FLASH-FLOOD PROCEDURE

Ralph C. Hatch and Gerald Williams
National Weather Service, River Forecast Center
Salt Lake City, Utah

I. INTRODUCTION

A self-help procedure is a method by which streamflow forecasts can be made by a local user with input data collected by the user or in cooperation with other agencies including the National Weather Service. Many types of procedures are available. This particular procedure was developed for use under circumstances where limited data may be available and estimates may be required. The results received from this procedure are based on defined 100-year 24-hour return period precipitation amounts from many years of data.

In using this procedure the user must input the amount of precipitation that has fallen, the time duration in which the precipitation fell, and the basin area (or the contributing portion of the basin) over which the precipitation occurred. When these data are known, the user can employ the self-help procedure effectively.

II. PURPOSE

The purpose of this study was to develop a self-help procedure that could be quickly and easily used in estimating runoff from thunderstorms in small basins (generally less than 200 square miles). Generally in these small basins there are very little hydrological data to work with, and a considerable number of flash floods that occur in the western United States happen in these small data-sparse basins.

III. DESCRIPTION OF PROCEDURE

This procedure is made up of three parts: A storm rainfall/duration graph, an area graph, and a total flow chart.

The storm rainfall/duration graph was developed by plotting the total rainfall (inches) against the return period (years) and drawing a family of curves depicting specific storm durations ranging from 5 minutes to 24 hours. Precipitation return periods (Miller, et al, 1973) for durations from 195 stations, in the Salt Lake City River Forecast Center area of responsibility, were computed and analyzed.

The area graph was calculated by plotting return periods against peak-flow per-unit area. A family of curves showing basin areas ranging from 1 square mile to 500 square miles was produced. This particular graph, developed by the Agricultural Research Service (Osborn and Laursen, 1973), has been portrayed by Williams (1975) in "A Study of Flash Flood Susceptibility--A Basin in Southern Arizona".

The total flow chart (Table I) is simply a chart delineating contributing area against peak-flow per-unit area. This gives the total peak

flow expected from a thunderstorm, for a basin or a defined area, with a given amount of precipitation, for a known duration.

In order to use this procedure properly and to get the best results, the user should use extreme care in defining the contributing area and the duration of storm as well as mean areal precipitation amount.

The contributing area and duration can be estimated with the aid of radar. Observer reports will also help in estimating the three needed variables.

An analysis of the return periods for the 24-hour, one-hundred-year precipitation amounts was plotted for the area (Figure 1). Three distinct subareas were recognized; therefore, a separate duration graph was drawn for each subarea. Basically the subareas divided themselves into three geographical sections: 1) The southern desert of Arizona which showed 4.0 inches of precipitation or greater, 2) The mountainous areas of Utah, northern Arizona, and southern Nevada, which had 3.0 to 4.0 inches, and 3) The Upper Colorado River Basin and the Humboldt River Basin which were calculated to be less than 3.0 inches.

IV. PROCEDURE

Precipitation amounts are entered in the left-hand column of Figure 2. Then it is horizontally moved to the right until the correct duration curve is reached. This value is then used by dropping vertically until the storm contributing area curve is reached. Moving horizontally to the left margin, the peak-flow per-unit area is obtained. The user then obtains the total expected maximum flow by referring to the flow chart (Table I) which is a linear relationship used to obtain total flow from flow per-unit area. The total flow is given in cubic feet per second and is the expected peak flow for a storm of the given duration and rainfall amount over the calculated contributing area. (See Appendix A.)

In using this procedure it must be remembered that in basins, where only a portion of the basin is contributing to the runoff, that the calculated total maximum flow applies only to affected portion of the basin, not the entire basin. If the contributing portion of the basin is in the headwater area and measurements are made downstream, the flow from the contributing area must be routed downstream to the measuring station. The routing of a peak flow downstream usually results in a lower crest unless additional contributing areas add significantly to the flow.

V. TEST RESULTS

Tests were made on a number of storms. However when adequate storm duration periods were lacking, many problems were encountered. On storms tested where the three variables were available, the results were very encouraging. A good example would be the September 2, 1960, storm over Farm Creek near Hanna, Utah. Rainfall totaling 1.27 inches fell in less than one hour at Hanna. The Farm Creek Basin area is 8.1 square miles. It is estimated from the available data that about 1.25 inches of precipitation fell over Farm Creek Basin in 60 minutes.

| | TOTAL AREA (Sq. Miles) | | | | | | | | |

Area Curve

Putting this data into the procedure, a total peak flow of 3650 CFS is realized. The measured maximum discharge was 4300 CFS; however, research data and logic indicate the duration may have been smaller which would yield a higher peak flow than was forecast.

In using this self-help procedure it is very important that caution be used since the variables employed are sensitive and an error in the data can result in significant changes in the forecast. Data listed in Table II and plotted on Figure 3 are the test data used in the study development.

VI. CONCLUSION

This self-help procedure should be an effective tool to aid meteorologists in alerting communities when time from rainfall to flood peak is relatively short. To effectively use this procedure, it is very beneficial for personnel from each office to review hydrology in as many drainages as possible. Since the procedure provides a reasonable estimate of the peak flow from the contributing area, it is necessary that a review of high flows be made to determine the extent of the damages for each basin of concern; hopefully, a similar type procedure can be automated for use in AFOS.

- NOTE: 1) Most of the test data used to develop these charts were obtained from subarea I. Consequently, additional test data verified best using subarea-I charts. However, it is suggested that for specific areas charts corresponding to that area be used. But it is felt that if data are limited for any area and questions exist with the results obtained in subareas II or III, the subarea-I chart may be used as an adequate backup.
- 2) These procedures are drawn in scale to fit most flash-flood events. This was done to facilitate clarity and accurate use of the figures. The flows of record for entire regions such as El Dorado, Nevada; Tonto Creek, Arizona (Arizona Labor Day storm 1970); Bruneo Wash, Arizona; Big Thompson, Colorado; Rapid City, South Dakota; and Heppner, Oregon; extend beyond the curves. Flows of these magnitudes are extremely difficult to measure adequately and errors tend to cause erratic plotting points.

However, peak-flow per-unit area on them is generally very high and approaching 1000 - 2000 CFS/square mile. When values obtained in the procedure extend beyond the curve, peak flows may be approaching record crests and immediate action should be considered.

TABLE II.

TEST DATA USED IN VERIFYING CURVE

(Much more data were used to develop curves.)

NOAA Technical Memoranda NWSR: (Continued)

- 92 Smoke Management in the Willamette Valley. Earl M. Bates, May 1974. (COM-74-11277/AS)
- 93 An Operational Evaluation of 500-mb Type Stratified Regression Equations. Alexander E. Macdonald, June 1974. (COM-74-11407/AS)
- 94 Conditional Probability of Visibility Less than One-Half Mile in Radiation Fog at Fresno, California. John D. Thomas, August 1974. (COM-74-11555/AS)
- 95 Climate of Flagstaff, Arizona. Paul W. Soranson, August 1974. (COM-74-11678/AS)
- 96 Map Type Precipitation Probabilities for the Western Region. Glenn E. Rasch and Alexander E. Macdonald, February 1975. (COM-75-10428/AS)
- 97 Eastern Pacific Cut-off Low of April 21-23, 1974. William J. Alder and George R. Miller, January 1976. (PB-250-711/AS)
- 98 Study on a Significant Precipitation Episode in the Western United States. Ira S. Brenner, April 1975. (COM-75-10719/AS)
- 99 A Study of Flash Flood Susceptibility--A Basin in Southern Arizona. Gerald Williams, August 1975. (COM-75-11360/AS)
- 100 A Study of Flash-Flood Occurrences at a Site Versus Over a Forecast Zone. Gerald Williams, Aug. 1975. (COM-75-11404/AS)
- 102 A Set of Rules for Forecasting Temperatures in Napa and Sonoma Counties. Wesley L. Tuff, Oct. 1975. (PB-246-802/AS)
- 103 Application of the National Weather Service Flash-Flood Program in the Western Region. Gerald Williams, January 1976. (PB-253-853/AS)
- 104 Objective Aids for Forecasting Minimum Temperatures at Reno, Nevada, During the Summer Months. Christopher D. Hill, January 1976. (PB-252-866/AS)
- 105 Forecasting the Mono Wind. Charles P. Ruscha, Jr., February 1976. (PB-254-630)
- 106 Use of MOS Forecast Parameters in Temperature Forecasting. John G. Plankinton, Jr., March 1976. (PB-254-649)
- 107 Map Types as Aid in Using MOS PoPs in Western United States. Ira S. Brenner, August 1976. (PB-259-894)
- 108 Other Kinds of Wind Shear. Christopher D. Hill, August 1976. (PB-260-437/AS) (PB-273-677/AS)
- 109 Forecasting North Winds in the Upper Sacramento Valley and Adjoining Forests. Christopher E. Fontana, Sept. 1976. (PB-264-655/AS)
- 110 Cool Inflow as a Weakening Influence on Eastern Pacific Tropical Cyclones. William J. Denney, November 1976. (PB-265-941/AS)
- 112 The MAN/MOS Program. Alexander E. Macdonald, February 1977. (PB-273-676/AS)
- 113 Winter Season Minimum Temperature Formula for Bakersfield, California, Using Multiple Regression. Michael J. Card, February 1977. (PB-273-694/AS)
- 114 Tropical Cyclone Kathleen. James R. Fors, February 1977. (PB-263-847)
- 116 A Study of Wind Gusts on Lake Mead. Bradley Colman, April 1977. (PB-272-831)
- 117 The Relative Frequency of Cumulonimbus Clouds at the Nevada Test Site as a Function of K-value. R. F. Quiring, April 1977. (PB-271-704/AS)
- 118 Moisture Distribution Modification by Upward Vertical Motion. Ira S. Brenner, April 1977. (PB-273-740)
- 119 Relative Frequency of Occurrence of Warm Season Echo Activity as a Function of Stability Indices Computed from the Yucca Flat, Nevada, Rawinsonde. Darryl Randerson, June 1977. (PB-271-290/AS)
- 121 Climatological Prediction of Cumulonimbus Clouds in the Vicinity of the Yucca Flat Weather Station. R. F. Quiring, June 1977. (PB-273-155/AS)
- 122 A Method for Transforming Temperature Distribution to Normality. Morris S. Mobb, Jr., June 1977. (PB-273-624/AS)
- 123 Study of a Heavy Precipitation Occurrence in Redding, California. Christopher E. Fontana, June 1977. (PB-273-155/AS)
- 124 Statistical Guidance for Prediction of Eastern North Pacific Tropical Cyclone Motion - Part I. Charles J. Neumann and Preston W. Leftwich, August 1977. (PB-273-155/AS)
- 125 Statistical Guidance on the Prediction of Eastern North Pacific Tropical Cyclone Motion - Part II. Preston W. Leftwich and Charles J. Neumann, August 1977. (PB-273-155/AS)
- 126 Climate of San Francisco. E. Jan Null, March 1976. (PB-279-975/AS)
- 127 Development of a Probability Equation for Winter-Type Precipitation Patterns in Great Falls, Montana. Kenneth B. Mielke, February 1976. (PB-281-387/AS)
- 128 Hand Calculator Program to Compute Parcel Thermal Dynamics. Dan Gudgeal, April 1978. (PB-283-080/AS)
- 129 Fire Whirls. David W. Coens, May 1978. (PB-283-866/AS)

NOAA SCIENTIFIC AND TECHNICAL PUBLICATIONS

NOAA, the *National Oceanic and Atmospheric Administration*, was established as part of the Department of Commerce on October 3, 1970. The mission responsibilities of NOAA are to monitor and predict the state of the solid Earth, the oceans and their living resources, the atmosphere, and the space environment of the Earth, and to assess the socioeconomic impact of natural and technological changes in the environment.

The six Major Line Components of NOAA regularly produce various types of scientific and technical information in the following kinds of publications:

PROFESSIONAL PAPERS—Important definitive research results, major techniques, and special investigations.

TECHNICAL REPORTS—Journal quality with extensive details, mathematical developments, or data listings.

TECHNICAL MEMORANDUMS—Reports of preliminary, partial, or negative research or technology results, interim instructions, and the like.

CONTRACT AND GRANT REPORTS—Reports prepared by contractors or grantees under NOAA sponsorship.

TECHNICAL SERVICE PUBLICATIONS—These are publications containing data, observations, instructions, etc. A partial listing: Data serials; Prediction and outlook periodicals; Technical manuals, training papers, planning reports, and information serials; and Miscellaneous technical publications.

ATLAS—Analysed data generally presented in the form of maps showing distribution of rainfall, chemical and physical conditions of oceans and atmosphere, distribution of fishes and marine mammals, ionospheric conditions, etc.

Information on availability of NOAA publications can be obtained from:
