970s (about 9% and 14%, respectively). On the other hand, Africa's competitive position in developed country markets for agricultural products suffered a sharp deterioration, and its aggregate share of these markets declined from 8.5% in 1970 to only 3.7% in 1981.

The decline in the relative position of developing countries in world agricultural exports also reflected, to a large extent, the inability of Africa to capitalize on growing markets for agricultural commodities. With its agricultural exports declining by 2% a year in constant terms, Africa accounted for only 3% of the world total in 1981 compared to 8% in 1970. The other main exporting regions, the Far East and Latin America, maintained shares of around 12% and 10%, respectively.

The 1970s witnessed a gradual strengthening in the position of developed countries as world agricultural exporters and a growing diversification in their export markets. Agricultural exports from developed countries represented 71% of world exports in 1981, compared to 67% ten years earlier. The counterpart of this increase was a reduction in the respective shares of developing countries, where difficulties of access to markets in some developed countries largely offset the moderate expansion that took place in agricultural trade between and within developing regions (Figure 1-9).

Figure 1 - 9 AGRICULTURAL* TRADE OF DEVELOPED AND DEVELOPING REGIONS, PERCENT SHARES BY ORIGIN AND DESTINATION, 1970 AND 1981



Source: UN, Monthly Bulletin of Statistics, May 1983.

* The definition of "agriculture" includes the following categories of the Standard International Trade Classification (SITC): 0+1+2+4 -27 -28.

A growing penetration of developed country agricultural exports in developing country markets also was evident, to varying degrees, in all regions. Most striking was the fast growth of shipments to Africa and the Near East that emerged as agricultural outlets of comparable importance to developed countries as the Far East and Latin America. The share of exports to Africa in total developed country agricultural exports rose from 3.8% in 1970 to over 7% in 1981, and that of the Near East from 1.7% to 5.4%. By comparison, the far more populous Far East region absorbed 8.3% of the total in 1981 and Latin America 6.4%.

The importance of markets in developing countries for the developed country agricultural sector is shown by the fact that 11 OECD countries (out of a total of 24) are net agricultural exporters to developing countries, or 42% 17/ of OECD agricultural exports go to developing countries, and these exports are equivalent to 14% of OECD agricultural GDP.

An important factor behind the strengthening in import demand from developing countries was the emergence of oil-exporting countries as major markets for agricultural products. Agricultural imports by Near Eastern countries rose by nearly 14% a year in constant value terms between 1970 and 1981 compared with 9% for developing countries as a whole. The Near East accounted for over 7% of world agricultural imports in 1981 compared to only 2-3% in the early 1970s.

Agricultural trade between and within developing regions tended to intensify although industrial nations still remain by far the main recipients of developing country agricultural exports.

Trade in agricultural products between developing regions during the 1970s increased twice as fast as their agricultural exports to developed countries. As a result, the share of agricultural trade between developing regions of their total agricultural exports rose from 19% to 31% between 1970 and 1981. Latin America and the Far East showed increasing surpluses in their agricultural trade with the other developing regions, while the Near East and Africa were net importers. Latin American exports to other developing regions, almost negligible in 1970, exceeded trade within Latin America in 1981. Africa and the Near East became increasingly important outlets for Far Eastern and centrally planned countries.

The intensity of trade between developing regions varied considerably, but was on the whole smaller (by about one-third) than trade within regions. Latin America and the Far East relied primarily on their own regions for their agricultural imports, while purchases by the Near East and Africa were increasing from other regions.

Agricultural trade within economic integration groupings and clearing arrangements such as ASEAN remained relatively small. The share of intra-trade among the major 11 groupings covered by UNCTAD studies ranged from about 8% to one-quarter of their total agricultural exports in 1980. 18/ However, agricultural trade within such groupings and arrangements increased considerably faster than their total agricultural trade during the 1970s.

17/ This percentage differs from that shown in Fig. 1-9 for total developed countries. This is because OECD calculations are based on a more restrictive product coverage (in particular, they exclude forest products) than used here. Also, the statistical category "total developed countries" in Fig. 1-9 includes both OECD and centrally-planned developed countries.

18/ See Trade Flows Among Developing Countries Participating in Clearing Arrangements, UNCTAD/ECDC/129.

Commodity composition of agricultural trade (crops and livestock). The instability that has characterized international commodity markets is responsible for wide year-to-year changes in the relative weight of individual commodities in the value of agricultural trade. Taking as reference points the annual averages for the periods 1971-73 and 1980-82, the following overall features and trends can be observed in Fig. 1-10.

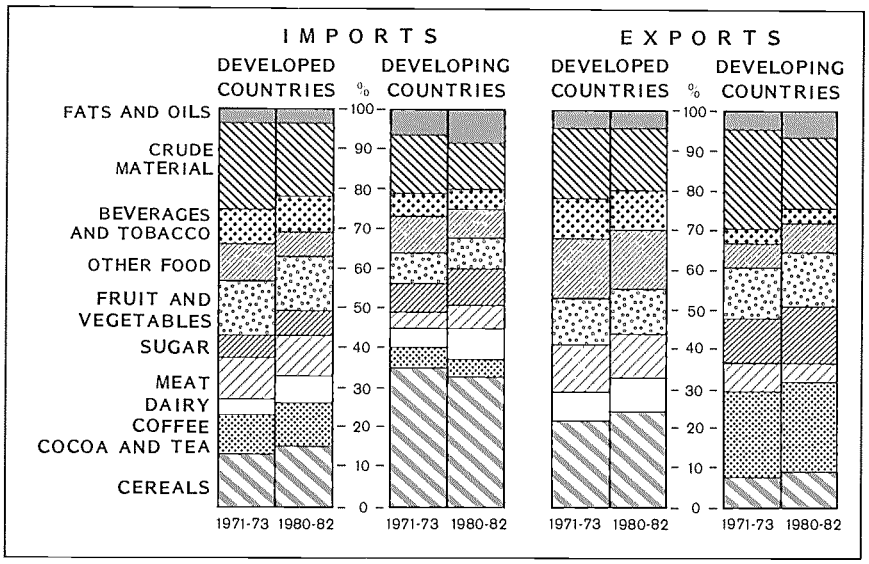


Figure 1-10

COMMODITY COMPOSITION OF AGRICULTURAL TRADE, DEVELOPED AND DEVELOPING COUNTRIES, 1971-73 AND 1980-82

Source: FAO, Stotistics Division.

Food products accounted for the greater part of total agricultural trade in both developed and developing countries. The share of food in total agricultural trade tended to increase, mainly at the expense of agricultural crude materials.

Cereals represented the largest group of agricultural export commodities, comprising nearly one-fourth of the total value of developed country agricultural exports and one-third of developing country agricultural imports.

Cereals and animal products accounted for nearly half of developed country agricultural exports. The relative importance of cereals and dairy products tended to increase while that of meat declined.

A high degree of concentration characterized the structure of developing country exports. Tropical beverages (coffee, cocoa and tea) provided nearly one-quarter of their agricultural exports during 1980-82 as against 21% during 1971-73. Nearly one-half of a group of 87 countries depended on these price-volatile commodities for 30% to over 90% of their total agricultural export earnings. 19/ Fruits, vegetables and sugar--the latter, another commodity with highly volatile free market prices--made up another quarter of developing country agricultural exports.

The declining role of crude materials in developing country exports was particularly striking: from one-fourth of the total to 17%. The decline was mostly because of smaller exports of textile fibres, although oil-seeds and natural rubber also lost ground.

19/ Developing country export earnings from tropical beverages fluctuated by 22%, on average, around their mean value from the mid-1960s to the late 1970s.

Developing countries imported significantly more meat, dairy products and sugar. The commodity composition of trade between developing countries was highlighted by the following:

- The share of trade between developing countries in relation to total trade rose in practically all commodity groups, with the notable exception of live animals.

- There was a high growth in trade of vegetable oils, fruits, and vegetables, sugar and animal feed, in contrast to the stable shares of more traditional exports, such as rice, tea, cotton, coffee, rubber and oil-seeds.

- Developing countries represented the main market for most processed foods exported by other developing countries, while most raw materials were exported to industrial countries.

Economic significance of food imports. For a large number of developing countries, food imports became an increasing and sometimes unbearable economic burden during the 1970s. In 60 of 111 countries, the food import-export ratio deteriorated. In both Africa and Latin America, the majority of countries showed adverse trends. In 21 countries food import expenditures represented half or more of total export earnings. Food imports were less of a burden for some countries (Seychelles, Comoros, Martinique) that rely primarily on non-merchandise transactions and remittances for earnings of foreign exchange, and for others (Egypt, Somalia, Jordan) where food aid has represented 20% to 25% of total food imports. However, in other mainly African countries (Benin, Gambia, Burkina Faso, Senegal), increasing recourse to food imports resulted in a decline in other imports crucial for development.

The situation appeared less unfavourable at an aggregate level. For developing countries as a whole, food imports during 1980-82 accounted for around 10% of total export receipts--down from 13% during 1971-73. However, the food import-export ratio ranged from 8% in the Near East to 16% in Africa. It tended to deteriorate in Africa but improve in Latin America and, more markedly, in the Far East. It remained stable in the Near East where food imports rose as rapidly as oil-based export earnings.

Agricultural and food imports in relation to income levels. Developing country agricultural imports, in the aggregate, are heavily concentrated in a small number of newly industrialized oil-exporting countries. In the populous Far East region, the Republic of Korea, Hong-Kong and Singapore, together accounted for nearly 60% of the region's total agricultural imports in the early 1980s. In Latin America, more than one-half of total imports were made by three of the highest income countries in the region--Brazil, Mexico and Venezuela--and in Africa, by Algeria, Morocco and Nigeria.

Taking food alone, the following features emerge about the relationship of food imports and per caput incomes (Table 1-20):

- Even though the absolute levels of per caput food imports in low-income countries ($4.20 in 1980-81) were minimal in relation to high-income developing and developed countries (nearly $58 and $100, respectively), they absorbed a comparatively larger proportion of per caput incomes in most of the periods considered.

- However, low-income countries appear to have encountered greater difficulties in bridging the food gap through imports. While per caput food imports rose faster than per caput incomes in all groups of countries, the increase in food imports was much smaller

in poorer countries where per caput income rose at half the rate of other income groups. As a consequence, there was an increasing gap between high- and low-income countries in the respective levels of both per caput income and per caput food imports.

TABLE 1-20. PER CAPUT FOOD IMPORTS, BY INCOME LEVELS, 1971-81

Trends in External Assistance to Agriculture

Total and concessional commitments. The savings rate of developing countries (21% in 1981) is comparable to that of developed countries (22%). However, developing countries have had to rely much more on external sources of financing to maintain their faster growth of investment, which increased by 7.5% annually during 1970-81, compared to 1.7% for developed countries. Therefore, it is of particular concern that the momentum of flows of official development assistance, which characterized the mid and late 1970s, appears to be faltering. The rate of growth in official commitments to agriculture (OCA) (broad definition) 20/ has slackened since 1979 and concessional commitments actually declined between 5% and 6% during the three years centred on 1982 (Table 1-21). Non-concessional commitments have partially compensated for this decline, but add further to the debt problem of developing countries.

Commitments for the early 1980s were about 40% short of the internationally agreed estimate of annual requirements during the period 1975-80 of $8 300 million at 1975 prices (about $13 100 million at 1980 prices), an estimate that originated in documents prepared for the World Food Conference and then endorsed by it. OCA (narrow definition) increased by 10% annually in real terms during the late 1970s to reach $8 200 million in 1980 (Table 1-10). Even if this rate of growth of OCA had continued up to 1983, OCA would still have fallen short of the estimated annual requirement by more than $2 000 million. In fact, the rate of growth has been only 2.5% in the early 1980s. In this respect progress since the World Food Conference has been disappointing.

Regional distribution of commitments. Asia and the Pacific and the Africa regions increased their shares of concessional capital assistance to agriculture by 12% and 2% ,respectively from 1974-76 to 1980-82 (Fig.1-11). The regional shares of the of the Near East and Latin America

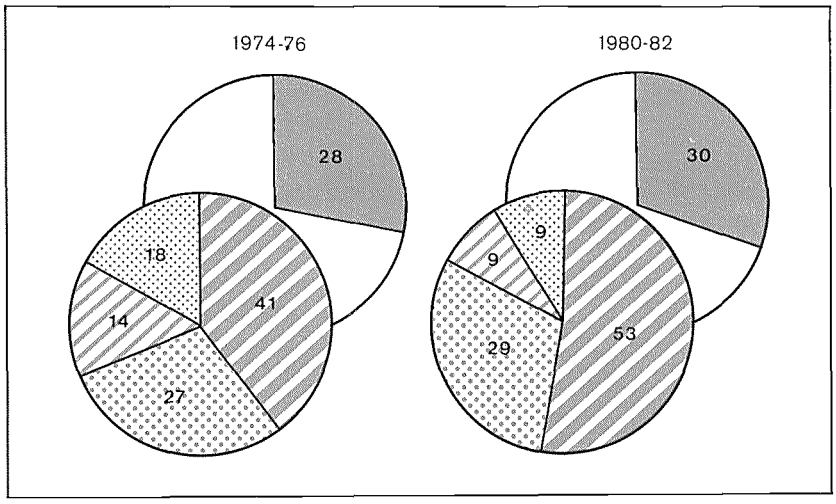

Figure 1-11

PERCENTAGE SHARES OF CONCESSIONAL CAPITAL COMMITMENTS TO AGRICULTURE IN THE FOUR DEVELOPING REGIONS AND LEAST DEVELOPED COUNTRIES

Source: FAO, Policy Analysis Division and OECD.

20/ The "broad definition" includes assistance directly to the agricultural sector, plus the following indirect activities: forestry, manufacturing of inputs, agro-industries, rural infrastructure and rural, regional or river development. The "narrow definition" corresponds to assistance directly to the sector. For complete definitions, see Explanatory Note or FAO, The State of Food and Agriculture 1981, p. 21.

decreased considerably in the same period. However, because of the great difference in regional populations, Africa receives more in per caput terms (Table 1-22). Indeed, the figures for Africa and the LDCs would be higher than those shown if technical assistance is taken into account because they receive the greater part of such assistance. However, a breakdown of technical assistance by recipient country is not available.

Allocation of capital assistance by purpose. Land and water development is the subsector receiving most of the capital assistance to agriculture in all regions except in Latin America, where the leading subsector is agricultural services. Over all regions, land and water received about 33% of all capital concessional assistance to agriculture (narrow definition) in 1980-82. This was followed by agricultural services (16%), inputs (14%) and crop production (13%). The share of research and training increased from less than 3% in 1974-76 to about 8% in 1980-82, but that of the livestock subsector fell to 4% in 1980-82 from 13% in 1974-76.

Although more capital concessional assistance went to fisheries and forestry in 1980-82 than in the mid-1970s, each still accounted for only 5%-6% of the total.

4. NATURAL RESOURCE SECTORS

Fisheries

Importance of fisheries. Fish is one of the most widely distributed food commodities in the world. It is generally less subject to social or religious restrictions on its consumption and probably less confined geographically in its production than many livestock products. It presently contributes about 6% of total protein supplies and, taking into account the indirect contribution of fishmeal fed to animals, about 24% of the world's animal protein supplies. Variations in the pattern of consumption are determined both by cultural factors--resting historically on availability--and on income levels. Thus the highest levels of consumption are found in Japan, Iceland, Norway and Denmark. However, the most vital nutritional impact of fish is in the developing countries of Asia and Africa where animal protein supplies are generally low, but where a high proportion are provided by fish.

For many developing countries, fish is an indispensable item of daily diets. About 60% of the population of the developing world derive 40% or more of their total annual protein supplies from fish. Fish and fish products are not only highly nutritious, with protein content varying between 15% and 20%, but their biochemistry and amino-acid characteristics make them particularly efficient in supplementing the cereal and tuber diets widely consumed in Asia and Africa.

Apart from its role as a provider of food, fishing is an important source of employment and also of income generation through the inducement it provides for the establishment of secondary industries. Present estimates suggest that throughout the world some 15 million people are engaged directly in fishing, but such global figures give little indication of the vital importance that fishing has for many small coastal communities that have little alternative employment opportunity. Taking into account dependents and those engaged in processing, marketing and ancillary activities, several hundred million people rely, either wholly or partly, on fisheries for their livelihood.

Fish is also an increasingly important source of foreign exchange earnings. World exports of the major fishery commodities now exceed $15 000 million annually, and while international trade in fish and fishery products is still dominated by the developed countries, developing countries are taking a larger share of this trade. Between 1974 and 1982 the volume of exports of fish and fishery products from developing countries doubled and their value trebled. The Republic of Korea, Mexico, Thailand, Peru, India, Chile, Indonesia, Mauritania, Senegal and Argentina are among those that have shown the most significant increases in fish exports.

Fisheries during 1973-1982. For fisheries, the last decade has been a period of far-reaching changes. The traditional concept of the freedom of the seas and the uncontrolled exploitation of fish stocks as a common property resource has been replaced, both in principle and as international and state practice, by recognition of the right of coastal states to national jurisdiction over the fish resources in zones extending typically 322 km (200 miles) from their shores. This new regime of the oceans is now embodied in the 1982 United Nations Convention on the Law of the Sea, and over 90% of the marine resources presently exploited now fall under national jurisdiction.

The new situation has evolved at a time when the nature of world fishing is undergoing a dramatic change. The rate of increase in the world fish catch has dropped sharply because many stocks of fish are either fully exploited or even overexploited. Whereas the total world catch grew by more than 6% annually from the late 1950s to 1970 from 28 million tons

to 62 million tons, since the early 1970s the average annual growth has been only 1.5%. A price-weighted output index shows a higher rate of growth than that of catch since 1970, although this rate is lower than it was previously (Fig 1-12). This was due mainly to a decline in catches of low-value species for fishmeal production and to higher prices for fish.

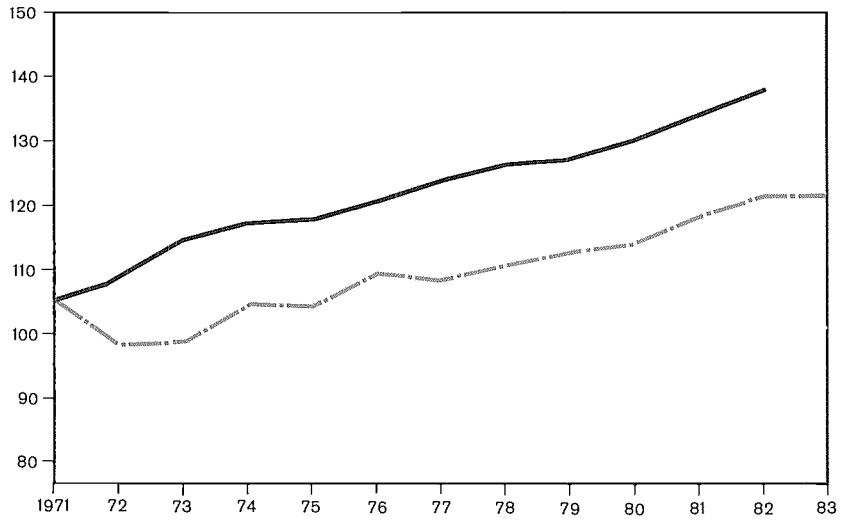

Figure 1-12

INDICES OF FISHERY PRODUCTION
(1969-71 = 100)

Source: FAO, Fishery Department.

World fish production in 1983-84. After increasing slowly but continuously for several years, the world fish catch in 1983, at 76.5 million tons, remained at about the level reached in the previous year (Table 1-23). The composition of catch changed, however, as the supply of food fish (compared with those destined for reduction to meal and oil) increased in 1983.

The developed countries, as a group, increased their catch for the fourth consecutive year by nearly 2% to 40 million tons. Most developing countries also increased their catch. However, as a group, their catch fell by 2% to 36.5 million tons. This decrease was mainly due to the fall of 2.3 million tons in the catches of Latin American countries. The principal factor contributing to this decline was the "El Niño" current, which adversely affected the small pelagic and tuna fisheries of Peru, Ecuador and Mexico. In Peru, landings declined by a massive 2 million tons--a 57% decline--while in Ecuador the catch also fell to less than one-half the level of 1982. However, Chile experienced an increase of 8% in landings and remained by a considerable margin Latin America's most important fishing nation, accounting for 44% of the region's total catch. In Mexico, the decline in landings of 250 000 tons was mainly in catches of sardines and anchovies.

Total fish production in Africa is estimated to have increased by some 280 000 tons, mainly due to higher catches by Namibia and Morocco that recorded increases of 70% and 23%, respectively. Some Asian countries also increased their catch: China (6%), Malaysia (9%), Indonesia (6%), India (8%), the Republic of Korea (5%), and Thailand (6%). The growth of production by the last two countries indicates that they were among those countries seriously affected by their exclusion from waters where they had traditionally fished.

Source: FAO, Fisheries Department.

The increased catches of developed countries were largely due to the partial recovery of Norwegian and Icelandic stocks and to higher landings by the United States, Japan and Poland. On the other hand, such important fish-producing countries as Canada, Denmark, the United Kingdom, Spain and the USSR experienced lower landings in 1983.

Data for 1984 are still incomplete, but there is some evidence of a moderate increase in total catch. Landings at Japan's 51 major fishing ports, which account for about 55% of the country's total production, registered an increase of 7% in the first nine months of 1984, as compared to the corresponding period of 1983, due mainly to record sardine landings. However, much of the higher Latin American catch of small pelagics and the Japanese catch of sardines are being used for fishmeal production. In the food fish sector, increased supplies of herring (in Western Europe), Alaska pollack and shrimp were reported in 1984.

International trade in fish and fishery products in 1983-84. The new regime of the ocean is stimulating changes in the pattern of trade in fish and fishery products. In terms of access to raw materials, both developed and developing countries have lost freedom of access to grounds where they previously fished or now pay licensing or other fees. Obstacles, both tariff and non-tariff, still remain however, which prevent developing countries from reaping fuller benefits from international trade in fish products.

The total volume of fishery products entering international trade in 1983 stayed at the same level as in 1982, but its total value increased due to recovery in prices of many products as compared to 1982, when average prices were particularly low. Seven of the ten leading fish exporters are developed countries (Canada, the United States, Denmark, Japan, the Netherlands, Norway and Iceland) and three are developing countries (the Republic of Korea, Thailand and Mexico). Significant increases in food fish exports were reported in the United States (especially salmon), Norway (groundfish and shrimp) and Thailand (canned fish, particularly tuna). The major exporting nations reporting a significant fall in food fish exports were Japan (especially frozen and canned mackerel) and Mexico (tuna).

The global quantity of imports of fish did not change in 1983. However, there were changes in both directions, the most noticeable being a drop in fishmeal imports by developed and developing countries alike. Total value of world imports increased as a result of higher prices of some food fish products and fishmeal. Japan, the largest importer of fish products in the world, increased its share of world imports (13% in quantity and 24% in value) for the fourth consecutive year. Nearly half of the additional quantity of imports consisted of fishmeal. U.S. imports increased by 6% in quantity and 20% in value. However, EEC countries showed a decrease in imports by 7% in quantity and 5% in value.

Import data for developing countries indicate an overall marked fall of 15% in the quantity of fishery product imports, most notably of fishmeal. Developing countries as a group accounted for 23% of world imports of fishery products in quantity and 14% in value. On the basis of available data, imports of food fish fell for the second consecutive year by 5% in quantity, the African countries appearing to be especially affected.

The data available on international trade in fish and fish products indicate that in 1984 the volume of fish trade probably remained at the level of 1983, with a slight rise in value. Imports of low-value frozen and canned mackerel and canned sardines into developing countries continued their downward trend, while the United States imported greater quantities of high-value fish such as canned tuna and shrimp, partly due to the strength of the U.S. dollar. In the case of Japan, the major fish importer, 1984 imports of shrimp probably reached a new high level.

Developing countries appear to have continued to increase their share of world fish exports in 1984, possibly reaching 45% in import value terms, mainly because of increased exports of canned tuna and shrimp.

FAO World Conference on Fisheries Management and Development. This conference, held at FAO Headquarters from 27 June to 6 July 1984, was a unique and historic occasion in the evolution of the world's fisheries. It was unique in size and level of representation, being attended by 147 national delegations, many of them led by ministers, and representatives of over 60 international intergovernmental and non-governmental organizations. It was historic in scope and outcome, being the first time that nearly all nations of the world, large and small, came together to reach agreement on comprehensive action to confront the practical implications of the new ocean regime and to use fully the potential of fisheries as a vital source of food, employment and income.

The conference endorsed a comprehensive Strategy for Fisheries Management and Development, comprising guidelines and principles for consideration by governments and organizations when planning and implementing fisheries management and development. The strategy covers eight major elements: the contribution of fisheries to national economic, social and nutritional goals; improved national self-reliance in fisheries; the rational management and optimum use of fish resources; the special role and needs of small-scale fisheries; international trade in fish and fish products; investment in fisheries; economic and technical cooperation; and international collaboration in fisheries.

In order to assist developing countries in the implementation of this strategy, the conference also approved an integrated package of five action programmes, involving the estimated expenditures of $15 million over a five-year period and urged bilateral and international donor agencies to provide the necessary support:

(1) Fishery planning, management and development. The purpose of this programme is to provide countries with access to fisheries management and development skills through FAO technical advisory services and long-term training to strengthen national capabilities. Advisory services will include short-term, multidisciplinary missions to assist countries in the formulation of their national fishery policies, plans and projects. Assistance will cover such varied areas as identifying investment projects, harmonizing fisheries legislation, establishing control procedures for fishing operations within Exclusive Economic Zones (EEZs), and assessing the distribution and migration of shared stocks.

(2) Small-scale fisheries. This programme is designed to assist small-scale fishermen raise their standard of living through the integrated development of fishing communities, investment and credit support, improved training and extension services. The role of women in small-scale fish production, processing, marketing and family maintenance will be given special attention.

(3) Aquaculture. Aquaculture is a potentially excellent source of food supply, especially in poor, rural areas. The goal of this action programme is to give emphasis to the development of small-scale aquaculture as a source of protein supply, alternative employment, especially for women, and increased income. FAO's worldwide network of regional aquaculture development and research centres will be expanded and strengthened.

(4) International trade. To assist developing countries to benefit further from trade in fish and fishery products, specific efforts will be made to identify marketing opportunities, upgrade product quality and conclude more favourable trade agreements. This action programme will be based on the positive experiences of FAO's existing Market Information

Service for Fishery Products in Latin America (INFOPESCA) and the Asia-Pacific regions (INFOFISH). Similar information services are being established for African and Arab countries together with a computer-based world fish market indicator service. Studies will be made of the means of improving the structure of world fish trade and of the possibilities of creating a multilateral framework for consultations on international trade in fishery products.

(5) Fish as food. This programme aims at increasing food fish supplies to the poorest and weakest, through measures to improve utilization, handling and processing, to reduce post-harvest losses, to strengthen research into low-cost products and to include nutritional goals into national fishery policies.

The conference recognized the key, catalytic role of FAO in worldwide fisheries development and endorsed the delivery of subregional, regional and interregional development programmes through the network of technical support units associated with FAO regional bodies.

In addition to resolutions endorsing the strategy and approving the programmes of action, the conference adopted a resolution regarding the follow-up actions required to implement the strategy and action programmes. Six other resolutions dealing with various aspects of fisheries management and development were also adopted by the conference. These resolutions called for the greater use of fish and fish products in food aid programmes; for greater priority to fishery investment projects; requested intensifeid action to protect fish resources against pollution; proposed the proclamation of an International Year of the Fisherman; recommended increased support for the development of fisheries in land-locked countries; and called for the further promotion of technical/economic cooperation among developing countries (TCDC/ECDC) in fisheries.

Forestry

Roles of the forest. The forests of the world provide a renewable source of materials, energy and services for nations and communities, contributing to their social and economic well-being and forming a vital component of their environment.

Forests make up 4 100 million ha, or 30% of the world's land area. They are distributed between the temperate zone, with 2 050 million ha, of which about 1 650 million ha are closed forests; the tropical zone, which has some 1 200 million ha of closed forests and 550 million ha of open woodland; and the arid zone, which contains some 300 million ha of forests, mainly open woodland. There are, in addition, about 1 000 million ha of land classified under other uses than forest with some shrubs or woody vegetation.

Some 11 million ha of forests are lost each year as they are cleared for agriculture, destroyed or degraded by shifting cultivation, fuelwood gathering, overgrazing and burning. Total tree planting of 1 million ha a year in tropical countries makes up for only one-tenth of the area of forests annually cleared and destroyed. The uncontrolled destruction of forest in the humid tropics and arid zones is of major concern both for the future supply of forest products in these regions and for the maintenance of the forests' conservation functions. Solving this problem involves a complex series of issues, including improved technical understanding and the resolution of conflicting pressures for the use of land.

The annual production of roundwood from forests is around 3 000 million m^3. Nearly one-fifth of this quantity provides raw material for mechanically processed wood products as materials for housing, construction, furniture, packaging and communication, or for paper. About 80% of the 1 300 m^3 produced in developed countries is used for such industrial

BOX 1-4. 1985: INTERNATIONAL YEAR OF THE FOREST

At its Eighty-Sixth Session in November 1984, the FAO Council formally declared the year 1985 to be FAO's International Year of the Forest. The event will coincide with the United Nations' International Youth Year and FAO's 40th Anniversary (1945-1985). The annual World Food Day celebration will also emphasize the central role of the forest as a global concern as well as forestry's role in food security. One of the highlights of activities in 1985 will be the Ninth World Forestry Congress, to be held in Mexico City 1-12 July 1985, where the International Year is a central item on the agenda.

The main impetus for the designation of 1985 as the International Year of the Forest was the growing realization of the negative impact of deforestation that, in recent years, has been increasing at an alarming rate. According to FAO estimates, over 11 million ha of tropical forests are disappearing each year. Large expanses of forest in northern Europe and North America are being threatened by acid rain and by other forms of atmospheric pollution. Forest fires are causing extensive damage in the Mediterranean region. Deforestation in arid zones has hastened the advance of desertification.

In its declaration, the FAO Council expressed deep concern "at the lack of political awareness of the social, economic and environmental consequences of continued excessive deforestation and of neglect of the world's forest resources." One of the major goals, the Council said, was to ensure "that every possible measure should be taken urgently in every country to accelerate the process of heightening political awareness of the critical importance for the future of mankind of adequate attention being given to the world's tropical forests."

FAO will concentrate its efforts during 1985 on encouraging activities at the local, national, regional and international levels designed to raise such political awareness. A wide range of informational material is being prepared, including a poster, a fact sheet, news features, a leaflet, an information packet, a press kit, radio spots and various display material.

purposes. However, the same proportion of the wood cut in developing countries is used as fuel (1 377 million m^3 in 1983), with Africa depending for more than one-half of its total energy supply on fuelwood. Other forest products include fruits, gums, resins, fodder and the meat of wild animals.

The number of people with direct dependence on forest products may be illustrated by means of the estimate of 2 000 million rural people who depend on wood supplies for their domestic energy and the more than 200 million people living in the forests themselves. Protecting soil from erosion and enhancing water catchments are functions of forests important to agriculture and communities.

The problem of the status of forest ownership in many countries is a major issue threatening the ability of the forestry sector to continue to perform its multiple roles. With the growth of population, forests are often regarded as a form of common property. In many cases, the forest has degenerated into a degraded common, with everyone removing what they can, but no one being in a position to care for its future production. Such a problem can only be solved by a major reassessment involving both the local community and government agencies. This is because some functions of the forest, such as watershed protection and wildlife preservation, and hence, investment in reforestation, may not be in the obvious short-term interest of an individual.

Fuelwood and energy. Despite the massive increase in petroleum-based fuel prices during the 1970s, total consumption of energy in developing countries nearly doubled to 60 000 million gigajoules by 1980, an annual rate of increase of nearly 6%. 21/ Although the use of fuelwood in developing countries also expanded, its contribution to total energy declined, particularly in Asia. Africa remains the region depending most heavily on fuelwood for its energy supply, but even in this region, the contribution of fuelwood declined from two-thirds in 1980 to little more than one-half in 1980-82 (Table 1-24).

Rapidly rising prices for and consumption of energy by developing countries had major financial implications. In 1970, it is estimated that energy only absorbed about 2.5% of private consumption expenditure (PCE) of developing countries. By the late 1970s, however, this share had risen to 18%, with fuelwood accounting for between 4% and 5% of PCE. In Africa, the share of expenditure on fuelwood alone accounted for 10% of PCE, and for the LDCs of Africa, this share was double that or 20%.

However, fuelwood did serve to mitigate the rising cost burden of imported fuel. Developing country imports of fuel rose by 50% between 1970 and 1982. They represented 20% of these countries' total imports by the end of this period compared with only 6% at the beginning. This share rose the least in Africa where fuelwood makes the greatest contribution to energy.

In Latin America the costs of fuel imports rose during 1970-82 from less than 10% of total imports to over 35%. With the rising costs of oil-based energy, a new emphasis on traditional fuels has emerged at a time when their availability was reduced by widespread forest destruction and degradation. For the rural community this has represented both a challenge and an opportunity. Increased demand for fuelwood-based energy has enhanced the economics of growing wood for fuel. For example, the demand for fuelwood in Ougadougou, the capital of Burkina Faso, has provided an additional source of income to small-scale farmers in nearby accessible areas. However, the adequate management of this source of income calls for the allocation of increasing resources for investment in planting and conservation to ensure future supplies. The current level of investment is still low in comparison with that needed to sustain the supply potential of forests.

Trends in output, 1974 to 1983. The output of forest products increased rather slowly during the decade under review, most of the increase coming from increased production by developing countries and mostly for fuelwood (Table 1-25). The post-1979 recession in developed countries resulted in a sharp decline in housing construction and consequently a contraction in the demand for processed wood products and hence their production. Production of mechanically processed wood products was the most adversely affected by the recession, and their production by developed countries decreased from the late 1970s. However, output of pulp and paper products continued to grow slowly.

In developing countries, progress in economic development led to greater growth in the use of wood-based panels, sawnwood and paper. The demand for lumber and panels was stimulated in particular by urgent housing and other construction programmes created by the rapid growth of urban centres.

The early 1970s was a period when production of roundwood for export by developing countries expanded rapidly--the all time high of 50 million m^3 was reached in 1973. Levels at the beginning of the 1980s were 30% lower. This was a consequence of the policies of several developing countries to replace exports of unprocessed raw material with those of processed products, although the recession in the international timber market

was a contributory factor. A number of developing countries experienced sharp declines in their exports of forest products, especially in the period 1980-82.

Production in 1983. World production of all forest products was stimulated in 1983 by the economic recovery of developed countries, especially in the United States, which resulted in an increased demand for processed wood products. World production of sawnwood was 451 million m^3 in 1983, recovering the previous peak of 1979 after some years of depressed outputs. This was mainly due to an increase of 11% in sawnwood production by developed countries, while developing countries recorded a level of output of this commodity only 2% higher. Wood-based panels also recorded higher production levels in 1983 reaching, with 104 million m^3, the peak level also last achieved in 1979. This was mainly due to the major recoveries in production in the United States and Canada.

Fuelwood still accounts for more than half the world production of roundwood, about 83% of which is produced and consumed in developing countries. However, fuelwood production of developing countries increased in 1983 by less than 2% and so less than their population growth rates. Production of industrial roundwood in 1983 also was only slightly higher than production in 1982, but the production level of 1 409 million m^3 is still far below the peak levels reached in 1979 and 1980. Pulpwood production increased significantly in 1983, because of high levels of activity in the pulp and paper industry, particularly in North America and Europe.

Trade in forest products in 1983. International trade in forest products, after years of depression, improved in 1983 as a consequence of the more positive economic situation in developed countries (Table 1-26). The volume of trade for the major commodities increased by amounts of between 3% and 14%. The value of trade in dollar terms, however, remained stable at the 1982 level, mainly due to the strong U.S. dollar.

Processed wood products increased their share of total trade of forest products, rising from around 50% in the mid-1970s to 65% in 1983. This was largely the consequence of policies of some developing countries, traditionally exporters of tropical logs, so as to encourage domestic production of processed wood products. In fact, developing countries decreased the volume of their exports of industrial roundwood by more than 3% in 1983 while their exports of sawnwood and wood-based panels increased by 8.5% and 14.5%, respectively. Indonesia illustrates this trend very dramatically. In 1983 Indonesian exports of sawlogs and veneer logs were only 3 million m^3 as compared to a peak of 19 million m^3 in 1978. On the other hand, its exports of plywood reached some 1.7 million m^3 in 1983, as compared with only 70 thousand m^3 in 1978.

Future trends. Policy discussion in the 7th Session of the Committee on Forestry (COFO), held in Rome from 7 to 11 May 1984, concentrated on the subject, "Forestry Beyond 2000 - Potentials, Problems and Prospects," with special emphasis on forest policies for the temperate, tropical and arid regions and at the global level. COFO defined the main problems affecting forestry as being degradation and depletion of forests in the humid tropics, fires and desertification in the Savanna and arid zones, and acid rains and other atmospheric pollution in the temperate zones. The committee stressed the critical importance of the maintenance of the world's forests. It also underlined the need for giving priority to investment in the forestry sector to ensure the sector's contribution to environmental protection and the production of essential goods and services.

The pressures of population and urbanization and a limited land resource present an immense challenge to the forestry sector. Confronting these pressures requires the commitment of people and governments. Meeting the increasing need for products of the forest and securing its ecological functions in conserving soil and water also requires the training of people, the development of skills and the evolution of an appropriate institutional environment, as well as commensurate levels of investment.

ANNEX 1-1. MAJOR ECONOMIC, MARKET AND INSTITUTIONAL EVENTS RELATED TO AGRICULTURE, 1973-1984

	ECONOMIC AND MARKET EVENTS	INSTITUTIONAL DEVELOPMENTS: NATURAL & HUMAN RESOURCES	INSTITUTIONAL DEVELOPMENTS: TRADE & DEVELOPMENT	INSTITUTIONAL DEVELOPMENTS: FOOD SECURITY
1984	Economic recovery gathers pace but uneven and uncertain. Inflation rates stabilize but interest rates remain high. Debt problems remain acute. More optimistic outlook on world food production. Worsening food situation in eastern Africa and Sahel. Major Food crisis in Ethiopia.	FAO World Conference on Fisheries Management and Development. UN World Population Conference (Mexico City).	Third Lomé Convention negotiated between EEC and 64 ACP states.	Interim System of Food Reserves generally supported by the Committee on World Food Security (CFS).
1983	Slow economic recovery in terms of output and trade. Inflation falls to below 5% in industrial countries but quickens to 44% in non-oil developing. Sharp decline in agricultural output in developed countries. Cereal imports decline, stocks increase to 19% of consumption and cereal prices ease. Indebtedness problem of non-oil developing countries at its worse (debt-to-export ratio 150%). Widespread drought causes large number of food emergency situations in southern and western Africa.	First review of Programme of Action of World Conference on Agrarian Reform and Rural Development (WCARRD). FAO Expert Consultation on Women In Food Production.	UNCTAD VI; Addressed the problems of protectionism and structural adjustment in world trade.	Food Aid Convention is renewed. CFS revises food security concept. Considerable increases in food and pledges to disaster-striken African countries. FAO/World Food Programme (WFP) task force established to monitor food situation in African countries.
1982	Economic recession at its deepest (zero growth in industrial output and reduction in volume of trade). Continued easing in inflation, including developing countries. Growth in agricultural output reduced (2.6%) but above long-term average. Cereal imports of developing countries stagnate, cereal prices and stocks recover (18% of consumption). Indebtedness of developing countries sharply worsens.	Concluding Session of UN Conference on the Law of the Sea.	Versailles Summit aims at monetary stability. GATT sets up Committee on Trade in Agriculture.	FAO Council established Regional Commission on Food Security for Asia and the Pacific.

(Cont.)

	ECONOMIC AND MARKET EVENTS	NATURAL & HUMAN RESOURCES	TRADE & DEVELOPMENT	FOOD SECURITY
1981	Recession begins to affect developing country output. Inflation eases in developed (10%), but not in developing countries. Agricultural output recovers (3.8%) particularly in developed countries. Further but less marked increases in cereal trade and prices. Cereal stocks decline further to 16% of consumption.	UN Conference on New and Renewable Sources of Energy.	UN Conference on LDCs adopts a substantial new Programme of Action for 1980s. Cancun Conference devises base for future UN multilateral trade negotiations.	IMF's Compensatory Financing Facility for cereal imports begins operation; CFS adopts agenda for consultations and possible action to deal with acute and large scale food shortages.
1980	Pace of industrial output and volume of merchandise trade slows significantly but inflation rises. The onset of world economic recession. No increase in agricultural output (a decline of 1.6% in developed countries). Sharp increase in cereal trade and prices. Decline in cereal stocks.	World conservation strategy is launched. UN World Water Decade initiated. World Conference on the UN Decade for Women.	Interntional Development Strategy (IDS) for 3rd UN Development Decade.	OAU's Special Economic Summit adopts Lagos Plan of Action. Food Aid Convention is enlarged.
1979	Pace of industrial output slows but inflation quickens (9% in industrial countries). Increase in agricultural output sharply reduced to less than 1%. Cereal trade continues to expand but cereal stocks rise to 19% of consumption. Cereal prices rise and sharp increase in price of petroleum (second oil shock).	World Conference on Agrarian Reform and Rural Development.	UNCTAD V: Structural adjustments related to trade and protectionism discussed. Comprehensive new Programme of Action for LDCs set up. GATT Tokyo Round ends. Lomé II signed by EEC and 58 ACP states.	Five-Point Plan of Action of CFS; breakdown of negotiations on international grain agreement.
1978	Moderate increases in industrial output and volume of merchandise trade. Rate of inflation falls (7.2% in industrial countries). Agricultural growth sharply increases and stocks fall sharply. Cereal prices begin to rise. Developing country indebtedness in relation to exports reaches 1970s' peak.		African Regional Food Plan presented to the 10th FAO Regional Conference for Africa.	
1977	Expansion of industrial output and trade decelerates. Growth rate in agricultural production doubles (2.8%), cereal trade stagnates and stocks rise to 18% of consumption. Cereal prices fall. Overall inflation rates remain high (8.4% in industrial countries).	UN Conference on Desertification.	Brandt Commission Report on North-South relations.	International Fund for Agricultural Development (IFAD) is established.

(Cont.)

	ECONOMIC AND MARKET EVENTS	NATURAL & HUMAN RESOURCES	TRADE & DEVELOPMENT	FOOD SECURITY
1976	Sharp increases in industrial ouput and volume of merchandise trade (5% and 10%-11%, respectively). Growth in agriculture output only 1.4%. Cereal trade increases and stocks remain at 14% of consumption. Inflation eases (8% in deveoped countries).		UNTAD IV sets up the Integrated Programme for Commodities. UNCTAD establishes a committee on Economic Cooperation Among Developing countries (ECDC).	African ministers of agriculture produce "Freetown Declaration" toward a regional food plan. First Session of the CFS. Enlargement of WFP's Committee on Food Aid Policies and Programmes (CFA).
1975	Recession deepens and industrial output declines (by about 0.5%). Agricultural output recovers (2.8%) growth, especially in developing countries. Cereal trade stagnates (but cereal stocks decline again) and commodity prices ease. Inflation eases but still high (11% in industrial countries). Sharp rise in external debt of non oil-exporting developing countries.	World Conference for the International Women's Year.	First Lomé Convention between EEC and ACP states. Paris Conference on International Economic Cooperation. Lagos Treaty establishes the Economic Community of West African States (ECOWAS).	International Emergency Food Reserve (IEFR) is established. Establishment of World Food Council. FAO Conference and Council set up CFS.
1974	Sharp slowdown in increase in industrial output. Agricultural output expands by only 1.8%. Recession begins and inflation accelerates to 13% in industrial countries. Commodity prices reach peak levels. Petroleum prices quadruple. Cereal stocks recover a little (15% of consumption).	Second Session of the 3rd UN Conference on the Law of the Sea. UN World Population Conference adopts a World Population Plan of Action (Bucharest).	UN General Assembly calls for a New Internatiional Economic Order.	World Food Conference emphasizes food security and resolves to set up a Global Information and Early Warning System for Food and Agriculture (GIEWS).
1973	Industrial output continues to expand. World agricultural production falls (-0.3%) but trade increases by nearly 16%. Beginning of world food crisis. Disappearance of major fish stocks off Peru. Commodity prices begin to increase.	UN Environmental Programme (UNEP) created.	UNCTAD III discusses trade liberalization.	

CHAPTER 2 URBANIZATION: A GROWING CHALLENGE TO AGRICULTURE AND FOOD SYSTEMS IN DEVELOPING COUNTRIES

1. INTRODUCTION

The growth of urban areas has traditionally been associated with socio-economic development. An increasingly progressive agriculture has also historically accompanied the growth of cities. The link between urban growth and a more productive agricultural sector was necessary for the transfer of food, labour and capital to the growing cities, which in turn, supplied agriculture with industrially based inputs and a growing market for agricultural products.

Sustained urban growth then required a sophisticated system of commercial agricultural markets that enabled agricultural production to satisfy consumer needs. However, the links among cultural transformation, economic prosperity, the growth of metropolitan areas and agricultural modernization appear to have been weakened in many developing countries as evidenced by growing slums, rising unemployment and low growth rates in agricultural output.

Rapid population growth combined with slower urban-based industrial growth has made the urban areas of some countries repositories of a people unable to provide themselves with the minimum means for a decent existence, which includes access to food. The problems in the cities of some developing countries often merely reflect even worse conditions in the countryside. Food and agricultural output has stagnated or declined in some cases and burgeoning urban populations are becoming increasingly dependent on imported food contributing to worsening balance of payments and debt problems.

The purpose of this chapter is to examine the problems and opportunities created by urbanization in developing countries as they relate to the production and consumption of food, its marketing and distribution. The second section of the chapter shows how urban and rural populations are expected to grow and examines some of the causes of this growth. The third and fourth sections examine the consequences of urban growth for agricultural production and nutrition, while the fifth section analyses its implications for food marketing. Examples mainly from developing regions are given. The sixth and final section presents suggestions for pacing the rate of urbanization to achieve harmony with broader development objectives and examines approaches that have been used by various countries to alleviate the problems for agriculture created by rapid urbanization.

2. POPULATION, URBANIZATION AND MIGRATION TRENDS, 1980-2000

Developing countries constituted 75% of the world population in 1980, and they are projected to be the source of all net additions to the world rural population and 84% of the net additions to the world urban population between 1980 and 2000 (Table 2-1).1/ During this period, it is

---

1/ Urban and rural definitions vary for each region and country. These definitions have been published in UN, Estimates and Projections of Urban, Rural and City Populations, 1950-2025: The 1980 Assessment, New York, 1982, pp. 15-27. The projections selected are the medium variant and are regularly revised.

TABLE 2-1. PROJECTED NET ADDITIONS AND PERCENTAGE OF CHANGE IN TOTAL, URBAN AND RURAL POPULATIONS, BY REGION, 1980-2000

Region a/	Net additions			Percentage of change		
	Total	Urban	Rural	Total	Urban	Rural
	.... millions			..... %		
World	1 687	1 310	377	38.1	71.9	14.5
Developed countries	141	205	-64	12.5	25.4	-19.6
Developing countries	1 546	1 105	441	46.8	108.8	19.3
Africa	383	226	157	81.5	166.7	46.9
East Asia	286	262	24	27.0	75.5	3.0

a/ Note that the regional groups shown conform to the UN definitions on which the projections are based.

Source: UN 1982a.

likely that nearly 500 million migrants will move from rural to urban areas in developing countries, helping to raise the percentage of the urban population from 31% to 44% of the total. Thus, two-thirds (1 105 million) of the net additions to the population of developing countries will reside in urban areas by 2000 (Table 2-1). Most will be without land to grow their own food. The remaining net additions to population in developing countries (441 million) will inhabit rural areas. Two out of three urban residents of the world and nine out of ten rural residents will be in the developing countries by 2000 (Figure 2-1).

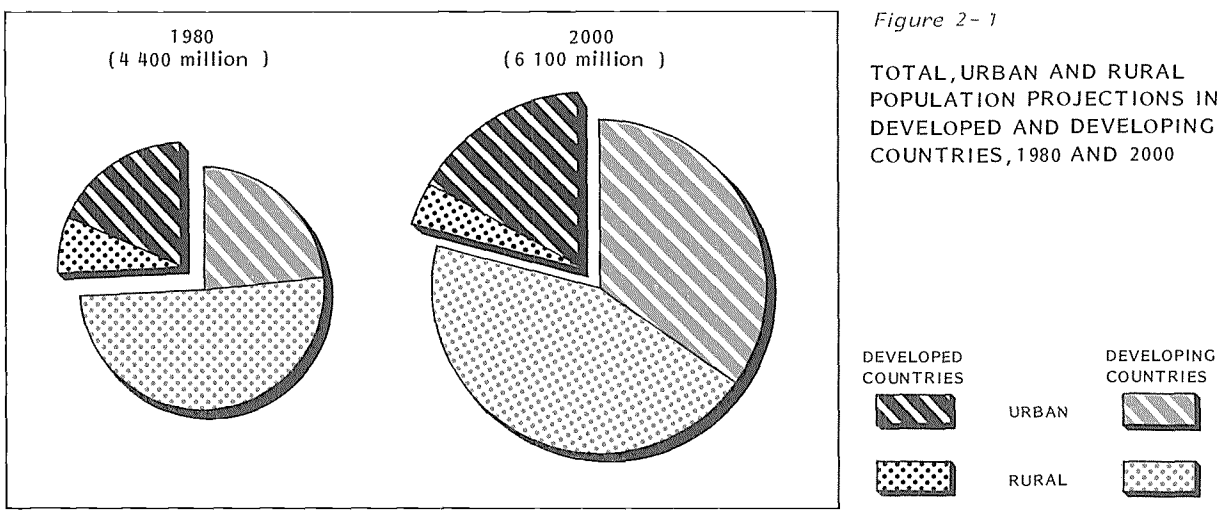

Figure 2-1

TOTAL, URBAN AND RURAL POPULATION PROJECTIONS IN DEVELOPED AND DEVELOPING COUNTRIES, 1980 AND 2000

Source: UN, Estimates and Projections of Urban, Rural and City Population, 1950-2025: The 1980 Assessment, New York, 1982.

The projected rate of urban growth in developing countries is particularly striking because there is no historical precedent for the sheer number of people being added to the urban sectors in these countries (Table 2-2). Yet high population growth rates in developing countries also mean that rural populations will increase further. It is projected that by 2000 over 2 700 million people in developing countries will be living in rural areas.

TABLE 2-2. TOTAL, URBAN AND RURAL POPULATION PROJECTIONS, BY DEVELOPING REGION, 1980-2000

The Primate City Phenomenon

Not only will the world become increasingly urbanized, but United Nations' projections show that by 2000 a large part of the population of developing countries will be concentrated in major urban centres of growth called 'primate cities'.2/ By 1980 at least one in five of the population in Argentina, Iraq, Peru, Chile, Egypt, the Republic of Korea, Mexico and Venezuela lived in a primate city. Cities such as Lima, Bangkok, Baghdad and Buenos Aires already account for over 40% of the total urban population of their respective countries. Furthermore, it is projected that 21 of 25 of the world's largest cities will be in the developing countries by 2000, compared with 13 of 25 in 1970 (Table 2-3).

BOX 2-1. THE PRIMATE CITY: MEXICO CITY

The primate city phenomenon is most obvious in Latin America. Mexico City is an outstanding current example. Mexico City's population grew from one million in 1930 to three million in 1950, nine million in 1970, 15 million in 1980 and is projected to be over 25 million by 2000. During the 1960-70 decade alone nearly 1.8 million rural migrants settled in Mexico City, representing 48% of the growth for that period, while the natural population increase accounted for 46% and physical incorporation 6%. In 1977, it was estimated that over 50% of the population over 20 years of age in Mexico City were migrants.

Mexico City's credentials as a primate city are borne out by the following facts: it has 21% of the total Mexican population, 46% of the GDP, 53% of manufacturing labour, 42% of higher education institutions, 52% of the theatres, 76% of the radio stations and all five television stations. Much of this imbalance has been caused by favouring urban-based industrial development over rural development through credit and price policies and investment in infrastructure. Consequently, the inhabitants of the densely populated rural regions that surround the federal district and who are largely subsistence farmers view Mexico City as a place of opportunity for economic, cultural and educational advancement (Reig 1984).

2/ Primate cities are not necessarily the largest in terms of population. For example, other considerations are economic, political, cultural and infrastructure development.

TABLE 2-3. PROJECTED POPULATIONS OF THE 40 LARGEST METROPOLITAN AREAS BY 2000 AND THEIR 1970-80 GROWTH RATES

	Metropolitan area	1970	1980	2000	Annual rate of change 1970-80
		.... millions			%
1.	Mexico City	9.2	15.0	26.3	4.9
2.	São Paulo	7.2	9.2	24.0	4.4

While urban growth is a necessary component of economic development, the high concentration of population in a few major cities is considered undesirable by most developed countries because it has led to more pollution, slums, crime and higher per unit costs of providing services (Salas 1984). This is a widely held view although the proportion of the population and the degree of concentration that is urban differ widely among developing regions (Table 2-4). The growth of primate cities is also disturbing since administrative, service and political activities of a nation are centred in one localized area, often to the detriment of

other areas. This has occurred in developed countries as well, which in some cases have introduced measures to promote decentralization and the devolution of political power to secondary regional centres.

TABLE 2-4. PROJECTED POPULATIONS, PERCENTAGE OF TOTAL URBAN POPULATIONS AND NUMBER OF CITIES LARGER THAN FOUR MILLION, BY 2000

Region	1980			2000		
	Population (millions)	% of urban	No. of cities	Population (millions)	% of urban	No. of cities

The cost per unit of providing services in primate or other large cities are frequently higher than in much smaller cities. For example, the per caput expenditure for public services in Bogota, the capital of Colombia, with a population of about 3 million in the mid-1970s, was nearly seven times as great as the average per caput public expenditure of four other urban areas in that country with populations of between 50 000 and 90 000 (Linn 1983).

While these apparent diseconomies of size may seem to weigh the argument heavily in favour of slowing the pace of urban concentration, other points must also be considered. For instance, higher per unit costs may reflect better quality service that urban residents are willing to pay for in higher taxes. Furthermore, the amount of industrialization is much greater in urban than in rural areas.

For example, Rio de Janeiro and São Paulo accounted for over 50% of Brazil's total industrial production in the 1970s (Wadehn 1981). Hence, the provision of services such as water, sewerage and electricity often must be much higher in urban areas. But some public investments in urban areas benefit the rest of the country. Examples are ports, transport terminals, warehousing and government offices, which indicate the additional costs incurred in urban areas versus rural areas, but which benefit both. However, large cities often capture a disproportionate share of national expenditure for nutritional intervention, housing and other services.

The United Nations also projects that by the year 2000 there will be 59 cities with populations greater than four million in developing countries. By then, these 59 cities will account for nearly one-quarter of the entire urban population of the developing world (Table 2-4) and for 31% of its total urban growth. The 236 smaller cities projected to have populations between one million and four million are expected to account for only slightly over 20% of the urban population growth of developing countries.

Composition of Urban Population Growth

There appears to be an evolution in the composition of the growth of urban population as economic development proceeds. At low levels of economic development and urbanization, most urban growth results from rural-urban migration, while during the transition stage from a rural-based to an urban-based economy, when urban growth is the most rapid, natural increases add more to urban population than migration (UN 1984). The latter phenomenon is not due to higher birth rates, but to lower mortality rates (see Box 2-3) more infants and mothers survive childbirth and more children survive early childhood. Better medical services in urban areas underlie these trends and constitute one of the attractions of metropolitan areas. At high levels of economic development, urban birth rates drop to such a low level that urban growth again results more from rural-urban migration.

For most developing countries, migration accounts for 40%-50% of the population growth of metropolitan areas, although this figure may be higher or lower in some regions. The migrant contribution to urban growth is greater than would appear from the numbers of migrants alone, since most of them are in the critical childbearing age group (migrants account for 60% of the growth rate of the 15-29 year-old urban age group). Thus, migrants tend to have a higher birth rate than urban residents. However, the results of studies comparing the fertility rates of native urban residents and rural immigrants are inconclusive when the data are adjusted for other factors such as age, income and education (UN 1982b).

Children born of migrant parents generally account for around 5% of net additions to the urban population. There are also some rural areas in countries that have been reclassified as urban because of population growth. Therefore, migrants, children born of migrants, and reclassifications, are considered to account for about half of the net additions to the urban population in developing countries.

Rural-Urban Migration

The rural-urban migrant normally reaps private benefits from migrating, while urbanization creates opportunities to modernize the agricultural sector that would not otherwise exist. Consequently, rural-urban migration can raise rural incomes if the means to increase agricultural productivity exist. In turn, higher rural incomes create markets for urban-based industrial goods. In this way, urbanization is both an inevitable and desirable component of modernizing a primarily agricultural-based rural society.

However, it is the relatively young and educated people who migrate from rural to urban areas. The rural exodus thus tends to result in rural areas having a less educated population and relatively fewer people of working age. For example, in Indonesia the 1971 census showed that illiteracy was much lower for both male and female migrants than for rural non-migrants. A similar pattern was shown by the 1970 Population and Housing Census of the Republic of Korea and has been generally shown for all countries surveyed (UN/ESCAP 1980).

Projections by the United Nations reveal the consequence of selective migration. Since it is the relatively young (15-35 year-old) age group that is most likely to migrate, rural population projections in all regions of the world continue to be proportionally higher for the very young and elderly age groups compared to urban areas. However, the difference between the age structure of rural and urban populations is narrowing largely because birth rates are slowing down in most regions and because the proportion of women of childbearing age in urban areas is growing.

Rural-urban migration takes place because of:3/

Expectations of benefiting from employment opportunities of the urban sector and the widening gap between rural and urban incomes;

Modernization of agriculture with labour-replacing methods;

Land scarcity from either a lack of cultivable land in relation to a growing population or the maldistribution of land;

Failure to improve rural living conditions as fast as in cities;

Natural or man-made disasters that drive people to urban centres in search of food and security where they remain even after rural conditions improve; and

Location of institutions of higher education largely in major cities.

The most frequently discussed issue is the rural-urban income gap that stimulates rural out-migration. A study of migration in various countries estimated the elasticity of migration with respect to urban wage rates to be very high at between 1.5 and 2.9. That is, for every 10% rise in urban wages relative to rural wages, the rate of migration to urban areas increased by 15% to nearly 30%.

Not all migration from rural to urban areas is permanent, nor is it confined within a country's borders. There are major movements of people that are temporary, such as those made by seasonal migrant workers. In some places there are rural-rural movements of tenants and landless workers to replace smallholders who have gone to the cities. There are also urban-rural movements in developed as well as in developing countries, such as by urban workers who take up part-time farming, retired people going into farming activities, and government-sponsored resettlement programmes to relieve urban pressures.

International migratory movements are also important and have increased since the early 1970s, particularly because of job opportunities in developed countries and, more recently, in oil-exporting and other developing countries that have been experiencing rapid economic growth. Remittances from these migrants are an important source of foreign exchange for several developing countries such as Egypt, Mexico, Turkey and Pakistan. 4/

Urbanization Profile by Developing Region 5/

The very large differences among regions with respect to their degree of urbanization will have decreased by 2000. Nevertheless, the differences will remain large as Latin America is already close to urbanization levels of developed countries (Table 2-5). There are likely to continue to be regional differences in other facets of urbanization and rural-urban migration.

3/ There is a very large body of literature on the factors (sometimes known as 'push-pull' factors) determining migration, which are only briefly summarized here.

4/ For a recent discussion of the financial impact of these remittances, see UN, "The Impact of Workers' Remittances on the Balance of Payments," Supplement to World Economic Survey 1983, New York, 1983, pp. 31-40.

5/ See Annex 2-1 for list of countries.

Latin America. In 1980, two of every three people in Latin America were urban dwellers. By 2000, that figure is projected to reach and even exceed the level of some developed countries, when three out of four Latin Americans will live in urban areas. Even with the continuing high growth rate of cities, the rural population is expected to increase in Latin America. The overall population growth rate is expected to remain above 2% annually through 2000. However, because of the already relatively low percentage of rural residents in the total population and a relatively high rate of rural-urban migration, total net additions to the rural population are projected to increase by only 11 million during the 1980-2000 period.

Latin America's transformation to a mainly urbanized society was established earlier than in either Asia or Africa. Consequently, the primate city phenomenon is relatively more advanced and is projected to remain so. For example, by 2000 the projected population of Mexico City (26.3 million) will account for 30% of the total urban population of Mexico, and São Paulo (24 million) and Rio de Janeiro (13.3 million) together will account for one-fourth of the total urban population of Brazil. The next two largest cities in Latin America will be Buenos Aires (13.2 million) and Lima (9.1 million), which will account for 45% and 38% of the total urban population of Argentina and Peru, respectively, by 2000. Projections indicate that 12 cities in Latin America will have populations of over 4 million by 2000.

TABLE 2-5. PERCENTAGE OF POPULATION LIVING IN URBAN AREAS, BY REGION, 1960-2000

Region	1960	1980	2000
	..... %		
World	33.9	41.1	51.2
Developed countries	60.2	71.3	79.4

East Asia	19.3	27.8	41.4
South Asia	18.4	24.8	37.1
Latin America	49.1	65.4	75.7

Source: UN 1982a.

Over one-half to two-thirds of recent Latin American urban growth has been attributed to internal migration. For example, rural-urban migration accounted for 70% of urban growth in Mexico from 1940 to 1970. Numerous studies from the region show that the prime motive for migrating is the search for more productive employment.

In Latin America more women migrate than men. Most studies have shown that the male-female migratory ratio is around 0.7 or 0.8:1. The younger and more skilled or educated are more inclined to migrate than the older and less skilled or educated.

Africa. The annual population growth rate of Africa is projected to be about 3% from 1980 to 2000, which would result in an 82% increase in the total population during the period and increases of 167% and 47% in the urban and rural populations, respectively.

Africa's rapid population growth over the last three decades is the result of improved medical care and public health facilities, which increased live births and reduced death rates. For example, the rates of the natural population increase for Tanzania have been 2%, 2.7%, and 3% for the 1948-57, 1957-67, and 1967-78 periods, respectively.

During the last decade, permanent rural-urban migration has become prevalent in Africa. While this movement could have been considered a normal step in the traditional rural-urban-rural migration cycle of Africa, the majority of the rural-urban migrants are now making permanent moves.

In sub-Saharan Africa, migration is dominated by single, young, relatively well-educated males. For example, the male-female ratio for city migrants in Kinshasa was 1.72:1. Generally, migration is to obtain employment, a higher income, and to meet the desire for those amenities, services and facilities that exist in urban areas.

BOX 2-2. URBANIZATION IN EAST AFRICA

The accelerating rate of urbanization and urban population growth in Africa can be appreciated by the rapid growth of established cities and the formation of new cities in Tanzania. For example, Dar-es-Salaam grew from 5 000 people in 1886 to 18 000 in 1900 and to 24 000 in 1931. By 1948 the population was still only around 70 000 but increased to 130 000 in 1957, 273 000 in 1967, and 852 000 in 1978. Since 1967, Dodoma grew particularly fast because of the decision to make it the capital of Tanzania.

POPULATION OF SELECTED URBAN CENTRES IN MAINLAND TANZANIA, 1948-1978

Town	Census year			
	1948	1957	1967	1978

a/ These towns were demarcated as urban districts, in the period after the 1967 census.

Source: Bureau of Statistics, Dar-es-Salaam.

Much of this growth--as much as two-thirds--was because of migration, predominantly from rural areas.

Urban population growth has also been spectacular in Kenya. Nairobi has increased ninefold in 40 years to approximately one million inhabitants today.

Rwanda and Benin appear to be exceptions to rapid urban growth and rural-urban migration phenomena. However, even in these countries, a large contingent of young men originally from rural areas are to be found in the cities searching for jobs and education.

In North Africa there is much international migration in addition to rural-urban migration. Egypt has an official policy to aid emigration in order to ease population pressures on its land and urban areas.

By the year 2000, 12 African cities are projected to have populations greater than four million compared with only one city of that size in 1980. These 12 cities will account for one-fifth of the entire urban population of Africa. The three largest cities in Africa by 2000 are projected to be Cairo (13.2 million) with 36% of Egypt's urban population; Kinshasa (8.9 million) with 32% of Zaire's urban population; and Lagos (8.3 million), with 17% of Nigeria's urban population.

East Asia. This region is dominated by China and the Republic of Korea that account for over 97% of its total population. East Asia is projected to have the lowest growth rate of both urban and rural populations than any other region in the developing world. This is largely owing to the relatively low birth rate in China. Nevertheless, because of its large population base, East Asia will have added 283 million people to its urban population between 1980 and 2000, nearly 12 times the number of net additions to its rural population. Indeed, the region is projected to begin losing its rural population by 1990.6/ All countries in the region, except Mongolia and the Democratic Republic of Korea, will show declines in their rural population by 2000.

The number of East Asian cities with populations greater than four million are projected to double from seven to 14 by the year 2000. By 2000 some of the world's largest cities will be in the Republic of Korea (Seoul, 13.5 million) and in China (Shanghai, 13.5 million and Beijing, 10.8 million). The migration from rural to urban areas is unpredictable in this region largely because demographic movement in China is highly sensitive to government programmes.

South Asia. South Asia is the developing world's most populous area, as it includes such countries as India, Pakistan, Bangladesh, Indonesia, the Philippines, Thailand, Burma, Viet Nam and Iran. Nearly 40% of the projected net additions to the world population between 1980 and 2000 will occur in this region. Therefore, this region is projected to make the greatest number of net additions to both the urban and rural populations of all regions, although its urban and rural growth rates are far below Africa's and the overall growth rate of its population is less than Latin America's.

The percentage of the total population living in urban areas is also the lowest of any developing region. In 1980, only one out of four people lived in urban areas, but it is projected that by 2000 the figure will reach 37%. This region is projected to account for 57% of the total net additions to the rural population of developing countries.

Projections indicate that 13 metropolitan areas in this region will have populations greater than eight million by 2000 and the region will have as many as 23 cities with populations of over four million. The five

---

6/ This situation may become apparent even earlier if China's recently announced policy to abandon rural communes and establish townships is successfully implemented.

largest cities in India--Calcutta (16.6 million), Bombay (16.0 million), Delhi (13.3 million), Madras (8.2 million) and Bangalore (8.0 million)-- will account for only 19% of India's urban population by 2000, a significantly lower proportion than in Latin America or Africa. However, city size may well be a problem for those Indian states in which the largest cities are located. For example, the next largest city in the state of West Bengal, where Calcutta is located, has fewer than 250 000 residents.

The remaining eight largest cities in this region will account for from 22%-53% of the total urban population of their respective countries by 2000, indicating the existence of the primate city phenomenon. These cities are: Jakarta (12.8 million), Indonesia; Baghdad (12.8 million), Iraq; Teheran (12.7 million), Iran; Karachi (12.2 million), Pakistan; Istanbul (11.9 million), Turkey; Dacca (11.2 million), Bangladesh; Manila (11.1 million), the Philippines; and Bangkok (9.5 million), Thailand.

The Urban Policy Dilemma

The concentration of economic activity and administrative services in the primate city and other major urban areas, encourages migration that may also contribute to the deterioration of urban living standards as well as create food supply and distribution problems. The extension of services to squatters and migrants tends to further increase the attracting power of the primate city and other metropolitan areas. Yet not providing new residents with services creates unsanitary living conditions and political problems. Providing services requires increased government expenditure for a population that is economically unable to contribute taxes proportional to its demand for such services. As more services are extended in the largest cities, the cost per unit will eventually rise.

On the other hand, through rural-urban migration, the city also benefits from investments in human capital made by other regions. Migrants represent educational and medical investments made by other, mostly rural, communities, the benefits of which accrue to the recipient city. Given the age group of the migrants, they also represent a cheap source of labour because they are usually entering the labour force for the first time and cannot negotiate advantageous wage rates.

A major problem for city planners and policymakers in the developing world is the unpredictability of rural-urban migration flows, unlike the more predictable natural increases in the population of urban areas. The rate of rural-urban migration is much more difficult to predict since it is higly dependent on economic and social phenomena such as rural-urban income differentials, employment rates and the availability and quality of services. Hence, successful urban planning requires the capacity to anticipate future population increases due to changes in the factors determining rural-urban migration.

Many developing and developed countries have demonstrated an urban bias through various policies that reflect the demands of political pressure exerted by the urban population. One of the most outstanding general examples of urban bias is a food policy that keeps producer prices low in order to keep urban food costs down. When food is directly subsidized, the tax revenue in most cases will have to be raised by levying taxes on agriculture, the dominant sector. Alternatively, government procurement of food at low prices is, in effect, a tax on agriculture. However financed, a cheap food policy is likely to provoke more migration. Furthermore, once implemented a cheap food policy is difficult to retract, as recent events in Morocco and Tunisia have shown.

There are various reasons why an urban bias will be accentuated in the future. Migrants in developing countries will tend to intensify the pressure for a cheap food policy, as they generally have lower incomes

than established urban residents and are not able to grow their own food. Studies have shown that migrants are conscious and rational participants in the political process when in the city and once they have a voice, will exert pressure for their own benefit.

Since the political process is already more sensitive to urban political organizations than to a dispersed rural population mainly comprised of subsistence farmers, it would seem inevitable that an urban bias, if not already expressed, will find greater cause to intensify. However, the experience of developed countries demonstrates that the shift from subsistence to commercial agriculture accelerates the political power of farmers.

Parallel with greater political power in urban areas is the likelihood that urban tastes will change food production and import patterns. Changes in food demand patterns generally start in urban areas where incomes are relatively high. In the past, this has resulted in rising food imports and increasing pressure on the foreign exchange balance when the domestic agricultural and marketing systems have failed to satisfy consumer demands.

Migration, Economic Development and Rural-Urban Links

Economic development may be distinguished according to the contributions to employment of the principal economic sectors: agriculture, manufacturing and services. These shifts are also characterized by concurrent developments in population movement, food demand, marketing and nutrition (Figure 2-2).

At a low level of economic development, agriculture predominates as the major employer of labour. The process of economic growth entails a massive transfer of labour from the agricultural to the manufacturing sector that is usually located in or near major metropolitan areas. High levels of economic development are associated with the rising importance of the service sector as an employer relative to manufacturing and an absolute decline in the number of agricultural workers. Most developed countries have followed this employment pattern.

Many developing countries appear to be moving directly from the first to the third level without creating a solid industrial base and, with rapid population growth, the number of agricultural workers continues to grow (Salas 84). In this situation, the additions to urban population are faced with relatively fewer jobs in the industrial sector, with consequent high numbers of unemployed and underemployed in the cities and in the countryside.

FIGURE 2-2. EVOLUTION OF POPULATION, FOOD PRODUCTION, MARKETING AND NUTRITION WITH ECONOMIC DEVELOPMENT

	Level of Development I	Level of Development II	Level of Development III
Demographic Factors	Majority rural. High birth and mortality rates. Hence slow population growth. Rural-urban migration small in number and low in rate.	Transition from rural to urban population. Heavy rural-urban migration. High birth rates, declining mortality rates. Growth of large cities.	Majority urban with rural-urban migration continuing and expansion of metropolitan areas into rural zones. Low birth and low mortality rates resulting in low population growth.
Production Factors	Subsistence farming main productive activity. Low-level technology, low yields. Modern sector exports. Little rural-urban trade.	Introduction of modern inputs, mechanization, high yields and surplus sold in the market. Appearance of dual economy with commercial agriculture the leading economic force. Landless labourers become more numerous. Cooperative ventures among small farms. More livestock production.	Large commercial farms dominate production. Specialization of production with livestock production still increasing but slowly. Farmers become sophisticated business managers.
Marketing Factors	Few goods traded with few middlemen active. Farmers sell directly to consumers.	More food shipped to urban areas. More middlemen appear as more food is stored, transported and processed. Wholesalers a key link in food marketing chain. Vertical integration beginning to appear.	Vertical integration dominates marketing methods and wholesalers start disappearing. Contract farming and supermarkets become common. Marketing bill takes about 2/3 of consumer expenditure for food.
Nutrition and Food Demand	People grow own food and hunger mostly caused by natural factors. Animal protein consumption relatively low. Elasticity of demand for food high and food expenditures take majority of income.	More people depend on market for food. More animal protein consumed. Food shortages caused by weather and bad policies. Urban bias and lower demand change food tastes and production patterns. Imports increase.	Nutritional requirements fulfilled in both rural and urban areas. Protein nutritional requirements available. Income elasticity of demand for food low. Food expenditures take a relatively small share of disposable income.

BOX 2-3. RURAL AND URBAN FERTILITY AND MORTALITY DIFFERENTIALS

Fertility levels in rural areas are higher than urban areas except for a few countries, mostly in Africa. This fact holds even when fertility levels are standardized by education and age for rural and urban areas. Generally there is also a lower fertility rate for the major urban area of a country relative to other urban areas of a country. However, mortality rates are higher in rural areas so that the population growth rates of urban and rural areas are approximately equal when adjusted for age, income and education.

RURAL-URBAN TOTAL FERTILITY RATES AND RATIOS

Country	Total Fertility rates		Rural-urban ratios
	Rural	Urban	
Bangladesh	6.2	6.1	1.02
Colombia	6.6	3.5	1.89
Costa Rica	4.7	2.9	1.62
Dominican Republic	7.1	4.1	1.73
Egypt	6.4	4.8	1.33
India	4.6	3.1	1.48
Indonesia	4.8	4.6	1.04

The difference is not difficult to comprehend. The basic causes for the difference between rural and urban fertility rates during these last two decades are income, educational opportunities and access to birth control technology. Family planning programmes are more cost-efficient in urban areas because the population is more concentrated and methods are more easily made available. Studies have shown that the use of contraceptives is consistently much higher in urban than in rural areas (UN 1984).

In rural areas children are seen as an addition to family labour and can relieve mothers of burdensome household duties. Children are also considered as a form of social security for parents in their old age. It has been suggested that raising the status of women in rural areas would thus affect their attitude toward limiting family size.

The higher infant mortality rate in rural areas also affects fertility. If a mother is sure of her children's survival, she is likely to have fewer children. Hence, improved medical care is likely to reduce fertility rates in rural areas in the long run.

3. EFFECTS OF URBANIZATION ON AGRICULTURAL PRODUCTION SYSTEMS

Urban growth influences agricultural production in the following principal ways:

- It accentuates the need to increase food production per agricultural worker because it increases the proportion of the population not producing its own food;
- It affects the composition of the agricultural and rural labour force because of the migration associated with urbanization;
- It causes the emergence of urban diets, and hence the changing pattern of food demand, which require similar adjustments in food production patterns; and
- It entails a conflict between urban and agricultural demands on natural resources--arable land, water and forests.

These issues have an important bearing on how much food must be produced per farmer, what food is to be produced, how it will be produced, by whom and where.

Unfortunately, as little research has focused on rural areas after migration, not much is really known about the impact of urban growth and rural out-migration on agricultural production and rural development.

The net economic effect of out-migration on the household, village, country or region can be positive or negative depending on migration patterns and many economic factors. There is a clear need for more research, particularly in Africa, on the relationship between a stagnating food and agricultural sector and high rates of migration.

Urban Growth, Food Demand and Agricultural Productivity

Rapid rates of urbanization can lead to dramatic shifts in the relative numbers of urban and rural residents. Most of the rural population of working age are food producers, but almost all of the urban residents will be consumers not producing their own food. Quite small changes or differences in growth rates in urban and rural populations are associated with large changes in the composition of the rural labour force, and hence, also in urban and rural dependency ratios (see Box 2-4).

From 1960 to 1980 there was almost a 1:1 ratio of net additions to urban and rural populations in developing countries. Projections for the period 1980-2000, however, indicate a ratio of urban-rural net additions of 2.5:1. The dimensions of the regional changes lying behind these average figures are striking (Table 2-6).

TABLE 2-6. URBAN-RURAL RATIO OF NET ADDITIONS TO POPULATION IN DEVELOPING COUNTRIES AND PERCENTAGE OF CHANGE IN RATIO

Region	1960-80	1980-2000	1960-80 to 1980-2000
	..... Ratio		... % ...
Africa	0.8	1.4	85
East Asia	0.7	4.1	483
South Asia	0.6	1.7	198
Latin America	8.3	17.3	109
Developing countries	0.9	2.5	190

Sources: FAO, Policy Analysis Division and UN 1982a.

These projected increases amount to approximately a doubling of the ratio in Africa and Latin America, but nearly a sixfold increase in East Asia.

Of course, these estimates understate the degree of urban-rural food dependency because proportionaly more of the rural population is younger or older than the urban population and is generally not employed in agriculture, while others are employed outside agriculture in rural areas. Adjusting the 1980-2000 figures to take account of age factors only (including the 15-59 age group) increases the urban-rural ratio of net additions mostly for Africa and South Asia, to 3.1:1. and 2.1:1, respectively, followed by East Asia with 4.7:1. The ratio for Latin America remains virtually unchanged at 17.4:1. Thus, rapid population growth--and hence an increasingly young population, particularly in Africa--and rural-urban migration cause radical changes in the numbers of urban food consumers per agricultural worker.

BOX 2-4. THE EFFECTS OF MIGRATION ON THE COMPOSITION OF THE LABOUR FORCE

Rural out-migration can have a profound effect on the age and sex composition of both rural and urban populations. The recent history of migration in different regions reflects significant differences in these compositions, as shown by the male-female ratios for urban and rural areas in selected age groups and regions in 1980.

Region		Age group in years 5-9	20-24	30-34	40-44
		... No. of males per 100 females ...			
Developed countries	- Urban	104.8	102.1	100.9	98.0
	Rural	105.3	109.1	102.7	97.6
Developing countries	- Urban	103.3	115.3	115.7	111.6
	Rural	104.5	97.2	99.7	100.4
Africa	- Urban	98.4	119.2	122.4	118.2
	Rural	101.8	91.3	87.5	87.7
Latin America	- Urban	101.4	96.9	96.4	94.8
	Rural	104.0	112.7	109.4	110.2
East Asia	- Urban	104.0	116.1	115.7	112.5
	Rural	104.2	96.1	103.6	106.7
South Asia	- Urban	106.3	123.6	121.9	115.8
	Rural	105.7	98.1	99.5	100.2

Source: UN 1982b.

The youngest age group reflects the normal sex ratio--boys generally slightly outnumber girls. For the 20-24 age group, the net effect of migration in most developing regions shows up very strongly. Latin America is exceptional in that more young women than men migrate from rural areas. In some regions, the 30-34 age group shows the most dramatic difference in urban-rural sex ratios. For example, in southern Africa these ratios were 128.7:100 and 65.3:100 (males-females) in urban and rural areas, respectively; a difference of almost 2:1. Eastern Africa showed similar ratios. For the older, 40-44 age group, the longevity of women, plus possibly lower migration rates of about 20 years earlier, are shown by the narrowing of these ratios.*

* For a discussion of these trends, see FAO, The State of Food and Agriculture 1983, Chapter 2, "Women in Developing Agriculture," Rome, 1984.

The dependency ratio, the number of very young and elderly directly supported by the population of working age, also varies widely among regions and between urban and rural areas. For example, the rural dependency ratio was five times greater in South Asia and Africa than in Latin America in 1980 where the dependency ratio is lower in the rural than in the urban areas.

Region	Urban	Rural
	dependency ratio a/	
Developed countries	47.7	23.0
Africa	76.6	199.6
Latin America	71.8	43.2
East Asia	53.8	116.4
South Asia	70.0	211.4

a/ Number of children aged 0-14 years and elderly persons aged 65 years and above per 100 people of working age (15-64).

A simple methodology was employed to arrive at a crude estimate of the production (measured in wheat equivalents) required to meet consumption needs of the net additions to urban areas in developing countries by 2000 (see Box 2-5). Production was then divided by the projected number of agricultural workers 7/ by the year 2000 to obtain a rough estimate of the additional food required from each worker to feed the additional urban population (Table 2-7).

TABLE 2-7. ADDITIONAL PRODUCTION EXPRESSED IN WHEAT EQUIVALENTS, REQUIRED PER AGRICULTURAL WORKER IN 2000 TO FEED ADDITIONS TO URBAN POPULATION, 1980 TO 2000

Region	Additional production per agricultural worker in 2000	Additional production per agricultural worker in 2000 as % of total production
	kg	%
Africa	330	24
Asia	244	16
Latin America	1 268	17
Total	340	17

Source: FAO, Policy Analysis Division.

7/ Agricultural workers per region in 2000 were calculated by taking the regional percentage of agricultural workers over total population in 2000 as given in the FAO study, Agriculture: Toward 2000, and multiplying by the total population of the corresponding region as projected by the UN. This extra step was necessary since the study did not cover all countries in the regions.

Although Africa has the lowest urban-rural ratio of net additions to population, it is the region where the proportion of production per agricultural worker to feed urban growth from 1980-2000 will be the greatest. The required increase is about one-quarter. What this result reflects is both the low level of production per agricultural worker in Africa and the high rate of urban growth.

From these estimates it may be seen that productivity per agricultural producer in Africa will have to increase by over 1% annually to cover the food needs of the additions to urban population alone. From past experience, doubts must be raised on whether such an increase can be achieved. It is estimated that during the period 1971-80, agricultural output per agricultural worker in sub-Saharan Africa increased by only about 0.5% annually.

The challenge to food production posed by increased urbanization in Asia and Latin America appears to be far more manageable. Not only are the required productivity gains lower than in Africa (0.7% and 0.8% annually per agricultural worker for Asia and Latin America, respectively), but their performance during 1971-80 of about 2.5% a year for Asia and nearly 2% a year for Latin America shows that such gains are achievable.

BOX 2-5. METHODOLOGY USED TO ESTIMATE FOOD PRODUCTION AND CONSUMPTION IN 2000

A period of 20 years was examined (1980-2000) for the three major developing areas: Asia, Africa and Latin America.

Population estimates were based on UN projections (UN 1982a). Production and consumption estimates were based on FAO's Agriculture: Toward 2000.* It was assumed that China and other countries not included in the study had the same per caput production as the region in which they were located. The 'A' scenario of 3.8% annual production increases was used for Asia and Latin America, while the 'B' scenario of 3.2% was used for Africa.

It was also assumed that the urban population consumes 15% less food per caput than the rural population and that 45% of urban population growth was due to rural-urban migration.

Calories were converted to metric tons of wheat equivalents using a conversion factor of 100 grams = 334 calories.

* FAO, Agriculture: Toward 2000, Rome, 1981, revised estimates. Consumption of fish and some minor food products are not included.

Rural-Urban Migration and Production Performance

Although there is circumstantial evidence that high rates of rural-urban migration may be harming agricultural production performance in sub-Saharan Africa, it is impossible to prove the point conclusively from the limited and aggregated data available. Clearly more case study material needs to be collected and analysed.

A recent FAO study of sub-Saharan Africa shows that some of the countries with the highest rates of increase in their agricultural labour force in the 1970s, i.e., where net migration may have been low, were associated with relatively high rates of growth in agricultural production (FAO 1984). Examples are Niger and Rwanda. Conversely, the lowest production gains were associated with low rates of increase in the agricultural labour force, possibly because of rural-urban migration. Ghana, Mozambique, Gabon, Congo, Lesotho and Sierra Leone are examples. There

were exceptions because the growth rate of the labour force is only one factor of agricultural performance. Indeed, it may be argued that the agricultural incentives or improved rural conditions that brought about relatively high growth rates in agricultural output also retarded migration.

Only a few of the microstudies that focused on whether production increased or decreased after rural out-migration found that there was any loss in production (Dasgupta 1984). The production declines were usually in African countries. In some cases the heavy out-migration of men created labour shortages in peak seasons for tasks traditionally done by men, such as land clearing. In other examples, plantations producing export crops were forced to cut back production because of seasonal labour shortages.

That rural-urban migration often does not decrease agricultural production has been traced to the following:

- Productivity may rise to replace workers lost through migration that may reduce underemployment, but may also mean that women, children and the elderly have to work more;

- Previously idle labour is employed or sufficiently high wages are offered to attract workers from other areas;

- Migrants may return to ease seasonal labour peaks;

- New cropping patterns are adjusted to overcome or accommodate labour constraints; and

- Agricultural production becomes mechanized (Dasgupta 1984).

Remittances from migrants may be used to allow agricultural production to be maintained; for example, to pay the wages of workers employed, to hire tractors or invest in livestock. However, most studies show that remittances are spent more on consumption goods, which may have the benefit of opening up the rural economy to industrial products, or on products that confer status. Remittances, nevertheless, are an important contribution to rural incomes and have been estimated to account for from 10% to 20% of total rural income in some countries (Gaude and Peck 1976).

Urbanization and the Changing Structure of Agriculture

Rural out-migration rarely causes agricultural production to decline. However, substantial modifications in production systems have to be introduced to sustain agricultural production and to accommodate the changing patterns of demand that urbanization involves. Important policy issues, therefore, are not whether food and agricultural production will decline, but whether it can increase fast enough, and what will be the implications for equity in rural areas.

United Nations' projections indicate that it is the 20-34 age group that will decline the most in rural areas from 1980 to 2000. For example, in eastern Africa the share of this age group in the rural population is projected to decline by almost 14% during the period. Those left behind may or may not have the special skills needed to adjust existing farming operations. Capital may become scarcer if the person who migrates fails to obtain work quickly or if local credit sources are not willing to make production loans to family members who have stayed on the farm.

The change in cropping patterns may be the most radical change to the agricultural system, particularly in farming areas adjacent to rapidly growing urban areas. The result may be toward more specialization in fruits, vegetables, feed crops, and livestock production. This process

BOX 2-6. MIGRATION AND URBAN GROWTH

What appear to be relatively minor differences between the growth rates in urban and rural populations, when combined with variations in the degree of urbanization, can produce major differences in the numbers of people being added to urban and rural areas. As examples of this process, three scenarios have been selected to show the impact of migration on the growth of urban populations:

Scenario A: The share of the urban population in the total population is 20% in the starting year (typical 'African' situation).

Scenario B: The share of the urban population in the total population is 40% in the starting year (typical 'East Asian' situation).

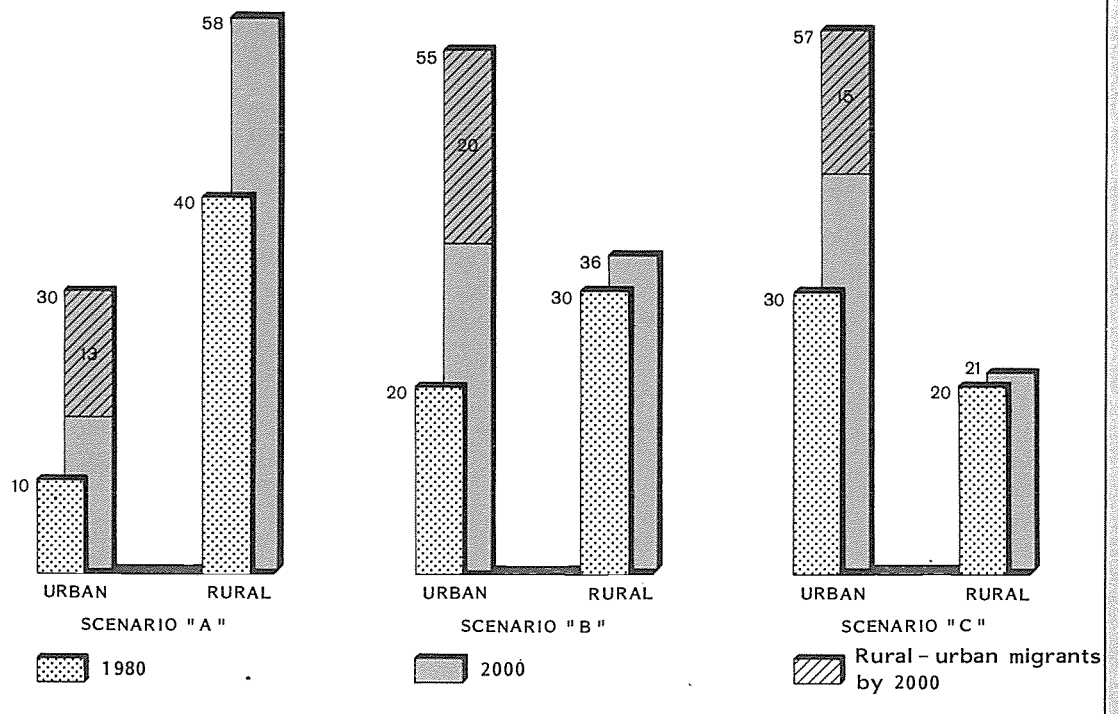
Scenario C: The share of the urban population in the total population is 60% in the starting year (typical 'Latin American' situation).

A procedure was developed to show the increase of urban and rural populations by the year 2000 and the importance of migrants in the growth of urban population. The procedure uses a migration rate that increases slowly but steadily with higher shares of urban population, reaching a peak of 3% (of rural population) when the urbanization rate reaches 54% of the total population. Migration decreases when urbanization is 75% of the total.

For each scenario, different but realistic natural growth rates have been selected: for scenario A, natural growth rates prevailing in Africa; for scenario B, those of East Asia; and for scenario C, those of Latin America.

The figure shows the increases of urban and rural populations by the year 2000 and the share of the urban population from migration over 20 years. The model is worked on the basis of a total population of 50 million in the year 1980, but any other population size would show the same growth patterns.

INCREASES IN URBAN AND RURAL POPULATION FOR THREE SCENARIOS BY 2000
(in millions)



Source: FAO, Policy Analysis Division.

usually leads to the wider use of improved technologies, and hence, a greater use of inputs, the monetization of small farms and modernization of the agricultural sector.

For example, the change in the composition of the value of agricultural production in the Republic of Korea from 1964 to 1979 (a period with a high rate of rural-urban migration) reflects the changing demand for food. Cereal production declined from 71% to 50%, while vegetable production increased from 7% to 22%; fruit production went from 2% to 4% and livestock production increased from 9% to 17%. The per caput consumption of livestock, fruit and vegetables all doubled between 1970 and 1981 (FAO 1983a).

One development, widespread in the past two decades in some countries and particularly in Latin America, was the replacement of crop farming by the raising of animals for meat production on an extensive scale. Such a farming system does not require intensive labour in planting and harvesting periods. In some cases, livestock production was combined with the mechanized production of feed grains, also to save labour. One example is Mexico where animal production and feed grain production outpaced the production of maize and beans (frijoles) for food consumption. The production of the latter two crops stagnated or declined from 1960 to 1980 while meat production increased by more than 6% a year and sorghum and soybean production grew by over 11% and 14% a year, respectively (Reig 1984).

In some cases such developments in production systems are in response to changing supplies of labour, that is, a response to rural out-migration. But in most cases, changing patterns in the demand for food may generate changes in production systems. While these changes provide the opportunity for growth in agriculture, the process of agricultural development frequently is associated with people being forced to leave the land or the rural economy entirely. Thus rural out-migration may be both the instigator and the consequence of the modernization of agriculture.

As urban markets grow, and the range of commodities expands, subsistence farmers with small plots are at a disadvantage because of their use of traditional practices, their lack of technical knowledge or access to inputs and credit. Some of these disadvantages may be offset somewhat by returning migrants who provide technical feedback and capital, but normally these benefits have been insufficient.

On the other hand, the transfer of labour from rural to urban areas should improve the overall income distribution in a country since former low-wage agricultural labour is usually paid more when employed in cities. In Brazil, for example, it was shown that rural-urban migration did in fact improve income distribution, partly because agricultural productivity increased. In the Republic of Korea and the Philippines, rural-urban migration helped improve income distribution between rural and urban areas, while rural inequalities increased partly because of remittances to rural areas sent by migrants (Gaude and Peck 1976).

Competition for Natural Resources

The impact of urbanization on agricultural production is not only felt through the changes it forces on production systems, but also through increased competition between rural and urban areas for land, water and wood.

According to one study, if present trends continue, 10 million ha of arable land will have been lost worldwide to urban encroachment from 1980 to 2000. Potential food supplies from this crop land could have fed 84 million people (Brown 1981). At the national level for example, the amount of land for urban use in Mexico is projected to increase by nearly

one-half between 1980 and 2000, and by the latter year will equal 3% of the cultivated area. Mexico City alone took 53 000 ha of agricultural land from 1960 to 1980 (Reig 1984).

Even if such a loss may not be so significant on a world or even a national scale, it gains in importance for the farming areas close to the fastest growing cities. For example, in the Delhi area of India, it has been estimated that more than 14 000 ha of land ceased to be used for agriculture between 1941 and 1971 because of urban encroachment (FAO 1983a).

Another example is Egypt where urban growth, mostly of Cairo, absorbed nearly 500 000 ha from agriculture from 1960 to 1980 (Parker and Cole 1981). In fact, urbanization has already removed from agricultural use an area of land equivalent to that brought into agricultural use by the Aswan Dam project.

Great urban centres are often located in rich agricultural zones, partly because surplus agricultural production freed labour to pursue non-agricultural occupations. Agricultural land of high productivity has been taken out of production in order to accommodate the housing, industrial and service needs of greater urban populations. Land of relatively lower productive capacity may have to be brought in at a greater rate than land taken by urban areas to compensate for the loss. For example, it was estimated that for every hectare of land taken out of production in eastern Canada because of urban growth, 2.3 ha of land in western Canada would be required to replace agricultural output lost (Brown 1981).

BOX 2-7. URBANIZATION AND THE INCREASING SCARCITY OF FUELWOOD IN SOME DEVELOPING COUNTRIES

It is said that in some parts of the developing world the fuel needed to prepare food for a meal is as important as the food itself. The increasing scarcity and cost of fuelwood and the much higher cost of fossil fuels since the early 1970s goes some way to explain the increasing demand, particularly in urban areas, for convenience foods that need little preparation.

It has been estimated that in Ouagadougou, the capital of Burkina Faso, the annual consumption of raw fuelwood is 438 kg per inhabitant and 29 kg fuelwood-equivalent in the form of charcoal (little charcoal is in fact consumed). It was also estimated that the potential yield of intact natural stands in the area is about 500-700 kg/ha/year. Putting these two estimates together it may be concluded that, for the population of Ouagadougou (260 000 in 1980), some 7 000 ha to 8 000 ha of intact forest would need to be clear-felled each year--the sustained yield from 200 000 ha to 300 000 ha of natural forest.

Higher yielding forest plantations would reduce this minimum area considerably to 30 000-40 000 ha, but the actual area of plantations around Ouagadougou was only one-sixth to one-seventh that size, and only 1 500 ha to 2 000 ha were about to come into production. Therefore, the fuel crisis in Ouagadougou can only worsen in the short run.

A similar situation is developing in and around Bamako, the capital of Mali in the same broad ecological zone. The per caput consumption figures are similar so that about 20 000 ha of intact forest would have to be cut to provide the fuel needs of Bamako district of between 500 000 and 600 000 people.

Most studies of domestic fuel needs assume the same per caput consumption in rural and urban areas. However, an FAO study found that in eastern Africa an additional 6% on average is required to cover urban service needs such as restaurants, small bakeries, blacksmiths, etc. (Kamweti 1984). Within this subregion, the range of this urban-service use varied from less than 1% of the total ir Somalia to 13% in Zambia.

A conflict also exists over water supplies. For example in Mexico, total water use is projected to increase 137% between 1980 and 2000. While water use in agriculture is responsible for much of this increase, the share of urban and industrial use is projected to rise from less than 20% to over 30% of total use during the 20-year period (Government of Mexico 1974).

The possible urban-rural conflict over water supplies is even more complex than that for land, since environmental damage can be traced to both urbanization and agricultural production. Water is subject to pollution from industrial and urban wastes, thus rendering it unusable for agricultural purposes. Yet water pollution can also occur if intensified farming results in the contamination of water by agrochemicals and the wastes from intensive livestock production systems.

The location of farms near an urban area will also affect what is produced and how it is produced. On one hand, there is ready access to expanding markets for high value products such as livestock products and fruits and vegetables. Electricity, telephones, equipment repair facilities and other services are more likely to be available, as well as training facilities and off-farm work for family members. However, urban growth is likely to increase land and water costs for adjacent farms. Higher taxes, labour costs, limits on manure disposal and agrochemical use may also represent constraints to production expansion.

Urbanization also intensifies the demand for energy and this has adverse implications for agriculture. In many developing countries, the domestic component of this demand is derived primarily from wood, either raw fuelwood or charcoal. The composition of energy sources varies widely among countries. For example, in Zambia, 20% of the population uses raw fuelwood and 80% charcoal, while in adjacent Malawi these percentages are completely reversed (Kamweti 1984). The use of fossil-fuels such as oil and gas is usually limited to high-income groups because of their cost, and the capital investment in household equipment needed to use them.

The increasing demand for fuelwood rapidly leads to the deforestation of the land around towns and cities and an increasingly reduced access to fuelwood. For example, in Ouagadougou (Burkina Faso) it is reported that by 1980 the distance to be covered to find fuelwood was 70-100 km along the main roads. Off the main roads, some limited supplies are still available closer to Ouagadougou, but transportation is much more difficult (Chauvin 1981).

In urban areas, the cost of fuelwood and charcoal has increased dramatically in recent years, especially in areas of Africa away from the equatorial zones and in parts of Asia. In Ethiopia, for example, purchases of fuelwood and charcoal use about 20% of the average household income. Again, in Ouagadougou the retail price of fuelwood in 1980 was about CFAF 9-11.50/kg depending on how it was sold. This was a heavy burden on the budgets of urban families, although the sale of fuelwood and the production of charcoal were useful additions to farmers' incomes.

The widening areas of degraded forests close to urban centres show an increasing threat of soil erosion and an increased risk of desertification. Furthermore, as fuelwood becomes scarcer and its price rises, there will be more incentive to use crop residues and dried livestock manure as a source of energy rather than as a fertilizer and soil conditioner. Yet efforts to overcome the shortage of fuelwood by establishing plantations close to towns will compete with crop production for land.

4. NUTRITIONAL CONSEQUENCES OF URBANIZATION

On the side of food demand, urbanization has the greatest consequence for agriculture because of the differences in the patterns of food consumption between urban and rural residents. These patterns will also influence peri-urban and nearby rural areas as well. Low-income urban residents and predominant among them, migrants, may not necessarily eat either adequately or well; and while malnutrition may be more widespread in rural areas, it is often more intense in low-income areas of cities.

Some ways of allowing low-income urban residents to improve their access to food may carry dangers to health. Urban backyard livestock and vegetable production may not comply with minimum sanitary requirements, while low-price providers of prepared foods, street-side food kiosks and vendors may consitute a public health threat.

Dietary Changes Associated with Urbanization

Urbanization is usually accompanied by changes in the kind of food consumed by those who have come from other places. Consumption surveys undertaken by FAO in Tunisia and Brazil illustrate this trend. The food staples (mainly hard wheat in Tunisia and maize and rice in Brazil) of the traditional rural diet become less important in the urbanized diet. They are replaced by other foods, particularly processed cereals such as bread and wheat flour, livestock products and vegetables (Table 2-8).

TABLE 2-8. CHANGES IN FOOD CONSUMPTION PATTERNS BETWEEN RURAL AREAS AND CITIES, TUNISIA AND BRAZIL

	Tunisia (1975)			Southern Brazil (1974-75)		
	Rural areas	Urban areas	Major cities	Rural areas	Urban areas	Major cities
	..... calories/person/day					
Cereals	1 662	1 307	1 129	1 057	910	897
of which:						
Traditional staples	1 250	498	222	637	405	431
Bread and wheat flour	246	607	764	405	426	434
Roots and tubers	24	40	40	183	101	75
Vegetables	62	87	80	21	23	28

Oils and fats	400	447	431	252	307	328
Share of basic foods in diet (% of calories)	69	62	57	60	53	51

Source: Adapted from FAO 1983b.

The consumption of food that provide energy and protein from vegetable sources is at its maximum in rural areas. The consumption of these foods decreases as a consequence of urbanization. This is due to the consumption of less traditional basic foods and the substitution, in lesser quantities, of more processed cereals. On the other hand, food consumed as a consequence of urbanization appears to be richer in animal protein, fats, and vitamin A, owing to a greater consumption of livestock products.

These dietary changes also have implications for the intake of micronutrients. For example, iron in the urban diet is more easily assimilated because this diet contains more iron of animal origin. The implications of urbanization in relation to calcium and vitamin C consumption are not clear, however.

Urbanization has consequences for food consumption patterns in rural areas as well. Through personal contacts, families of migrants remaining in rural areas tend to make some changes in diets that are similar to the changes made by the migrants themelves because of demonstrated effects and the receipt of remittances. Rural dwellers may also consume some of the new foods they produce for urban markets. As farmers specialize in crop production in response to changes in food demand, the variety of food produced in local rural areas may become more limited and can adversely affect the diets of the low-incomes rural population.

Access to Food and Urban Malnutrition

Most nutritional studies show that malnutrition is more widespread in rural than in urban areas of developing countries, but that the intensity of malnutrition is worse and becoming more severe in urban areas, particularly for children. This is mostly because access to food in cities is almost totally dependent on monetary income and the employment situation in many urban areas in developing countries is worsening.

For the newly arrived migrant, apart from income itself, crucial factors determining whether he or she can obtain an adequate diet are the length of period of unemployment following arrival and whether or not there are family members or friends who can provide food and lodging during the waiting period.

In addition, remittances to family members remaining at home in the rural areas may demand a significant portion of the migrant's income once a job is found. Because rural-urban migrants often constitute the majority of low-income groups in urban areas, where malnutrition is most frequently found, it is expected that they represent a significant proportion of those who do not have access to adequate diets.

Caloric intake in rural areas is usually higher than in urban areas (Table 2-9). However, this is partly because energy requirements are higher in rural areas owing to the greater amount of manual labour performed there.

TABLE 2-9. DIFFERENCES IN AVERAGE URBAN AND RURAL CALORIC INTAKE IN SELECTED COUNTRIES

Country	Urban	Rural
	... calories/day ...

Regardless of the level of income, the availability of food in cities influences the adequacy of the diet. In regions where food cultivated in backyards or gardens plays an important role in diversifying the rural diet, rural-urban migrants may not have access to sufficient land--if they have any at all--on which to grow vegetables or fruits, or to raise poultry or other small animals. Such foods can be available in cities, but prices may put them beyond the reach of most migrant families.

People in urban areas with low incomes spend most of their income on food and consequently have little choice as to what kinds of food they are able to buy (Table 2-10). Most migrants find themselves in this situation initially and are less likely to have had any nutritional guidance. The resulting diet may rely heavily on low-price staples and processed foods that may not provide the best nutrition for the expenditure.

TABLE 2-10. PERCENTAGE OF INCOME SPENT ON FOOD BY THE LOWEST INCOME QUARTILE IN SELECTED CITIES IN LATIN AMERICA

Country/City	Percentage of income spent on food

These conditions may explain the urban bias often apparent in food distribution that can lead to large cities receiving a disproportionate share of public food. The cost of administering food distribution programmes may mean that rural areas--that are less accessible--will have to receive less attention.

Urban Slums and Nutrition

The most severe nutritional problems in many countries exist in the so-called peri-urban or suburban areas of large cities, where rural-urban migrants tend to congregate. The problem of poor nutrition in these areas is not only because of low incomes, but to limited access to food, since urban transportation is frequently not available and local markets are often far away. An emerging problem in these zones is the large number of households headed by working women who have little time to shop and prepare food for their children. Their time available for breast-feeding is also severely limited and babies have to be weaned early. It is reported that malnutrition among children in these areas is increasing (Nelson 1978).

People with low incomes in urban areas often have to buy food at small local outlets that have higher prices than supermarkets. But the small stores give credit that low-income consumers are often forced to use because of unemployment and low wages. While the large supermarket is

able to buy large volumes on credit and sell large volumes for cash, the small food store must buy small volumes with cash and sell on credit, thus giving the large stores a financial advantage. Therefore, small stores usually sell lower quality food at higher prices so that food takes an even greater percentage of the income of the poor.

Urbanization and Food Safety

Methods of solving the nutritional problems of cities, such as developing urban agriculture, may raise other problems related to food safety. Uncontrolled or unregulated food crop and livestock production in densely populated urban areas can lead to serious sanitary and health problems. Such a situation caused a social worker in Mexico City to comment that the poor can die from what they eat as well as from a lack of food. On another continent, the feasibility of establishing rural cooperative dairies in India (the successful 'Operation Flood' programme) partially rested on the need to phase out, on public health grounds, the dairies that were situated in the midst of many Indian cities.

The density of population in urban areas makes adequate sanitary regulations of food handling most important. The wide variety and scale of food processing facilities, markets and retail outlets, particularly the street vendors and food kiosks, typical in the urban environment of developing countries, pose a challenge to the formulation of sanitary regulations that are sufficiently effective, but which do not impose high costs. This is becoming increasingly difficult as city dwellers turn to raising their own food, and the unregulated urban informal sector is usually focused on the marketing and preparation of food.

5. URBAN GROWTH AND FOOD MARKETING

Rapid urbanization in developing countries signifies a greater reliance on markets to supply the food needs of the urban population. Rural-urban migration implies that proportionately fewer people are able to grow their own food, which in turn means that food marketing facilities and channels must grow faster than overall population growth rates. Urban populations of developing countries depended on imports for nearly half of their food consumption in the late 1970s, and this can only worsen without substantial developments in marketing systems (Austin 1980).

Estimating Food Marketing Needs

According to a simple calculation, an additional 131 million tons of food in wheat equivalent will have to be shipped to urban areas in developing countries to feed those who will have migrated to urban areas between 1980 and 2000 (Table 2-11).8/ The actual amount produced on farms will have to be greater than the 131 million tons quoted because of food losses in storage, transportation, processing and distribution. Another 160 million tons of food in wheat equivalent will be required to feed the additional urban population due to natural increase.

The projected requirements in wheat equivalent of over 290 million tons in 2000 from the net addition to urban populations in developing countries between 1980 and 2000 provide a general idea of the additional food to be marketed owing to urbanization growth.

The marketing needs of the urban population of different countries and regions will vary because of differing rates of urban growth and present levels of marketing systems. Africa clearly seems to be in a precarious position as it will have to increase food marketing by nearly the same amount to urban areas as Latin America, but without the same degree of market infrastructure. Inability of the market to adjust to the urban

8/ See Box 2-5 for the methodology employed.

TABLE 2-11. ESTIMATED INCREASE IN FOOD REQUIREMENTS (WHEAT EQUIVALENT) FROM ADDITIONAL URBAN POPULATION BY 2000

Region	Total urban additions 1980-2000	Urban migrants 1980-2000	Natural additions 1980-2000
	.....million tons.....		
Africa	56.9	25.6	31.3
Asia	173.6	78.1	95.5
Latin America	59.6	26.8	32.8
Total	290.1	130.5	159.6

Source: FAO, Policy Analysis Division.

demand for food, plus the difficult production situation, could combine to put Africa in a serious food import position leading to greater balance of payment problems and the need for more food aid.

The large population base in Asia means that the net additional quantities marketed in urban areas will be roughly three times those of Latin America and Africa, even though Asia has both lower population growth and rural-urban migration rates.

Food Marketing and Urban Consumer Demand

The main challenges to marketing systems in developing countries as a result of urbanization are the major adjustments that must be made to meet the changing demand for food as well as the increase in the quantity of food to be marketed, and the need for agricultural input markets to provide the necessary quantity and mix of inputs required to produce the food products for urban markets. The food produced domestically will have to reflect the change in demand, and marketing channels will have to be expanded and created, in some cases, to satisfy domestic demand. The failure of the marketing system to work efficiently can result in lower prices to farmers, higher prices to consumers, and increasing food imports.

The demand for livestock products, fruits and vegetables will grow more rapidly than the demand for food grains as urbanization expands. While the importance of grains as a staple food will not diminish much and will remain crucial to the nutritional needs of low-income people in urban areas, an increasing demand for non-grain foods will require the rapid creation and expansion of marketing systems. Since these products are more perishable, greater market specialization in terms of physical facilities and management will be necessary.

Market adjustments will also occur in the provision of inputs for increased production of livestock products, fruits and vegetables. Clearly, pharmaceutical items will have to be supplied to provide for the health of animals as well as provisions of coarse grain and feed concentrates for intensive animal feeding in order to satisfy the growing demand for meat and milk. Also, increasing inputs of pesticides and herbicides specific to fruit and vegetable cultivation will have to be made available.

Evolution of Marketing with Development

As economic development progresses, the marketing component of the consumer's expenditure for food increases because more raw food products must be processed, packed and distributed to consumers. Yet the food system's share of a country's total economic activity declines as incomes rise, even as the need for food marketing functions rises. These trends can be observed in Colombia where, from 1970 to 1982, the food system's

share of economic activity declined from 38% to 34%. During the same period the off-farm component of the food system increased its share from nearly one-third of the system's economic activity to almost one-half, while the share of on-farm food production declined proportionally (Silva et al. 1984).

The case of the Republic of Korea also provides an example of the rapid growth of marketing as economic development proceeds. The ratios of marketed volume to total production of some commodity groups at the beginning and end of the 1967-80 period were as follows: rice 39%-46%; wheat and barley 26%-73%; miscellaneous grains 48%-94%; and vegetables 57%-77% (FAO 1983a).

During the initial phases of urbanization, the lack of an infrastructure and responsiveness to changing conditions appear to be the biggest problems in marketing. Critical bottlenecks are likely to occur in the transportation of food from rural areas to cities and in the overcrowding of access roads to markets.

Frequently, developing country transport systems have been built to facilitate the export of products rather than to move local produce to domestic urban centres. When urban food supplies are heavily dependent on imported foods, little domestic transport is needed other than to move foodstuffs from ports to major distribution points in cities. Inadequacies in the domestic transport sector may make it cheaper to import food rather than to acquire it locally. Importing food is also attractive because governments can more easily control prices and availability compared to domestic production, and quality standards are often more reliable.

Conversely, when a large share of food is produced domestically, an extensive transportation system is required to transfer food from principal food-producing to food-deficit zones. Roads must be built, improved and maintained, so that more products can move at faster speeds and incur less damage. Greater speed is needed to reduce ton-per-mile costs, since more perishable goods such as fruit, vegetables and livestock products have to be moved greater distances than formerly because of urban growth. Speed is crucial because an increasing demand for perishables by urban areas make transport costs and wastage important factors affecting both producer and consumer prices.

Storage presents a problem that is normally ranked second only to transport as the primary bottleneck in the transfer of food to urban areas. As the commercial production of grains and perishable crops increases above immediate market requirements, not only is a greater storage capacity required, but storage facilities may be required in more places. The marketing of processed foods requires different storage facilities as urban tastes begin to dominate food demand patterns.

The need to preserve food and transport it long distances will require new food processing methods. Food processing can have serious nutritional consequences because important nutrients can be lost either because the process cannot economically utilize the whole product, or because of spoilage. On the other hand, the fortification of processed foods by adding nutrients and vitamins can improve nutrition in cities as well as in rural areas.

Traditional and modern marketing

The traditional food marketing system is often characterized by inefficient marketing services with many small-volume, high unit-cost transactions and high food losses. Yet modern marketing systems often by pass low-income people in urban areas and may leave them worse off.

Modern marketing developments in some countries have failed to alleviate urban nutritional problems in some countries. The development of commercial supermarkets in Latin America and, in some cases, in Asia, has generally taken place in relatively affluent neighbourhoods where clients have their own automobiles and a bank account and are normally required to shop at modern supermarkets where large-purchase, one-stop shopping is the norm. A refrigerator is also necessary to store perishables once shopping ceases to be a daily activity. Clearly, low-income residents in urban areas have neither the means nor the access required to utilize such facilities.

The trend toward supermarkets in Latin America is particularly demonstrated in the metropolitan area of Mexico City. From 1970 to 1975, the proportion of total food sold in Mexico City at small neighbourhood stores plummeted from 63% to 27%. The share of supermarket chains meanwhile increased from 10% to 37%, and the share of sales of speciality food shops rose from 27% to 35% (FAO 1977).

BOX 2-8. URBANIZATION AND FOOD IMPORTS

Increased urbanization in developing countries leads to increased dependency on food imports. This is supported by evidence provided by 61 developing countries (with populations of more than 1 million) for which data between 1970 and 1980 on food imports in relation to total food supplies and urbanization were available (see chart).

In 43 of the 61 countries, the importance of agricultural imports in food supplies increased; and in all but one country, the share of urban population per total population also increased.

However, other factors are important in determining the level of a country's imports of food. For example, urbanization is highly correlated with level of income, and both urbanization and income are associated with changing food tastes. Other important factors are the country's ability to finance food imports (foreign exchange balances, debt position, and access to food aid) and yearly changes in domestic food production. All of these factors and others mentioned here interact to obscure the relationship between urbanization and food imports. Nevertheless, when the 61 countries are classified according to the rate of increase in urbanization between 1970-1980, those that urbanized fastest (more than a 30% change) increased their dependency on food imports faster than those that urbanized more slowly (less than a 10% change). Economic growth (as measured by average annual changes in GDP in constant dollars) was similar for both groups of countries.

The adjacent figure shows changes in urbanization and food imports in relation to food supply.

Changes in Urban to Total Population, 1970-80

The expanding influence of marketing functions

As rural-urban migration proceeds, incomes rise, tastes change, and consumers demand marketing services beyond those required for simply moving food to the city. The demand for greater convenience in food preparation and higher quality food generally rise as incomes and population concentrations increase. This is particularly true since time and facilities available for food preparation are different in urban and rural areas. This tendency has been shown in most countries by the demand for wheat bread over the local staple, as well as an increase demand for meat, fruit, vegetables and pasteurized milk in place of food grains and untreated milk. When marketings are inadquate or the marketing system is too inefficient and unable to compete against imported products, the result is an increase in food imports.9/ A critical issue in developing countries, where the cost of food is also the principal component of the cost of living, is how marketing services are provided at minimum costs.

The role of the small farmer also changes as food and input markets evolve. Many of the transport functions formerly performed by the small farmer are usually taken over by trucking operations directed by entrepreneurs. A growing share of the purchases from farmers will be made by wholesalers or processors who reach back as well as forward in the marketing system.

On the supply side, production may have to be geared to new processing schedules and equipment that are required by a changing marketing system. More important is the need to plan production around commercial tolerance guides for grades and standards. For example, contract farming requires the farmer to deliver a certain quality and quantity during a specific period of time.

On the consumption side, more people concentrated in urban areas will result in a greater influence of advertising on consumption habits compared to rural areas. In addition, there will be a less face-to-face relationship in the market place so that the names of processors and merchandisers will be more important in food choices. Consumers will be the crucial element on the demand side and the final arbiter of the marketing system.

6. POLICY OPTIONS

It is clear that economic development means slower growth in farm than non-farm employment opportunities. Unless jobs are provided in rural areas to absorb those released from agricultural production, migration also must accompany economic development. It is equally clear that urbanization and migration are not self-adjusting processes and if not controlled or directed to some degree, can result in deteriorating living conditions for both rural and urban people.

However, few goverments have provided the guidance, incentives or actions required to ensure an orderly transition from an agricultural to a non-agricultural based economy. Instead, the common pattern has been major imbalances in socio-economic conditions between rural and urban areas.

Governments and their development planners must recognize the interdependent nature of agriculture, rural development and demographic phenomena, including urbanization and migration. They must seek a coordinated approach to policies that affect development and welfare objectives and the implementation of the policies among the agencies that formulate them.

9/ The exchange rate is, of course, a major factor in determining the relative local cost of domestically produced and imported food.

The simple relationship in Figure 2-2, Section 2, depicts the simultaneous movements in demographic, production, marketing and nutrition factors that correspond to different levels of development. While the complexity of economic and social factors cannot be fully represented this way, any one of these factors can create a bottleneck in the course of development.

Direct Actions

Apart from the need to better integrate policies and programmes in a wide variety of fields across various governmental agencies, a number of policy options are available to mitigate some of the worst problems associated with the effects of urbanization and rural-urban migration. Policies can be directed towards:

1. Modifying migration, population redistribution and population growth;

2. Helping food systems adjust; and

3. Competition and natural resource use.

Modifying Migration

The development process includes the transfer of labour from agricultural to non-agricultural occupations as agriculture modernizes. This inevitably leads to some rural-urban migration when jobs are created in the industrial and service sectors. However, the growth of an urban bias in national policies and development strategies has become perceptible that encourages excessive rural-urban migration with ultimate negative consequences for both urban and rural areas.

The role of government in creating and extending an urban bias towards major urban centres has been pervasive through such activities as: industrial promotion in or near major cities; higher education centered in urban areas; food subsidy programmes in cities; low prices to producers of agricultural products; subsidized urban housing and urban services; better medical facilities in urban areas; industrial protection policies that increase agricultural input prices; and concentration of investment in infrastructure in urban areas. These policies have helped to widen the gap in living standards between urban and rural areas, providing a major impetus to out-migration from the latter.

Clearly, governments will have to modify their development policies and programmes to slow down migration in order to promote orderly and cost-effective development for both urban and rural people. Such modification have already been set down in the programme of action of the World Conference on Agrarian Reform and Rural Development (WCARRD) in 1979 (FAO 1981b).

Improving rural infrastructure, services and living conditions. Apart from correcting an urban bias in policies, policymakers and planners have been urged to improve the incomes and living conditions of rural areas in order to retard rural out-migration. Rural electrification, more and better schools, medical facilities, and recreational outlets are among the amenities most sought.

The greatest obstacle to such investments is that the cost per caput of delivering such services in rural areas is normally higher than in all but the largest urban areas, mainly because population densities are lower. It is also difficult to attract and retain staff in relatively isolated places.

Some of the more successful attempts to improve living conditions in rural areas have concentrated on promoting in such areas economic growth

centres. Such developments have often led to an improvement in living standards by providing jobs and have created a tax base so that rural communities can become more self-sufficient in providing services.

Rural industries. The need to create employment and income-earning opportunities in rural areas is a crucial issue. Rapid urbanization requires a more productive agriculture that usually results in fewer people being employed in agriculture. This creates a reserve of low-cost labour relative to urban areas where relatively high wages result, often from a statutory minimum wage and pressure from labour unions.

A commonly advocated alternative to metropolitan growth is the location of industry in rural areas to provide part- or full-time employment to local people. The creation of jobs and the resulting multiplier effect provide an economic base that can lead to agglomeration economies and further economic growth. The extension of agricultural processing, grading and assembly points to rural areas can help increase employment and incomes.

This approach has been effective in many developed countries and is now increasingly advocated in developing countries. For example, in Kenya a combination of capital investment by peasants and small businessmen, principally in labour-intensive agro-processing industries, provided jobs to many rural people, including farmers. In the late 1970s, in some areas about one-half of the farming households had off-farm incomes and two-thirds of those employed off-farm had full-time jobs (Freeman and Norcliffe 1983).

In China efforts have been taken to shift excess agricultural labour into other occupations in rural areas. This is achieved through the establishment of enterprises in rural areas such as food processing plants; the manufacture of building and construction materials, and other goods; the maintenance and repair of farm equipment; rural energy production; and small-scale mining and other light industries that employ and keep people in rural areas. The Chinese government attaches importance to such measures as a means of relieving the pressure on the big cities and of promoting the balanced development of industry and agriculture as well as urban and rural areas.

Rural family planning assistance. Programmes to reduce population growth through economic development are generally long term in scope as research has shown that socio-economic factors have a mitigating influence on fertility rates only after a relatively high level of income has been reached. An initial reaction to economic progress may be larger families, as education, income and job opportunities increase. However, after critical minimum income and educational levels are reached and infant mortality rates are reduced dramatically, birth rates will most likely begin to fall. But this is a slow process that may not take effect before more drastic methods are required.

Since the 1974 World Population Conference in Bucharest, profound changes in attitudes toward family planning and population distribution have taken place in many countries. Most countries have begun family planning programmes and while not all of the programmes have been successful, the overall population growth rate for developing countries has fallen from about 2.6% a year during the late 1960s to 2.1% a year currently.

As mentioned, the fertility rate in rural areas is higher than in urban areas. Although available figures for mortality rates in rural and urban areas clearly show that mortality rates are considerably higher in rural areas--largely because of the lack of medical services and health education--they will drop as socio-economic conditions improve, thus increasing population growth.

The fact that rural population growth may accelerate and contribute even more to rural out-migration pressures, suggests that family planning services should be intensified in rural areas. While the costs of a rural family planning programme may be higher than an urban one, the benefits to society are still likely to be greater than the costs.

BOX 2-9. THE INTERNATIONAL CONFERENCE ON POPULATION 1984

The International Conference on Population was held in Mexico City in August 1984 to appraise the implementation of the World Population Plan of Action adopted in Bucharest in 1974. The conference reaffirmed the validity of the principles and objectives that have served as a guide to action in the field of population for governments and for international and non-governmental organizations. However, it was noted that the demographic, social, economic and political conditions of the world have changed considerably since then. While progress has been made in achieving some goals of the plan, other goals such as those relating to mortality, have not been met. Some important gaps in knowledge have been filled, but new issues have emerged to challenge the international community.

Urbanization was among the major issues raised by the Plan of Action. It was noted that the urban population continued to increase far more rapidly than the total population in most regions of the world. Furthermore, rapid urban population growth had become a matter of growing policy concern to most governments, particularly in developing regions where urban unemployment levels remain extremely high.

In the preparatory work for the conference, four expert group meetings convened in 1983 to review developments in four priority areas:
(1) fertility and the family;
(2) population distribution, migration and development;
(3) population, resources, environment and development; and
(4) mortality and health policies.

The 88 recommendations regarding the Plan of Action, that arose from these and other meetings and that were discussed and endorsed by the conference, included several related to urbanization and migration.

Given the rapid growth of urbanization, it was recommended that population distribution policies should be integrated with economic and social policies. Governments were encouraged to base such policies upon a broad cost-benefit analysis of individuals, families, different socio-economic groups, communities, regions and the country as a whole.

It was pointed out that if governments wanted to slow rural-urban migration, they should implement population distribution policies through incentives instead of through coercive measures, since the latter are difficult to implement and could violate human rights.

Governments that had adopted or were going to adopt an urbanization policy were encouraged to try to incorporate it in the overall process of development planning. Specific measures to reduce rural-urban migration were noted, such as the development of small- and medium-sized urban centres, and the reduction of inequalities among regions as well as rural and urban areas.

Source: UN 1984.

Population redistribution. Policies that encourage the expansion of and migration to secondary cities and towns not far from rural peoples' origins, have been successful in some countries. For example, both the Republic of Korea and Pakistan have met with some success in promoting such a policy and their secondary cities are growing faster than Seoul and Karachi, their respective primate cities.

BOX 2-10. AN INTEGRATED PROGRAMME: THE CASE OF THE REPUBLIC OF KOREA

The Republic of Korea initiated a comprehensive programme of population and income redistribution more than twenty years ago. The initial policy guidelines revolved around the geographic allocation of economic activities because of the role of economic incentives in determining people's movements. Three criteria were then outlined to determine subsequent investment: the need to specialize regional production; the calculation of the costs and benefits of economic efficiencies; and long-term environmental consequences.

Concurrent policies for urban and rural areas were then implemented in the 1960s under the 'New Community Movement' that aimed to improve social and economic conditions for all regions, while reducing regional imbalances and urban-rural disparities. These were accompanied by a programme of land reform.

A tenfold increase in real farm income during the 1970-81 period has been claimed. Added employment in new rural occupations also increased non-farm incomes of farmers from 18% to 33% of all earnings. A rural housing programme and national education and transportation networks were developed to reduce regional disparities. The location of economic activities in secondary cities such as Inchon and Pusan are believed to be an important element in the reduced rate of migration to Seoul, the capital city.

Sources: Shin, Dong-Wan and Yang-Boo Chui 1983. Shin, Dong-Ju and Koe-Won Lee 1983.

The development of new or satellite towns near other large cities has also been attempted in some countries, such as India, to achieve a better population distribution. However, most efforts in developing countries to redistribute population in this way have not been very successful largely because of the cost involved and the tremendous amount of planning required. Mexico attempted to develop four cities to alleviate the population pressure on its federal district. The results of the project are not yet available, but preliminary indications have not been favourable.

Some countries provide monetary incentives to encourage migration from crowded to underpopulated regions. Indirect subsidies have also been utilized in the form of the provision of services to a sparsely populated area in an effort to attract people. The establishment of Brasilia is an example. Government-sponsored resettlement schemes have also been attempted to relieve population pressure. The transmigration programme of Indonesia is an often cited example of an attempt to expand agricultural frontiers in order to reduce urban population growth rates.

Rural development programmes should also have a population retention component through the setting up of infrastructure necessary for the location of industrial and service activities and the creation of jobs in rural areas. A major purpose of some programmes could be to involve local rural inhabitants in the planning of projects that are to be implemented in the area. The panchayat experiment introduced in West Bengal (India) in 1978 is an example in that it mobilizes partly remunerated labour in rural development. Such programmes can offer a partial alternative solution to migration.

BOX 2-11. TRANSMIGRATION: THE EXPERIENCE OF INDONESIA

Transmigration in Indonesia has its roots in the colonization programme of the Dutch colonial administration and even in pre-colonial days, with people moving from the densely populated inner islands of Indonesia such as Java to the lightly settled outer islands, particularly Sumatra. However, the transmigration programme proper was reinstituted in 1950 by the newly independent Indonesian Government. It was seen originally as a way to reduce poverty and later as a programme to alleviate population pressure on the overcrowded island of Java. However, it has become recognized that transmigration itself can have little impact on the rate of population growth in Java except in specific locations. The officially held view is that transmigration brings unused resources into production and is a means of regional development. In these respects, the programme has been successful.

Although there have been extensive modifications to the transmigration programme throughout its long history and the categories of transmigrants and the eligibility of people for participation in the programme have changed over time, there is a basic distinction between general and spontaneous transmigrants. The former receive full support from the government, including all transport costs, 2 ha of prepared land, food until the initial harvest and--on a repayment basis--housing, utensils and agricultural inputs. Spontaneous transmigrants have to pay for their transportation costs but receive land and other assistance at their destination in the outer islands.

The programme has had a history of overly optimistic targets and rising budgetary costs. For example, in the 1950s only 28 4000 people were settled compared with the target of over 6 million. The modest target of 40 000 families settled in the first five-year development plan, Repelita I (1969-74) was exceeded, but that of Repelita II (1974-79) of over 250 000 families was achieved to an extent of only one-third. Repelita III (1979-84) had a target to settle 500 000 families, but the figure has not been attained. Budgetary expenditures have soared from Rp 2 300 million in 1972/73 to Rp 360 000 million in 1981/82; international agencies also have increased their participation in the programme.

Problems encountered have been of essentially three categories: administrative, insufficient preparation in the destination areas, and socio-cultural difficulties. Although greater attention is being given to site selection and preparation, the mass movement of relatively young, and hence fertile, couples and their children to a different environment, inevitably poses major challenges to health and educational systems that are not well developed. Queries are now being raised about the population supporting capacity of the outer islands themselves and land shortages there could well emerge.

Helping Food Systems Adjust

Direct policy measures can be undertaken in the food production, marketing and nutrition components of a country's food system to help adjust to the changes brought about by urbanization and to prepare for likely problems. There is ample scope for improving the commercial and public sectors of most developing countries to meet the needs of food producers and consumers, increase food production, establish efficient marketing systems and enhance access to food.

Food and agricultural production

More food will have to be produced by relatively fewer people as urbanization proceeds. Production patterns will have to change to meet changing food consumption patterns and to allow for the changing size and structure of the agricultural labour force (relatively more women in Africa and Asia, and the young and elderly in all regions). Pressures will increase for mechanized methods of farming to be introduced and, in situations where land ownership is already skewed, greater inequality in the access to land is likely to emerge. Without some form of intervention, the operation of market forces may mean that the opportunities offered by expanding urban markets are grasped by a privileged few and bypass the majority.

Some of the ways to help food producers meet the challenge of urbanization can only be outlined here since they embrace a very wide range of possible interventions in agricultural development. Measures meeting the needs of the rural poor and small-scale farmers will help to ensure that development reduces rather than increases the flow of migrants to overcrowded cities. Such measures can be on the following lines:

- Extension services have to be strengthened in several ways. Different types of farmers will have to be contacted, particularly women farmers, which means the recruitment of more women extension staff. New technologies will have to be introduced to intensify the production of existing food products. Farmers will need to learn how to cultivate new crops such as vegetables on the periphery of towns. Extension staff may have to be retrained or equipped to handle these problems and applied agricultural research programmes may also have to be reoriented to generate the technologies needed to produce existing food products in new ways and to produce new or non-traditional crop and livestock products.

- Inputs will have to be more widely available. Clearly, more intensive production generally implies greater input use and hence the wider distribution of inputs. Seeds and planting material will be needed for new or non-traditional crops and stock for new livestock enterprises. Decisions will have to be made on what forms of mechanization should be promoted (if any) and whether to improve existing livestock or to take the opportunity to introduce improved and possibly exotic breeds, which may lead to more capital-intensive production systems. Better and more efficient distribution channels for inputs will have to be sought.

- Greater input use implies a greater need for working capital and hence credit. Here again the need for greater access by women farmers, often discriminated against in this area, must be taken into account.

- Land reform measures, such as limits on farm size and redistribution, may have to be introduced to prevent deterioration in the structure of land ownership or access.

Marketing development

Large-scale commercial operations. A major feature of the successful development in delivery systems in the commercial sector has been the proliferation of vertical coordination by which producers are linked with food distributors. It is widely held that efficient vertical integration will be the key to efficient food production and delivery in many developing countries as marketing channels become longer and more complex, and as the scale of handling food increases geometrically with urban growth. However, such a marketing structure carries the danger of an excess concentration of bargaining power from both the producer's and consumer's viewpoint. It also lends itself to the adoption of imported technology and advertising.

Small-farmer cooperation. A complement to vertical coordination for marketing purposes is horizontal coordination among small-scale producers in order for them to undertake various cooperative ventures that enhance access to lower cost services and supplies and reduce marketing costs. Small farmers can join together to form supply and marketing cooperatives to obtain inputs and services and to assemble, grade, transport and sell their products to varying degrees. However, in many developing countries small farmers often lack the managerial skills needed for such ventures to succeed, let alone the organizational and business background. Employing experienced managers is usually essential and government can provide guidance in their selection and training.

The role of government in marketing. In addition to needed attention to the structure of food marketing, concomitant developments in public institutions are crucial to the effective evolution of a food supply system capable of satisfying the needs of a rapidly urbanizing population. Direct state intervention has been used successfully in some cases to stabilize the prices paid by low-income consumers for basic foods during periods of economic stress and food shortages. In other cases, governments have successfully played a role of facilitator to improve performance of commercial markets rather than as controller of food prices and have intervened in food distribution. This facilitating role is particularly important to the servicing of rapidly growing urban areas that will require greater volumes of perishable food (meat, fish, vegetables, fruits and dairy products) on a daily basis.

Governments are frequently involved in making markets more efficient, which in most cases could be achieved by making the process of market price formation more transparent. Many countries have been advised to use auctions to help food buyers and sellers arrive at prices efficiently. Crop reporting, market information and outlook services can be important in enabling food systems to adjust. India is even looking to computerization as a means of providing price information on a continuing basis.

Each of the basic food groups has distinct characteristics that determine the appropriate type of marketing channel. Recognizing the important role of grains in meeting the nutritional needs of low-income urban groups, governments often intervene to ensure cereal availability and stable prices. This is relatively easy since grains are easily stored for long periods compared to more perishable produce.

A difficult decision for governments to make is whether to provide a subsidy on food grains and, if so, whether targeted or blanket subsidies should be used. Targeted subsidies include food stamps and food shops that are available to qualified low-income people, whereas the blanket subsidy is available to all. Successful programmes using blanket subsidies either make subsidized food available in areas where only low-income consumers live and work or subsidize food that is consumed mostly by low-income people.

Other direct intervention schemes for staple foods, such as the 'fair shop' programme in India and various food stamp or food rationing programmes in other countries, are likely to continue to play an important role in food distribution, even though they may encourage rural-urban migration by lowering the cost-of-living in urban areas. To be fully effective, fair price shops should be located in the local market or bazaar in low-income neighbourhoods. However, such shops do not replace the need to expand and improve wholesale and retail markets to serve the other income groups in cities.

Price control and other direct forms of market intervention for meat are difficult, particularly in tropical climates since meat is perishable. Marketing specialists advise governments to concentrate their efforts more on introducing and implementing standards of sanitation and hygiene in the

markets and shops where meat is sold. The grading of meat for quality is not important where low-price meat is cut or chopped and sometimes combined with other foods before consumption. For example, in Kenya where price controls have been applied to meat, only two grades were used: bone-in and bone-out.

The perishability of fresh products such as fruit and vegetables makes effective price control by government agencies virtually impossible. The grading of the many types involved also poses problems. A system that allows the daily supply to be sold on the same day is often necessary for the efficient marketing of such perishable products. Prices can be arrived at through auction or bargaining. These activities may not require government regulation beyond ensuring access to them by small-scale buyers and sellers.

Sanitary and hygienic control by governmental personnel is also important for fish and seafood marketing. However, the extreme perishability of these products renders direct market intervention by governments hazardous.

The availability of trained personnel is crucial to the efficient operation of an urban food marketing system. Training programmes have to be expanded in line with anticipated technological advances and investments in marketing facilities and infrastructure if operational bottlenecks are to be avoided. There are clear roles for governments in the provision of technology, economic analyses, logistics, information and regulatory training programmes related to food marketing, as well as for donor agencies in supporting them.

Local market development. For most developing countries, the establishment of large open bazaar-type markets throughout major cities can help accommodate the needs of growing urban areas. Most urban food marketing studies have shown that food shoppers are willing to walk about 700 metres or 15 minutes one way to shop for food. In the developing world's cities this would mean that food markets so dispersed would accommodate from 3 000 to 5 000 families. Servicing this number of families could require from 100 to 200 food shops in each retail market (FAO 1975).

Typically, the local government collects fees and takes care of the land and sanitation services, but advertizing, management and physical upkeep of the market depends on the retailers themselves. Government control of weights, measures and produce quality (where appropriate) can be important in protecting consumers and ensuring their confidence in the market.

One of the greatest needs regarding the food delivery system in developing countries that experience rapid urban growth will be the development of strategically located wholesale markets for perishable foods. The efficient planning, management and organization of such markets are crucial to ensure fair prices for consumers. The keys to success of such markets include adequate facilities, product specialization and access to transportation and credit. Brazil has recently completed plans and construction for 22 wholesale markets with details such as these incorporated into the overall design.

The periodic market, which rotates to different points in rural areas every few days, is another market development that has been successful in some Asian countries and could be introduced elsewhere to assemble food for shipment to urban areas. The competition among wholesalers promoted by this type of market allows farmers a choice in selling their produce and is more likely to ensure an acceptable market performance. The role of the entrepreneur has also been encouraged in more traditional bazaar-type markets. In all, successful examples of these market developments and the role of the government have been limited to regulation and organization and do not extend to price interventions.

Public and private complementarity in food marketing. Numerous studies in developing countries have shown that middlemen or traders' margins are not necessarily excessive. Indeed, a lack of middlemen willing to serve outlying rural markets with small volumes of produce to sell is often a greater problem. The same studies have shown that parastatal marketing margins are often higher than those of private traders. They usually recommend training in business practices for wholesalers and retailers and the gathering of food commodities into a wholesale market so that large retailers need only go to a single location to obtain the range of commodities they need. Price information in the wholesale market must be publicized so that all traders can participate.

From such studies it is clear that cooperation between the private and the public sectors is a requirement for overcoming the food production, marketing, and distribution problems faced by developing countries with rapidly growing urban populations. The need for coordinated and coherent policies across government agencies is a minimum requirement for success. Increasingly efficient market operations have resulted from government policies and actions that have supported and facilitated the development of private food markets in urban areas.

Better nutrition for low-income urban groups

Some direct measures can also be taken to improve inadequate diets of low-income groups in urban areas that often include many rural-urban migrants.

One interesting development, which may have its antecedents in the urban allotment movement in the industrial cities of Great Britain in the nineteenth century, is the growth of urban agriculture. China, for example, has been very successful in growing vegetables in urban areas as its cities are 85% self-sufficient in this produce. Two of its largest cities, Shanghai and Beijing, are totally self-sufficient in vegetable production (Wade 1981).

The urban agriculture programme in Lusaka, Zambia is another example. The programme provides seeds and technical assistance and encourages community organization in the city to promote urban gardening. It is estimated that 10%-20% of Zambia's perishable food is currently produced within the city (Ledogar 1978).

Town planners are being encouraged to include areas for urban agriculture in their city designs. Urban agriculture can take advantage of the food growing skills of rural-urban migrants. However, uncontrolled growth of food supplies in urban areas can lead to sanitary and public health problems regarding food crop and livestock production.

The health hazards posed by unsanitary conditions and untrained staff in food preparation and handling have already been noted in Section 4 when the growth of informal food kiosks or cafes in urban centres in developing countries was discussed. These informal vendors provide a service needed by the urban poor who are often single, lack cooking facilities and may have to travel long distances to their place of work or to look for work. The food retailed by these places is usually a traditional staple, simply prepared; it must be low cost. Basic sanitary requirements must be met without significantly raising costs.

Closely related to this are needs to educate the urban public about food safety, the nutritional aspects of convenience foods, and the dangers of being influenced too much by food advertising.

Competition and Natural Resources Use

The competition for land, water and forest resources often assume serious proportions as cities grow. Two examples indicate some of the measures that can be taken.

The first example suggests that urban water supplies are often subsidized so that less is available for the most useful purposes. For example, it is claimed that Mexico City residents only pay about 20% of the real costs of supplying them with water. This causes the wasteful use of a scarce resource that must travel hundreds of kilometers and be lifted over 2 200 vertical metres (Leal 1984).

The other example concerns legislative means to regulate land use through zoning laws. For example, Tunisia has introduced legislation with the objective of protecting its scarce agricultural land. Land within this law are divided into three types or zones:

1. Zones where urban development is forbidden, such as around public irrigation schemes and forest areas;
2. Zones where agricultural use is protected in the national interest; and
3. Zones comprising all agricultural land, apart from the first two listed, which are placed under government control to prevent their unauthorized conversion to non-agricultural use.

Other ways of dealing with land and water problems, as regards pollution and speculation in peri-urban land markets that drive up prices of agricultural products, usually centre around governmental methods of imposing taxes or fines or passage of land use legislation. Industrial and agricultural polluters can be fined according to the net societal costs of the pollution activity. However, the difficulty in measuring the source and effects of pollution, whether agricultural or industrial, has been illustrated in court cases in many developed countries. While the costs of establishing legal precedents and institutions to effectively deal with pollution problems are high, the long-term societal cost of not doing so may be much higher.

Methods of taxation can be used to avoid rapidly rising prices of farmland due to land speculation near urban centres. Such methods include the taxing of windfall profits that would result if agricultural land is sold for urban development at market prices. A judicious use of taxes and zoning laws could prevent the price of farmland from rising to levels where farming is no longer a viable option near urban areas.

Concluding Remarks

Rural-urban migration, rapid urbanization, and the excessive rise of primate cities can be modified by governmental actions in a manner so that the negative effects on people of too rapid modernization on an agrarian society can be eased. The sum of such measures may amount to no more than the removal of an urban bias in development policies or coordinating such policies. In other cases, more substantive measures may be required involving movements of people from one rural area to another or bringing jobs to rural people. Again these may range from merely assisting spontaneous movements to more elaborate and expensive government-sponsored settlement schemes and rural industrialization programmes. Policies designed to control the rate of overall population growth over the long term will make the situation easier to manage.

The success of such policies will be seen in making both urban and rural areas better places in which to live, possibly without the polarization that exists between many rural and urban environments today. A thriving, progressive agricultural sector, well-integrated with the industrial and service sectors of the economy, is a reasonable goal to aim for.

FAO PUBLICATIONS

FAO publishes a number of annuals, periodicals and other publications covering a wide range of topics. A selected list of these is given below.

Annuals

FAO Production Yearbook
FAO Trade Yearbook
FAO Fertilizer Yearbook
FAO Yearbook of Fishery Statistics: Catches and Landings
FAO Yearbook of Fishery Statistics: Fishery Commodities
FAO Yearbook of Forest Products
FAO/WHO/OIE Animal Health Yearbook
Commodity Review and Outlook

Periodicals

World Animal Review
Monthly Bulletin of Statistics
Food and Nutrition
Unasylva

Others

Agricultural Commodity Projections 1975-1985
Forestry Paper No. 18: Forest Product Prices 1960-78
Fourth World Food Survey

"There is ... general agreement that the ultimate aim of world food security is to ensure that all people, at all times, have both physical and economic access to the basic food they need. Unfortunately, the practical achievement of this goal appears as remote as ever."

"A major policy reorientation in Africa toward strengthening domestic food production is clearly called for, and indeed to some extent is already under way. But such an undertaking cannot be regarded solely as an exercise in planning the food sector, or even agriculture as a whole. It is the entire development model that must be changed."

"We therefore need to consider, not merely the growth of total food requirements, but also the increase in urban food needs ... the basic issue being how to expand marketed supplies, as distinct from subsistence production."

EDOUARD SAOUMA
Director-General
Food and Agriculture Organization
of the United Nations
